ZOONOSES MONITORING

AUSTRIA

The Report referred to in Article 9 of Directive 2003/99/EC

TRENDS AND SOURCES OF ZOONOSES AND ZOONOTIC AGENTS IN HUMANS, FOODSTUFFS, ANIMALS AND FEEDINGSTUFFS

including information on foodborne outbreaks, antimicrobial resistance in zoonotic agents and some pathogenic microbiological agents

IN 2006

INFORMATION ON THE REPORTING AND MONITORING SYSTEM

Country: **Austria**

Reporting Year: **2006**

Institutions and laboratories involved in reporting and monitoring:

Laboratory name	Description	Contribution
Central Veterinary Services	Federal Ministry for Health, Family and Youth	Data concerning notifiable zoonoses in animals; Revision of the draft of the Trend Report; Approval of the Trend Report for Submission
Food Office	Federal Ministry for Health, Family and Youth	Revision of the draft of the Trend Report
DG Public Health	Federal Ministry for Health, Family and Youth	Revision of the draft of the Trend Report
Provincial Veterinary Services	9 Provences, 1 Veterinary Service per Provence	Data concerning notifiable Zoonoses in Animals
Regional Health Boards	One Regional Health Board per province	Collection of the data concerning food borne outbreaks
Statistics Austria	Federal Statistics is the Federal Government's non-personal information system, which provides data on the economy, demography, environment and social and cultural situation in Austria to federal bodies to assist them with planning, laying the groundwork for decisions and controlling measures implemented, and also to the scientific community, business and the public.	Demographic and livestock census data
Competence Centre Infectious Diseases Epidemiology (CC-INFE)	Austrian Agency for Health and Food Safety, AGES	Compilation, validation, data entry and submission of the Zoonoses Trend Report

National Reference Centre for Salmonella Institute for Medical Microbiology and Hygiene, (IMED), Graz	Austrian Agency for Health and Food Safety, AGES	Data concerning salmonellosis in feedingstuff, animals, foodstuff and humans
Institute for Biostatistics	Austrian Agency for Health and Food Safety, AGES	Analysis of antimicrobial resistance of Campylobacter spp. and E. coli
National Reference Laboratory for Campylobacter, Institute of Hygiene	Medical University of Graz	Data concerning campylobacteriosis in humans
National Reference Laboratory for Tuberculosis, Institute for Medical Microbiology and Hygiene (IMED), Vienna	Austrian Agency for Health and Food Safety, AGES	Data concerning mycobacteriosis in humans
National Reference Center for EHEC (VTEC) and Listeria, Department of Hygiene, Microbiology and Social Medicine, Division of Hygiene & Medical Microbiology	Innsbruck Medical University	Data concerning VTEC and listerisosis in humans

National Reference Laboratory for Yersinia Institute for Medical Microbiology and Hygiene (IMED), Linz	Austrian Agency for Health and Food Safety, AGES	Data concerning yersiniosis in humans
National Reference Laboratory for Toxoplasmosis, Echinococcosis, Toxocarosis and other Parasitic Diseases, Clinical Institute for Hygiene and Medical Microbiology	Medical University of Vienna	Data concerning parasitic diseases in humans
Official Food Control Laboratories (ILMU)	Austrian Agency for Health and Food Safety, AGES; Laboratories in Graz, Innsbruck, Linz, Salzburg and Vienna	Data concerning investigations in foodstuffs
Food Safety Department of the City of Vienna	Regional Food Laboratory	Data concerning investigations in foodstuffs
Carinthian Institute for Food Analysis and Quality Control	Regional Food Laboratory	Data concerning investigations in foodstuffs
Institute for Environment and Food Safety of the State of Vorarlberg	Regional Food Laboratory	Data concerning investigations in foodstuffs

National Reference Laboratory for Rabies, Institute for Veterinary Disease Control, Moedling	Austrian Agency for Health and Food Safety, AGES	Data concerning rabies
National Reference Laboratory for Tuberculosis in Animals, Institute for Veterinary Disease Control, Moedling	Austrian Agency for Health and Food Safety, AGES	Data concerning tuberculosis in animals
National Reference Laboratory for Trichinellosis in Animals, Institute for Veterinary Disease Control, (IVET), Innsbruck	Austrian Agency for Health and Food Safety, AGES	Data concerning trichinellosis in animals
Institutes for Veterinary Disease Control (IVET)	Austrian Agency for Health and Food Safety, AGES; Laboratories in Graz, Innsbruck, Linz and Moedling	Data concerning investigations in animals; bacteriological investigation in slaughtered animals
National Reference Laboratory for Brucellosis, Institute for Veterinary Disease Control, (IVET), Moedling	Austrian Agency for Health and Food Safety, AGES	Data concerning brucellosis in animals and humans

Carinthian Institute for Veterinary Disease Control, Ehrental	Regional Veterinary Laboratory	Data concerning investigations in animals
Austrian Poultry Health Service	Association installed by law, running different programs e.g. salmonella control and hygiene programs, Control of veterinarians and poultry farmers	Data concerning the Austrian poultry industry
Institute for Agricultural Analysis, Linz	Austrian Agency for Health and Food Safety, AGES	Data concerning feeding stuff

PREFACE

This report is submitted to the European Commission in accordance with Article 9 of Council Directive 2003/99/EC[1]. The information has also been forwarded to the European Food Safety Authority (EFSA).

The report contains information on trends and sources of zoonoses and zoonotic agents in Austria during the year 2006. The information covers the occurrence of these diseases and agents in humans, animals, foodstuffs and in some cases also in feedingstuffs. In addition the report includes data on antimicrobial resistance in some zoonotic agents and commensal bacteria as well as information on epidemiological investigations of foodborne outbreaks. Complementary data on susceptible animal populations in the country is also given.

The information given covers both zoonoses that are important for the public health in the whole European Community as well as zoonoses, which are relevant on the basis of the national epidemiological situation.

The report describes the monitoring systems in place and the prevention and control strategies applied in the country. For some zoonoses this monitoring is based on legal requirements laid down by the Community Legislation, while for the other zoonoses national approaches are applied.

The report presents the results of the examinations carried out in the reporting year. A national evaluation of the epidemiological situation, with special reference to trends and sources of zoonotic infections, is given. Whenever possible, the relevance of findings in foodstuffs and animals to zoonoses cases in humans is evaluated.

The information covered by this report is used in the annual Community Summary Report on zoonoses that is published each year by EFSA.

---

1 Directive 2003/99/EC of the European Parliament and of the Council of 12 December 2003 on the monitoring of zoonoses and zoonotic agents, amending Decision 90/424/EEC and repealing Council Directive 92/117/EEC, OJ L 325, 17.11.2003, p. 31

LIST OF CONTENTS

1. ANIMAL POPULATIONS

The relevance of the findings on zoonoses and zoonotic agents has to be related to the size and nature of the animal population in the country.

A. Information on susceptible animal population

Sources of information:

The Statistics Austria is the Federal Government's non-personal information system, which provides data on the economy, demography, environment and social and cultural situation in Austria to federal bodies to assist them with planning, laying the groundwork for decisions and controlling measures implemented, and also to the scientific community, business and the public.

It has to be mentioned that the number of holdings and animals is based on extrapolations of the latest livestock census from the year 1999 in combination with the data of the yearly random sample survey performed by Statistics Austria. Exception: The number of holdings is created from the official database for cattle and the Veterinary Information System (VIS).

Dates the figures relate to and the content of the figures:

All data relate to 2006.

Table Susceptible animal populations

* Only if different than current reporting year

Animal species	Category of animals	Number of herds or flocks	Year*	Number of holdings	Year*	Number of slaughtered animals	Year*	Livestock numbers (live animals)	Year*
Cattle (bovine animals)	in total			80161		682763		2002919	
Gallus gallus (fowl)	in total					59680606			
Goats	animals under 1 year							22872	
	animals over 1 year							46175	
	milk goats			3337				20581	
	in total			10548		41625		69047	
Pigs	breeding animals							313285	
	fattening pigs			37741		5263066		1103920	
	in total			52450		5361710		3160819	
Sheep	milk ewes			861				17683	
	animals under 1 year (lambs)							158033	
	animals over 1 year							218294	
	in total			15896		310092		376327	
Turkeys	in total					2037066			

2. INFORMATION ON SPECIFIC ZOONOSES AND ZOONOTIC AGENTS

Zoonoses are diseases or infections, which are naturally transmissible directly or indirectly between animals and humans. Foodstuffs serve often as vehicles of zoonotic infections. Zoonotic agents cover viruses, bacteria, fungi, parasites or other biological entities that are likely to cause zoonoses.

2.1. SALMONELLOSIS

2.1.1. General evaluation of the national situation

A. General evaluation

History of the disease and/or infection in the country

Human salmonellosis still poses a major problem for human health. But in 2006, the number of notified cases of campylobacteriosis exceeded the number of notified salmonellosis cases.

National evaluation of the recent situation, the trends and sources of infection

The incidence of human salmonellosis has significantly declined since the peak in 1998/1999. The salmonella-contamination of poultry meat has declined from more than 33% to less than 10%. Consumption eggs are presently the major source of human infection.

The number of salmonellosis cases presented in this report reflects the number of primary human isolates and respectively the number of laboratory confirmed cases sent to the National Reference Centre for Salmonella (n = 5,379). According to the Federal Ministy of Health, Family and Youth the official number of notified cases is 4,985 (by 8th May 2007, vorlÃ¤ufiger Jahresausweis Ã¼ber angezeigte FÃ¤lle Ã¼bertragbarer Krankheiten 2006). Compared to the number of notified cases of campylobacteriosis (see chapter campylobacteriosis) salmonellosis is only the second most important cause for enteric diseases in Austria.

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

In feedingstuffs the prevalence of salmonella (<1%) is still decreasing. Salmonella is only of minor relevance in Austrian cattle and pigs. Poultry is considered the main source for human infection. Although only few eggs were positive for salmonella (approx. 0.1 - 1%), infected eggs pose the main source of human infections.

Recent actions taken to control the zoonoses

There were various programs implemented to improve the situation in poultry, concerning meat and egg production. The main effort is directed onto sanitation of breeding flocks.

Suggestions to the Community for the actions to be taken

Continue the efforts already started, especially efforts for harmonization of national monitoring and control programs along the food chain.

Additional information

Nil

2.1.2. Salmonellosis in humans

A. Salmonellosis in humans

Case definition

Clinical picture compatible with salmonellosis, e. g. diarrhoea, abdominal pain, nausea and sometimes vomiting. The organism may cause extraintestinal infections.

Laboratory criteria for diagnosis: Isolation of Salmonella spp. (non-typhi, non-paratyphi) from a clinical specimen.

Case classification

â ¢ Probable case: A laboratory confirmed isolate without clinical information or, a case with clinical symptoms that has an epidemiological link

â ¢ Confirmed case: A clinically compatible case that is laboratory confirmed

Diagnostic/analytical methods used

Bacteriology: Sample material is processed as described in Richtlinien fÃ¼r die Diagnostik von Salmonellen (Anonymus: Standardisierung und QualitÃ¤tssicherung in der mikrobiologischen Diagnostik. Richtlinien. Bundesministerium fÃ¼r Soziale Sicherheit und Generationen. ISBN 3-84123-126-0, Wien, 2001, pg. 11-12).

At the NRL Salmonella all strains are serotyped according to the Kauffmann-White-Scheme. And further all S. Enteritidis and S. Typhimurium isolates are phage typed according to the methods used by HPA, Colindale, UK.

Notification system in place

Specialists in Laboratory Diagnosis or Microbiology and Hygiene and the attended physicians are subjected to notification. Notification of salmonellosis according to the epidemic act has been mandatory since 1950 (BGBl. 1950/186 Epidemiegesetz, as amended). Since 2002 a note of the Federal Ministry for Social Security and Generations has been implemented (Meldepflicht infektiÃ¶ser Erkrankungen fÃ¼r Labors GZ: 21.700/5- VIII/D/5/02), in which medical doctors specialised in Laboratory Diagnosis or Microbiology and Hygiene are subjected to notification.

The number of salmonellosis cases presented in this report reflects the number of primary human isolates and respectively the number of laboratory confirmed cases sent to the National Reference Centre for Salmonella.

On July 24th 2006 the amendment of the epidemic act (114. Bundesgesetz: Ã nderung des Epidemiegesetzes 1950) has been published: Accordingly, all zoonotic agents that are isolated in a laboratory and that are notifiable have to be sent to the corresponding reference laboratory for speciation.

History of the disease and/or infection in the country

In 1989 and 1990, human infections with S. Enteritidis increased markedly in Austria. After a peak in 1992, the incidence of salmonella illness decreased, but the number of infections has remained at a high level until 2003. Since that year the number of laboratory confirmed cases of human Salmonella infections decreased by approx. 30 % but from 2005 to 2006 only by 4 %.

National evaluation of the recent situation, the trends and sources of infection

The number of laboratory confirmed cases of human Salmonella infections decreased lower than the previous years.

The proportion of S. Enteritidis decreased slightly to 79 % (compared to 83 % in 2005). The distribution of the three most phage types PT4, PT8 and PT21 are very similar, 27 %, 23 % and 21

%. The number of S. Typhimurium isolates increased from 385 in 2005 to 627 (12 % of all Salmonella spp. isolates from humans). Amongst others this is due to three large foodborne outbreaks of S. Typhimurium DT46 (2 x) and DT41 (for more details see chapter food borne outbreaks).

The overall resistance rates against antibiotics remained stable over the past years. Table eggs are probably still the main source of human infections of S. Enteritidis and S. Typhimurium.

Relevance as zoonotic disease

In 2006, the number of notified human cases of campylobacteriosis exceeded the number of salmonellosis cases; due to EU wide control programs and targets for reduction of prevalences of salmonella in laying hen flocks and broilers the number of human salmonellosis cases is expected to be reduced.

B. Antimicrobial resistance of Salmonella spp. in humans

History of the disease and/or infection in the country

The overall resistance-rates against antibiotics remained stable over the past years. High level resistances against Ciprofloxacin and third generation cephalosporins (Cefotaxime) were still extremely rare.

National evaluation of the recent situation, the trends and sources of infection

In 2006, there is no difference detectable in resistance-rates. The increase in the number of resistant isolates against ampicillin is due to more human cases affected by ampicillin resistant S. Enteritidis PT6a (2006: 185 cases, 2005: 18 cases).

Recent actions taken to control the zoonoses

2.1.3. Salmonella in foodstuffs

A. Salmonella spp. in food

Monitoring system

Sampling strategy

No surveillance programmes are applied.

Foodstuff was sampled according to the Erlass der Bundesministerin fÃ¼r Gesundheit und Frauen: Revisions- und Probenplan fÃ¼r das Jahr 2006; Richtlinien Ã¼ber die Vollziehung der Ã berwachung des Verkehrs mit den durch das LMG 1975 erfassten Waren (GZ BMGF-75500/0164-IV/B/10/2005 of 26.01.2006). The Revision-Plan determines the number of food enterprises e.g. restaurants, dairies, retail etc. that have to be tested randomly per province according to the number of food enterprises per province. Each business has to be sampled at least once per year. The inspection can comprise sampling, hygienic investigations of the employees, checking of HACCP, control of manufacturing processes etc.

The sampling plan determines the number of samples of each class of goods, as raw meat, fresh or frozen; sausages; cheeses; milk; preserved food etc. that have to be investigated randomly.

Additionally to the routine monitoring plan there is an extra one for special food items.

In the year 2006, the following programs according to the Erlass der Bundesministerin fÃ¼r Gesundheit und Frauen: Schwerpunktprogramm 2006 (GZ BMGF-75500/0162-IV/B/10/2005) were conducted Austrian-wide:

Campaign A005: food item: Tiramisu, industrially produced, from retail

Investigation period: February â March

Pathogen: Salmonella: 95 samples were tested

Campaign A008: food item: meat preparation from bovine meat â intended to be eaten cooked, from retail

Investigation period: March - May

Pathogen: 112 samples were tested for Salmonella, Listeria, EHEC, Yersinia and for Campylobacter

Campaign A020: food item: meat products, raw from poultry (sausages), from retail

Investigation period: April â May

Pathogen: 104 samples were tested for Salmonella and Listeria

Campaign A029: food item: dried pasta with eggs, from retail

Investigation period: May - June

Pathogen: Salmonella: 99 samples were tested

Campaign A035: food item: salads from communal feeding, retail

Investigation period: Juli

Pathogen: Salmonella: 95 samples were tested

Campaign A045: food item: pig meat, raw, from retail

Investigation period: September â November

Pathogen: 96 samples were tested for Salmonella, Listeria, Yersinia and for Campylobacter

Campaign A051: food item: peeled shrimps, deep frozen, from retail trade

Investigation period: October â November

Pathogen: Listeria: 105 samples were tested

Samples from suspected foodstuffs are taken following outbreak investigation, complaint, confiscation, violation etc.

Diagnostic/analytical methods used

According to ISO 6579: 1999, with modifications: After preenrichment, selective enrichment in modified semisolid Rappaport-Vassiliadis or Diasalm, 18-24 hours at 42Â°C. Subsequently plating on XLD agar, Brilliant green-Phenolred-Lactose-Saccharose agar (BPLS), Salmonella Detection and Identification Medium (SMID) or Rambach agar.

25 g of raw material for egg products or 25 g of pooled content of 5 table eggs are either incubated directly or preenriched in peptone water. Further steps are performed as described above.

All isolates are sent to the NRL Salmonella and serotyped according to the Kauffmann-White-Scheme. All S. Enteritidis and S. Typhimurium isolates are phage-typed according to the methods used by HPA, Colindale, UK.

