Next the available data were evaluated. In the study report it was stated that due to the relative high mobility of FOE Sulfonic acid, conformed by batch sorption studies and lysimeter studies, the substantial leaching from the topsoil (0-30 cm layer) cannot be ruled out and as a result may be quantitatively relevant dissipation process, needed to be separated from degradation. As the most appropriate measure to do that the inverse modeling was applied. That was done using two modeling tools: PEST and PEARL. The selection of PEARL, used to separate degradation from other dissipative processes, in the assessment was justified in the following way (the wording of the justification is that provided by the Applicant in the study report):

- it "is a state-of-art soil transport model recommended by FOCUS for pesticides and well accepted for regulatory exposure assessment.";
- "the model used in the inverse procedure is the same which is used for later exposure assessment and guarantees thereby maximum consistency between the derivation and application of the parameters optimised."

PEST was selected being "a versatile and well-established optimization tool which can be coupled with any stand-alone models". RMS also determined that PEST is one of the recommended tools for inverse modeling listed in the reference documents used to verify the validity of this study.

The parameters that were listed to be fitted in the inverse modeling were:

- the DT₅₀ values for Flufenacet and FOE Sulfonic acid,
- the formation fraction *ff* for FOE Sulfonic acid,
- the mass applied.

The reference temperature for the DT₅₀ values was set to T = 20°C and soil moisture to 100%FC, in line with recommendations given by FOCUS. Other not optimised parameters were estimated based on the site-specific

information on soil, weather and crop according to the best practice. In case of not optimised substance-specific parameters, namely sorption parameters for Flufenacet and FOE Sulfonic values, the values were the same as reported in the EU-agreed LoEP.

Because of the constraints of the modeling tool PEARL – in that model the degradation is described by the SFO kinetic model, none of the bi-phasic models was used.

The depth of the soil profile used in the estimation was 1 metre. This assumption was made to minimise the influence of the lower boundary of the simulation domain onto the region of interest – 0-30 cm layer. It was divided into 2.5-cm layers. The lower boundary conditions was set to free drainage to represent well drained soils not affected by shallow ground water.

The soil properties for each trial were defined in line with the description of each test soil provided in the relevant study report. The last horizon was defined to reach the bottom of the simulated soil profile. Hydraulic parameters were derived from soil texture using the class pedotransfer function of Schaap and Leij and soil bulk density was estimated using the pedotransfer function implemented in PEARL.

In case of the cropped trials standard crop parameters from the FOCUS scenario Piacenza were used for each crop reported in the relevant study report. The emergence and harvest dates were set according to the agricultural practices at the specific site assuming 10-days interval between sowing and emergence. That was done also for the trial 30248/1 Fresne-L'Archeveque, initially incorrectly characterized by the Applicant as performed on bare soil.

Other parameters required for modelling were set to the FOCUS default values. The Arrhenius molar activation energy were set to 65.4 kJ/mol, corresponding to $Q_{10} = 2.58$, in line with the up-to-date FOCUS recommendations.

The output of the inverse modeling – the mass in the top 30 cm, was used as modeled results to be compared with the pre-processed measured values.

The PEARL modeling tool, used to simulate water and heat flow, was its 3.0 version. PEST software was used for optimization, consisting on the minimization of the sum of squared differences between measured and calculated data using the Gauss-Marquardt-Levenberg algorithm.

The kinetic analysis of the data was performed in line with the recommendations provided by FOCUS Kinetics guidance document. The applicant stated that for that purpose the earliest accepted version of the Guidelines – 1.0 dated on 2005, was used (n.b. RMS noticed that the date of the issuing of the report implies that the currently recommended version 2.0 of 2006 of that document should rather be used). Although FOCUS Kinetics recommends that four kinetic models – SFO, FOMC, DFOP and HS, should be considered, in practice, due to the constraints related to the PEARL model used in the inverse modeling, only SFO model was used. The weighting of data was not performed in the kinetic analysis.

The obtained fits were evaluated in line with recommendations given by FOCUS, by assessing the goodness of fit visually and statistically. The principles of that assessment were similar to those used by the Applicant in other kinetic evaluations performed for Flufenacet and its degradation products, outlined in the study summaries presented under the point B.8.1.1.2.1.1. of this Renewal Assessment Report.

Results and their discussion:

The results of the initial optimization of the kinetic parameters is presented below in the table B.8.1.1.2.2.1._CA-134. Next table – B.8.1.1.2.2.1._CA-135 presents the optimised ff values with their CIs and correlation coefficients between ff and corresponding DT_{50} value for FOE Sulfonic acid ($c(ff - DT_{50 \text{ FOE SA}})$) for the given trial. Evaluating the results the Applicant stated that for the parent compound the χ^2 error was in most cases lower than 15% and always below 20%, indicating that the fit was good. As for the degradation product – FOE Sulfonic acid, the χ^2 error was in most cases lower than 30%, what was considered to be a good result taking into account low residue levels.

