

The new BMD methodology

- Insights and understandings

Marc Aerts

February 15, 2023

What's new?

- extension of current PROAST implementation
 - ▷ more candidate models for continuous endpoints
 - ▷ unifying framework across types of endpoints
 - ▷ Bayesian implementation
 - ▷ informative priors
 - ▷ preliminary tests
 - ▷ computationally sufficiently fast
 - ▷ user R4EU interface
- all methodological and technical details

- Main statistical methodology
 - ▷ Components of the models
 - ▷ Bayesian inference
 - ▷ Model averaging
- Preliminary statistical tests
- Some further illustrations
- Summary simulation study

Components of dose response model

- distribution of the response at a specified dose level $y|x$
- effect of dose x on the median $\text{Med}(x)$ of this distribution

$$y|x$$

response | dose

?

Continuous response (Example 3.1, Figure C.3 in guidance)

Continuous response (Example 3.1, Figure C.3 in guidance)

Continuous response (Example 3.1, Figure C.3 in guidance)

- **continuous**

- ▷ normal

$$y|x \sim \mathbf{N}(\mu(x), \sigma^2)$$

- ▷ log-normal

$$y|x \sim \mathbf{LOGN}(\mu(x), \sigma^2)$$

- **quantal**

- ▷ Bernoulli

$$y|x \sim \mathbf{Bernoulli}(\pi(x))$$

- Extension to **clustered** observations

- Extension to **covariates**

Continuous response (Example 3.1, Figure C.3 in guidance)

Data at highest dose

Data at highest dose

Data at highest dose

Data at highest dose

The fetal weight example (dataset `das5.rda` in PROAST)

Fetal weight control group

$$P(\text{weight} < 0) = 2.05 \times 10^{-30}$$

$$y \sim N(\mu, \sigma^2) \quad \text{or} \quad y \sim \text{LOGN}(\mu, \sigma^2)$$
$$\updownarrow$$
$$\log(y) \sim N(\mu, \sigma^2)$$

Mixing up notation: μ 's refer to different parameters (σ 's as well)

$$y \sim N(\mu, \sigma^2) \quad \text{or} \quad y \sim \text{LOGN}(\mu, \sigma^2)$$
$$\updownarrow$$
$$\log(y) \sim N(\mu, \sigma^2)$$

	$N(\mu, \sigma^2)$	$\text{LOGN}(\mu, \sigma^2)$
mean	μ	$e^{\mu + \sigma^2/2}$
median	μ	e^μ
variance	σ^2	$(e^{\sigma^2} - 1)e^{2\mu + \sigma^2}$
coefficient of variation	σ/μ	$\sqrt{e^{\sigma^2} - 1}$