National evaluation of the recent situation, the trends and sources of infection

Salmonella spp. could be detected in fresh or raw meat samples, intended to be eaten raw or cooked in 6.2 % single broiler meat samples (49 out of 795), in 14.5 % single turkey meat samples (11/76), and in 12 out of 246 samples (4.9 %) of cooked broiler meat, ready-to-eat. In the monitoring program for raw meat products from poultry (A20) Salmonella spp. was found in 3 out of 104 samples (2.9 %). In pig meat fresh 4 out of 356 single samples including those of the monitoring program A45 (1.1 %) were detected positive. In fresh bovine meat none of the 217 tested single samples (including monitoring program A8) were found positive.

In 2006, the percentage of positive samples has been halved in broiler meat (11.7 % to 6.2 %), but has increased in turkey meat (11.3 % to 14.5 %). In comparision to 2005, there was no change in the numbers of positive samples in pig and bovine meat.

2,759 samples from milk, milk products and cheeses were tested for Salmonella spp. Only from two samples (1 ice cream and 1 cheese made from raw or low heat treated cow milk) Salmonella spp. could be isolated.

1,711 sample units containing 25 g of table eggs sampled at packing centre or at retail level were examined, in 48 samples (2.8 %) Salmonella spp. was detected, 47 times S. Enteritidis, and one time S. Duisburg.

The percentage of positive table eggs samples has increased from 1.6 % to 2.8 % in comparison to the year 2005.

2.1.4. Salmonella in animals

A. Salmonella spp. in Gallus gallus - breeding flocks for egg production and flocks of laying hens

Monitoring system

Sampling strategy

Breeding flocks (separate elite, grand parent and parent flocks when necessary)

There are only parent flocks existing in Austria. Permanent monitoring by a national program takes place at hatchery; each flock is tested regularly as well by the farmer as by the Veterinary Authority.

If S. Enteritidis, S. Typhimurium, S. Pullorum Gallinarum and S. Arizonae is isolated from breeding flocks at the hatchery the flock is banned and a sample of 20 birds at random from within the incriminated flock has to be taken. Inner organs as ovaries, liver and intestinal content are investigated.

If a parent flock is positive for other salmonellas Official Veterinarians take pooled feces samples from the incriminated flock. After a second positive result for Salmonella spp., within a period of two weeks organs from a minimum of 20 chickens were tested.

Laying hens flocks

Earliest 3 weeks prior to slaughter cloacal swabs have to be taken. Other programs are not foreseen, only voluntary sampling by the farmer or sampling according to private cooperatives is performed.

Frequency of the sampling

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Day-old chicks

Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! Every flock is tested at day one.

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Rearing period

Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! 1. Routinely: Every flocks is tested at the age of 4 and 12 weeks and 2 weeks before the laying period starts. 2. Confirmation: If Salmonella was isolates from day old chicks.

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Production period

Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! Monitoring by national program, takes place at hatchery, each flock is tested every two weeks at hatch by the farmer, and every 6 weeks by the Veterinary Authority; additional each flock is tested every 4 weeks by the farmer by boot swabs.

Laying hens: Day-old chicks

Other: no legal requirements, e.g. at day one each flock

Laying hens: Rearing period

Other: no legal requirements, e.g. 2 times at week 12 and 2 weeks before the laying period start

Laying hens: Production period

Other: no legal requirements, according to the program of the cooperatives (e.g. every three month, every eight weeks)

Laying hens: Before slaughter at farm

Other: 3 weeks before slaughter at farm

Laying hens: At slaughter

Other: no sampling

Eggs at packing centre (flock based approach)

Other: According to the program of the cooperatives voluntary surface swabs (e.g. every eight weeks)

Type of specimen taken

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Day-old chicks

Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! Visibly soiled hatcher basket liners, dead chicks if available

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Rearing period

Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! Routine testing: drag swabs, pooled feces. For confirmation: organs as ovaries, liver and intestinal content from a minimum of 20 chickens.

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Production period

Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! Routine testing: Drag swabs, pooled feces and dust in the hatchery, meconium, broken eggshells and hatched eggs. For confirmation: Inner organs as ovaries, liver and intestinal content from a minimum of 20 chickens. Inner organs of 5 chickens or intestinal content of 5 chickens were pooled.

Laying hens: Day-old chicks

Other: no legal requirements, e.g. visibly soiled hatcher basket liners

Laying hens: Rearing period

Other: no legal requirements, e.g. pooled feces

Laying hens: Production period

Other: no legal requirements, e.g. pooled feces or drag swabs

Laying hens: Before slaughter at farm

Other: 9 cloacal swabs per flock

Laying hens: At slaughter

Other: no sampling

Eggs at packing centre (flock based approach)

Other: Voluntary e.g. surface swabs

Methods of sampling (description of sampling techniques)

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Day-old chicks

There were no separate elite and grand parent flocks in Austria, only parent flocks! Visibly soiled hatcher basket liners, dead chicks if available

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Rearing period

There were no separate elite and grand parent flocks in Austria, only parent flocks! Routine testing: 60 pooled droppings a 1gram per flock, collection of dust. For confirmation: Diagnostically killing of 20 random chickens from within the incriminated flock

Breeding flocks: Production period

There were no separate elite and grand parent flocks in Austria, only parent flocks!

Routine testing: 1 drag swab, pooled feces, collection of dust. For confirmation: Diagnostically killing of 20 random chickens from within the incriminated flock

Laying hens: Day-old chicks

No legal requirements, e.g. visibly soiled hatcher basket liners

Laying hens: Rearing period

No legal requirements, e.g. 60 pooled droppings a 1 gram per flock

Laying hens: Production period

No legal requirements, e.g. 60 pooled droppings a 1 gram per flock or 1 drag swab

Laying hens: Before slaughter at farm

9 cloacal swabs per flock

Laying hens: At slaughter

No sampling

Eggs at packing centre (flock based approach)

No legal requirements, e.g. surface swabs

Case definition

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Day-old chicks

There were no separate elite and grand parent flocks in Austria, only parent flocks!

Routine testing: Salmonella spp. isolated from hatcher basket liners

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Rearing period

There were no separate elite and grand parent flocks in Austria, only parent flocks!

Salmonella spp. isolated from inner organs or from content of intestines of chickens killed for diagnosis

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Production period

There were no separate elite and grand parent flocks in Austria, only parent flocks!

Salmonella spp. isolated from inner organs or from content of intestines of chicken

Laying hens: Day-old chicks

No legal requirements, e.g. Salmonella spp. isolated from hatcher basket liners

Laying hens: Rearing period

No legal requirements

Laying hens: Production period

No legal requirements

Laying hens: Before slaughter at farm

Salmonella spp. isolated from cloacal swabs

Laying hens: At slaughter

No sampling

Eggs at packing centre (flock based approach)

Salmonella spp. isolated from surface swabs

Diagnostic/analytical methods used

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Day-old chicks

Bacteriological method: Other: There were no separate elite and grand parent flocks in Austria, only parent flocks! Sample material is incubated in liquid medium. Modification of ISO 6579 (2002), where a semi solid medium (MSRV) is used as the single selective enrichment medium. The semi solid medium is incubated at 41.5+/-1Â°C for 24 or 48 hours. All isolates are sent to the NRL Salmonella and serotyped according to the Kauffmann-White-Scheme. All S. Enteritidis and S. Typhimurium isolates are phage-typed according to the methods used by HPA, Colindale, UK.

Breeding flocks (separate elite, grand parent and parent flocks when necessary): Rearing period

Vaccination policy

Breeding flocks (separate elite, grand parent and parent flocks when necessary)

There were no separate elite and grand parent flocks in Austria, only parent flocks! The national program for parent flocks made vaccination against Salmonella mandatory for all flocks

Laying hens flocks

The national program recommended vaccination against S. Enteritidis

Other preventive measures than vaccination in place

Breeding flocks (separate elite, grand parent and parent flocks when necessary)

Nil

Laying hens flocks

Nil

Control program/mechanisms

The control program/strategies in place

Breeding flocks (separate elite, grand parent and parent flocks when necessary)

There were no separate elite and grand parent flocks in Austria, only parent flocks! The Austrian control program is conducted according to the National Poultry Hygiene Regulation (BGBl 243/2000, Gefluegelhygieneverordnung 2000 of 28 July 2000). The Austrian program for monitoring and eradication of Salmonella in breeding flocks of poultry was again (already since 2000) approved for the year 2006 by Commission Decision 2005/887/EG of 12 December 2005.

Laying hens flocks

The Austrian control program is conducted according to the National Poultry Hygiene Regulation (BGBl 243/2000, Gefluegelhygieneverordnung 2000 of 28 July 2000).

Recent actions taken to control the zoonoses

Nil

Suggestions to the Community for the actions to be taken

Nil

Measures in case of the positive findings or single cases

Breeding flocks (separate elite, grand parent and parent flocks when necessary)

There were no separate elite and grand parent flocks in Austria, only parent flocks!

Measures according to the National Poultry Hygiene Regulation:

â ¢ Banning of the incriminated sector of the holding

â ¢ Culling of the infected flock

â ¢ Disposal of the hatched eggs

â ¢ Abolishing of the restriction after cleaning and disinfection

â ¢ If necessary prescriptions of GMP to prevent re-infection

Laying hens flocks

Flocks were either treated with antimicrobials or competitive exclusion and a hygiene plan is performed. Slaughtering was only permitted for Salmonella negative flocks.

Notification system in place

All positive findings in parent flocks had to be notified to the local authority and via the Austrian Poultry Health Service to the Federal Ministry of Health and Women.

National evaluation of the recent situation, the trends and sources of infection

In 2005, Salmonella spp. was not detected in any parent flock.

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Slaughtering was only permitted for Salmonella negative flocks.

D. Salmonella spp. in animal

Monitoring system

Sampling strategy

This information only concerns animals except poultry!

1. Feces from animals suffering from diarrhea that were sent to a veterinary laboratory are examined for salmonellosis

2. After findings of enteritis in course of pathological examinations of deceased animals intestinal content is tested for Salmonella.

3. After slaughtering in course of the ante- and post mortem inspection act, all animals that are objected to bacteriological examination are tested for salmonella.

Frequency of the sampling

Animals at farm

Other: Samples sent to a bacteriological laboratory are examined.

Animals at slaughter (herd based approach)

Other: NO HERD BASED APPROACH! After emergency slaughtering or targeted when a carcass seems not to be fit for consumption.

Type of specimen taken

Animals at farm

Other: Feces or intestinal content

Animals at slaughter (herd based approach)

Other: NO HERD BASED APPROACH! 2 parts from muscles, 2 lymph nodes, parts of lever, spleen and kidney and if present pathological alterations

Methods of sampling (description of sampling techniques)

Animals at farm

No special methods

Animals at slaughter (herd based approach)

Samples were wrapped in sterile plastic bags. After cooling down to 4Â°C the samples were sent in a polystyrene box after adding cooling units to the locally appropriate Institute of Veterinary Diseases Control.

Case definition

Animals at farm

Salmonella spp. isolated from the sample

Animals at slaughter (herd based approach)

NO HERD BASED APPROACH! Salmonella spp. isolated from the sample

Diagnostic/analytical methods used

Animals at farm

Other: Sample material is incubated in liquid medium. Modification of ISO 6579 (2002), where a semi solid medium (MSRV) is used as the single selective enrichment medium. The semi solid medium is incubated at 41.5+/- 1Â°C for 24 or 48 hours. All isolates are sent to the NRL Salmonella and serotyped according to the Kauffmann-White-Scheme. All S. Enteritidis and S. Typhimurium isolates are phage-typed according to the methods used by HPA, Colindale, UK.

Animals at slaughter (herd based approach)

Other: see animals at farm.

Vaccination policy

No vaccination is performed in these animals.

Other preventive measures than vaccination in place

None

Control program/mechanisms

The control program/strategies in place

No control programs in place

Suggestions to the Community for the actions to be taken

Europe wide harmonized standards for monitoring programs would be highly welcome.

Measures in case of the positive findings or single cases

1. and 2. No measures

3. According to BGBl 1982/522, Fleischuntersuchungsverordnung, as amended and BGBl 1994/395, Fleischuntersuchungsverordnung, as amended: The carcass is unfit for human consumption and must be removed. In all slaughtered animals descending from the same holding a post-mortem bacteriological examination has to be initiated.

Notification system in place

1. and 2. Notification not mandatory

3. According to BGBl 1994/395, Â§10 (8), Fleischuntersuchungsverordnung, as amended: The competent authority has to notify to the finding to the local authority.

National evaluation of the recent situation, the trends and sources of infection

Meat from animals other than poultry plays a neglecting role as source of infection for human salmonella sases.

2.1.5. Salmonella in feedingstuffs

A. Salmonella spp. in feed - All feedingstuffs - in total - Monitoring - official sampling

Monitoring system

Sampling strategy

Sampling is as well random as targeted without regional criteria. The sampling is performed by competent authorities; the samples were taken on farms, slaughterhouses, processing plants, retailers. The sampling is part of the permanent monitoring.

Frequency of the sampling

Domestic feed material of plant origin

Other: Sampling distributed evenly throughout the year, each farm, processing plant, and retailer is sampled at least two times per year. Control is conducted in the final product. Suspected batches are sampled.

Domestic feed material of animal origin

Other: as above

Imported feed material of plant origin

Other: as above

Imported feed material of animal origin

Other: as above

Process control in feed mills

Other: as above

Compound feedingstuffs

Other: as above

Type of specimen taken

Domestic feed material of plant origin

Oil seed meals and cakes

Domestic feed material of animal origin

Fish meal, dried animal by-products for pets

Imported feed material of plant origin

Oil seed meals and cakes

Imported feed material of animal origin

Fish meal, dried animal by-products for pets

Process control in feed mills

Not applicable (n. a.)

Compound feedingstuffs

Feed for poultry

Methods of sampling (description of sampling techniques)

Domestic feed material of plant origin

Sampling is performed according EC-Directive 76/371/EEC applying special hygiene requirements or sampling of original packaged products.

Domestic feed material of animal origin

As above

Imported feed material of plant origin

As above

Imported feed material of animal origin

As above

Control program/mechanisms

The control program/strategies in place

National legislation: BGBl. Nr. 139/1999 (Futtermittelgesetz 1999, Â§ 3) and BGBl. Nr. 93/2000 (Futtermittelverordnung 2000, as amended) containing general requirements for feedingstuffs and BGBl. II Nr. 243/2000 (GeflÃ¼gelhygieneverordnung 2000).

EC: salmonella monitoring, general requirements for feed material and compound feed, coordinated annual control program

Suggestions to the Community for the actions to be taken

Nil

Measures in case of the positive findings

Domestic feed material of plant origin

Notification of the positive findings and the confiscation and prescription of following official measures as withdrawal from the market, recall of feed, decontamination of the feed, disposal or other use of the feed, exploration and elimination of the sources of contamination and operational measures to prevent future contaminations.

Domestic feed material of animal origin

As above

Imported feed material of plant origin

As above

Imported feed material of animal origin

As above

Process control in feed mills

As above

Compound feedingstuffs

As above

Notification system in place

Notification to the local authority according the Rapid Alert System for Food and Feed (RASFF) that is in place since 1979. The legal basis of the RASFF is Regulation EC/178/2002.

National evaluation of the recent situation, the trends and sources of infection

In the last 20 years the situation in feed has improved due to the increase of numbers of farms, processing plants and retailer using HACCP concepts, traceability of contaminated feed/components of feed, palletizing feed/contaminated feed.

2.1.6. Salmonella serovars and phagetype distribution

The methods of collecting, isolating and testing of the Salmonella isolates are described in the chapters above respectively for each animal species, foodstuffs and humans. The serotype and phagetype distributions can be used to investigate the sources of the Salmonella infections in humans. Findings of same serovars and phagetypes in human cases and in foodstuffs or animals may indicate that the food category or animal species in question serves as a source of human infections. However as information is not available from all potential sources of infections, conclusions have to be drawn with caution.

2.1.7. Antimicrobial resistance in Salmonella isolates

Antimicrobial resistance is the ability of certain microorganisms to survive or grow in the presence of a given concentration of antimicrobial agent that usually would kill or inhibit the microorganism species in question. Antimicrobial resistant Salmonella strains may be transferred from animals or foodstuffs to humans.

A. Antimicrobial resistance of Salmonella spp. in animal

Sampling strategy used in monitoring

Frequency of the sampling

see Antimicrobial resistance of Salmonella spp. in food!

B. Antimicrobial resistance of Salmonella spp. in humans

History of the disease and/or infection in the country

The overall resistance-rates against antibiotics remained stable over the past years. High level resistances against Ciprofloxacin and third generation cephalosporins (Cefotaxime) were still extremely rare.

National evaluation of the recent situation, the trends and sources of infection

In 2006, there is no difference detectable in resistance-rates. The increase in the number of resistant isolates against ampicillin is due to more human cases affected by ampicillin resistant S. Enteritidis PT6a (2006: 185 cases, 2005: 18 cases).

Recent actions taken to control the zoonoses

Nil

Suggestions to the Community for the actions to be taken

Nil

Additional information

Nil

C. Antimicrobial resistance of Salmonella spp. in food

Sampling strategy used in monitoring

Frequency of the sampling

There is no monitoring program in Austria. All Salmonella spp. isolated in veterinary and food laboratories, as well as all primary isolates from humans were sent to the NRC-S and there the susceptibility testing has been performed using the disk diffusion method.

Type of specimen taken

Clinical samples from humans; for animals and food see chapters Salmonella spp. in animal species and Salmonella spp. in food.

Methods of sampling (description of sampling techniques)

Clinical samples from humans; for animals and food see chapters Salmonella spp. in animal species and Salmonella spp. in food.

Procedures for the selection of isolates for antimicrobial testing

All Salmonella spp. isolated in veterinary and food laboratories, as well as all primary isolates from humans were sent to the NRC-S and there the susceptibility testing has been performed using the disk diffusion method.