The DT_{50} values for the parent compound – Flufenacet, were considered well defined, i.e. sufficiently reliable, but that was not a case for the DT_{50} values for FOE Sulfonic acid, which had large CI. Those values were also strongly correlated with the corresponding ff values, displaying as well significant level of uncertainty. To solve that problem the Applicant decided to use in the final estimation the fixed $ff = 0.26$ – the mean value obtained in the laboratory studies and reported during the first evaluation of Flufenacet for its authorization in the EU. RMS has to indicate that as a result of the repeated kinetic analysis that value was reduced to 0.195, what is close to the mean field $ff = 0.18$ obtained in the presently evaluated study report.

As a next step the optimisation procedure was repeated using the refined parameters – the kinetic formation fractions for each trial fixed to $ff = 0.26$. The graphical results of the fitting are presented below, individually for each trial, on figures B.8.1.1.2.2.1._CA-85 – B.8.1.1.2.2.1._CA-100. The numerical results of the fitting - optimised parameters and the statistical evaluation, is provided further down the report in the table B.8.1.1.2.2.1._CA-136.

11.5.2.1 Trial 30159/0, Breitenfelde, Germany

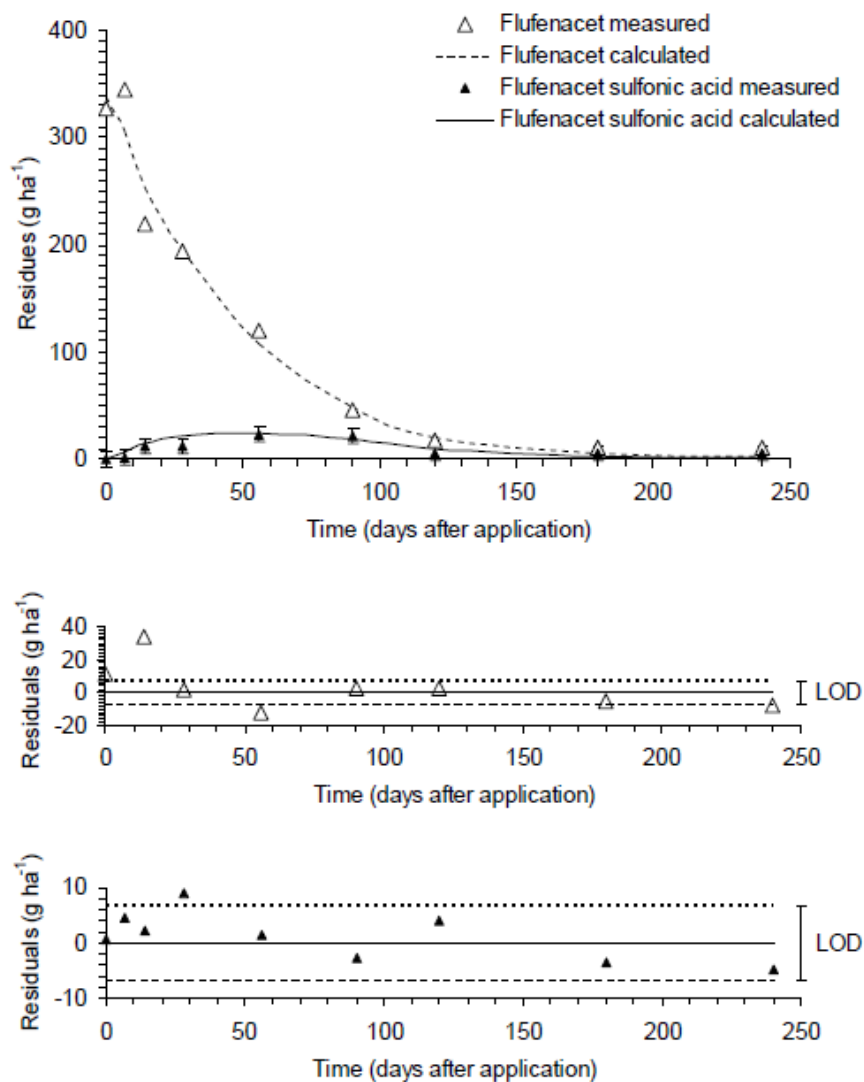

Figure 3: Modelled (solid line) and measured (symbols) residues of flufenacet and flufenacet - sulfonic acid (top), residuals of flufenacet (middle) and flufenacet - sulfonic acid (bottom) for trial 30159/0, Breitenfelde, Germany.

Analysing the results obtained in refined kinetic evaluation of the data the Applicant stated that the values obtained for Flufenacet changed slightly, but significant improvement was obtained for FOE Sulfonic acid. They became more reliable and consistent.

At the same time in case of the two trials – **30164/7 Burscheid** and **30251/1 Laudun**, the Applicant stated that for FOE Sulfonic acid the results cannot be considered reliable because of the insufficient goodness of fit, what is reflected in very high value of χ^2 error. Also in case of their trial 40494/2 Ravenna, the fit is not appropriate. The Applicant stated that the residues in the early phase were underestimated, while those in the medium phase overestimated (however, in the study report it was not explained what the terms “early phase” and “medium phase” meant). The χ^2 error was also high, although lower than in case of the two rejected fits. N.b the RMS noticed that in case of the trials **30251/1 Laudun** and **40494/2 Ravenna** the levels of χ^2 error were comparable – 72.3% and 68.8% respectively, what may indicate that the problems with fitting were similar, what is confirmed by very similar shape of the kinetic curve in relation to the distribution of the data points, as well as range, distribution and individual values of the residuals. RMS also noticed that in case of the trial **30251/1 Laudun** the range of CI for DT₅₀ for FOE Sulfonic acid was narrower than that determined in case of the trial **40494/2 Ravenna**. Therefore the whole approach adopted by the Applicant seems inconsistent – the results obtained for FOE Sulfonic acid in both trials shall be either rejected (in RMS's opinion recommended solution), or accepted and hence included into the data base (solution not recommended, in RMS's opinion, due to the listed above deficiencies of both fits). Finally, it shall be noted that these two trials were also identified by the RMS in course of the kinetic analysis aimed on the determination of the persistence endpoints as those for which it was not possible to obtain the reliable fit for FOE Sulfonic acid, although the available data enabled the fitting.