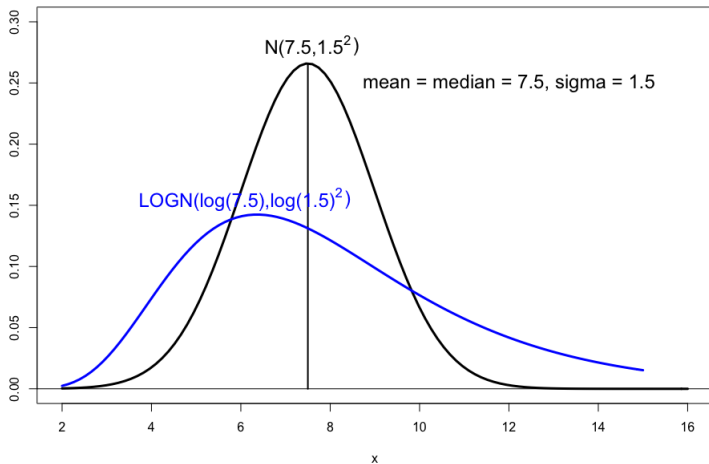

$$y \sim N(\mu, \sigma^2) \quad \& \quad y \sim \text{LOGN}(\mu, \sigma^2)$$

$$y \sim N(\mu, \sigma^2) \quad \& \quad y \sim \text{LOGN}(\mu, \sigma^2)$$

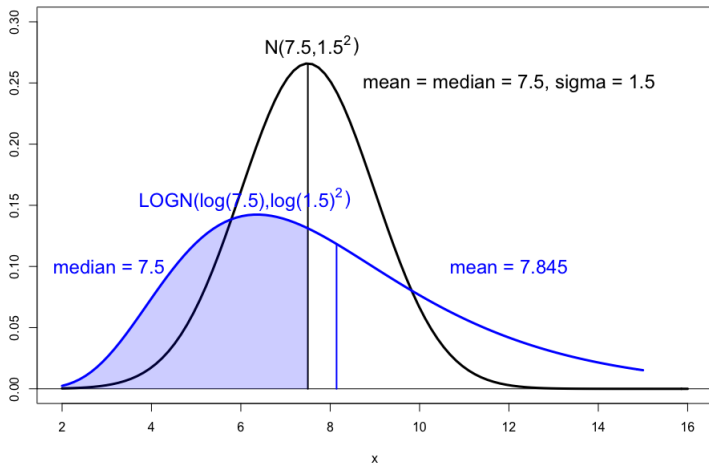

$$y \sim N(\mu, \sigma^2) \quad \& \quad y \sim \text{LOGN}(\mu, \sigma^2)$$

$$y \sim N(\mu, \sigma^2) \quad \& \quad y \sim \text{LOGN}(\mu, \sigma^2)$$

What do we mean by
median $\text{Med}(x)$ of
response | dose= x
?

	$N(\mu, \sigma^2)$	$\text{LOGN}(\mu, \sigma^2)$
mean	μ	$e^{\mu + \sigma^2/2}$
median	μ	e^μ
variance	σ^2	$(e^{\sigma^2} - 1)e^{2\mu + \sigma^2}$
coefficient of variation	σ/μ	$\sqrt{e^{\sigma^2} - 1}$

	$N(\mu(x), \sigma^2)$	$\text{LOGN}(\mu(x), \sigma^2)$
mean	$\mu(x)$	$e^{\mu(x) + \sigma^2/2}$
median $\text{Med}(x)$	$\mu(x)$	$e^{\mu(x)}$
variance	σ^2	$(e^{\sigma^2} - 1)e^{2\mu(x) + \sigma^2}$
coefficient of variation	$\sigma/\mu(x)$	$\sqrt{e^{\sigma^2} - 1}$

- **Median** for continuous response

- ▷ normal $\text{Med}(x) = \mu(x)$

- ▷ log-normal $\text{Med}(x) = e^{\mu(x)}$

$$\text{BMR} = \frac{\text{Med}(\text{BMD}) - \text{Med}(0)}{\text{Med}(0)}$$

- **Adverse event probability** for quantal response $\pi(x)$

$$\text{BMR} = \frac{\pi(\text{BMD}) - \pi(0)}{1 - \pi(0)}$$

Table 2: Candidate models for both distributional assumptions

Family	Model	$y x \sim N(\mu(x), \sigma^2)$	$y x \sim \text{LOGN}(\mu(x), \sigma^2)$
		Dose-response function $(\mu(x))$	Dose-response function $(e^{\mu(x)})$
1a	Exponential ⁽ⁱ⁾	$a \cdot (1 + (c-1) \cdot (1 - e^{-b \cdot x^d}))$	$e^a \cdot (1 + (c-1) \cdot (1 - e^{-b \cdot x^d}))$
	Inverse Exponential	$a \cdot (1 + (c-1) \cdot e^{-b \cdot x^d})$	$e^a \cdot (1 + (c-1) \cdot e^{-b \cdot x^d})$
	Hill ⁽ⁱⁱ⁾	$a \cdot (1 + (c-1) \cdot (1 - \frac{b}{b + x^d}))$	$e^a \cdot (1 + (c-1) \cdot (1 - \frac{b}{b + x^d}))$
	Log-Normal	$a \cdot (1 + (c-1) \cdot \Phi(\log(b) + d \cdot \log(x)))$	$e^a \cdot (1 + (c-1) \cdot \Phi(\log(b) + d \cdot \log(x)))$
1b	Gamma ⁽ⁱⁱⁱ⁾	$a \cdot (1 + (c-1) \cdot \frac{\gamma(d, b \cdot x)}{\Gamma(d)})$	$e^a \cdot (1 + (c-1) \cdot \frac{\gamma(d, b \cdot x)}{\Gamma(d)})$
	LMS-two stage	$a \cdot (1 + (c-1) \cdot (1 - e^{-b \cdot x - d \cdot x^2}))$	$e^a \cdot (1 + (c-1) \cdot (1 - e^{-b \cdot x - d \cdot x^2}))$
2	Probit increasing	$a \cdot \Phi(c + b \cdot x^d)$	$e^a \Phi(c + b \cdot x^d)$
	Probit decreasing	$a \cdot (1 + \Phi(c)) - a \cdot \Phi(c + b \cdot x^d)$	$e^a \cdot (1 + \Phi(c)) - a \cdot \Phi(c + b \cdot x^d)$
	Logistic increasing	$a \cdot \frac{e^{c+b \cdot x^d}}{1 + e^{c+b \cdot x^d}}$	$e^a \frac{e^{c+b \cdot x^d}}{1 + e^{c+b \cdot x^d}}$
	Logistic decreasing	$a \cdot (1 + \frac{e^c}{1 + e^c}) - a \cdot \frac{e^{c+b \cdot x^d}}{1 + e^{c+b \cdot x^d}}$	$e^a \cdot (1 + \frac{e^c}{1 + e^c}) - a \cdot \frac{e^{c+b \cdot x^d}}{1 + e^{c+b \cdot x^d}}$