Laboratory methodology used for identification of the microbial isolates

See chapter salmonellosis in humans

Laboratory used for detection for resistance

Antimicrobials included in monitoring

All Salmonella isolates were susceptibility tested (disc diffusion) according to NCCLS. See corresponding tables!

Control program/mechanisms

The control program/strategies in place

All Salmonella spp. isolates that were sent to the NRL-S have been tested.

Suggestions to the Community for the actions to be taken

Europe wide harmonized standards for antimicrobial resistance monitoring would be highly welcome.

Additional information

Nil

D. Antimicrobial resistance of Salmonella spp. in animal - Gallus gallus (fowl) - broilers - sampling in the framework of the broiler baseline study - at farm

Sampling strategy used in monitoring

Frequency of the sampling

According to the technical specifications 365 flocks all over Austria have been sampled..

Type of specimen taken

In each flock 5 boot swabs were collected.

Procedures for the selection of isolates for antimicrobial testing

Each isolated Salmonella spp. was tested for the antimicrobial susceptibility by the disk diffusion test. In each flock positive for Salmonella spp., each strain was tested in the microdilution test for the minimal inhibition concentrations, e.g. if S. Enteritidis PT4 was isolated from 3 different samples within one flock, the microdilution test was performed only once with this strain.

Laboratory methodology used for identification of the microbial isolates

The method given in the technical specifications was used.

Control program/mechanisms

Recent actions taken to control the zoonoses

The baseline survey has been performed and the targets to reduce S. Enteritidis and S. Typhimurium set for the future.

Table Antimicrobial susceptibility testing of S.Enteritidis in animals

n = Number of resistant isolates

	S. Enteritidis							
	Cattle (bovine animals)		**Pigs**		**Gallus gallus (fowl)**		**Turkeys**	
Isolates out of a monitoring programme	no		no		no		no	
Number of isolates available in the laboratory	0		1		183		0	
Antimicrobials:	**N**	**n**	**N**	**n**	**N**	**n**	**N**	**n**
Tetracyclines								
Tetracyclin					183	1

2.2. CAMPYLOBACTERIOSIS

2.2.1. General evaluation of the national situation

A. Thermophilic Campylobacter general evaluation

History of the disease and/or infection in the country

In 2006, for the first time the number of notified human campylobacteriosis cases in Austria has exceeded the number of notified salmonellosis cases.

National evaluation of the recent situation, the trends and sources of infection

In the last years the number of notified cases of campylobacteriosis â with the exception of 2003 â steadily increased reaching a new peak of 5,110 cases in 2006.

The sources of infection are still unclear; the few published outbreaks in Austria were due to contaminated cowâ s milk or chicken meat. Pets are considered as another possible source.

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

Feedingsstuffs has no obvious relevance. Animals are heavily infected: broiler flocks up to 53 %.The actual source of infection is unknown in most cases, chicken meat may account for approx. 40% of human infections.

Recent actions taken to control the zoonoses

On 1st January 2006 the Federal Zoonoses Act (128. Bundesgesetz: Zoonosengesetz, published on 18th November 2005) has been implemented. The subject of this Act is to ensure that zoonoses, zoonotic agents and related antimicrobial resistance are properly monitored, that food-borne outbreaks receive proper epidemiological investigation, to enable the collection of the information necessary in the EU. According to this Zoonoses Act, to survey and combat the zoonoses in Austria,

a Federal Commission for Zoonoses (Zoonoses Commission) has been founded to advise the Federal Minister. The first meeting took place on May 3rd 2006. The tasks of this Zoonoses Commission are

â ¢ Securing of effective and continuous teamwork of special fields concerned

â ¢ Cooperation based on free exchange of general information and where necessary, of specific data

â ¢ Determination of measures in case of Austrian-wide food borne outbreaks (concerning several provinces by one outbreak)

â ¢ Issues the annually report on trends and sources of zoonoses in Austria

â ¢ Preparation of risk based, integrated monitoring and surveillance programmes

The Austrian wide monitoring program on the trends of campylobacter prevalence and antimicrobial resistance of campylobacter in poultry and bovine animals was continued for the third year according to the directive 2003/99/EC of the European Parliament and the Council of 17 November 2003 and the Federal Zoonoses Act (128. Bundesgesetz: Zoonosengesetz, published on 18th November 2005). The sampling was carried out from January 16th to November 17th 2006 and follow up programs will be realized in the forthcoming years.

Suggestions to the Community for the actions to be taken

Continue to work for harmonization of monitoring programs

Additional information

Nil

2.2.2. Campylobacteriosis in humans

A. Thermophilic Campylobacter in humans

Case definition

Clinical picture compatible with campylobacteriosis, e.g.: diarrheal illness of variable severity and isolation of Campylobacter spp. from stool.

Diagnostic/analytical methods used

Stool samples are plated on selective media and incubated in microaerobic atmosphere at 37- 42 Â°C for a minimum of 36 hours (Anonymus: Standardisierung und QualitÃ¤tssicherung in der mikrobiologischen Diagnostik. Richtlinien. Bundesministerium fÃ¼r Soziale Sicherheit und Generationen. ISBN 3-84123-126-0, Wien, 2001, pg. 13). Campylobacter is confirmed by observing the typical colony morphology and characteristic motility and morphology under the microscope. For typing and differentiation of isolates to species level the production of catalase and oxidase, the reaction in hippurate and indoxylacetate-hydrolysis is performed. The differentiation to species-level is not performed in each laboratory.

Notification system in place

Notification of campylobacteriosis since 1996 according to the epidemic act (BGBl. 1950/186 Epidemiegesetz, as amended): Primarily the attending physicians have to notify. Since 2002 an order has been implemented (Meldepflicht infektiÃ¶ser Erkrankungen fÃ¼r Labors GZ: 21.700/5-VIII/D/5/02), in which medical doctors specialised in Laboratory Diagnosis or Microbiology and Hygiene are subjected to notification.

The number of campylobacter cases presented in this report reflects the number of laboratory primary human isolates and respectively the number of laboratory confirmed cases.

On July 24th 2006 the amendments of the epidemic act (114. Bundesgesetz: Ã nderung des Epidemiegesetzes 1950) has been published: Accordingly, all zoonotic agents that are isolated in a laboratory and that are notifiable have to be sent to the corresponding reference laboratory for speciation.

History of the disease and/or infection in the country

In 2006, the number of notified human campylobacteriosis cases in Austria for the first time has exceeded the number of notified salmonellosis cases.

Results of the investigation

see table

National evaluation of the recent situation, the trends and sources of infection

Following the number of notifications per year, campylobacteriosis is the most frequently notified food borne enteric disease in 2006. It seems to be that there are two main reasons for this new situation: The improvement of the notification system and the higher awareness of possible Campylobacter infections by physicians and laboratories. Additionally the amendments of the epidemic act have been published on July 24th 2006 (114. Bundesgesetz: Ã nderung des Epidemiegesetzes 1950): Accordingly, all zoonotic agents that have been isolated from humans and that are notifiable have to be sent to the corresponding reference laboratory for speciation.

The main sources of infections seem to be chicken meat and raw milk (Feierl G. 2007. Jahresbericht 2006 der Nationalen Referenzzentrale fÃ¼r Campylobacter. Mitteilungen der SanitÃ¤tsverwaltung 4/2007).

Relevance as zoonotic disease

In 2006, campylobacteriosis has become the most frequently notified food borne disease in Austria.

Additional information

On July 24th 2006, the amendments of the epidemic act (114. Bundesgesetz: Ã nderung des Epidemiegesetzes 1950) have been published: Accordingly, all zoonotic agents that have been isolated from humans and that are notifiable have to be sent to the corresponding reference laboratory for speciation.

B. Antimicrobial resistance of thermophilic Campylobacter spp., unspecified in humans

History of the disease and/or infection in the country

A sentinel surveillance program for Campylobacter isolates from human infections was installed in October 2006. On a monthly basis, the first 10 isolates collected at each of four diagnostic laboratories serving different provinces in Austria are sent to the National Reference Laboratory for Campylobacter for speciation analysis and antimicrobial resistance testing.

Stool specimens were plated on Campylobacter blood-free selective media at 37 Â°C or 42 Â°C for 48 hours under micro aerobic conditions, and organisms were identified as Campylobacter spp. by oxidase testing and cell morphology. Isolates were speciated by hippurate hydrolysis, indoxyl acetate hydrolysis, katalase production, and species-specific real-time PCR.

Broth micro dilution susceptibility testing of Campylobacter spp. isolates was done using customised SensititreÂ® susceptibility micro titre plates (TREK Diagnostic Systems, Ltd., East Grinstead, West Sussex, and England). Briefly, Campylobacter spp. strains were subcultivated on Columbia blood agar and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Inocula from fresh cultures were prepared by suspension in physiological saline to obtain a turbidity equivalent to that of a McFarland standard 0.5. The suspension was added to Mueller Hinton bouillon for a final concentration of approximately 5x105 cfu/ml and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Campylobacter jejuni ATCC 33560 was used as control.

The number of isolates that are fully sensitive and the number of isolates resistant to 1, 2, 3, 4 and > 4 antimicrobials for Campylobacter includes only resistance to tetracycline, erythromycin, ciprofloxacin, gentamicin, and streptomycin!

National evaluation of the recent situation, the trends and sources of infection

Due to the fact that this sentinel surveillance system has been established for the first time in 2006 and the human isolates have been tested using the micro dilution method a comparison of results is not possible.

Suggestions to the Community for the actions to be taken

Continue to work for harmonization of monitoring programs.

Additional information

The newly established sentinel surveillance system will be continued.

2.2.3. Campylobacter in foodstuffs

A. C.,thermophilic in food

Monitoring system

Sampling strategy

No surveillance programmes are applied.

Foodstuff was sampled according to the Erlass der Bundesministerin fÃ¼r Gesundheit und Frauen: Revisions- und Probenplan fÃ¼r das Jahr 2006; Richtlinien Ã¼ber die Vollziehung der Ã berwachung des Verkehrs mit den durch das LMG 1975 erfassten Waren (GZ BMGF-75500/0164-IV/B/10/2005 of 26.01.2006). The Revision-Plan determines the number of food enterprises e.g. restaurants, dairies, retail etc. that have to be tested randomly per province according to the number of food enterprises per province. Each business has to be sampled at least once per year. The inspection can comprise sampling, hygienic investigations of the employees, checking of HACCP, control of manufacturing processes etc.

The sampling plan determines the number of samples of each class of goods, as raw meat, fresh or frozen; sausages; cheeses; milk; preserved food etc. that have to be investigated randomly. Samples from suspected foodstuffs are taken following outbreak investigation, complaint, confiscation, violation etc.

Information about the special monitoring programs (Schwerpunktprogramm 2006) for Campylobacter can be found on page 14.

Diagnostic/analytical methods used

Samples are cultured either according to ISO 10272: 1995 or preenriched in Bolton bouillon at 42 Â°C for 48 hours and subsequent plated on CCDA- or modified CCDA agar at 42 Â°C for 48 hours microaerophilic. Campylobacter-like colonies were identified serologically, observing their characteristic motility and morphology under the microscope and the production of catalase and oxidase. Not all isolates of Campylobacter spp. are differentiated.

Results of the investigation

see tables

National evaluation of the recent situation, the trends and sources of infection

366 single samples of poultry meat, fresh or raw were tested and in 18.3 % (=67 samples) thermophilic Campylobacter was found. In 2006, the percentage of positive samples has been doubled in broiler meat (9.3 % to 18.3 %).

In 1 out of 93 tested single pig meat samples of the special monitoring program A045 and in none of the 103 tested bovine meat samples (A008) thermophilic Campylobacter could be detected.

2.2.4. Campylobacter in animals

A. Thermophilic Campylobacter in Gallus gallus

Monitoring system

Sampling strategy

Monitoring program on the occurrence and trend of antimicrobial resistance in thermophilic Campylobacter is based on the prevalence of campylobacter in slaughter batches: At an estimated percentage of resistance in antimicrobials of 40 to 60 % and a desired accuracy of 5 % for a confidence level of 95%, 382 isolates of Campylobacter jejuni/coli from poultry were required.

To obtain this number of isolates, as primary sample size, 597 slaughter batches of poultry had to be tested, calculated on approximately more than 10,000 slaughter batches of poultry in 2004 in Austria, with an estimated prevalence of Campylobacter jejuni/coli of 61.4 %, based on the results from the monitoring in 2005, and at a desired accuracy of 5% for a confidence level of 95%. As a secondary sample size caeca of 10 animals had to be collected. The secondary sample size gives the number of birds to be sampled per batch and had been computed on slaughter batches of more than 2000 broilers, an expected prevalence of 30% within the batch and a confidence level of 95%. The sampling had been stratified on the number of slaughter batches by slaughter plants all over Austria. The date of sampling was randomized over the period of the study.

Sampling was performed in the 8 poultry slaughter plants with slaughter batches consisting of >2000 animals in Austria in 2004. The 8 slaughter plants included in the monitoring program accounted for almost 100% of broilers and turkeys of the total production in Austria.

Frequency of the sampling

At slaughter

Other: Detection of annual prevalence in slaughter batches of 61.4 % at a 5% desired accuracy for a 95% level of confidence. The sampling was distributed by randomization over the period of the study from January 16th to November 17th 2006.

Type of specimen taken

At slaughter

Other: Intestines of 10 animals.

Methods of sampling (description of sampling techniques)

At slaughter

The sampling was performed by official veterinarians carrying out the post-mortem inspection. At time of evisceration the whole intestines of 10 animals were taken and wrapped in a sterile plastic bag. After cooling down to 4 Â°C the sample was sent in a hobbock or polystyrene box after adding cooling units to the locally appropriate Institute of Veterinary Diseases Control (IVET). In the laboratory a caecum of each intestinal convolute was identified, some content of each caecum pooled and plated on selective medium suitable for Campylobacter jejuni/coli.

Case definition

At slaughter

A slaughter batch is considered to be infected with thermophilic Campylobacter following isolation of Campylobacter jejuni or C. coli from its colon.

Diagnostic/analytical methods used

At slaughter

Bacteriological method: The pooled samples were examined by direct inoculation on modified CCD agar (mCCDA) that was incubated in microaerophilic atmosphere at 42 Â± 1 Â°C for 48 hours. Campylobacter-like colonies were identified by observing their characteristic motility and morphology under the microscope and the production of catalase and oxidase. For typing and differentiating of C. jejuni and C. coli isolates, hippurate reaction and indoxylacetate-hydrolysis was performed. All C. jejuni and C. coli isolates were frozen in proteose peptone solution containing 10% glycerol or thioglycolat-broth at -70 Â°C. For quality control Campylobacter jejuni ATCC 33560, Escherichia coli ATCC 25922 and internal control isolates C. jejuni and C. coli were used. Statistical analysis was performed with EpiInfo version 3.3.2.

Vaccination policy

Vaccination is not performed in Austria.

Other preventive measures than vaccination in place

None.

Control program/mechanisms

The control program/strategies in place

None.

Recent actions taken to control the zoonoses

None.

Suggestions to the Community for the actions to be taken

Emphasis should be placed on education of the people for a better care in kitchen hygiene.

Measures in case of the positive findings or single cases

None.

Notification system in place

Findings of C. jejuni and C. coli are not notifiable in poultry in Austria.

Results of the investigation

See table.

National evaluation of the recent situation, the trends and sources of infection

In 2006, 52.7 % (315 out of 598) of the tested poultry slaughter batches/flocks were positive for thermophilic Campylobacter. There was again a decrease in the prevalence compared to the previous years. The prevalence in broiler flocks was 52.2 % (287 out of 550) and 59.1 % (13 out of 22) in turkey flocks. Due to the fact that poultry is the animal species with the highest prevalence of Campylobacter jejuni and coli, poultry meat seem to be the most risky food combined with mistakes in kitchen hygiene for acquiring an infection with C. jejuni/coli.

Additional information

Nil

B. Campylobacter spp. in animal - Pigs - at slaughterhouse - animal sample - faeces - Monitoring - official sampling - objective sampling

Monitoring system

Sampling strategy

Contrarily to the previous years and due to the fact that 99 % of the isolated thermophilic campylobacters in pigs are C. coli, which are only rarely detected in humans (approx. 5 %, see tables), there was no monitoring program conducted in pigs in 2006.

C. thermophilic Campylobacter spp., unspecified in animal - Cattle (bovine animals) - at slaughterhouse - animal sample - faeces - Monitoring - official sampling - objective sampling

Monitoring system

Sampling strategy

The monitoring program on the occurrence and trends of antimicrobial resistance in thermophilic Campylobacter is based on the prevalence of campylobacter in slaughtered animals: At an estimated percentage of resistance in antimicrobials of 40 to 60 % and a

desired accuracy of 6 % for a confidence level of 95%, 256 isolates of Campylobacter jejuni/coli from bovine animals were required.

To obtain this number of isolates, as sample size 1,347 slaughtered bovine animals had to be tested, calculated on approximately 650.000 slaughtered bovine animals in 2004 in Austria, with an estimated prevalence of Campylobacter jejuni/coli of 19 %, based on the results of the monitoring in 2005, and at a desired accuracy of 5% for a confidence level of 95%. The sampling had been stratified on the number of slaughtering by abattoirs all over Austria. The date of sampling was randomized over the period of the study.

In Austria, all 68 abattoirs in which more than 500 bovine animals were slaughtered in 2004 accounted for approximately 83% of the total annual bovine production. Sampling was planned in 51 of the 68 abattoirs excluding those in which only one sampling in the whole period of the study would have been carried out.

Frequency of the sampling

The sampling was distributed by randomization over the period of the study from January 16th to November 17th 2006.

Type of specimen taken

Other: Caecum containing a minimum of 50 to 100 grams of faeces.