RMS is also of the opinion that the reliability of the results of the kinetic analysis for FOE Sulfonic acid obtained for the trials in which the detectable amounts of that compound were <LOQ are of very limited reliability because of the significant uncertainty of the input data. As a result they should not be reported and hence used to derive the averaged field DegT₅₀ value for FOE Sulfonic acid. This concerns the following five trials: **30162/2 Kirchlauter**, **30163/9 Monheim**, **30164/7 Burscheid**, **30499/9 Burscheid** and **40495/0 S. Romualdo**.

Therefore in case of FOE Sulfonic acid the results for only eight following trials should be further examined:

- 30159/0 Breitenfelde,
- 30248/1 Fresne-L'Archeveque,
- 30250/3 Fresne-L'Archeveque,
- 30251/1 Laudun,
- 30253/8 St. Etienne du Gres,
- 40163/3 Laudun,

- 40164/1 St. Etienne du Gres,
- 40494/2 Ravenna.

Of them the following should be considered as not providing the reliable kinetic endpoints for FOE Sulfonic acid – **30251/1 Laudun** and **40494/2 Ravenna**. In case of the first of them the fit for FOE sulfonic acid was identified as not reliable by the Applicant, in case of the second such conclusion was drawn by the RMS after thorough comparative analysis of the results. The conclusion is supported by the results of the kinetic analysis performed by the RMS and aimed on the identification of best-fit kinetic model and determination of the persistence endpoints.

In case of the six remaining trials the results of the fitting for FOE Sulfonic acid may be considered reliable and included into final data set, although in case of the trials **30159/0 Breitenfelde** and **40163/3 Laudun** the results should be considered with care because RMS in the kinetic analysis aimed on the identification of best-fit kinetic model and determination of the persistence endpoints was not able to obtain the reliable, robust fit for FOE Sulfonic acid.

In case of Flufenacet the results obtained for all sixteen trials may be considered reliable.

The final set of results of evaluation, with the conclusions of RMS taken into consideration, is presented below in the table B.8.1.1.2.2.1._CA-137. RMS also decided to indicate the results that should be considered with care by giving them in italics.

In the next table – B.8.1.1.2.2.1._CA-138, are provided the results of the estimation of the amounts of FOE Sulfonic acid leached below the soil depth of 30 cm. The results are given as they were provided by the Applicant in the study report. In case of the trials indicated by the RMS as not providing reliable results, the values are given in italics.

Table B.8.1.1.2.2.1._CA-137: The optimised parameters obtained at the final step of evaluation, the ultimate set of the values.

Information on the trial		Optimised parameters						
		M_0 [g a. s./ha]	Kinetic parameters for Flufenacet and their statistical evaluation			Kinetic parameters for FOE Sulfonic acid and their statistical evaluation		
			DT ₅₀ [days]		χ^2 error [%]	DT ₅₀ [days]		χ^2 error [%]
Trial number	Trial site - name		value	CI range		value	CI range	
30159/0	Breitenfelde	341	17.1	14.3 – 20.3	10.2	17.7	5.6 – 55.7	24.8
30162/0	Kirchlauter	402	33.3	23.5 – 47.0	19.5	No values > LOQ, data set not reliable as well as the fitting results		
30163/9	Monheim	252	31.8	24.6 – 41.0	15.4	No values > LOQ, data set not reliable as well as the fitting results		
30164/7	Burscheid	473	11.4	10.1 – 12.9	7.4	No values > LOQ, data set not reliable as well as the fitting results		
30248/1	Fresne-L'Archeveque	474	31.4	24.9 – 39.4	14.4	18.1	1.7 – 189.2	40.4
30250/3	Fresne-L'Archeveque	399	32.9	28.5 – 38.0	8.8	20.8	4.6 – 94.5	42.0
30251/1	Laudun	588	24.7	20.8 – 29.3	10.6	Obtained fit not reliable		
30253/8	St. Etienne du Gres	434	37.6	33.1 – 42.6	8.9	19.6	5.9 – 65.2	32.0
30254/6	Saussay-la-Campagne	164	6.0	3.9 – 9.3	11.5	No values > LOD, assessment not performed		
30455/7	Fresne-L'Archeveque	135	7.1	5.4 – 9.5	10.8	No values > LOD, assessment not performed		
30499/9	Burscheid	192	8.5	7.2 – 10.1	9.3	No values > LOQ, data set not reliable as well as the fitting results		
30500/6	Monheim	157	14.7	9.5 – 22.7	13.5	No values > LOD, assessment not performed		
40163/3	Laudun	362	45.3	33.7 – 60.8	16.5	21.8	0.8 – 629.7	35.1
40164/1	St. Etienne du Gres	391	41.0	30.7 – 54.7	16.2	25.0	1.2 – 523.7	25.8
40494/2	Ravenna	483	36.2	27.9 – 47.1	14.5	Obtained fit not reliable		
40495/0	S. Romualdo	539	51.1	42.2 – 61.9	10.3	No values > LOQ, data set not reliable as well as the fitting results		

Table B.8.1.1.2.2.1._CA-138: The results of the estimation of the amounts of FOE Sulfonic acid leached below the depth of 30 cm – as reported by the Applicant.