Exponential model in previous guidance is defined as

$$a[c - (c - 1)e^{-bx^d}]$$

which equals the expression in the new guidance

$$\begin{aligned} a[c - (c - 1)e^{-bx^d}] &= a[c - (1 - c)(-e^{-bx^d})] \\ &= a[c - (1 - c)(-e^{-bx^d} + 1 - 1)] \\ &= a[c - (1 - c)(-e^{-bx^d} + 1) + (1 - c)] \\ &= a[1 - (1 - c)(-e^{-bx^d} + 1)] \\ &= a[1 + (c - 1)(1 - e^{-bx^d})] \end{aligned}$$

For all models

- a and c determine background and maximum response
e.g. for family 1 with the normal distribution
 - ▷ background = a
 - ▷ maximum response = ac
- b and d determine the monotone functional pattern of the model from background to maximum response

Reparameterisation

- **natural** parameters
 - ▷ background response
 - ▷ maximum response
 - ▷ BMD
- **technical** parameters
 - ▷ parameter d
 - ▷ σ for continuous responses

Back to the simulated example based on the exponential model
background = 7.5, maximum = 15, BMD = 0.229 (BMR = 0.1), $d = 1.8$

What is the effect of different values for the parameter d
on a particular model?

Technical parameter d in the exponential model

Technical parameter d in the exponential model

Technical parameter d in the exponential model

Technical parameter d in the exponential model

Technical parameter d in the exponential model

Maximum response at very large dose (in limit to infinity)

How do models differ with all parameters fixed,
including parameter d ?

Technical parameter $d = 1.8$ in the exponential model

Technical parameter $d = 1.8$ fixed for family 1a

Technical parameter $d = 1.8$ fixed for family 1a,b

Technical parameter $d = 1.8$ fixed for family 1a,b and 2

2 parameters less

- no variance parameter σ
- max response equals 1

Same 8 candidate models

- family 1 (a & b) $ac = 1 \Rightarrow c = 1/a$

$$a(1+(c-1)F(x; b, d)) = a(1+(\frac{1}{a}-1)F(x; b, d)) = a+(1-a)F(x; b, d)$$

Table 3: Candidate models for quantal endpoints

Family	Model	$\mathbf{y x} \sim \mathbf{Bernoulli}(\boldsymbol{\pi}(\mathbf{x}))$
		Dose-response function ($\boldsymbol{\mu}(x)$)
1a	Exponential	$a + (1-a) \cdot \left(1 - e^{-b \cdot x^d}\right)$
	Inverse Exponential	$a + (1-a) \cdot e^{-b \cdot x^{-d}}$
	Hill	$a + (1-a) \cdot \left(1 - \frac{b}{b + x^d}\right)$
	Log-Normal	$a + (1-a) \cdot \Phi(\log(b) + d \cdot \log(x))$
1b	Gamma	$a + (1-a) \cdot \frac{\gamma(d, b \cdot x)}{\Gamma(d)}$
	LMS-two stage	$a + (1-a) \cdot \left(1 - e^{-b \cdot x - d \cdot x^2}\right)$
2	Probit increasing	$\Phi(a + b \cdot x^d)$
	Logistic increasing	$\frac{e^{a+b \cdot x^d}}{1+e^{a+b \cdot x^d}}$

Questions ?

- Main statistical methodology
 - ▷ Components of the models
 - ▷ Bayesian inference
 - ▷ Model averaging
- Preliminary statistical tests
- Some further illustrations
- Summary simulation study

- extension of maximum likelihood (ML) inference
- parameters get distributions as well
- prior distribution $\xrightarrow{\text{data}}$ posterior distribution

- 2-year study in rats
- 3 doses of a substance
- changes in thyroid epithelial cell vacuolisation
- in 2017 and 2022 guidance

Dose (mg/kg day)	No of animals with thyroid epithelial vacuolisation	No of animals in dose group
0	6	50
3	6	50
12	34	50
30	42	50

Dose (mg/kg day)	No of animals with thyroid epithelial vacuolisation	No of animals in dose group
0	6	50
3	6	50
12	34	50
30	42	50