Methods of sampling (description of sampling techniques)

The sampling was performed by official veterinarians carrying out the post-mortem inspection. At time of evisceration a part of the colon was ligated and wrapped in a sterile plastic bag. After cooling down to 4Â°C the sample was sent in a hobbock or polystyrene box after adding cooling units to the locally appropriate Institute of Veterinary Diseases Control (IVET). In the laboratory some content of each colon was inoculated in selective bouillon suitable for Campylobacter jejuni/coli.

Case definition

A bovine animal is considered to be infected with thermophilic Campylobacter following isolation of Campylobacter jejuni or C. coli from its caecum.

Diagnostic/analytical methods used

Approximately 1 gram of content of the colon was enriched in Preston bouillon in microaerophilic atmosphere for 24 hours at 42 Â°C. Subsequently the preenrichment was plated on modified CCD agar (mCCDA) and incubated in microaerophilic atmosphere at 42 Â± 1 Â°C for 48 hours. Campylobacter-like colonies were identified by observing their characteristic motility and morphology under the microscope and the production of catalase and oxidase.

For typing and differentiating of C. jejuni and C. coli isolates, hippurate reaction and indoxylacetate-hydrolysis was performed. All C. jejuni and C. coli isolates were frozen in proteose pepton solution containing 10% glycerol or thioglycolate-broth at -70 Â°C.

For quality control Campylobacter jejuni ATCC 33560, Escherichia coli ATCC 25922 and internal control isolates of C. jejuni and C. coli.

Statistical analysis was performed with EpiInfo version 3.3.2.

Vaccination policy

Vaccination is not performed in Austria

Other preventive measures than vaccination in place

None

Control program/mechanisms

The control program/strategies in place

None

Recent actions taken to control the zoonoses

None

Suggestions to the Community for the actions to be taken

Emphasis should be placed on education of the people for a better care in kitchen hygiene.

Measures in case of the positive findings or single cases

None

Notification system in place

Findings of C. jejuni and C. coli are not notifiable in poultry in Austria.

Results of the investigation

See table

National evaluation of the recent situation, the trends and sources of infection

In 2006, 19.4 % (258 out of 1,329 samples) of slaughtered bovine animals were positive for thermophilic Campylobacter. In meat production animals thermophilic Campylobacter could be detected in 28.6 % compared to 24.1 % in calves and 14.2 % in dairy cows. There was no significant change in the prevalence compared to the previous years. Compared to 52.7 % of poultry slaughter batches positive for thermophilic Campylobacter, it seems that the risk for humans to get infected after consumption of beef or veal remains of less relevance.

2.2.5. Antimicrobial resistance in Campylobacter isolates

A. Antimicrobial resistance in Campylobacter jejuni and coli in cattle

Sampling strategy used in monitoring

Frequency of the sampling

Described in chapter: Thermophilic campylobacter in bovine animals

Type of specimen taken

Described in chapter: Thermophilic campylobacter in bovine animals

Methods of sampling (description of sampling techniques)

Described in chapter: Thermophilic campylobacter in bovine animals

Procedures for the selection of isolates for antimicrobial testing

All 218 isolates of Campylobacter jejuni and 40 isolates of C. coli obtained in the monitoring program were sent to the AGES Institute for Medical Microbiology and Hygiene in Graz where the antimicrobial susceptibility testing of all isolates of Campylobacter spp. was performed.

Methods used for collecting data

All informations concerning the tested animals, sampled slaughterhouses and results of the antimicrobial testing were entered and analysed in a MicrosoftÂ® Excel tables.

Laboratory methodology used for identification of the microbial isolates

Described in chapter: Thermophilic campylobacter in bovine animals.

Broth micro dilution susceptibility testing of Campylobacter spp. isolates was done using customised SensititreÂ® susceptibility micro titre plates (TREK Diagnostic Systems, Ltd., East Grinstead, West Sussex, and England). Briefly, Campylobacter spp. strains were subcultivated on Columbia blood agar and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Inocula from fresh cultures were prepared by suspension in physiological saline to obtain a turbidity equivalent to that of a McFarland standard 0.5. The suspension was added to Mueller Hinton bouillon for a final concentration of approximately 5x105 cfu/ml and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Campylobacter jejuni ATCC 33560 was used as control.

MIC values have been entered in a MicrosoftÂ® Excel datasheet.

The number of isolates that are fully sensitive and the number of isolates resistant to 1, 2, 3, 4 and > 4 antimicrobials for Campylobacter includes only resistance to tetracycline, erythromycin, ciprofloxacin, gentamicin, and streptomycin!

Laboratory used for detection for resistance

Antimicrobials included in monitoring

B. Antimicrobial resistance in Campylobacter jejuni and coli in pigs

Sampling strategy used in monitoring

Frequency of the sampling

Contrarily to the previous years and due to the fact that 99 % of the isolated thermophilic campylobacters in pigs are C. coli, which are only rarely detected in humans (approx. 5 %, see tables), there was no monitoring program conducted in pigs in 2006.

C. Antimicrobial resistance in Campylobacter jejuni and coli in poultry

Sampling strategy used in monitoring

Frequency of the sampling

Described in chapter: Thermophilic Campylobacter in poultry

Type of specimen taken

Described in chapter: Thermophilic Campylobacter in poultry

Methods of sampling (description of sampling techniques)

Described in chapter: Thermophilic Campylobacter in poultry

Procedures for the selection of isolates for antimicrobial testing

All 179 isolates of Campylobacter jejuni and 136 isolates of C. coli obtained in the monitoring program were sent to the IMED in Graz where the antimicrobial susceptibility testing of all isolates of Campylobacter spp. was performed.

Methods used for collecting data

All informations concerning the tested flocks, sampled slaughterhouses and results of the antimicrobial testing were entered and analysed in a MicrosoftÂ® Excel tables.

Laboratory methodology used for identification of the microbial isolates

Described in chapter: Thermophilic Campylobacter in poultry.

Laboratory used for detection for resistance

Antimicrobials included in monitoring

Broth micro dilution susceptibility testing of Campylobacter spp. isolates was done using customised SensititreÂ® susceptibility micro titre plates (TREK Diagnostic Systems, Ltd., East Grinstead, West Sussex, and England). Briefly, Campylobacter spp. strains were subcultivated on Columbia blood agar and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Inocula from fresh cultures were prepared by suspension in physiological saline to obtain a turbidity equivalent to that of a McFarland standard 0.5. The suspension was added to Mueller Hinton bouillon for a final concentration of approximately 5x105 cfu/ml and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Campylobacter jejuni ATCC 33560 was used as control.MIC values have been entered in a MicrosoftÂ® Excel datasheet.

Antimicrobials included in monitoring, see tables.

The number of isolates that are fully sensitive and the number of isolates resistant to 1, 2, 3, 4 and > 4 antimicrobials for Campylobacter includes only resistance to tetracycline, erythromycin, ciprofloxacin, gentamicin, and streptomycin!

D. Antimicrobial resistance of thermophilic Campylobacter spp., unspecified in humans

History of the disease and/or infection in the country

A sentinel surveillance program for Campylobacter isolates from human infections was installed in October 2006. On a monthly basis, the first 10 isolates collected at each of four diagnostic laboratories serving different provinces in Austria are sent to the National Reference Laboratory for Campylobacter for speciation analysis and antimicrobial resistance testing.

Stool specimens were plated on Campylobacter blood-free selective media at 37 Â°C or 42 Â°C for 48 hours under micro aerobic conditions, and organisms were identified as Campylobacter spp. by oxidase testing and cell morphology. Isolates were speciated by hippurate hydrolysis, indoxyl acetate hydrolysis, katalase production, and species-specific real-time PCR.

Broth micro dilution susceptibility testing of Campylobacter spp. isolates was done using customised SensititreÂ® susceptibility micro titre plates (TREK Diagnostic Systems, Ltd., East Grinstead, West Sussex, and England). Briefly, Campylobacter spp. strains were subcultivated on Columbia blood agar and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Inocula from fresh cultures were prepared by suspension in physiological saline to obtain a turbidity equivalent to that of a McFarland standard 0.5. The suspension was added to Mueller Hinton bouillon for a final concentration of approximately 5x105 cfu/ml and incubated for 48 hours at 37 Â°C in a microaerophilic atmosphere. Campylobacter jejuni ATCC 33560 was used as control.

The number of isolates that are fully sensitive and the number of isolates resistant to 1, 2, 3, 4 and > 4 antimicrobials for Campylobacter includes only resistance to tetracycline, erythromycin, ciprofloxacin, gentamicin, and streptomycin!

National evaluation of the recent situation, the trends and sources of infection

Due to the fact that this sentinel surveillance system has been established for the first time in 2006 and the human isolates have been tested using the micro dilution method a comparison of results is not possible.

Suggestions to the Community for the actions to be taken

Continue to work for harmonization of monitoring programs.

Additional information

The newly established sentinel surveillance system will be continued.

Table Antimicrobial susceptibility testing of C. coli in Cattle (bovine animals) - at slaughterhouse - animal sample - faeces - Monitoring - official sampling - objective sampling - quantitative data [Dilution method]

2.3. LISTERIOSIS

2.3.1. General evaluation of the national situation

A. Listeriosis general evaluation

History of the disease and/or infection in the country

Listeriosis can be regarded as a relatively rare infectious disease in Austria with an annual incidence between 0.1 and 0.25 cases per 100,000 inhabitants in the years 1996 to 2005. In 2006 a total of 10 culturally verified human cases of listeriosis were recorded for Austria, one of them was associated with pregnancy. The incidences are similar to those of most other western European countries (0.2-0.7). Lethality was high with 20% (2 out of 10) in 2006. This (usually) high rate and the sometimes severe permanent disabilities demand every effort to ascertain potential food-associated outbreaks as early as possible. However, the geographical distribution and the molecular subtyping results argue against any epidemic in Austria in 2006 (WÃ¼rzner R, Heller I, Grif, K 2006. Taetigkeitsbericht fÃ¼r das Jahr 2006. Mitteilungen der Sanitaetsverwaltung 4/2007: in press)

National evaluation of the recent situation, the trends and sources of infection

See 2.3.1.A. History of the disease

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

Listeriosis is a rare disease, but not a rare bacterium, which means that a systemic disease develops only under certain particular predispositions, including pregnancy and immunosuppression.

Although dairy products and salmon are likely candidates, the source of an infection often remains unclear. Ready-to-eat meat and meat products harbour listeria in 0 â 7 % and ready-to-eat smoked fish in 9 %.

Recent actions taken to control the zoonoses

A monthly report is sent to the Ministry of Health by the National Reference Center, whereas outbreaks are reported immediately.

Restrictions tightened to sell unpasteurised milk in remote areas (Alps).

Suggestions to the Community for the actions to be taken

More widespread information for pregnant and immunocompromised persons should be provided.

Additional information

The National Reference Center at Innsbruck Medical University coordinates the confirmation, subtyping and comparison of isolates.

2.3.2. Listeriosis in humans

A. Listeriosis in humans

Reporting system in place for the human cases

A monthly report is sent to the Ministry of Health by the National Reference Center, whereas outbreaks are reported immediately.

Case definition

A clinically compatible case that is laboratory confirmed after isolation of L. monocytogenes from a normally sterile site or vaginal swabs.

Diagnostic/analytical methods used

Bacteriology: Smears of the samples are Gram stained. Specimen from normally sterile sites are inoculated in blood culture broth or thioglycollate broth and Columbia blood agar plates, vaginal swabs are plated only directly on Columbia blood and colistin-nalidixic acid (CNA) agar. L. monocytogenes is identified by catalase and Api Coryne test.

All isolates obtained in Austria are sent to the National Reference Center for confirmation, subtyping and comparison.

Notification system in place

Medical doctors specialised in Laboratory Diagnosis or Microbiology and Hygiene and the attended physicians are subjected to notification. Infections, fatal cases and suspected cases of listeriosis have to be notified according to the National Regulation 254/2004 (BGBl. II, 254/2004, Anzeigepflichtige Ã¼bertragbare Krankheiten 2004).

History of the disease and/or infection in the country

See 2.3.1.A. History of the disease

National evaluation of the recent situation, the trends and sources of infection

See 2.3.1.A. History of the disease

Relevance as zoonotic disease

Listeriosis is a rare disease, but not a rare bacterium, which means that a systemic disease develops only under certain particular predispositions, including pregnancy and immunosuppression.

Although dairy products and salmon are likely candidates, the source of an infection often remains unclear.

Additional information

The National Reference Center at Innsbruck Medical University coordinates the confirmation, subtyping and comparison of isolates.

2.3.3. Listeria in foodstuffs

A. Listeria spp., unspecified in food

Monitoring system

Sampling strategy

No surveillance programmes are applied.

Foodstuff was sampled according to the Erlass der Bundesministerin fÃ¼r Gesundheit und Frauen: Revisions- und Probenplan fÃ¼r das Jahr 2006; Richtlinien Ã¼ber die Vollziehung der Ã berwachung des Verkehrs mit den durch das LMG 1975 erfassten Waren (GZ BMGF-75500/0164-IV/B/10/2005 of 26.01.2006). The Revision-Plan determines the number of food enterprises e.g. restaurants, dairies, retail etc. that have to be tested randomly per province according to the number of food enterprises per province. Each business has to be sampled at least once per year. The inspection can comprise sampling, hygienic investigations of the employees, checking of HACCP, control of manufacturing processes etc.

The sampling plan determines the number of samples of each class of goods, as raw meat, fresh or frozen; sausages; cheeses; milk; fish; preserved food etc. that have to be investigated randomly. Samples from suspected foodstuffs are taken following outbreak investigation, complaint, confiscation, violation etc.

Information about the special monitoring programs (Schwerpunktprogramm 2006) for Listeriosis can be found on page 14.

Diagnostic/analytical methods used

At the production plant

Other: Qualitative detection of Listeria spp. is performed according to ISO

At retail

Other: Qualitative detection of Listeria spp. is performed according to ISO

National evaluation of the recent situation, the trends and sources of infection

Listeria monocytogenes was detected in samples of cheeses in 0.5 % from cow milk (5/926, 0% from goat milk (0/43) and 15.6 % from sheep milk (7/45). In one sample of soft cheeses from pasteurised cow milk the content of L. monocytogenes was >100 cfu/g.

In 8/359 fresh poultry meat samples (2.2%), 14/152 fresh pig meat samples (9.2%) and in 6/62 fresh bovine meat samples (9.6%) L. monocytogenes was found but always at a lower content than 100/g.

4.8% of samples from fishery products (20/413) revealed a contamination with L. monocytogenes; the quantification showed 1 sample with a higher cfu than 100 per gram and 6 samples contained L. innocua.

2.3.4. Listeria in animals

A. Listeria spp., unspecified in animal

Monitoring system

Sampling strategy

There is no active surveillance system and detection of cases is based on clinical observations.

Frequency of the sampling

When there is a suspected case.

Case definition

A case may be defined with positive histopathology and/or positive bacteriology. The animal is the epidemiological unit.

Diagnostic/analytical methods used

The diagnostic methods used include histopathology and bacteriology.

Measures in case of the positive findings or single cases

None

Notification system in place

Listeriosis is not notifiable in animal species.

Relevance of the findings in animals to findings in foodstuffs and to human cases (as

a source of infection)

As Listeria spp are present in the environment and also to a small degree in food-producing animals, a risk of contracting domestic listeriosis does exist.

Table Listeria in animals

2.4. E. COLI INFECTIONS

2.4.1. General evaluation of the national situation

A. Verotoxigenic Escherichia coli infections general evaluation

History of the disease and/or infection in the country

In the year 2006, 345 samples were investigated at the Austrian Reference Center for Enterohemorrhagic Escherichia coli (EHEC). Thereby, 83 isolates (from 54 human, 5 veterinarian und 24 food samples) were confirmed, including 35 human EHEC, 19 human LP-STEC (Shiga toxin producing E. coli without eae-gene) and 2 serologically identified EHEC cases were diagnosed (56 human cases in total). Compared to the year before the number of EHEC O157 (16 isolates and 2 serologic cases) decreased a little bit, whereas the number of EHEC non-O157 was similar to the year before. Among the 56 diagnosed human EHEC and STEC cases in 2006, 5 cases with hemolytic uremic syndrome (HUS) as post infectious complication were diagnosed (2 caused by O157, one by O71:H8, one by O174:H21 and one by a double infection of ONT:H18 and O148:H-). The incidence of HUS in children in Austria due to EHEC and STEC was 0.23 HUS-cases per 100.000 children of age between 0 and 14 years in the year 2006.

The number of EHEC/STEC cases varied drastically between the different provinces, led by the province Tyrol with 37 confirmed EHEC/STEC cases. The reason for that may lie in a new EHEC screening program initiated in 2004.

There were no big outbreaks in Austria in 2006, only 4 small family outbreaks.

National evaluation of the recent situation, the trends and sources of infection

See History of the disease

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

In 2005, 6.0% (CI 3.1 â 10.5; 12 out of 201 samples) of slaughtered bovine animals were positive in the VT ELISA. VTEC could be isolated from 3.0% (CI 1.1 â 6.4; 6 out of 201 samples). One isolate, an E. coli O157:H7, positive for stx1 and stx2, was the only that harboured the eae-gene for the virulence factor Intimin. In 2004, in 1 out 287 samples (0.3%) E. coli O163:H- harbouring stx1, eae and EHEC-hly could be detected.

4.3% (CI 1.2 â 10.8; 4 out of 92 samples) of slaughtered sheep were positive in the VT-ELISA and from all 4 samples VTEC could be isolated. None of these isolates harboured the intimin gene.

The data of two outbreaks in Austria in 2003 involving environmental transmission or animal contact have been published as full papers (Grif et al., 2005, Eur J Clin Microbiol Infect Dis 24: 268-271 & Orth et al., 2006, Epidemiol Infect, in press).