Information on the trial			Amount of FOE Sulfonic acid leached (% of formed)
<i>Trial number</i>	<i>Trial site - name</i>	<i>Location - country</i>	
30159/0	Breitenfelde	Germany	9.2
30162/0	Kirchlauter	Germany	1.0
30163/9	Monheim	Germany	17.0
30164/7	Burscheid	Germany	Not applicable
30248/1	Fresne-L'Archeveque	France (North)	16.8
30250/3	Fresne-L'Archeveque	France (North)	20.7
30251/1	Laudun	France (South)	Not applicable
30253/8	St. Etienne du Gres	France (South)	7.9
30254/6	Saussay-la-Campagne	France (South)	Not applicable
30455/7	Fresne-L'Archeveque	France (North)	Not applicable
30499/9	Burscheid	Germany	64.7
30500/6	Monheim	Germany	Not applicable
40163/3	Laudun	France (South)	12.9
40164/1	St. Etienne du Gres	France (South)	13.6
40494/2	Ravenna	Italy	6.4
40495/0	S. Romualdo	Italy	0.9

The results obtained for FOE Sulfonic acid were also validated by their comparison with lysimeter studies. That was done by calculating the PEC_{GW} values for that compound using the lab and field geomean DT_{50} values for FOE Sulfonic acid and the average lab ff for that compound. The calculations were carried out using modified FOCUS Hamburg scenario. The reference lysimeter data were taken from the two German lysimeter studies – by [Hellpointner; 1996] and [Hellpointner; 1997] summarized under the point B.8.1.3.3. of this Renewal Assessment Report as respectively **Study 1** and **Study 2**. The FOCUS scenario used in calculations was modified with regard to key environmental parameters – rainfall, temperature and topsoil OC content which were adjusted to the lysimeter conditions. The application and crop data were same as those recorded in the lysimeter studies. Finally, the evaluation depth was set to 1.35 m., equal to the length of the lysimeter soil cores. The model calculations were carried out using FOCUS PEARL modeling tool.

The values, which were validated this way were:

- lab mean $DT_{50} = 81.4$ days determined for FOE Sulfonic acid (n.b.: this value is not valid any more, as for FOE Sulfonic acid the refined normalized lab. geomean $DT_{50} = 40.97$ days);
- field geomean $DT_{50} = 21.7$ days determined for FOE Sulfonic acid (n.b.: this value is also not fully valid, because the recalculated geomean, after removal of the results considered not reliable, is $DT_{50} = 20.5$ days, but that difference is minimal in comparison to the change in averaged lab DT_{50} , which was reduced by the factor of 2).
- The lab mean $ff = 0.26$ (that value was also modified as a result of the repeated kinetic analysis for FOE Sulfonic acid, the results of which are presented under the point B.8.1.1.2.1.1. of this Renewal Assessment Report).

The results of the comparative analysis are presented below in the table B.8.1.1.2.2.1._CA-139. They shall be considered only as indicative, because the calculations were performed for Flufenacet applied as a parent compound, from which FOE Sulfonic acid was formed. The parametrisation for Flufenacet was also based on the endpoints defined for the previous authorization of Flufenacet in the EU, which became refined as a result of the current evaluation.

Table B.8.1.1.2.2.1_CA-139: The results of the comparison between an annual concentrations of FOE Sulfonic acid in leachates measured in lysimeter studies and calculated using FOCUS GW modeling tool.

Reference - lysimeter	Data on Application				Mean annual concentration of FOE Sulfonic acid [µg/L] in leachate:		
	Number of applications	Application time (season/year)	Application rate [g a.s./ha]	Crop	Measured – lysimeters	Modelled (PEC_{GW} calculations)	
						using lab DT_{50}	using field DT_{50}
<i>Hellpointner; 1996</i>	2	Spring/ year 1	480	Maize	1.616	11.07	3.53
		Autumn/ year 1	180	Winter wheat			
<i>Hellpointner; 1997</i>	2	Spring/ year 1	480	Maize	0.596	12.05	3.43
		Spring/ year 2	480	Maize			

The results of the comparison show that the model exposure assessment performed for FOE Sulfonic acid using the geomean field DT_{50} value determined using the inverse modelling approach will provide overestimated values in comparison to the results obtained in lysimeter studies. Therefore the geomean field DT_{50} value determined in this kinetic assessment study may be considered sufficiently conservative for the purpose of the GW modelling exposure assessment.