Consider the estimation of the **proportion** $\pi(0)$ for control group

- data: 6 out of 50
- frequency estimator

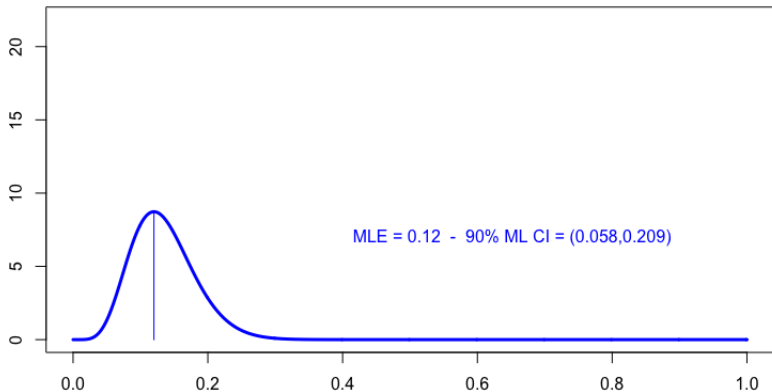

$$\hat{\pi}(0) = \frac{6}{50} = 0.12$$

- ? maximum likelihood estimate (MLE)

MLE for proportion at control level

- likelihood expresses the plausibility of the observed data as a function of proportion $\pi(0)$
- the ML estimate maximizes this plausibility or likelihood
- the likelihood function is determined by the distribution for the response
- all evidence, obtained from an experiment, about an unknown quantity is contained in the likelihood function
- for quantal data: the binomial distribution

Central formula

$$P(B|A) = \frac{P(A|B)P(B)}{P(A)}$$

or

$$f(\text{parameters}|\text{data}) = \frac{f(\text{data}|\text{parameters})f(\text{parameters})}{f(\text{data})}$$

or

$$\text{posterior distribution} \propto \text{likelihood} \times \text{prior distribution}$$

or

$$\text{prior distribution} \xrightarrow{\text{data}} \text{posterior distribution}$$

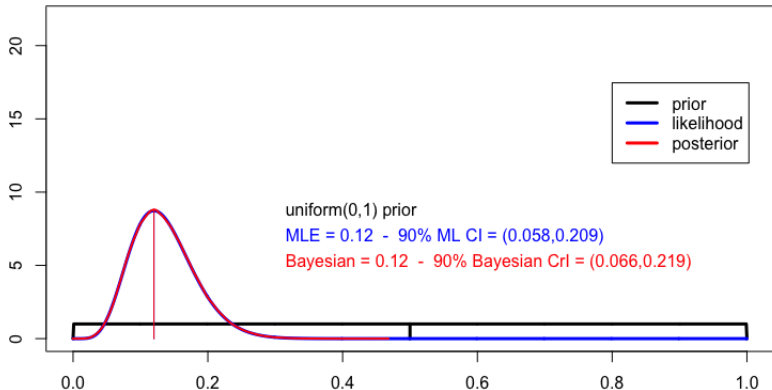

uninformative U(0,1) prior for $\pi(0)$

uninformative U(0,1) prior for $\pi(0)$

uninformative $U(0,1)$ prior for $\pi(0)$

Central formula

posterior distribution \propto likelihood \times prior distribution

so

frequentist estimation

\cong Bayesian estimation with uninformative prior

and

$\xrightarrow{\text{other info}}$ prior distribution $\xrightarrow{\text{current data}}$ posterior distribution

Use of **informative prior**

- determined before analysis
- informed decision to use (or not) prior information
- sensitivity analysis
- construction of informative prior based on
 - ▷ literature, e.g. reported estimates, confidence intervals
 - ▷ expert opinion
 - ▷ historical data

Information from **historical data** about $\pi(0)$

- 10 adverse events, out of 100
- similar experimental conditions

How to use these historical data?

How to use these historical data?

How to construct the informative prior from posterior?

Posterior distribution from historical data and uninformative prior

- point estimate 0.1: 10 out of 100 adverse events
- 99% Bayesian CrI: [0.044, 0.200]

Construction of informative prior using PERT distribution with

- ▷ mode = 0.1
- ▷ min = 0.044, max = 0.200
- ▷ shape ?

PERT distribution

- widely used in risk analysis
- defined by the minimum, most likely and maximum value, and shape

Figure 4: PERT densities with minimum = 0, mode = 5, maximum = 20 (vertical red lines) and shape. Varying from 0 (dotted line), 1 (dashed line) to 4 (solid line)