Recent actions taken to control the zoonoses

An Austrian wide monitoring program on the trends of VTEC prevalence in bovine animals and sheep/goats was implemented according to the directive 2003/99/EC of the European Parliament and the Council of 17 November 2003 in the National Order GZ: BMGF-74600/0092--IV/B/8/05 (Ã berwachungsprogramme 2005 zu ausgewÃ¤hlten Zoonosen und Antibiotikaresistenzen). The sampling was carried out from 30 May to 2 December 2005 and follow up programs will be realized in the forthcoming years.

Suggestions to the Community for the actions to be taken

More widespread information for parents, paediatrics and general practioners.

Additional information

The National Reference Center at Innsbruck Medical University coordinates the confirmation, subtyping and comparison of isolates.

In addition, the Reference Center is involved in outbreak investigations. When EHEC is diagnosed in a patientâ s specimen the patient and his family are interviewed using a questionnaire. Thereby, information about the clinical illness of the patient and the exposure in the 6 days prior to the onset of the illness is collected. Thus, the Reference Center contributes to finding the source of infection. The Reference Center is also in close contact with the Local and Regional Health Authorities by reporting EHEC cases and discussing the necessary environmental investigations.

2.4.2. E. Coli Infections in humans

A. Verotoxigenic Escherichia coli infections in humans

Reporting system in place for the human cases

A monthly report is sent to the Ministry of Health by the National Reference Center, whereas outbreaks are reported immediately.

Case definition

Clinical description: Clinical picture compatible with EHEC infection, e.g. diarrhoea (often bloody) and abdominal cramps. Illness may be complicated by haemolytic uraemic syndrome (HUS) or thrombotic thrombocytopenic purpura (TTP).

Laboratory criteria for diagnosis: Detection of genes coding for Stx1/Stx2 production.

For probable cases: Isolation of E. coli belonging to a serogroup known to cause enterohaemorrhagic disease.

Serological confirmation in patients with HUS or TTP (only in selected cases).

Diagnostic/analytical methods used

1. Detection of E. coli O157 (most prominent serotype in HUS cases):

- Bacteriology: Isolation of O157 colonies on Sorbitol-MacConkey agar after incubation for 24 hours at 37 Â°C. O157 is confirmed via the E. coli O157 Latex Test.

- Serology: This method is constantly used at the German HUS-"Konsiliarlabor"; anti-O157 antibodies of IgG and IgM types can be distinguished.

2. Detection of Verotoxin (VTEC)-producing strains (used at the National Reference Center for EHEC/VTEC/STEC in Innsbruck): Stools are enriched overnight in a medium containing mitomycin C (EHEC Direct Medium, Heipha, Heidelberg, Germany). Enriched cultures are investigated for presence of Shiga toxins by commercial EIA (e.g. Premier, Novitec). Isolate identification is further confirmed by conventional biochemical tests (API 20 E, bioMerieux, Marcy-lÂ´Etoile, France). Enrichments are plated on Sorbitol-MacConkey agar and incubated for 24 hours at 37 Â°C. Detection of stx1 and stx2 genes and of the genes encoding EHEC hemolysin (hlyA) and intimin (eae) is done by PCR (Gerber et al. (2002) J Infect Dis 186:493-500).

All EHEC/STEC/VTEC isolates obtained in Austria are sent to the National Reference Center for confirmation, subtyping and comparison. All Shiga toxin producing E. coli are serotyped with E. coli antisera (E. coli antisera, Statens Serum Institut, Copenhagen, Denmark). Comparison of the isolates is done by Pulsed-Field-Gel-Electrophoresis and Ribotyping.

Notification system in place

Medical doctors specialised in Laboratory Diagnosis or Microbiology and Hygiene and the attended physicians are subjected to notification. Notification of bacteriological food-borne illness according to the epidemic act has been mandatory since 1950 (BGBl. 1950/186 Epidemiegesetz, as amended).

History of the disease and/or infection in the country

See History of the disease, general evaluation.

Results of the investigation

See table.

National evaluation of the recent situation, the trends and sources of infection

See History of the disease, general evaluation.

Relevance as zoonotic disease

HUS is a rare disease, but EHECs themselves are not rare, which means that a systemic disease develops only under certain particular predispositions, most of which are currently unknown. Although uncooked meat and unpasteurised dairy products are likely candidates to contract the bacterium, the source of an infection often remains unclear.

Additional information

The National Reference Center at Innsbruck Medical University coordinates the confirmation, subtyping and comparison of isolates.

2.4.3. Escherichia coli, pathogenic in foodstuffs

A. Verotoxigenic E. coli (VTEC) in food

Monitoring system

Sampling strategy

No surveillance programmes are applied.

Foodstuff was sampled according to the Erlass der Bundesministerin fÃ¼r Gesundheit und Frauen: Revisions- und Probenplan fÃ¼r das Jahr 2005; Richtlinien Ã¼ber die Vollziehung der Ã berwachung des Verkehrs mit den durch das LMG 1975 erfassten Waren (GZ BMGF-75500/0087--IV/B/10/2004 of 23.12.2004). The Revision-Plan determines the number of food enterprises e.g. restaurants, dairies, retail etc. that have to be tested randomly per province according to the number of food enterprises per province. Each business has to be sampled at least once per year. The inspection can comprise sampling, hygienic investigations of the employees, checking of HACCP, control of manufacturing processes etc.

The sampling plan determines the number of samples of each class of goods, as raw meat, fresh or frozen; sausages; cheeses; milk; preserved food etc. that have to be investigated randomly.

Samples from suspected foodstuffs are taken following outbreak investigation, complaint, confiscation, violation etc.

Information about the special monitoring programs (Schwerpunktprogramm 2006) for VT E.coli can be found on page 14.

Diagnostic/analytical methods used

Suspected food was preenriched in modified tryptic soy bouillon containing novobiocin at 37

Â°C for 24 hours. The enrichment is plated on FluorocultÂ® ECD Agar or Chromocult Coliformen Agar at 37 Â°C for 24 hours. The enrichment or E. coli colonies are tested in PCRs for harbouring Shiga Toxin 1 and/or 2 genes (Brian MJ et al., 1992: Polymerase chain reaction for diagnosis of enterohemorrhagic Escherichia coli infection and haemolytic-uremic syndrome. J. Clin. Microbiol. 30, pp. 1801-1806). Each Shiga-Toxin producing E. coli is serotyped in the National Reference Laboratory for EHEC and virulence factors are determined.

National evaluation of the recent situation, the trends and sources of infection

In 5 out of 112 bovine meat preparation samples (4.5%) from the special food programme A08, VT E.coli was detected. Also in 2 of the 164 samples (1.2%) of minced meat â intended to be eaten cooked, the pathogen was found.

2.4.4. Escherichia coli, pathogenic in animals

A. Verotoxigenic Escherichia coli in cattle (bovine animals)

Monitoring system

Sampling strategy

The monitoring program on the prevalence of VTEC in slaughtered animals: At an estimated prevalence for VTEC of 5.9 %, based on the weighted results from the monitoring in 2004 and 2005, and a desired accuracy of 5 % for a confidence level of 95%, a VTEC ELISA test sensitivity of 95 % and specificity of 98 %, 288 slaughtered bovine animals had to be tested, calculated on approximately 650,000 slaughtered bovine animals in Austria in 2004.

The sampling had been stratified on the number of slaughtering by abattoirs all over Austria. The date of sampling was randomized over the period of the study.

In Austria, all 68 abattoirs in which more than 500 bovine animals were slaughtered in 2004 accounted for approximately 83% of the total annual bovine production. Sampling was planned in 51 of the 68 abattoirs excluding those in which only one sampling in the whole period of the study would have been carried out.

Frequency of the sampling

Animals at slaughter (herd based approach)

Other: The sampling was distributed by randomization over the period of the study from January 16th to November 17th 2006.

Type of specimen taken

Animals at slaughter (herd based approach)

Other: Colon containing a minimum of 50 to 100 grams of faeces.

Methods of sampling (description of sampling techniques)

Animals at slaughter (herd based approach)

The sampling was performed by official veterinarians carrying out the post â mortem inspection. At time of evisceration a part of the colon was ligated and wrapped in a sterile plastic bag. After cooling down to 4 Â°C the sample was sent within the same day in a hobbock or polystyrene box after adding cooling units to the locally appropriate AGES Institute of Veterinary Diseases Control (IVET). All samples were forwarded to the IVET in Linz, where the VTEC â examinations were carried out. In the laboratory some content of each colon was inoculated into bouillon.

Case definition

Animals at slaughter (herd based approach)

An animal is considered to be infected with VTEC following the isolation of VTEC from its intestine.

Diagnostic/analytical methods used

Animals at slaughter (herd based approach)

Other: At first approximately 1 g of content of the colon was preenriched in modified tryptic soy bouillon containing novobiocin (mTSB + n) for 5 hours at 37 Â°C on a shaker. Then 1 ml was inoculated into mTSB + n containing mitomycin C for 18-20 hours at 37Â°C on a shaker too. The process was followed by testing the enrichment for the occurrence of verotoxin in an enzyme immune assay (RidascreenÂ®, Premier (TM) EHEC). Positive enrichments were plated on MacConkey (MAC) - and on cefixime tellurite sorbitol MAC (CTSMAC) agar and incubated for 24 hours at 37Â°C. 2-4 colonies from each of the plates were subcultered on MAC as well as on CTSMAC. Afterwards the genomes of subcultered E. coli were investigated in a real time PCR for harboring the genes for Verotoxin 1, Verotoxin 2, Intimin and Enterohemolysin (Reischl U. et al. (2002): Real-Time Fluorescence PCR Assays for Detection and Characterization of Shiga Toxin, Intim and Enterohemolysin Genes from Shiga Toxin-Producing Escherichia coli. Journ. of Clin. Microb., 40, p. 2555-2565).

Vaccination policy

No vaccination

Other preventive measures than vaccination in place

No measures

Control program/mechanisms

Suggestions to the Community for the actions to be taken

Harmonization of methods

Measures in case of the positive findings or single cases

No measures foreseen

Notification system in place

Findings of VTEC in animals are not notifiable.

Results of the investigation

See tables

National evaluation of the recent situation, the trends and sources of infection

The prevalence of isolated VTEC for cattle and small ruminants is stable below 5 %.

Additional information

Nil

B. Verotoxigenic E. coli (VTEC) in animal - Sheep and goats - at slaughterhouse - animal sample - faeces - Monitoring - official sampling - objective sampling

Monitoring system

Sampling strategy

Monitoring program on the prevalence of VTEC in slaughtered animals: At an estimated prevalence for VTEC of 3.7 %, based on the weighted results from the monitoring in 2004 and 2005, and a desired accuracy of 5% for a confidence level of 95%, a VTEC ELISA test sensitivity of 95 % and specificity of 98 %, 101 slaughtered sheep and goats had to be tested, calculated on approximately 340,000 slaughtered sheep and goats in Austria in 2004.

The sampling had been stratified on the number of slaughtering by abattoirs all over Austria. The date of sampling was randomized over the period of the study.

In Austria, all 11 abattoirs in which more than 200 sheep and goats were slaughtered in 2004 accounted for more than 90% of the total annual sheep and goat production. Sampling was performed in the 11 abattoirs.

Frequency of the sampling

Animals at slaughter (herd based approach)

Other: The sampling was distributed by randomization over the period of the study from January 16th to November 17th 2006.

Type of specimen taken

For some EIA positive samples (Verotoxigenic E. coli - VTEC, unspecified) no VTEC isolation was possible. EIA = Enzyme immune assay.

2.5. TUBERCULOSIS, MYCOBACTERIAL DISEASES

2.5.1. General evaluation of the national situation

A. Tuberculosis general evaluation

History of the disease and/or infection in the country

Human tuberculosis has steadily declined during the last decades. In 2006, Mycobacterium bovis accounted for 3 and M. caprae for 2 of all human cases (definite cases). Incidence of definitive human tuberculosis was 6.24/100,000 (521 cases) and an overall incidence of 10.04/100,000 (830 cases definite and other than definite cases combined) in 2006.

National evaluation of the recent situation, the trends and sources of infection

Bovine tuberculosis poses no major public health problem. Cattle, sheep, goats and pigs are free of bovine tuberculosis: no single case was detected in 2006

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

Absence of positive findings in 2006

Recent actions taken to control the zoonoses

No new measures implemented

Suggestions to the Community for the actions to be taken

Continuation of the existing control programs.

Additional information

Nil

2.5.2. Tuberculosis, Mycobacterial Diseases in humans

A. Tuberculosis due to Mycobacterium bovis in humans

Case definition

Definite: A case with isolation of M. tuberculosis complex (except M. bovis BCG) from any clinical specimen.

Other than definite: A case that meets the clinical criteria above but does not meet the laboratory criteria of a definite case.

Diagnostic/analytical methods used

- Definite: Staining: Ziehl-Neelsen, Auramin-Rhodamin stains are performed on histological preparation and smears of the sample material

- Culture: After decontamination of the homogenised sample material in NALC-NaOH and centrifugation, the sample material is transferred in parallel on Loewenstein-Jensen agar containing glycerol and PACT and Stonebrink agar containing PACT and MGITmedium.

The media are incubated at 37 Â°C up to 8 weeks.

Confirmation of the species by Amplicor (Roche)

- Other than definite: A skin test and an X-Ray of the thorax are performed.

Notification system in place

The person who diagnoses (laboratory/hospital/general practitioner) has to notify definite (M. tuberculosis and M. bovis) and other than definite cases (this excludes radiologists) to the local health authority (Federal Law BGBl. 127/1968: Tuberkulose-gesetz, as amended; National Regulation BGBl. Nr. 254/2004: Anzeigepflichtige Ã¼bertragbare Krankheiten 2004). M. bovis is notifiable since 2004 (National Regulation BGBl. Nr. 254/2004: Anzeigepflichtige Ã¼bertragbare Krankheiten 2004).

History of the disease and/or infection in the country

The National Reference Laboratory for Tuberculosis (NRL-T) has been nominated since 1995. Since 1998 all data are compiled in a national Database.

National evaluation of the recent situation, the trends and sources of infection

The 5 human cases (3 M. bovis, 2 M. caprae cases) are under investigation.

Relevance as zoonotic disease

The relevance is inconsiderable; in average only five of 830 human tuberculosis cases are caused by M. bovis/M caprae.

Table Mycobacterium in humans - Species/serotype distribution

Mycobacterium	Cases	Cases Inc.	Autochthon cases	Autochthon Inc.	Imported cases	Imported Inc.

2.5.3. Mycobacterium in animals

A. Mycobacterium bovis in bovine animals

Status as officially free of bovine tuberculosis during the reporting year

The entire country free

The entire country free: Yes

Additional information

According to Council Directive 64/432/EWG from June 26th 1964 Austria has the status Officially Tuberculosis Free Member State declared in the Commission Decision 1999/467/EC from July 15th, 1999, replaced by Commission Decision 2003/467/EC from June 23rd, 2003. The national surveillance programme is regulated by the Directive GZ 39.624/9-IX/A/8/00. The monitoring programme is based on the compulsory ante-mortem and post-mortem inspection in which all cattle and goats originating from an official tuberculosis free holding have to be tested for tuberculous alterations.

Monitoring system

Sampling strategy

Specimen from carcasses with macroscopically alterations suspicious for tuberculosis of are sampled in slaughterhouses and sent to an Institute for Veterinary Diagnosis.

Frequency of the sampling

Permanent post-mortem inspections of each slaughtered bovine and caprine animal.

Type of specimen taken

Organs/ tissues: Macroscopically tuberculous alterations and lymph nodes

Methods of sampling (description of sampling techniques)

The alterations and lymph nodes are excised and sent to the laboratory.

Case definition

According to Order Richtlinien fÃ¼r die veterinÃ¤rbehÃ¶rdliche Ã berwachung zur Erhaltung der Freiheit der Ã¶sterreichischen RinderbestÃ¤nde von Rindertuberkulose und zur DurchfÃ¼hrung und Beurteilung der intrakutanen Tuberkulinprobe (GZ 39.624/9-IX/A/8/00): Tubercles pathognomically for tuberculosis detected in course of the post-mortem inspection or Mycobacterium bovis or Mycobacterium tuberculosis isolated from suspected material.

Diagnostic/analytical methods used

Staining: Ziehl-Neelsen stains are performed on histological preparation and smears of the sample material

Culture: After decontamination of the homogenised sample material in NALC and centrifugation, the sample material is transferred in parallel on Loewenstein-Jensen agar containing glycerol and PACT and Stonebrink agar containing PACT and Middlebrook medium. The media are incubated at 37Â°C up to 8 weeks.

Confirmation of the Mycobacterium species by PCR (De los Monteros et al. 1998: Journal of Clinical Microbiology 36: 239-242) in the National Reference Laboratory for Tuberculosis in Animals.

Vaccination policy

Vaccination is prohibited.

Other preventive measures than vaccination in place

Compulsory ante-mortem and post-mortem inspection of all slaughtered bovine and caprine carcasses originating from official tuberculosis free holding.

Control program/mechanisms

The control program/strategies in place

The control programs are based on the compulsory ante-mortem and post-mortem inspection of all slaughtered bovine and caprine carcasses originating from an official tuberculosis free holding.

Recent actions taken to control the zoonoses

No need at the moment.

Suggestions to the Community for the actions to be taken

Nil

Measures in case of the positive findings or single cases

The carcass is condemned.

Loss of the status OTF for the holding from which the animal was originated and for contact holdings.

Slaughtering of cows and goats from NON-OTF-holdings is forbidden

Prohibition of keeping these animals together with animals from OTF-holdings on mountain pastures or market places etc.

Regaining the status OTF:

There are no animals in the holding showing signs of clinical tuberculosis

All animals are recruited from an OTF-holding

- M. bovis reactors after performing the skin test and contact animals have been eliminated as well as the compulsory follow-up examination and disinfection have been carried out

No reactors identified after two intradermal testings of all animals in the holding older than 6 months examined earliest 60 days (first tuberculin test) and earliest 4 months (second tuberculin test) but latest 12 months after elimination of the last reactor.

