

# **Overview on Dietary Reference Values for the EU population as derived by**

# the EFSA Panel on Dietetic Products, Nutrition and Allergies (NDA)

The term Dietary Reference Value (DRV) is an umbrella term for the complete set of nutrient reference values which include, among others, concepts like the Population Reference Intakes, the Average Requirements, Adequate Intakes and Reference Intake ranges for macronutrients (EFSA NDA Panel, 2010), which indicate the amount of an individual nutrient that people need for good health depending on their age and gender.

In its opinions, EFSA used four types of DRVs:

- The **Population Reference Intake (PRI)**, which is the level of (nutrient) intake that is adequate for virtually all people in a population group. On the assumption that the individual requirements for a nutrient are normally distributed within a population and the interindividual variation is known, the PRI is calculated on the basis of the AR plus twice its standard deviation (SD). This will meet the requirements of 97.5% of the individuals in the population.
- The Average Requirement (AR), which is the level of (nutrient) intake estimated to satisfy the physiological requirement or metabolic demand, as defined by the specified criterion for adequacy for that nutrient, in half of the people in a population group, given a normal distribution of requirement.
- The Adequate Intake (AI), which is the value estimated when a PRI cannot be established because an AR cannot be determined. An Adequate Intake is the average observed or experimentally determined approximations or estimates of nutrient intake by a population group (or groups) of apparently healthy people that is assumed to be adequate. The practical implication of an AI is similar to that of a PRI, i.e. describe the level of intake that is considered adequate for health reasons. The terminological distinction relates to the different way in which these values are derived and to the resultant difference in the "firmness" of the value.
- The **Reference Intake range (RI)**, which is the intake range for macronutrients, expressed as % of the energy intake. These apply to ranges of intakes that are adequate for maintaining health and associated with a low risk of selected chronic diseases.

The work done by EFSA in this area was based on a request from the European Commission, which asked EFSA to update previous European advice (SCF, 1993), taking into account new scientific evidence and recent recommendations issued at national and international level.

This document provides an overview about the outcome of EFSA's scientific deliberations. The detailed reasoning for establishing individual values can be found in the related opinions of the NDA Panel. Links to the respective opinions are included in Table 7 of this document.

### Table 1: Summary of Average Requirements (ARs) for energy

d, day; F, female; M, male; mo, months; PAL, physical activity level; y, years

<sup>(a)</sup> 1 MJ = 238.83 kcal

<sup>(b)</sup> ARs for energy are calculated by multiplying estimates of resting energy expenditure (REE), derived from predictive equations, with PAL values. For estimating REE in adults, anthropometric data from representative national surveys in EU Member States were used. ARs for energy were not calculated for adults ≥ 80 years because of a lack of anthropometric data from EU countries for this age group.

<sup>(c)</sup> PAL values of 1.4, 1.6, 1.8 and 2.0 reflect low active (sedentary), moderately active, active and very active lifestyles (EFSA NDA Panel, 2013).

<sup>(d)</sup> in addition to the AR for energy of non-pregnant, non-lactating women