Posterior distribution: 99% Bayesian CrI: [0.044, 0.200] around 0.1

PERT with mode = 0.1, min = 0.044, max = 0.2, shape = 0

PERT with mode = 0.1, min = 0.044, max = 0.2, shape = 1

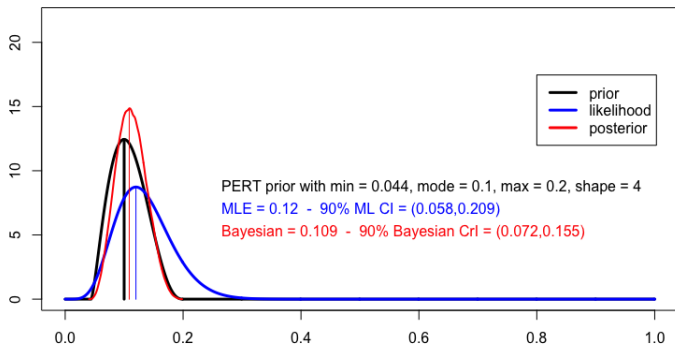

PERT with mode = 0.1, min = 0.044, max = 0.2, shape = 4

Analysis with informative prior using PERT with shape = 4

Sensitivity analysis

prior	$\hat{\pi}(0)$	CrIL	CrIU	CrIU/CrIL
uninformative	0.120	0.066	0.219	3.31
PERT shape=0	0.120	0.067	0.187	2.80
PERT shape=1	0.115	0.068	0.174	2.55
PERT shape=4	0.109	0.072	0.155	2.16

Dose (mg/kg day)	No of animals with thyroid epithelial vacuolisation	No of animals in dose group
0	6	50
3	6	50
12	34	50
30	42	50

Construction of priors

- a challenge in non-linear models
- PERT prior on natural parameters, based on
 - ▷ insights from simulations
 - ▷ practical considerations

and normal priors on transformed technical parameters d and σ^2

Default priors for natural parameters

C,Q BMD: uniform (=PERT) on the full dose range

C,Q background: PERT with mode on observed average in control group and with wide range

C maximum: PERT with mode on observed average at max dose and with wide range

Default priors for technical parameters

C,Q $\log(d)$: $N(1,1)$ truncated at 5

C $\log(1/\sigma^2)$: normal, loosely based on the scale of the data

Inverse exponential model using $BMR=0.1$, with **default priors**

$BMD=3.99$ ($BMDL=2.64, BMDU=6.09$) $BMDU/BMDL=2.31$

Inverse exponential model using $BMR=0.1$, with **default priors**

$BMD=3.99$ ($BMDL=2.64, BMDU=6.09$) $BMDU/BMDL=2.31$

Inverse exponential (IE) using $BMR=0.1$, with **default priors**

$BMD=3.99$ ($BMDL=2.64, BMDU=6.09$) $BMDU/BMDL=2.31$

Inverse exponential (IE) using $BMR=0.1$, with **default priors**

$BMD=3.99$ ($BMDL=2.64, BMDU=6.09$) $BMDU/BMDL=2.31$

Consider **informative** priors on BMD

- $min=2.5, mode=4, max=6, shape=4$
- $min=4.5, mode=7.5, max=8, shape=4$

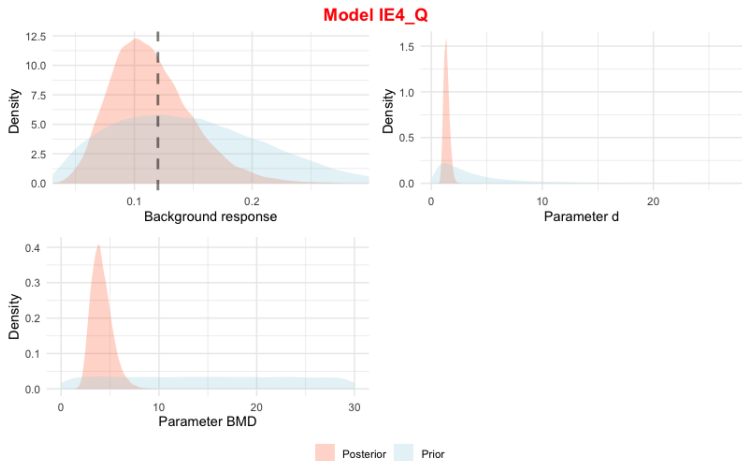

Priors on BMD

How do different priors affect the BMD estimation and the BMDL, BMDU?

IE MODEL with **default priors**

BMD=3.99 (BMDL=2.64,BMDU=6.09) BMDU/BMDL=2.31

IE MODEL with BMD prior **PERT(2.5,4,6,sh=4)**

BMD=4.02 (BMDL=3.06, BMDU=5.28) BMDU/BMDL=1.73

IE MODEL with BMD prior **PERT(4.5,7.5,8,sh=4)**

BMD=6.52 (BMDL=5.36, BMDU=7.91) BMDU/BMDL=1.47

IE MODEL with BMD priors

prior	BMD	BMDL	BMDU	BMDU/BMDL
U(0,1)	3.99	2.64	6.09	2.31
PERT(2.5,4,6,sh=4)	4.02	3.06	5.28	1.73
PERT(4.5,7.5,8,sh=4)	6.52	5.36	7.91	1.47

all models with default priors

all models with default priors

Questions ?