Notification system in place

A suspicion of tuberculosis has to be notified by the veterinarian/animal keeper/the person who takes care of the animals/other persons to the mayor, by the veterinarian additionally to the local authority and the diagnostic finding by the institute for Veterinary diagnosis as well to the local authority as to the office of the provincial government responsible for the holding, from which the tuberculosis-positive animal was originated. (BGBl. 1994/395, Fleischuntersuchungsverordnung, Â§ 10 (8), as amended or BGBl. 1909/177, Tierseuchengesetz, as amended).

National evaluation of the recent situation, the trends and sources of infection

In the area of Northern Tyrol and Southern Bavaria there is an endemic area for deer infected with M. caprae (Prodinger, W. M., A. Eigentler, F. Allerberger, M. Schonbauer, and W. Glawischnig.

2002. Infection of red deer, cattle, and humans with Mycobacterium bovis subsp. caprae in Western Austria. J. Clin. Microbiol. 40:2270-2272). Following the excretion of mycobacteria by the deer on mountain pastures the cows could be infected pasturing on the contaminated feedlots. (Last cases in cows notified in 2002).

In Austria, in the Tyrolean northern pre-Alps tuberculosis due to Mycobacterium caprae has been detected in 13 wildlife red deer since 1998. Animal contacts between farmed and wildlife deer shall be deemed to be theoretically because all deer farms are fenced in.

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Nil

Additional information

M. caprae is differentiated in Austria.

B. Mycobacterium bovis in farmed deer

Monitoring system

Sampling strategy

Nil

Frequency of the sampling

Every shot farmed deer that is foreseen to be used as a food is subjected to pre and post mortem inspection. Pre mortem inspection can be performed by the livestock owner if the owner is trained in this special inspection and if the Veterinarian has assured himself of the physical health of the animal within the last month prior to slaughtering.

Type of specimen taken

Other: Macroscopically tuberculous alterations and lymph nodes

Methods of sampling (description of sampling techniques)

The alterations and lymph nodes are excised and sent to the laboratory

Case definition

Tubercles pathognomically for tuberculosis detected in course of the post-mortem inspection or Mycobacterium bovis or Mycobacterium tuberculosis isolated from suspected material

Diagnostic/analytical methods used

Staining: Ziehl-Neelsen stain is performed on histological preparation and smears of the sample material

Culture: After decontamination of the homogenised sample material in NALC and centrifugation, the sample material is transferred in parallel on Loewenstein-Jensen agar containing glycerol and PACT and Stonebrink agar containing PACT and Middlebrook medium. The media are incubated at 37 Â°C up to 8 weeks.

Confirmation of the Mycobacterium species by PCR (De los Monteros et al. 1998: Journal of Clinical Microbiology 36: 239-242) in the National Reference Laboratory for Tuberculosis in Animals

Vaccination policy

Vaccination is prohibited.

Other preventive measures than vaccination in place

Nil

Control program/mechanisms

The control program/strategies in place

The control programs are based on the compulsory ante-mortem and post-mortem inspection of all slaughtered carcasses originating from an official tuberculosis free holding

Recent actions taken to control the zoonoses

No need at the moment

Measures in case of the positive findings or single cases

The carcass is condemned. Further measures according to Tierseuchengesetz RGBl. 1909/177 as amended.

Notification system in place

The suspicion and finding of tuberculosis is notifiable according to BGBl. 1994/395, Fleischuntersuchungsverordnung, as amended) and RGBl. 1909/177, Tierseuchengesetz, as amended.

National evaluation of the recent situation, the trends and sources of infection

No cases in 2006 in Austria.

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

No cases in 2006 in Austria.

Additional information

Nil

C. Mycobacterium spp., unspecified in animal

Monitoring system

Sampling strategy

Samples from macroscopically suspected swine are taken in slaughterhouses

Frequency of the sampling

Permanent post-mortem inspections of each slaughtered animal

Type of specimen taken

Other: Macroscopically tuberculous alterations and lymphnodes

Methods of sampling (description of sampling techniques)

The alterations and lymph nodes are excised and sent to the laboratory

Case definition

Tubercles pathognomically for tuberculosis detected in course of the post-mortem inspection or Mycobacterium bovis or Mycobacterium tuberculosis or Mycobacterium avium isolated from suspected material

Diagnostic/analytical methods used

Staining: Ziehl-Neelsen stains are performed on histological preparation and smears of the sample material

Culture: After decontamination of the homogenised sample material in NALC and centrifugation, the sample material is transferred in parallel on Loewenstein-Jensen agar containing glycerol and PACT and Stonebrink agar containing PACT and Middlebrook medium. The media are incubated at 37Â°C up to 8 weeks.

2.6. BRUCELLOSIS

2.6.1. General evaluation of the national situation

A. Brucellosis general evaluation

History of the disease and/or infection in the country

Since decades, in Austria human brucellosis is considered to be an imported infectious disease. Austria has the status Officially Brucellosis Free (OBF).

National evaluation of the recent situation, the trends and sources of infection

All human cases occurring in Austria in 2006 (n = 1) concerned immigrant workers who returned from their holiday at home and were most likely acquired abroad.

Recent actions taken to control the zoonoses

No new measures implemented

Suggestions to the Community for the actions to be taken

Continuation of the existing control programs

Additional information

Nil

2.6.2. Brucellosis in humans

A. Brucellosis in humans

Reporting system in place for the human cases

Nil

Case definition

Clinical description: Clinical picture compatible with brucellosis, e.g. acute or insidious onset of fever, night sweats, undue fatigue, anorexia, weight loss, headache and arthralgia.

Diagnostic/analytical methods used

- Serological examination: Serum samples are tested in the Complement Fixation Test (CFT) with reference standard antisera from CVL-Weybridge. Participation in international ring trials: Brucellosis European Ring Trial 2000 and 2002 (VLA Weybridge) with ELISA, CFT, RBT and SAT.

- Bacteriological: Several blood samples are inoculated in blood culture broth in consecutive days. The incubation lasted 4 to 6 weeks, once per week medium is transferred on brucella agar and incubated 5-10% CO2 atmosphere (Anonymus: Standardisierung und QualitÃ¤tssicherung in der mikrobiologischen Diagnostik. Richtlinien. Bundesministerium fÃ¼r Soziale Sicherheit und Generationen. ISBN 3-84123- 126-0, Wien, 2001, pg. 56).

- The genus is identified by microscopic examination, catalase-, oxidase- and the slide agglutination test using brucella serum. The species is identified by CO2 requirement, H2S formation, urease activity, growth on media containing standard concentrations of basic fuchsin or thionin and agglutination with monospecific sera and by PCR (Real-time detection of Brucella abortus, Brucella melitensis and Brucella suis. 2001: Redkar et al., Mol Cell Probes. 2001 Feb;15(1):43-52.)

Notification system in place

Medical doctors specialised in Laboratory Diagnosis or Microbiology and Hygiene and the attended physicians are subjected to notification. Notification of brucellosis according to the epidemic act has been mandatory since 1950 (BGBl. 1950/186 Epidemiegesetz, as amended).

History of the disease and/or infection in the country

Austria is OBF and OBmF. All cases are epidemiologically linked to holidays in endemic countries or foreign workers from endemic countries.

National evaluation of the recent situation, the trends and sources of infection

This zoonosis has no relevance in Austria.

Relevance as zoonotic disease

Nil

2.6.3. Brucella in foodstuffs

A. Brucella spp., unspecified in food

Monitoring system

Sampling strategy

Due to the fact that Austria is OBF and OBmF, food is not investigated for Brucella spp.

2.6.4. Brucella in animals

A. Brucella abortus in bovine animals

Status as officially free of bovine brucellosis during the reporting year

The entire country free

Yes

Additional information

According to the Council Directive 64/432/EEC of 26 June 1964, Austria revealed upon request in Commission Decision of July 15th 1999, CD 1999/466/EC, as amended, the status officially brucellosis-free for bovine herds.

Monitoring system

Sampling strategy

- Periodical monitoring scheme: Blood samples from cattle older than 2 years are monitored by means of serological tests. Samples are taken in the holdings; the sampling is part of a periodical monitoring scheme.

Abortion or premature birth: Abortive material and blood of the cow is sampled

Frequency of the sampling

- Periodical monitoring scheme: Annually in 20% of the holdings in each province all cattle >= 2 years had to be examined. All holdings in each province were tested at least once in five years. Principally the sampling was performed during the cold season, between January and May and in November and December when the animals were kept in the stables.

- Abortion or premature birth: Abortion material and blood from the cow that had an abort was sampled immediately post abortion. If the result of the first serological examination was negative, a second blood sample was taken 2 weeks post abortion and tested again serologically. If this result was negative again, sampling and testing was repeated after two weeks.

Type of specimen taken

Other: - Periodical monitoring scheme: Blood samples

Methods of sampling (description of sampling techniques)

- Periodical monitoring scheme: Individual blood samples are taken in the holdings and sent to the laboratories.

- Abortion or premature birth: Abortive material and blood samples of the cow that had an abort had been sent to a veterinary laboratory.

Case definition

An animal is considered to be positive for Brucella abortus, in case of positive serological test result and the epidemiological situation of the herd indicates the possibility that a brucella infection has been introduced to the herd (BGl 1957/280, Bangseuchen-Verordnung, Â§2 Untersuchungsergebnisse) or in case of bacteriological isolation. Although detection can be done on a single animal, the epidemiological unit in tracing back and tracing on is the herd.

Diagnostic/analytical methods used

Periodical monitoring scheme: Routinely single serum samples or serum pools (5 sera in one

pool) were tested in the Indirect-ELISA (I-ELISA) using the three OIE ELISA Brucella Standard Sera (OIE ELISAwpSS, OIE ELISAspSS, OIE ELISAnSS) and the OIE Brucella abortus Positive International Standard Antiserum (OIEISS) to calibrate the method (Commission Regulation 535/2002/EC of 21 March 2002 amending Annex C to Council Directive 64/432/EEC and amending Decision 2000/330/EC). Following a positive or suspected test result in the IELISA single serum samples were also tested in the Complement Fixation Test (CFT), Rose Bengal test (RBT) and Competitive ELISA (C-ELISA). Participation in international ring trials:

Brucellosis European Ring Trial 2000 and 2002 (VLA Weybridge) with ELISA, CFT, RBT and Serum Agglutination Test (SAT). The National Reference Laboratory for Brucellosis, Institute for Veterinary Disease Control in Moedling organized the national Brucellosis Ring Trials for all Veterinary Institutes.

Abortion or premature birth: Abortive material was tested bacteriologically and the cow that had an abort serologically as described above.

Bacteriology: Smears of the samples are stained by StableforthÂ´s method. Brucella agar and Columbia agar (Merck) containing selective additives were used (Oxoid). After inoculation the media were incubated for 4-10 days at 37 Â°C in an atmosphere containing 10% CO2. The genus was identified by microscopic examination, catalase-, oxidase- and the slide agglutination test using brucella serum. The species was differentiated by CO2 requirement, H2S formation, urease activity, growth on media containing standard concentrations of basic fuchsin or thionin and agglutination with monospecific sera and by PCR (Real-time detection of Brucella abortus, Brucella melitensis and Brucella suis. 2001: Redkar et al., Mol Cell Probes. 2001 Feb;15(1):43-52.).

Vaccination policy

Vaccination is not allowed (BGBl. 1957/147, Bangseuchengesetz, Â§ 13 Impfung)

Other preventive measures than vaccination in place

Periodical examinations, culling of reactors

Control program/mechanisms

The control program/strategies in place

Periodical monitoring scheme according the National Regulation BGBl 2003/526 (Bangseuchen-Untersuchungsverordnung 2004). Abortion or premature birth: Compulsory notification according BGBl 1957/147, Bangseuchengesetz, as amended, Â§11 Anzeigepflicht;

BGBl 1957/280, Bangseuchen-Verordnung, as amended, Â§9 Anzeigepflicht)

B. Brucella melitensis in sheep

Status as officially free of ovine brucellosis during the reporting year

The entire country free

Yes.

Additional information

According to Commission Decision Nr. 93/52/EWG, as amended, Austria has the status officially brucellosis (B. melitensis) free (ObmF).

Monitoring system

Sampling strategy

To maintain the status officially brucellosis (B. melitensis) free, according to BGBl. 2002/184 (Brucella melitensis-Ã berwachungsverordnung, of 14 May 2002) representative samples had been examined with a confidence level of 95% to detect infected holdings at a target prevalence of 0.2 %. Sampling was performed by the competent authority or under its supervision, by bodies to which it had delegated this responsibility. Samples were taken in the holdings;

Abortion material and blood samples from the animal that had an abort were also investigated.

Frequency of the sampling

Principally the sampling was performed during the cold season, between January and May and in November and December when the animals were kept in the stables.

Methods of sampling (description of sampling techniques)

Individual blood samples and abortion material are taken in the holdings and sent to the laboratories.

Case definition

An animal is considered to be infected with B. melitensis in case of bacteriological isolation or positive serological test result.

Diagnostic/analytical methods used

- Routinely single serum samples were tested in the Indirect ELISA. Confirmation of

suspected or positive results was performed by the Complement Fixation Test (CFT) with reference standard antisera from CVL-Weybridge. Participation in international ring trials: Brucellosis European Ring Trial 2000 and 2002 (VLA Weybridge) with ELISA, CFT, RBT and SAT. The National Reference Laboratory for Brucellosis, Institute for Veterinary Disease Control in Moedling organized the national Brucellosis Ring Trials for all national Veterinary Institutes.

Bacteriology: Smears of the samples were stained by StableforthÂ´s method.

Brucella agar and Columbia agar (Merck) containing selective additives (Oxoid) were used. After inoculation the media are incubated for 4-10 days at 37 Â°C in an atmosphere containing 10% CO2. The genus was identified by microscopic examination, catalase-, oxidase- and the slide agglutination test using brucella serum. The species were differentiated by CO2 requirement, H2S formation, urease activity, growth on media containing standard concentrations of basic fuchsin or thionin and agglutination with monospecific sera and by PCR (Real-time detection of Brucella abortus, Brucella melitensis and Brucella suis. 2001: Redkar et al., Mol Cell Probes. 2001 Feb;15(1):43-52.).

Vaccination policy

According to BGBl. 2002/184 (Brucella melitensis-Ã berwachungsverordnung, of 14 May 2002, Â§4, Impfverbot) vaccination is not allowed.

Other preventive measures than vaccination in place

Monitoring program and investigation of aborts.

Control program/mechanisms

Nil

D. B. suis in animal - Pigs - breeding animals - at farm - animal sample - blood - Clinical investigations - suspect sampling

Monitoring system

Sampling strategy

Abortion material and blood samples from pigs that had an abort are examined in veterinary laboratories.

Frequency of the sampling

Targeted, following abortion and in positive cases contact holdings.

Type of specimen taken

Other: Monitoring: Blood samples; Clinical cases: Abortion material and blood samples from the animal that had an abort.

Methods of sampling (description of sampling techniques)

Monitoring: Blood samples; Clinical cases: Abortion material and blood samples from the animal that had an abort.

Case definition

An animal is considered to be serologically positive for brucellosis following one/more positive CFT Complement Fixation Test (CFT) and RBT Rose Bengal test (RBT) results (B. abortus used antigen) or infected with B. suis in case of bacteriological isolation.

Diagnostic/analytical methods used

- Due to the fact that a Brucella suis antigen is not available, the B. abortus antigen is used for the Complement Fixation Test (CFT) and the Rose Bengal test (RBT) because B. abortus shows cross reactions with B. suis antibodies.

- ELISA and CFT is not available, the B. abortus ELISA and CFT are used because these tests show cross reactions with B. suis antibodies.

- Participation in international ring trials: Brucellosis European Ring Trial 2000 and 2002 (VLA Weybridge) with ELISA, CFT, RBT and Serum Agglutination Test (SAT). The National Reference Laboratory for Brucellosis, Institute for Veterinary Disease Control in Moedling organized the national Brucellosis Ring Trials for all Veterinary Institutes.

Bacteriology: Quality control: Laboratory strains

- Smears of the samples are stained by StableforthÂ´s method

- Brucella agar and Columbia agar (Merck) containing selective additives (Oxoid) were used. After inoculation the media are incubated for 4-10 days at 37Â°C in an atmosphere containing 10% CO2. 2.7. YERSINIOSIS

2.7.1. General evaluation of the national situation

A. Yersinia enterocolitica general evaluation

History of the disease and/or infection in the country

Yersiniosis is not considered a major food borne illness in Austria. The incidence of human disease is low when compared to salmonellosis or campylobacteriosis.

National evaluation of the recent situation, the trends and sources of infection

In 2006, a total of 154 human infections were notified. 111 isolates from patients were sent to the National Reference Laboratory for Yersinia. The sources of infections are unclear. Neither studies on sporadic cases nor scientific outbreak investigations were performed in Austria so far.

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

No valid data are available for animals and feedingstuffs.

In 2006, a total of 96 single pig meat - raw samples (special food program A045) were tested for Yersinia spp. with 25 samples positive for Yersinia spp.

During the special food program A008 in 112 tested samples of bovine meat preparation (intended to be eaten cooked), 11 samples were found positive for Yersinia spp.

Recent actions taken to control the zoonoses

None

Suggestions to the Community for the actions to be taken

Nil

Additional information

Nil

2.7.2. Yersiniosis in humans

A. Yersinosis in humans

Case definition

Clinical description: An illness of variable severity characterised by diarrhoea, fever, nausea, cramps and tenesmus.

Laboratory criteria for diagnosis: Isolation of Yersinia enterocolitica Serogroup O3, O9 or O5 or Y. pseudotuberculosis from a clinical specimen.