RMS comments and evaluation of the study:

The study in general follows the recommendations of the relevant Guidelines and the consulted reference documents. The assessment procedure is well documented. RMS however noticed that some key parameters determining the reliability of the derived kinetic endpoints are not provided – that in particular concerns the statistical evaluation of the rate constants, for which the values of the T-test, even if provided in the PEST output files are difficult to be identified.

Problematic is also normalisation of the data – the absence of the adequate climatic data forced the application of the method which is admissible, but not recommended as primary normalisation method by the current Guidelines. Additionally from the study report it is not easy to deduce how exactly it was performed, so it puts some uncertainty over it.

Finally, it has to be indicated that using the inverse modeling approach the Applicant took into account the fact that FOE Sulfonic acid is mobile in soil profile and may leach to the deeper soil layers. Therefore one of the major dissipation processes was considered in the fitting and the kinetic endpoints adequately modified in order not to take it into account. This process was demonstrated to be of a minor relevance for Flufenacet so it was not taken into account when the kinetic endpoints for that compound were derived.

However, the process that does not seem to be addressed adequately, or that was not clearly explained in the study report, was the plant uptake. The issue shall be clarified, also because half of the trials were performed on the cropped fields. It shall be also indicated that already in the former EU Assessment Report for Flufenacet, prepared by the then-RMS – France, it was stated that the dissipation of Flufenacet was faster on the cropped trial sites. That effect may not necessarily be due to the plant uptake, but this shall be clarified.

RMS also assessing the validity of the kinetic endpoints and their acceptability as input parameters in the EU modelling exposure also consulted the Ctgb checklist which may be still considered as a standard verification tool, and which is presented below.

Field studies into rate of degradation

Checklist for assessing whether a field study on pesticide persistence in soil can be used to estimate transformation rates in soil.

1. *Check that only a non-significant fraction of the dose can have leached out of the soil layers that were sampled (consider the amount of rainfall and concentration measured in the deepest sampled layer);*
2. *Check that only a non-significant fraction of the dose disappeared via processes at the soil surface such as volatilisation or photochemical transformation (consider the period between spraying and the first significant rainfall event; check additionally that there is no initial fast decline followed by a slower decline; a recovery in the field that is much lower than the dose is also an indication of losses at the soil surface);*

3. Check that the decrease of the total amount with time corresponds reasonably well with first-order kinetics (either via curve-fitting or via applying a simulation model); if there is much scatter in the relationship between total amount with time (probably due to an inadequate sampling strategy) the estimation of a transformation rate in soil may be not acceptable;
4. Check whether the soil has been characterised (organic matter, clay etc.);
5. Check whether the location can be considered representative with respect to soil type and climate for Dutch conditions;
6. Check whether meteorological data are available, and whether a correction for the difference between the actual soil temperature (mean temperature measured during the day in top soil layer) and 20°C has been made (an acceptable alternative is temperature during the day in air measured on location, or nearby weather station);
7. Check whether the dose is reported and whether the formulated product is relevant (no granulate or slow release);
8. If inverse modelling was used, check whether the model used is acceptable (see focus document: soil persistence models and EU registration, 1996);
9. Check whether analytical procedure was documented well and whether recovery was acceptable;
10. Check history of pesticide use on plot. In preceding years no active ingredient or structure analogue should be used;
11. Check method of application. Pesticide should not be applied below soil surface;
12. Check method of sampling. Method of sampling should be adequate;
13. Check influence of crop. Uptake of pesticide by crop should be negligible.

Not all points are of equal importance. Crucial points are 1, 2, 5, 6 (temperature), 7, 9, 10, 12, and 13. When a study does not meet (one of) the other points, the quality and usefulness of the study should be evaluated by expert judgement.

All points should be checked and reported. A conclusion should be drawn whether from the field study the dissipation DT_{50} can be attributed to transformation only. In the light of all available information in the dossier, it should be determined whether the field DT_{50} can be used to predict leaching of the compound.

It was stated that the kinetic evaluation in general complies with it, although it displays several deficiencies already listed above.

As a result, the RMS is of the opinion that the kinetic endpoints for Flufenacet and, in particular, FOE Sulfonic acid determined in this study may be considered as input parameters for Tier-2 modelling with refined input parameters and as such be used in refined GW, and possibly SW, modelling exposure assessment at zonal or MS levels of assessment. That however shall be done after careful examination of the study report aimed on the clarification of all listed problems identified by the RMS.

As for purpose of the current EU assessment RMS is of the opinion that the kinetic endpoints derived from this study, and in particular the DT_{50} values for FOE Sulfonic acid, bear to significant level of uncertainty to be used in GW and SW model exposure assessment.

For that reason RMS decided not to include the kinetic endpoints determined in this study into the List of EndPoints.

The final set of the results is given below in the table B.8.1.1.2.2.1._CA-140. Only the reliable fitting results are provided.

Table B.8.1.1.2.2.1_CA-140: The final results of the kinetic evaluation of the data obtained in field dissipation trials aimed on derival of the modelling endpoints for Flufenacet and FOE Sulfonic acid.

Footnotes to the table:

- 1) Determined in 0.01M CaCl₂;
- 2) The DIN 19682 classification presented because the USDA classification not provided; in another report it was stated to be Sandy loam (USDA) containing 58.5% sand, 22.7% silt and 18.8% clay.