- Main statistical methodology
 - ▷ Components of the models
 - ▷ Bayesian inference
 - ▷ Model averaging
- Preliminary statistical tests
- Some further illustrations
- Summary simulation study

- multi-model inference
- suite of models should be rich enough
- frequentist model averaging

$$\text{averaged model fit} = \sum_{\text{model}} w_{\text{model}} \times \text{fitted model}$$

- model weight w_{model} based on goodness-of-fit criterion (AIC)
- use averaged model fit to determine BMD
- BMDL (and BMDU) based on bootstrap

- same rationale
- priors and posteriors on two levels
 - ▷ on the parameters of each specific model
 - ▷ on the models within the suite of candidate models
- different implementation

averaged BMD posterior =
 weighted mixture of model specific BMD posteriors

 weights = posterior probabilities of the models
- BMDL (and BMDU) defined as quantiles of averaged posterior

Default prior distribution on set of candidate models

C uniform distribution: probability $1/16$ for each model

Q uniform distribution: probability $1/8$ for each model

Technical issue:

- for the posterior probabilities of the models
- not analytically tractable integrals

Solutions:

- approximation of integrand: Laplace approximation
- numerical methods to compute integrals: Bridge sampling

all models with default priors

Laplace approximation

BMD=3.67 (BMDL=1.94, BMDU=5.88) BMDU/BMDL=3.04

Bridge sampling

BMD=4.08 (BMDL=2.23, BMDU=6.28) BMDU/BMDL=2.81

Questions ?

- Main statistical methodology
 - ▷ Components of the models
 - ▷ Bayesian inference
 - ▷ Model averaging
- Preliminary statistical tests
- Some further illustrations
- Summary simulation study

- For continuous response

$$y|x \sim N(\mu(x), \sigma^2), \quad y|x \sim \text{LOGN}(\mu(x), \sigma^2)$$

- ▷ constant variance (normality) & constant coefficient of variation (log-normality)
- ▷ constant variance & coefficient of variation for individual data
- ▷ normality & log-normality for individual data
- Testing for no dose effect
- Testing best model fits sufficiently well
- Data suitable for estimating the BMD (next presentation)

- **Frequentist** hypothesis testing: based on **p-value**
- **Bayesian** hypothesis testing: based on **Bayes factor**

Frequentist For continuous response

$$y|x \sim \text{N}(\mu(x), \sigma^2), \quad y|x \sim \text{LOGN}(\mu(x), \sigma^2)$$

- ▷ constant variance (normality) & constant coefficient of variation (log-normality)
- ▷ constant variance & coefficient of variation for individual data
- ▷ normality & log-normality for individual data

Bayesian Testing for no dose effect

Bayesian Testing best model fits sufficiently well

Indirect test focusing on the **variability across dose levels**

Normality assumption

$$y|x \sim N(\mu(x), \sigma^2)$$

implying **null hypothesis of homoscedasticity**

$$H_0 : \sigma_1^2 = \dots = \sigma_N^2 = \sigma^2$$

Bartlett test for constant variance using only summary statistics

Log-normality assumption

$$y|x \sim \text{LOGN}(\mu(x), \sigma^2) \Leftrightarrow \log(y)|x \sim \text{N}(\mu(x), \sigma^2)$$

implying **null hypothesis of homoscedasticity**

$$H_0 : \sigma_1^2 = \dots = \sigma_N^2 = \sigma^2 \text{ on log-scale}$$

$$H_0 : \text{CV}_1 = \dots = \text{CV}_N = \sqrt{e^{\sigma^2} - 1} \text{ on original scale}$$

with

$$\text{CV} = \text{coefficient of variation} = \frac{\sqrt{\text{Var}(y|x)}}{E(y|x)}$$

Bartlett test for constant coefficient of variation

Continuous response (Example 3.1, Figure C.3 in guidance)

Continuous response (Example 3.1, Figure C.3 in guidance)

- Distributional assumption of constant variance for the normal distribution is not met, Bartlett test p-value is $3e-04$
- Distributional assumption of constant coefficient of variation is met, Bartlett test p-value is 0.4295

Conclusion: evidence against the normal distribution

Same hypotheses

- normal distribution

$$H_0 : \sigma_1^2 = \dots = \sigma_N^2$$

- log-normal distribution

$$H_0 : CV_1 = \dots = CV_N$$

Levene test using individual data

Continuous response (Example 3.1, Figure C.3 in guidance)

SD Distributional assumption of constant variance for the normal distribution is not met, **Bartlett test p-value is 0.0003**

ID Distributional assumption of constant variance for the normal distribution is not met, **Levene test p-value is 0.0046**