Diagnostic/analytical methods used

Faecal (Yersinia enterocolitica) or resection (Y. pseudotuberculosis) sample material is plated directly on cefsulodin-irgasan-novobiocin (CIN) agar and incubated for 18 hours at 30 Â°C. Suspicious colonies are identified in an Api 20 E reaction and API 50 CHE reaction. Y. enterocolitica is agglutinated with sera against serogroups O3, O5, O9 and O8. Biovar and pathogenicy are defined.

Notification system in place

Medical doctors specialised in Laboratory Diagnosis or Microbiology and Hygiene and the attended physicians are subjected to notification. Notification of salmonellosis according to the epidemic act has been mandatory since 1950 (BGBl. 1950/186 Epidemiegesetz, as amended).

History of the disease and/or infection in the country

Nil

Results of the investigation

See tables.

National evaluation of the recent situation, the trends and sources of infection

The number of human cases has been similar in the last years.

Relevance as zoonotic disease

Compared to salmonellosis and campylobacteriosis, yersiniosis is not an important food borne pathogen.

Additional information

Nil.

2.7.3. Yersinia in foodstuffs

A. Yersinia spp., unspecified in food

Monitoring system

Sampling strategy

No surveillance programmes are applied.

Foodstuff was sampled according to the Erlass der Bundesministerin fÃ¼r Gesundheit und Frauen: Revisions- und Probenplan fÃ¼r das Jahr 2006; Richtlinien Ã¼ber die Vollziehung der Ã berwachung des Verkehrs mit den durch das LMG 1975 erfassten Waren (GZ BMGF-75500/0164-IV/B/10/2005 of 26.01.2006). The Revision-Plan determines the number of food enterprises e.g. restaurants, dairies, retail etc. that have to be tested randomly per province according to the number of food enterprises per province. Each business has to be sampled at least once per year. The inspection can comprise sampling, hygienic investigations of the employees, checking of HACCP, control of manufacturing processes etc.

The sampling plan determines the number of samples of each class of goods, as raw meat, fresh or frozen; sausages; cheeses; milk; preserved food etc. that have to be investigated randomly.

Samples from suspected foodstuffs are taken following outbreak investigation, complaint, confiscation, violation etc.

Information about the special monitoring programs (Schwerpunktprogramm 2006) for Yersinia can be found on page 14.

Diagnostic/analytical methods used

Detection of Yersinia enterocolitica is performed according to ISO 10273:1994.

2.7.4. Yersinia in animals

A. Yersinia spp., unspecified in animal

Monitoring system

Sampling strategy

Relevant only for Carinthian Institute for Veterinary Disease Control, Ehrental:

Animals with different clinical symptoms that have been dissected and fecal samples are tested for pathogenic bacteria. Organs and fecal samples are bacteriological cultured.

Frequency of the sampling

Clinical cases suspisious for different infectious diseases.

Type of specimen taken

Other: Different organs, feces and intestinal content

Case definition

Yersinia spp. isolated from clinical samples.

Diagnostic/analytical methods used

Specimen are plated on McConkey â and Blood agar plates. Plates are incubated at 37 Â°C in aerobic condition. Suspicious colonies are identified by API 20E.

Vaccination policy

No vaccination.

Other preventive measures than vaccination in place

2.8. TRICHINELLOSIS

2.8.1. General evaluation of the national situation

A. Trichinellosis general evaluation

History of the disease and/or infection in the country

No documented human infections in 2006.

National evaluation of the recent situation, the trends and sources of infection

No documented human infections in 2006.

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

No documented infections in food-animals in 2006.

Recent actions taken to control the zoonoses

No new measures implemented

Suggestions to the Community for the actions to be taken

Reconsider the necessity of routine trichinella meat inspection in pig carcasses.

Additional information

Nil

2.8.2. Trichinellosis in humans

A. Trichinellosis in humans

Case definition

Clinical description: A disease caused by ingestion of Trichinella larvae. The disease has variable clinical manifestations. Common signs and symptoms among symptomatic persons include eosinophilia, fever, myalgia, and periorbital edema. Laboratory criteria for diagnosis: Demonstration of Trichinella larvae in tissue obtained by muscle biopsy, or positive serologic test for Trichinella.

Diagnostic/analytical methods used

ELISA and Westernblot.

Notification system in place

Notification of trichionellosis according to the epidemic act since 1950 (BGBl. 1950/186 Epidemiegesetz, as amended).

History of the disease and/or infection in the country

The last autochthonous cases have been reported in 1970.

Results of the investigation

No cases in 2006.

Description of the positive cases detected during the reporting year

No cases identified during 2006.

National evaluation of the recent situation, the trends and sources of infection

Nil

Relevance as zoonotic disease

No relevance in Austria

Additional information

2.8.3. Trichinella in animals

A. Trichinella in pigs

Monitoring system

Sampling strategy

General

Targeted sampling of all slaughtered except pigs slaughtered by the farmer for his own consumption (=hause-slaughtering); the sampling is performed by competent authorities and not stratified by geographical regions; the samples are taken at slaughterhouses; the sampling is part of a permanent monitoring scheme.

Frequency of the sampling

General

Permanent post-mortem sampling of each slaughtered pig.

Type of specimen taken

General

Muscles: Diaphragm (crus), tongue, masseter and abdominal muscles.

Diagnostic/analytical methods used

General

According to the Manual of OIE-standards trichinelosis chapter 2.2.9; no modification);

â ¢ Compression method: Two muscles in a size of a haselnut where taken from the diaphragma of a slaughtered pig from both muscles 7 small parts in the size of a oatcorn will be investigated in the compressorium (=14 parts from the diaphragma of one pig);

â ¢ Digestion method: maximum 100 samples (=100 pigs) - 1g muscle per each sample, digestion with pepsin, water and hydrochloric acid, incubation about 30-60 min, sedimentation and investigation with a stereo- or trichinoscope.

Preventive measures in place

Nil.

Control program/mechanisms

The control program/strategies in place

Austrian post mortem meat inspection law for trichinosis (BGBl. 522/1982), RL 92/117/EWG, RL 77/96/EWG

Recent actions taken to control the zoonoses

Nil

Suggestions to the Community for the actions to be taken

Nil

Measures in case of the positive findings or single cases

According to BGBl 1982/522, Fleischuntersuchungsverordnung, as amended and BGBl 1994/395, Fleischuntersuchungsverordnung, as amended: The carcass is unfit for human consumption and must be removed. If trichinosis was detected using the digestion method and the carcass infected with trichinella cannot be identified, after cold treatment applied to all carcasses pooled in the sample their meat is fit for human consumption.

Notification system in place

According to BGBl 1994/395, Â§10 (8), Fleischuntersuchungsverordnung, as amended: The competent authority has to notify the finding to the local authority and to the office of the provincial government responsible for the holding, from which the trichnellosis-positive animal was originated.

Results of the investigation including description of the positive cases and the verification of the Trichinella species

No findings in slaughtered pigs

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Nil.

Additional information

Nil.

B. Trichinella in horses

Monitoring system

Sampling strategy

Targeted sampling of all slaughtered horses; the sampling is performed by competent authorities and not stratified by geographical regions; samples are taken at slaughterhouses; the sampling is part of a permanent monitoring scheme.

Frequency of the sampling

Permanent post-mortem sampling of each slaughtered horse.

Type of specimen taken

Muscles from tongue, masseter, diaphragm and neck.

Methods of sampling (description of sampling techniques)

Appropriate muscle is excised out of the carcass.

Case definition

When trichinosis is detected with one of the given methods.

Diagnostic/analytical methods used

According to the Manual of OIE-standards trichinelosis chapter 2.2.9; no modification).

â ¢ Compression method: Two muscles in a size of a haselnut where taken from the diaphragma of a slaughtered horse from both muscles 7 small parts in the size of a oatcorn will be investigated in the compressorium (=14 parts from the diaphragma of one horse);

â ¢ Digestion method: maximum 100 samples (=100 horses)- 1g muscle per each sample, digestion with pepsin, water and hydrochloric acid, incubation about 30-60 min, sedimentation and investigation with a stereo- or trichinoscope.

Results of the investigation including the origin of the positive animals

See table.

Control program/mechanisms

The control program/strategies in place

If trichinosis was detected using the digestion method and the carcass infected with trichinella cannot be identified, after cold treatment applied to all carcasses pooled in the sample their meat is fit for human consumption.

Notification system in place

According to BGBl 1994/395, Â§10 (8), Fleischuntersuchungsverordnung, as amended: The competent authority has to notify the finding to the local authority and to the office of the provincial government responsible for the holding, from which the trichinellosis-positive animal was originated.

National evaluation of the recent situation, the trends and sources of infection

Nil

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Nil.

Additional information

Nil.

C. Trichinella spp., unspecified in animal - Wild boars

Monitoring system

Sampling strategy

Sampling of all hunted or harvested wild boars; the sampling is performed by hunters with special knowledge about trichnella investigation or by competent authorities; the sampling is stratified by geographical regions depending to the habitats of wild boar in Austria; samples are taken after shouting or at the cold storage depots; the sampling is part of a monitoring scheme.

Frequency of the sampling

All farmed wild boars are controlled for trichinella; only about 50% of all free-living Austrian wild boars (1998-2000) were investigated for trichinella parasites.

Type of specimen taken

Diaphragm muscles (crus), tongue, masseter and abdominal muscles.

Methods of sampling (description of sampling techniques)

Appropriate muscle is excised out of the carcass.

Case definition

When trichinosis is detected with one of the given methods.

Diagnostic/analytical methods used

According to the Manual of OIE-standards trichinelosis chapter 2.2.9; no modification)

â ¢ Compression method: Farmed and free-living wild boars: pieces from muscles in a size of a haselnut where taken from the tongue, diaphragma, masseter, forearm and intercostals part from all muscles 28 small parts in summary in the size of a oatcorn should be investigated in the compressorium.

â ¢ Digestion method: Farmed and free-living wild boars-maximum 100 samples (=100 wild boars)- 1g muscle per each sample, digestion with pepsin, water and hydrochloric acid, incubation about 30-60 min, sedimentation and investigation with a stereo- or trichinoscope.

2.9. ECHINOCOCCOSIS

2.9.1. General evaluation of the national situation

A. Echinococcus spp. general evaluation

History of the disease and/or infection in the country

Austria is a low risk country for both forms of echinococcosis

National evaluation of the recent situation, the trends and sources of infection

We expect the prevalence to be low also in future. We see approx. 1-2 human cases of Echinococcus multilocularis infestation in Austria per year; in 2006 there were even 24 patients with the large majority of cases who acquired the cystic infection during childhood in countries like former Jugoslawia or Turkey (in 2005: 31 imported cases). 2 cases of alveolar echinococcosis were probable autochtone cases.

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

Alveolar echinococcosis: Due to the infection rates of red foxes in Austria (0-40 %) there is a relatively elevated risk for hunters, cat owners and farmers. Austrian sheep are no relevant source for cystic echinococcosis in Austrian patients.

Recent actions taken to control the zoonoses

Tools for preventive serological screening of hunters (and also other persons) have been established to detect Echinococcus multilocularis infections in an early stage. The early detection of the infection is the prerequisite for a successful curative treatment.

Suggestions to the Community for the actions to be taken

Nil

Additional information

Nil

2.9.2. Echinococcosis in humans

A. Echinococcus spp. in humans

Case definition

Clinical apparent case (differentiation between alveolar and cystic echinococcosis necessary) with laboratory diagnostic confirmation: = histopathology or combination of imaging (ultrasound, X-ray, computed tomography or others) and positive serology or combination of specific DNA (by PCR) and positive serology).

Diagnostic/analytical methods used

ELISA and Westernblot technique, participant of the UK National External Quality Assessment Service for Microbiology, National Reference Laboratory for Echinococcosis.

Notification system in place

Echinococcosis is a notifiable disease since June 2004 according to the National Regulation 254/2004 (BGBl. II, 254/2004 of 18 June in 2004, Anzeigepflichtige Ã¼bertragbare Krankheiten 2004)

History of the disease and/or infection in the country

â ¢ Alveolar echinococcosis has been known in Austria since 1897; annual incidence (1897- 2004): 0-6 cases, mean incidence: 2.4 cases/year (only autochthonous cases); geographic distribution in Austria: mainly in the western provinces (Vorarlberg, Tyrol, Salzburg), but cases are known from each province; outbreaks are not known.

â ¢ Cystic echinococcosis has been known in Austria at least since 1819; Cases of cystic echinococcosis have been registered in the Clinical Institute of Hygiene and Medical Microbiology (Medical University Vienna) regularly since the beginning of the 1980ies. Annual incidence (1984 - 2006): 20 - 60 cases; mean incidence: 31 cases per year, one third of patients are of Austrian origin; two thirds are from abroad. Geographic distribution in Austria is unknown; a few autochthonous infections could be observed mainly in the eastern and southern provinces (Lower Austria, Burgenland, Styria); outbreaks are not known.

National evaluation of the recent situation, the trends and sources of infection

â ¢ Alveolar echinococcosis: We expect the prevalence to be low in future; sources of infection: fox faeces (contaminated hands and fingers, vegetables, water).

â ¢ Cystic echinococcosis: We expect the prevalence to be low in future; sources of infection: dog faeces, presumably in a very few foci (in or around farmers houses)

Relevance as zoonotic disease

Low prevalence of both forms of echinococcosis

Table Echinococcus in humans - Species/serotype distribution

	Cases	Cases Inc.	Autochthon cases	Autochthon Inc.	Imported cases	Imported Inc.

2.9.3. Echinococcus in animals

A. Echinococcus spp., unspecified in animal

Monitoring system

Sampling strategy

Targeted sampling of all in abattoirs slaughtered animals; the sampling is performed by competent authorities in course of the post-mortem meat inspection; the sampling is part of a permanent monitoring scheme

Frequency of the sampling

Permanent post-mortem sampling of each slaughtered animal

Methods of sampling (description of sampling techniques)

All organs and muscles that were used for human consumption

Case definition

Each carcass in which cystic or alveolar hydatids are detected in muscles or organs

Vaccination policy

No vaccination

Other preventive measures than vaccination in place

No measures

Control program/mechanisms

The control program/strategies in place

Post mortem meat inspection act according to BGBl. 1982/522, Fleischuntersuchungsgesetz, as amended

Recent actions taken to control the zoonoses

Nil

Suggestions to the Community for the actions to be taken

Nil

Measures in case of the positive findings or single cases

According to BGBl 1982/522, Fleischuntersuchungsverordnung, as amended and BGBl 1994/395, Fleischuntersuchungsverordnung, as amended: The carcass is unfit for human consumption and must be removed.

Notification system in place

According to BGBl 1994/395, Â§10 (8), Fleischuntersuchungsverordnung, as amended: The competent authority has to notify the finding to the local authority.

National evaluation of the recent situation, the trends and sources of infection

In 2006 no case was detected in the post-mortem inspection.

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Cystic or alveolar echinococcosis in animals that are used for food production do not play a role for the infection of humans; it is primarily a hygienic problem. Only when infected waste from animals is used as feed for carnivores the risk of infection for humans increases.

2.11. RABIES

2.11.1. General evaluation of the national situation

A. Rabies general evaluation

History of the disease and/or infection in the country

Rabies in humans was a major public health issue in the 1960s.

National evaluation of the recent situation, the trends and sources of infection

In 2006, there was (no) one case of a positive fox in Austria, but the differentiation revealed that the virus was vaccination strain.

Relevance of the findings in animals, feedingstuffs and foodstuffs to human cases (as a source of infection)

Nil

Recent actions taken to control the zoonoses

In 2006 there was still vaccination programs carried out.

Suggestions to the Community for the actions to be taken

Nil

Additional information

Nil

2.11.2. Rabies in humans

A. Rabies in humans

Case definition

Laboratory criteria for diagnosis

Detection by direct fluorescent antibody of viral antigens in a clinical specimen (preferably the brain or the nerves surrounding hair follicles in the nape of the neck)

Detection of rabies nucleic acid in clinical specimen

Isolation (in cell culture or in a laboratory animal) of rabies virus from saliva, cerebrospinal fluid (CSF), or central nervous system tissue

Identification of a rabies-neutralising antibody titre (complete neutralization) in the serum or CSF of an unvaccinated person.

Diagnostic/analytical methods used

Liquor, smears from pharynx, swab from conjuntivae biopsy at the nape of the neck and serum were examined in the fluorescent antibody test (FAT), immunohistochemistry and RT-PCR (Ito M., Itou T., Sakai T., et al. (2001). Detection of Rabies Virus RNA isolated from several species of animals in Brazil by RT-PCR. Journal of Veterinary medicine Science 63(12): 1309-1313.).

Notification system in place

Rabies and bite of an infected animal or an animal suspected to be infected according to the epidemic

act (BGBl. 1950/186 Epidemiegesetz, as amended).

History of the disease and/or infection in the country

Nil

National evaluation of the recent situation, the trends and sources of infection

Nil

Relevance as zoonotic disease

Nil

2.11.3. Lyssavirus (rabies) in animals

A. unspecified Lyssavirus in animal - Foxes

Monitoring system

Sampling strategy

According to (GZ:39.642/14-VII/B/03): 8 foxes per 100kmÂ² in rabies infested and rabies endangered areas, 4 foxes per 100kmÂ² in not endangered and free areas (definition of areas: GZ 30.517/35-IV/12/03).

Frequency of the sampling

8 foxes per 100 kmÂ² in rabies infested and rabies endangered areas, 4 foxes per 100kmÂ² in not endangered and free areas.

Methods of sampling (description of sampling techniques)

Whole animals or heads of the dead animals are sent to the laboratories; sometimes brain tissue (derived from other laboratories). Brain-Tissue (e.g. 1 cmÂ²) is examined.

Case definition

An animal is considered positive if the fluorescent antibody test (FAT) shows a positive signal.

Diagnostic/analytical methods used

The routine test was the fluorescent antibody test (FAT).

RTCIT (rabies tissue culture infection test) was performed on mouse neuroblastoma cells.