Additionally there were identified and classified as relevant three publications dealing with the issue of the field dissipation of Flufenacet. They are summarised below as **Studies 8 - 10**. It shall be indicated that although they were identified as relevant, RMS is of the opinion that they can be used only as a source of supporting data, not to be used to derive the regulatory endpoints.

Study 8:

Report: Rouchaud J.^{a)}, Neus O.^{a)}, Cools K.^{b)}, Bulcke R.^{b)} (1999): “Dissipation and mobility of the oxyacetamide flufenacet herbicide in corn and wheat crops.”; Laboratory of Phytopharmacy, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium (a) and Weed Research Center, Universiteit Ghent, B-9000 Gent, Belgium; published study - published in: “Mededelingen – Faculteit Landbouwkundige en Toegepaste Biologische Wetenschappen, Universiteit Gent”, vol 64, No. 3b, 1999, pp 673 – 677.

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper;

RMS comments: The paper presents the results of the examination of persistence of Flufenacet in soil under realistic – field conditions. The compound was performed on one trial site located in Belgium, on which cereals and maize were grown. The test compound – Flufenacet was applied to the soil as pre-emergent pesticide in application rate 600 g/ha for spring/summer crops (corn/maize) and 240 g/ha for winter crops (winter wheat). degradation was examined for two fortification levels. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with other, regulatory field dissipation studies. The level of detail was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and conformatory to the endpoints provided by the regulatory studies submitted by the Applicant and should not be used as a source of regulatory endpoints.

Summary:

The paper contains an abstract, outlining the aims of the experiment and its key results, which was made available on-line. However, due to the copyright restrictions RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the persistence and mobility of Flufenacet in soil under realistic – field conditions and on cropped field. The experiment was performed on one trial site, at Melle in Belgium. The soil on the test fields was classified as Sandy loam (55% sand, 38% silt and 7% clay), containing 2.2% OM and having pH = 6.2.

The experiment was carried out in three variants:

- on the field with spring corn as a test crop;
- on the field with summer corn as a test crop;
- on the field with winter wheat as a test crop.

The whole experiment on the trial site was initiated in Autumn 1997 by starting the variant with winter wheat as a test crop.

It was initiated by preparing the sowing bed on the test field, by tilling the soil to the depth of 10 cm. Then Next, on 21st November 1997 Flufenacet was applied to the bare soil in amount 240 g/ha, the application rate typical for winter wheat. The field was left bare (no crop cover) until the spring (early May) of the next year – 1998, to simulate failure of the Winter wheat. Then on the 7th May 1998 the field was rotary tilled and the succeeding crops – spring wheat, corn, sugar beet, oat and probably others, were sown in bands. They were grown on the test field until mid-August 1998.

The soil samples were collected from four replicate plots randomly located on the test field. They were taken at pre-defined (not reported in the paper) intervals. The soil samples from the topmost 0-10cm soil layer were

taken from each of the four plots. Additionally, from two plots were taken samples from 0-10 cm layer divided into 2-cm sections, 10-15 cm layer and 15-20 cm layer. In case of the samples taken before sowing of succeeding crops, but after the sowing bed was prepared, the soil samples were taken only from the layers 10-15 cm and 15-20 cm because the topmost layer had been disturbed by tilling. Collected soil samples were analysed separately shortly after being sampled.

The variant with the spring corn was initiated by preparing a sowing bed on the test field. That was done by rotary tilling the field firstly in November 1997 and then in late March 1998, when the sli was tilled to the depth of 10 cm. Next the test compound – Flufenacet was applied to the soil surface in application rate 600 g/ha. Then, on the 7th of May Corn was sown on the test field and grown until harvested in mid-October 1998. On the trial field four randomly located replicate plots were designated, from which at pre-defined interval soil samples from the top 0-10 cm layer were taken. Additionally from the two replicate plots soil samples from 0-10 cm, 10-15 cm and 15-20 cm layers were taken. Collected samples were analysed separately, shortly after sampling.

For the third variant – with summer corn, the whole procedure looked very similarly to that described for the variant with spring corn. The test field was prepared for sowing in late May, after what Flufenacet was applied to the soil surface at 600 g/ha. The crop was sown on the 8th June 1998 and collected in mid-October of the same year. Soil sampling procedure was identical to that described above for the variant with spring corn.

The collected soil samples were processed in a following way:

- they were extracted with the mixture acetone/water;
- the extracts were collected and the organic solvent evaporated;
- the remaining aqueous extract was partitioned with ethyl acetate, the organic phase collected, cleaned by repeated TLC and then analysed by GC and GC-MS.

The LOD for the analytical method used in the study was 3 µg Flufenacet/kg soil.

The persistence of Flufenacet in soil of the trial site was determined using the linear regression method.

The results obtained in all three variants demonstrated that the residues of Flufenacet were confined to the top 10 cm layer with little migration to the layers below that depth. The movement within 0-10 cm layer was examined only for variant with winter wheat (in fact that was the variant with bare soil). It was stated that after application the compound was confined to 0-2 cm section and one month after treatment it was detected predominantly in the section 2-4 cm, where it was recorded in highest amounts until spring of the following year. Progressive movements to the deeper sections of 0-10 cm layer: 4-6 cm section, 6-8 cm section and 8-10 cm section, was reported in the paper. The analysis of the graph illustrating that movement showed that it was not significant by comparison to the dissipation of the compound from 2-4 cm section and it decreased with depth, becoming almost insignificant for the lowest section of the layer – 8-10 cm. No significant residues of Flufenacet were detected during that period in deeper layers – 10-15 cm and 15-20 cm. The compound was also not detected in significant amounts in those layers after May tillage and sowing of succeeding crops. For the variant with winter wheat (on bare soil) the persistence of Flufenacet was not determined.