SD Distributional assumption of constant coefficient of variation is met, **Bartlett test p-value is 0.430**

ID Distributional assumption of constant coefficient of variation is met, **Levene test p-value is 0.550**

Conclusion: evidence against the normal distribution

Frequentist For continuous response

$$y|x \sim \text{N}(\mu(x), \sigma^2), \quad y|x \sim \text{LOGN}(\mu(x), \sigma^2)$$

- ▷ constant variance (normality) & constant coefficient of variation (log-normality)
- ▷ constant variance & coefficient of variation for individual data
- ▷ normality & log-normality for individual data

Bayesian Testing for no dose effect

Bayesian Testing best model fits sufficiently well

Individual data: **Shapiro-Wilk** frequentist test for normality

- normality assumption

$$H_0 : y|x \sim \text{normal distribution}$$

- log-normality assumption

$$H_0 : y|x \sim \text{log-normal distribution}$$

$$H_0 : \log(y)|x \sim \text{normal distribution}$$

Continuous response (Example 3.1, Figure C.3 in guidance)

Continuous response (Example 3.1, Figure C.3 in guidance)

- at each dose level
- collapsing all dose levels (after centering)

Results

- there is no evidence against normality at level 5%
- there is evidence against normality at level 10% for dose 3
- there is no evidence against log-normality at level 5%
- there is evidence against log-normality at level 10% for dose 3

Frequentist For continuous response

$$y|x \sim \text{N}(\mu(x), \sigma^2), \quad y|x \sim \text{LOGN}(\mu(x), \sigma^2)$$

- ▷ constant variance (normality) & constant coefficient of variation (log-normality)
- ▷ constant variance & coefficient of variation for individual data
- ▷ normality & log-normality for individual data

Bayesian Testing for no dose effect

Bayesian Testing best model fits sufficiently well

- measures change prior \rightarrow posterior in favor of H_0
- central equation

$$\frac{P(H_0|\text{data})}{P(H_a|\text{data})} = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)} \times \frac{P(H_0)}{P(H_a)}$$

$$\frac{P(H_0|\text{data})}{1 - P(H_0|\text{data})} = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)} \times \frac{P(H_0)}{1 - P(H_0)}$$

prior odds for H_0 = Bayes factor \times prior odds for H_0

prior odds for H_0 $\xrightarrow{\text{Bayes factor}}$ posterior odds for H_0

$$BF = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)}$$

Bayes factor	interpretation
$BF > 10$	strong evidence favoring H_0 against H_a
$3 < BF \leq 10$	some evidence favoring H_0 against H_a
$1/3 \leq BF \leq 3$	insufficient evidence favoring any hypothesis
$1/10 \leq BF < 1/3$	some evidence favoring H_a against H_0
$BF < 1/10$	strong evidence favoring H_a against H_0

H_0 : no effect of dose & H_a : any effect of dose

$$\text{BF} = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)}$$

Bayes factor	interpretation
$\text{BF} > 10$	strong evidence favoring H_0 against H_a
$3 < \text{BF} \leq 10$	some evidence favoring H_0 against H_a
$1/3 \leq \text{BF} \leq 3$	insufficient evidence favoring any hypothesis
$1/10 \leq \text{BF} < 1/3$	some evidence favoring H_a against H_0
$\text{BF} < 1/10$	strong evidence favoring H_a against H_0

H_0 : no effect of dose & H_a : any effect of dose

$$BF = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)}$$

Bayes factor	interpretation
$BF > 10$	sufficient evidence that there is no dose-effect
$BF \leq 10$	insufficient evidence that there is no dose-effect

Continuous response (Example 3.1, Figure C.3 in guidance)

Output

- Bayes factor in favor of null model over SM:

$$BF = 0.000 \leq 10$$

- there is insufficient evidence that there is no dose effect

H_0 : best model & H_a : saturated model

$$\text{BF} = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)}$$

Bayes factor	interpretation
$\text{BF} > 10$	strong evidence favoring H_0 against H_a
$3 < \text{BF} \leq 10$	some evidence favoring H_0 against H_a
$1/3 \leq \text{BF} \leq 3$	insufficient evidence favoring any hypothesis
$1/10 \leq \text{BF} < 1/3$	some evidence favoring H_a against H_0
$\text{BF} < 1/10$	strong evidence favoring H_a against H_0

H_0 : best model & H_a : saturated model

$$\text{BF} = \frac{P(\text{data}|H_0)}{P(\text{data}|H_a)}$$

Bayes factor	interpretation
$\text{BF} \geq 1/10$	best fitting model fits sufficiently well
$\text{BF} < 1/10$	none of the models provide an adequate fit do the data

Continuous response (Example 3.1, Figure C.3 in guidance)

LogNormal distribution

Output

- best fitting model fits sufficiently well

$$BF = 9.404 \geq 1/10$$

Questions ?