(The MIT (mouse inoculation test) was used to confirm positive findings) MIT is only performed on demand, not for routine confirmation

Vaccination policy

Oral vaccination of foxes twice a year according to GZ: 30.517/52-IV/12/03

Other preventive measures than vaccination in place

No measures

Control program/mechanisms

The control program/strategies in place

Fuchs-TollwutbekÃ¤mpfungsverordnung BGBl II 2001/75, Tierseuchengesetz TSG RGBl 1909/177 as amended, BGBl I 2002/65 IV. Abschnitt, Â§41, Â§42, Tierseuchengesetz-DurchfÃ¼hrungsverordnung 1909/178 as amended: BGBl 1955/76 TSG-DVO zum IV. Abschnitt Wutkrankheiten

â ¢ Control of vaccination: Detection of tetracycline in jaw bones of randomly chosen fox from the vaccination area; additionally an ELISA is performed to proof seroconversion.

Recent actions taken to control the zoonoses

In 2006, there were still vaccination programmes carried out (due to rabies in fox in 2003).

Suggestions to the Community for the actions to be taken

Nil

Measures in case of the positive findings or single cases

Tierseuchengesetz TSG RGBl 1909/177 as amended, BGBl I 2002/65 IV. Abschnitt, Â§41, Â§42, and vaccination of the Fox Population

Notification system in place

According to Tierseuchengesetz TSG RGBl 1909/177 as amended, BGBl I 2002/65 IV. Abschnitt, Â§41, Â§42

Results of the investigation

Nil

National evaluation of the recent situation, the trends and sources of infection

The virus isolated from a dead fox was not a wild rabies strain, but a vaccination strain. It is well known that vaccination of fox populations can cause lethality in very young animals.

Relevance of the findings in animals to findings in foodstuffs and to human cases (as a source of infection)

Nil

B. unspecified Lyssavirus in animal

Monitoring system

Sampling strategy

Sampling is targeted when animals are observed with central nervous symptoms or after biting a person. The suspicious animal is killed or euthanized and the carcasses or heads sent to the laboratory.

Frequency of the sampling

In case of suspicion

Methods of sampling (description of sampling techniques)

Routinely there will be taken one site from the brain either a part from the amonÂ´s horn, brain stem or cerebellum. If an animal has bitten a person then 2 sites from the brain will be taken: ammonÂ´s horn and brain stem.

Case definition

An animal is considered positive if the fluorescent antibody test (FAT) or the rabies tissue culture infection test or the mouse inoculation test reveal a positive result.

Diagnostic/analytical methods used

The routine test was the fluorescent antibody test (FAT).

RTCIT (rabies tissue culture infection test) was performed on mouse neuroblastoma cells.

(The MIT (mouse inoculation test) was used to confirm positive findings); MIT is only performed on demand, not for routine confirmation.

Vaccination policy

Voluntary vaccination of pets.

Other preventive measures than vaccination in place

No measures

Control program/mechanisms

The control program/strategies in place

Tierseuchengesetz TSG RGBl 1909/177 as amended, BGBl I 2002/65 IV. Abschnitt, Â§41, Â§42; Tierseuchengesetz-DurchfÃ¼hrungsverordnung 1909/178 as amended: BGBl 1955/76

Recent actions taken to control the zoonoses

3. INFORMATION ON SPECIFIC INDICATORS OF ANTIMICROBIAL RESISTANCE

3.1. ESCHERICHIA COLI, NON-PATHOGENIC

3.1.1. General evaluation of the national situation

A. Escherichia coli general evaluation

History of the disease and/or infection in the country

Resistance monitoring was started in Austria in 2004 and continued in 2005 and 2006.

Recent actions taken to control the zoonoses

The Austrian wide monitoring program on the trends of antimicrobial resistance of E. coli in poultry, bovine animals and pigs was implemented according to the directive 2003/99/EC of the European Parliament and the Council of 17 November 2003 in the National Order GZ: BMGF-74600/0092-IV/B/8/2005 (Ã berwachungsprogramme 2005 zu ausgewÃ¤hlten Zoonosen und Antibiotikaresistenzen). The sampling was carried out from January 16th to November 17th 2006.

Suggestions to the Community for the actions to be taken

Europe wide harmonized standards for antimicrobial resistance monitoring would be highly welcome.

Additional information

Nil

3.1.2. Antimicrobial resistance in Escherichia coli, non-pathogenic isolates

A. Antimicrobial resistance of E. coli in animal - Cattle (bovine animals) - at slaughterhouse - animal sample - faeces - Monitoring - official sampling - objective sampling

Sampling strategy used in monitoring

Frequency of the sampling

Monitoring program on the occurrence and trend of antimicrobial resistance in E. coli is based on the prevalence of E. coli in slaughtered animals: At an estimated percentage of resistance in antimicrobials of 5.2 % in cattle and a desired accuracy of 6 % for a confidence level of 95%, 210 isolates of E. coli from bovine animals were required.

To obtain this number of isolates, as sample size 229 slaughtered bovine animals had to be tested, calculated on approximately 664.000 slaughtered bovine animals in 2004 in Austria, with an estimated prevalence of E. coli of 95 % based on the results from the monitoring in 2005, and at a desired accuracy of 5% for a confidence level of 95%. The sampling had been stratified on the number of slaughtering by abattoirs all over Austria. The date of sampling was randomized over the period of the study.

In Austria, all 68 abattoirs in which more than 500 bovine animals were slaughtered in 2004 accounted for approximately 83% of the total annual bovine production. Sampling was performed in 51 of the 68 abattoirs excluding those in which only one sampling in the whole period of the study would have been carried out.

Methods of sampling (description of sampling techniques)

The sampling was performed by official veterinarians carrying out the post-mortem inspection. At time of evisceration a part of the colon was ligated and wrapped in a sterile plastic bag. After cooling down to 4 Â°C the sample was sent in a hobbock or polystyrene box after adding cooling units to the locally appropriate Institute of Veterinary Diseases Control (IVET). In the laboratory some content of each colon was plated on selective medium suitable for E. coli.

Procedures for the selection of isolates for antimicrobial testing

All 206 E. coli isolated from bovine animals were sent from the involved laboratories to the AGES Institute for Veterinary Disease Control in Graz where the antimicrobial susceptibility testing of all isolates of E. coli were performed.

Laboratory methodology used for identification of the microbial isolates

E. coli colonies were identified after isolation on MacConkey plates and subculture on Columbia sheep blood agar plates by oxidase and spot indole test. All E. coli isolates were frozen in proteose pepton solution containing 10% glycerol at -70 Â°C. The susceptibility testing was done with SensititreÂ® Microbiology Systems (MCS Diagnostics). The frozen E. coli were subcultivated on Columbia agar (Oxoid) and incubated 24 hours at 37 Â°C. 3-5 colonies were suspended in physiological NaCl solution and adjusted to a McFarland of 0.5. 10 Î¼l of the suspension was inoculated in 10 ml Mueller Hinton bouillon and incubated 24 hours at 37 Â°C. MIC values have been entered in a MicrosoftÂ® Excel datasheet.

Control program/mechanisms

The control program/strategies in place

Samples from food animals were monitored for antimicrobial residues according to a randomized sampling scheme (BMGF-74320/0003-IV/B/7/2006, RÃ¼ckstandsuntersuchung-DurchfÃ¼hrungserlass 2006)

Suggestions to the Community for the actions to be taken

Europe wide harmonized standards for antimicrobial resistance monitoring would be highly welcome.

B. Antimicrobial resistance of E. coli in animal - Pigs - at slaughterhouse -

animal sample - faeces - Monitoring - official sampling - objective sampling

Sampling strategy used in monitoring

Frequency of the sampling

Monitoring program on the occurrence and trend of antimicrobial resistance in E. coli based on the prevalence of E. coli in slaughtered animals: At an estimated percentage of resistance in antimicrobials between 40 and 60 % and a desired accuracy of 6 % for a confidence level of 95%, 381 isolates of E. coli from pigs were required.

To obtain this number of isolates, as sample size, 410 slaughtered pigs had to be tested, calculated on approximately 5,400,000 slaughtered pigs in 2004 in Austria, with an estimated prevalence of E. coli of 95 %, based on the results from the monitoring in 2005, and at a desired accuracy of 5% for a confidence level of 95%. The sampling had been stratified on the number of slaughtering by abattoirs all over Austria. The date of sampling was randomized over the period of the study.

In Austria, 73 abattoirs in which more than 3,500 pigs were slaughtered in 2004 accounted for approximately 90% of the total annual pig production. Sampling was performed in 48 of the 73 abattoirs excluding those in which only one sampling in the whole period of the study would have been carried out. The remaining 25 samples were distributed over the 48 abattoirs.

Type of specimen taken

Caecum containing 50 to 100 grams of faeces.

Methods of sampling (description of sampling techniques)

The sampling was performed by official veterinarians carrying out the post-mortem inspection. At time of evisceration a part of the colon was ligated and wrapped in a sterile plastic bag. After cooling down to 4 Â°C the sample was sent in a hobbock or polystyrene box after adding cooling units to the locally appropriate Institute of Veterinary Diseases Control (IVET). In the laboratory some content of each colon was plated on selective medium suitable

for E. coli.

Procedures for the selection of isolates for antimicrobial testing

Al 372 E. coli isolated from pigs were sent from the involved laboratories to the AGES Institute for Veterinary Disease Control in Graz where the antimicrobial susceptibility testing of all isolates of E. coli were performed.

Laboratory methodology used for identification of the microbial isolates

E. coli colonies were identified after isolation on MacConkey plates and subculture on Columbia sheep blood agar plates by oxidase and spot indole test.

Laboratory used for detection for resistance

Antimicrobials included in monitoring

All E. coli isolates were frozen in proteose pepton solution containing 10% glycerol at -70Â°C.

The susceptibility testing was done with SensititreÂ® Microbiology Systems (MCS Diagnostics). The frozen E. coli were subcultivated on Columbia agar (Oxoid) and incubated 24 hours at 37Â°C. 3-5 colonies were suspended in physiological NaCl solution and adjusted to a McFarland of 0.5. 10 Î¼l of the suspension was inoculated in 10 ml Mueller Hinton bouillon and incubated 24 hours at 37 Â°C.

MIC values have been entered in a MicrosoftÂ® Excel datasheet.

Control program/mechanisms

The control program/strategies in place

Samples from food animals were monitored for antimicrobial residues according to a randomized sampling scheme (BMGF-74320/0003-IV/B/7/2006, RÃ¼ckstandsuntersuchung-DurchfÃ¼hrungserlass 2006).

Suggestions to the Community for the actions to be taken

Europe wide harmonized standards for antimicrobial resistance monitoring would be highly welcome.

Additional information

Nil

C. Antimicrobial resistance of E. coli in animal - Gallus gallus (fowl) and turkeys - at slaughterhouse - animal sample - faeces - Monitoring - official sampling - objective sampling

Sampling strategy used in monitoring

Frequency of the sampling

Monitoring program on the occurrence and trend of antimicrobial resistance in E. coli based on the prevalence of E. coli in slaughter batches: At an estimated percentage of resistance in antimicrobials between 40 to 60 % and a desired accuracy of 6 % for a confidence level of 95%, 372 isolates of E. coli from poultry were required.

To obtain this number of isolates, as sample size, 396 slaughter batches of poultry had to be tested, calculated on approximately more than 10,000 slaughter batches of poultry in 2004 in Austria, with an estimated prevalence of E. coli of 95 %, based on the results from the monitoring in 2005, and at a desired accuracy of 5% for a confidence level of 95%. As the secondary sample size caeca of 10 animals had to be collected. The secondary sample size gives the number of birds per batch to be sampled and had been computed on slaughter batches of more than 2000 broilers, an expected prevalence of 30% within the batch and a confidence level of 95%. The sampling had been stratified on the number of slaughter batches by slaughter plants all over Austria. The date of sampling was randomized over the period of the study.

Sampling was performed in the 8 poultry slaughter plants with slaughter batches consisting of >2000 animals in Austria in 2003. The 8 slaughter plants included in the monitoring program accounted for almost 100% of broilers and turkeys of the total production in Austria.

Type of specimen taken

The whole intestines of 10 animals

Methods of sampling (description of sampling techniques)

The sampling was performed by official veterinarians carrying out the post-mortem inspection. At time of evisceration the whole intestines of 10 animals were taken and wrapped in a sterile plastic bag. After cooling down to 4Â°C the sample was sent in a hobbock or polystyrene box after adding cooling units to the locally appropriate Institute of Veterinary Diseases Control (IVET). In the laboratory a caecum of each intestinal convolute was identified, some content of each caecum pooled and plated on selective medium suitable for E. coli.

Procedures for the selection of isolates for antimicrobial testing

All 381 E. coli isolated from poultry flocks were sent from the involved laboratories to the AGES Institute for Veterinary Disease Control in Graz where the antimicrobial susceptibility testing of all isolates of E. coli were performed.

Laboratory methodology used for identification of the microbial isolates

E. coli colonies were identified after isolation on MacConkey plates and subculture on Columbia sheep blood agar plates by oxidase and spot indole test.

Laboratory used for detection for resistance

Antimicrobials included in monitoring

All E. coli isolates were frozen in proteose pepton solution containing 10% glycerol at -70 Â°C.

5. FOODBORNE OUTBREAKS

Foodborne outbreaks are incidences of two or more human cases of the same disease or infection where the cases are linked or are probably linked to the same food source. Situation, in which the observed human cases exceed the expected number of cases and where a same food source is suspected, is also indicative of a foodborne outbreak.

A. Foodborne outbreaks

System in place for identification, epidemological investigations and reporting of foodborne outbreaks

Presently, the individual district (Austria = 98 + Vienna) is responsible for outbreak investigation. Food borne outbreaks affecting more than one district or even more than one province (Austria = 9 provinces) is regulated by the Federal Zoonoses Act (Zoonosengesetz, BGBl. I, 128/2005 entered into force on 1. January 2006, see chapter salmonellosis). According to this Zoonoses Act, to survey and combat the zoonoses in Austria, a Federal Commission for Zoonoses (Zoonoses Commission) had been founded to advise the Federal Minister. One main subject of the law is that food-borne outbreaks receive proper epidemiological investigation. It determines measures in case of Austrian-wide food borne outbreaks (concerning several provinces affected by one outbreak) and forces the Heads of the affected Provincial Governments to provide operative units to investigate suspicious or confirmed food borne outbreaks. Data concerning epidemiological criteria, potential implicated food items and the source of the outbreak must be collected and adequate epidemiological and microbiological examinations must be conducted. Short reports according to the data necessary for this Report summarising each outbreak have to be communicated to the Federal Commission for Zoonoses and to the AGES.

Description of the types of outbreaks covered by the reporting:

Since there is no coordinated approach for outbreak investigation in most provinces, the large majority (515 of 609) of food borne outbreaks are called family outbreaks. A coordinated Austrian wide outbreak investigation - not hampered by district limits - will drastically decrease the total number of outbreaks.

National evaluation of the reported outbreaks in the country:

Trends in numbers of outbreaks and numbers of human cases involved

In 2006, 609 food borne outbreaks have been reported affecting 2530 people. 493 persons of the diseased were hospitalized and 3 persons deceased following the infection. This reveals nearly the same number of outbreaks compared to 2005 (n = 606). 12 % (7.6 % in 2005) of

the reported outbreaks were acquired abroad. 22.5 % of all food borne outbreaks acquired in Austria were caused by Campylobacter spp. (n =137), 74.2 % by Salmonella spp. (n = 390) and 89.7 % of these by the serotype Enteritidis (n = 350).

In contrary to the similar number of food borne outbreaks the number of diseased person affected by an outbreak revealed an increase of 32.5 %. We conclude that this is due to successful investigation of outbreaks that lead to a merging of the cases of several family outbreaks and apparently unrelated sporadic cases into single general outbreaks.

Relevance of the different causative agents, food categories and the agent/food category combinations

Salmonella and Campylobacter pose the most important agents causing 97 % of all food borne outbreaks. The data quality does presently not allow conclusions on the relevance of different food categories.

Relevance of the different type of places of food production and preparation in outbreaks

The data quality does presently not allow conclusions on the relevance of different food categories.

Evaluation of the severity and clinical picture of the human cases

Neither hospitalization nor lethality is presently ascertained in a valid way: Nevertheless, 19.5 % of patients affected by the reported food borne outbreaks are reported as hospitalized (19.3 % in 2005) and 3 cases as lethal (1 case lethal in 2005).

Descriptions of single outbreaks of special interest

(1) : 9 children only of one group of a kindergarten who participated in an excursion to a bakery and presumptively tasted a raw dough containing raw eggs. The origin of the eggs could be traced back to two holdings of laying hens. In one holding the outbreak strain was detected in fecal samples; further sporadic cases could be linked to the use of eggs from the same holding of laying hens.
(2) : A hotel associated outbreak. Eggs from Germany were the most probable vehicle (the outbreak strain could not be detected in the incriminated eggs but a nother strain)
(3) : One outbreak affecting one province; one holding of laying hens epidemiologically and bacteriologically identified. Other PT6 outbreaks were not thoroughly enough investigated and were not traced back to the incriminated holding.
(4) : One Austrian wide outbreak, one holding of laying hens epidemiologically and bacteriologically identified; assumed sporadic cases are included.
(5) : Two Austrian wide outbreaks, two holdings of laying hens bacteriologically identified; it was not possible to link all of the cases with one of the holdings; assumed sporadic cases are included.
(6) : S. Enteritidis PT 8 + S. Enteritidis RDNC
(7) : S. Enteritidis PT 8 + S. Hadar
(8) : One outbreak affecting one province; one holding of laying hens epidemiologically and bacteriologically identified.
(9) : S. Enteritidis PT 4 + PT 7
(10) : S. Enteritidis PT8 + S. Anatum