The persistence of Flufenacet in the top 0-10 cm layer of soil was determined for all three variants of the experiment. The calculations were performed using the linear regression method and the equation:

$$\ln y = kt + b$$

where:

y – concentration of Flufenacet in soil in [µg/kg];

t – time elapsing from application in [days];

k – dissipation rate constant;

The calculated half-lives, expressed as DisT₅₀ values, were:

- for the variant with winter wheat (on bare soil): DisT₅₀ = 98 ± 5 days;
- for variant with spring corn: DisT₅₀ = 74 ± 4 days;
- for variant with summer corn: DisT₅₀ = 56 ± 3 days.

On the basis of the obtained results it was stated that neither application rate (what was demonstrated in the separate trial) nor the crop cover had any significant influence on the rate of dissipation of Flufenacet on the trial site. The observed differences in the soil half-lives were attributed to the different environmental conditions recorded on the trial site, in particular temperature and soil microbial activity.

In the paper it was also stated that after 4 months of crop growing period following application of the test compound the rate of dissipation of Flufenacet increased, becoming greater than that predicted by the 1st order kinetics. That may indicate that the dissipation of Flufenacet on the trial site bore traits of a bi-phasic process.

RMS comments:

The obtained kinetic endpoints are compliant with those obtained for Flufenacet in regulatory studies. However, because of the method of their derivation they shall be considered only as indicative and not used as regulatory endpoints. The results of the study also clearly indicate that Flufenacet in field is confined to the top 10- to 20-cm layer and displays no tendency to move to the deeper soil layers. That statement conforms the

observation made in the regulatory studies aimed on the examination of the field dissipation of that compound, that Flufenacet is not expected to dissipate from the top 30-cm soil layer by leaching to the deeper ones.

However, as RMS stated at the beginning of the whole summary of the study, presenting its evaluation, the results are only conformatory and indicative. As such they cannot be reported in the EU List of End Points.

Study 9:

Report: Rouchaud J.^{a)}, Neus O.^{a)}, Cools K.^{b)}, Bulcke R.^{b)} (1999): “Flufenacet Soil Persistence and Mobility in Corn and Wheat Crops.”; Laboratory of Phytopharmacy, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium (a) and Weed Research Center, Universiteit Ghent, B-9000 Gent, Belgium; published study - published in: “The Bulletin of Environmental Contamination and Toxicology”, vol 63, 1999, pp 460 – 466.

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper;

RMS comments: The paper presents the results of the examination of persistence of Flufenacet in soil under realistic – field conditions. The compound was performed on one trial site located in Belgium, on which cereals and maize were grown. The test compound – Flufenacet was applied to the soil as pre-emergent pesticide in application rate 600 g/ha for spring/summer crops (corn/maize) and 240 g/ha for winter crops (winter wheat). degradation was examined for two fortification levels. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with other, regulatory field dissipation studies. Analysing its content RMS stated that it reported the results of the same study that was characterised in the previously summarised publication – **Study 8**. However, it provided more detailed information about the analytical procedure used to process the collected soil samples and the numerical results of the analysis of the residues of Flufenacet in soil. Therefore RMS decided to provide its summary focusing on the pieces of information not presented in the **Study 8**.

The level of detail was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and conformatory to the endpoints provided by the regulatory studies submitted by the Applicant and should not be used as a source of regulatory endpoints.

Summary:

The Editor has not provided the abstract for that publication. However the paper contained the introduction, clearly outlining the aims and scope of the research activity described in it, which may be considered a summary of the study. Due to the copyright restrictions, RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the persistence and mobility of Flufenacet in soil under realistic – field conditions and on cropped field. The experiment was performed on one trial site, at Melle in Belgium. The soil on the test fields was classified as Sandy loam (55% sand, 38% silt and 7% clay), containing 2.2% OM and having pH = 6.2.

The experiment was carried out in three variants:

- on the field with spring corn as a test crop;
- on the field with summer corn as a test crop;
- on the field with winter wheat as a test crop.

The whole experiment on the trial site was initiated in Autumn 1997 by starting the variant with winter wheat as a test crop.

It was initiated by preparing the sowing bed on the test field, by tilling the soil to the depth of 10 cm. Then Next, on 21st November 1997 Flufenacet was applied to the bare soil in amount 240 g/ha, the application rate typical for winter wheat. The field was left bare (no crop cover) until the spring (early May) of the next year – 1998, to simulate failure of the Winter wheat. Then on the 7th May 1998 the field was rotary tilled and the

succeeding crops – spring wheat, corn, sugar beet, oat and probably others, were sown in bands. They were grown on the test field until mid-August 1998.