- Main statistical methodology
 - ▷ Components of the models
 - ▷ Bayesian inference
 - ▷ Model averaging
- Preliminary statistical tests
- Some further illustrations
- Summary simulation study

ILLUSTRATION 1

The simulated continuous response

Example 3.1, Figure C.3 in guidance

Continuous response (Example 3.1, Figure C.3 in guidance)

- one dataset generated from a log-normal exponential model
- $a = 2.015, b = 1.5, c = 1.344, d = 1.8, \sigma = 0.05$
- natural parameters
 - ▷ median background response = $e^{2.015} = 7.501$
 - ▷ median maximum response = $e^{2.015 \times 1.344} = 15.002$
 - ▷ BMD = 0.2287, with BMR = 0.10
- dose levels 0, 0.5, 1, 2, 3
- constant group size of 20

Wrapping-up

- insufficient evidence that there is no dose-effect
- best model (gamma) fits sufficiently well
- evidence the homoscedastic normal distribution does not fit well
- no such evidence against the log-normal distribution

Two analyses: individual data & summary data
differences?

- Shapiro-Wilk tests only in case of individual data
- with individual data exact geometric summary statistics
 - ▷ for control group: exact (individual data)
 $gmean = 7.528749$, $gsdev = 1.042578$
 - ▷ for control group: approximate (summary data)
 $gmean = 7.528454$, $gsdev = 1.042420$

Dataset `das5.rda` in PROAST

The fetal weight example (dataset `das5.rda` in PROAST)

$BMR = 0.05$

Frequentist For continuous response

$$y|x \sim N(\mu(x), \sigma^2), \quad y|x \sim \text{LOGN}(\mu(x), \sigma^2)$$

- ▷ constant variance (normality) & constant coefficient of variation (log-normality):
reject both, p-val 0.0000, 0.0000 resp.
- ▷ constant variance & coefficient of variation for individual data: reject both, p-val 0.0003, 0.0000 resp.
- ▷ normality & log-normality for individual data:
reject both except at dose 970 and 1250

Bayesian Testing for no effect
insufficient evidence of no dose-effect (BF=0.0000)

Bayesian Testing best model fits sufficiently well
best fitting model fits sufficiently well (BF>2900)

Clustered or hierarchical data

- total of 2184 fetuses
- total of 213 litters
- within cluster/litter correlation ρ
 - ▷ $\rho = 0 \rightarrow$ 2184 independent units of information
 - ▷ $\rho = 1 \rightarrow$ 213 independent units of information
 - ▷ $0 < \rho < 1 \rightarrow 213 < \text{effective sample size} < 2184$
- correlated data \rightarrow implicit reduced sample size
- correlated data \rightarrow wider CrI

- no covariate effect on the distribution itself (normal or log-normal)
- each parameter may depend on covariate $\rightarrow 2^5 \times 16 = 512$ submodels !!!
- reduction to 4 submodels, for each model
 - ▷ background and variance σ^2 , **both** depend on covariate, **or none**
 - ▷ BMD and parameter d , **both** depend on covariate, **or none**

Strategy

- for each model: select best submodel
- at least one best submodel with covariate-dependent BMD?
 - ▷ yes: group dependent model averaged BMD
 - ▷ no: a single model averaged BMD

Snapshot of submodels

male PND42	0.976	3.444	12.407

Questions ?

- Main statistical methodology
 - ▷ Components of the models
 - ▷ Bayesian inference
 - ▷ Model averaging
- Preliminary statistical tests
- Some further illustrations
- Summary simulation study

Strengths

- mimic real case
- true mechanisms known
- effect of single & multiple factors
- different performance measures
- insight in performance
- recommendations

Limitations

- limited to selected scenarios
- data of real case generated by more complex mechanisms

General settings

- scenarios used by US-EPA
- mimic a typical rat bioassay (Piao et al. 2013)
- body weight loss and liver weight gain
- experimental designs based on FDA's Redbook 2000
- 120 scenarios for both endpoints
- 1000 datasets generated for each scenario

- **background informative prior:** less influential
- **maximum response informative prior:**
 - ▷ very useful when data do not contain information about asymptote
 - ▷ can affect the estimation beneficially
- **BMD informative prior:** highly influential
 - ▷ only use $\text{shape}=4$ if sufficient evidence about most likely value is available

- sensitivity analysis for impact of different weakly informative priors for d , especially if fits for the default choice seem less optimal
- if evidence is available that the BMD is to be expected within the experimental range
 - ▷ switch **extended range** off for default prior for BMD
 - ▷ consider sensitivity analysis

Thank you for your attention !

Questions ?