The soil samples were collected from four replicate plots randomly located on the test field. They were taken at pre-defined (not reported in the paper) intervals. The soil samples from the topmost 0-10cm soil layer were taken from each of the four plots. Additionally, from two plots were taken samples from 0-10 cm layer divided into 2-cm sections, 10-15 cm layer and 15-20 cm layer. In case of the samples taken before sowing of succeeding crops, but after the sowing bed was prepared, the soil samples were taken only from the layers 10-15 cm and 15-20 cm because the topmost layer had been disturbed by tilling. Collected soil samples were analysed separately shortly after being sampled.

The variant with the spring corn was initiated by preparing a sowing bed on the test field. That was done by rotary tilling the field firstly in November 1997 and then in late March 1998, when the sli was tilled to the depth of 10 cm. Next the test compound – Flufenacet was applied to the soil surface in application rate 600 g/ha. Then, on the 7th of May Corn was sown on the test field and grown until harvested in mid-October 1998. On the trial field four randomly located replicate plots were designated, from which at pre-defined interval soil samples from the top 0-10 cm layer were taken. Additionally from the two replicate plots soil samples from 0-10 cm, 10-15 cm and 15-20 cm layers were taken. Collected samples were analysed separately, shortly after sampling.

For the thirs variant – with summer corn, the whole procedure looked very similarly to that described for the variant with spring corn. The test field was prepared for sowing in late May, after what Flufenacet was applied to the soil surface at 600 g/ha. The crop was sown on the 8th June 1998 and collected in mid-October of the same year. Soil sampling procedure was identical to that described above for the variant with spring corn.

The collected soil samples were processed in a following way:

- 100-g aliquots of the collected soil samples were stir-extracted with 200-mL portions of acetone/water 8:2 mixture for 1 hour at $T = 20^{\circ}\text{C}$; the collected extract was filtered;
- The extraction was repeated using the same extracting solution; that step lasted 30 minutes;
- The filtered extracts were combined, 100 mL of water was added and acetone removed by evaporation under vacuum at $T = 30^{\circ}\text{C}$;
- The remaining aqueous extract was partitioned, after addition of 15 g NaCl, with two 200-mL portions of $\text{CH}_3\text{COOC}_2\text{H}_5$; the organic phase was collected and dried by stirring for 1 hour with Na_2SO_4 at $T = 20^{\circ}\text{C}$;
- Dried ethyl-acetate extract was concentrated in a three-step procedure to 0.5 mL and the concentrate subjected to chromatographic fractionation using TLC;
- The band containing the test compound – Flufenacet (both isomers) was collected and further purified using column chromatography technique; the elution was carried out using acetone;
- The acetone extract was once again concentrated to 0.5 mL in two-step procedure and once again purified by chromatographic fractionation on TLC plates; the relevant TLC band was collected and processed in the same manner as described above;
- The final extract, having a volume of 1 mL, was subjected to GC and GC-MS analysis.

The GC analysis was performed on glass column 1.8-metre long and having the internal diameter of 2 mm and containing 5% SE30 on chromosorb W-HP 80-100 mesh. The carrier gas was N_2 flowing through the system at rate 50 mL/min. The temperature of the column oven was set to $T = 190^{\circ}\text{C}$. In case of the GC analysis the detection was performed using the ECD detector.

For GC-MS analysis chromatographic conditions were the same. The MS analysis was performed in EI (electron impact) or CI (chemical ionisation) modes. Mass spectra were recorded at 70 eV.

The determined for the whole analytical method LOD = 3 $\mu\text{g/kg}$ soil.

The detailed numerical results of the study: the soil concentrations of Flufenacet recorded at each sampling point are reported below, separately for each variant in tables B.8.1.1.2.2.1._CA-141 – B.8.1.1.2.2.1._CA-143. Analysing the results presented in the paper RMS noticed that in case of the variant with winter wheat there were a clear discrepancies in the values obtained in 0-10 cm when analysed as a whole profile and dissected into 2-cm sections. The reason for that was not given in the study report, but may be possibly attributed to the way of the processing of the results.

Table B.8.1.1.2.2.1_CA-141: The results of the study – soil concentrations of Flufenacet obtained in the variant with winter wheat (bare soil).

Footnotes to the table:

1) n. d. = not detected.

The results obtained in all three variants demonstrated that the residues of Flufenacet were confined to the top 10 cm layer with little migration to the layers below that depth. The movement within 0-10 cm layer was examined only for variant with winter wheat (in fact that was the variant with bare soil). It was stated that after application the compound was confined to 0-2 cm section and one month after treatment it was detected

predominantly in the section 2-4 cm, where it was recorded in highest amounts until spring of the following year. Progressive movements to the deeper sections of 0-10 cm layer: 4-6 cm section, 6-8 cm section and 8-10 cm section, was reported in the paper. The analysis of the graph illustrating that movement showed that it was not significant by comparison to the dissipation of the compound from 2-4 cm section and it decreased with depth, becoming almost insignificant for the lowest section of that layer – 8-10 cm. No significant residues of Flufenacet were detected during that period in deeper layers – 10-15 cm and 15-20 cm. The compound was also not detected in significant amounts in those layers after May tillage and sowing of succeeding crops. For the variant with winter wheat (on bare soil) the persistence of Flufenacet was not determined.

The persistence of Flufenacet in the top 0-10 cm layer of soil was determined for all three variants of the experiment. The calculations were performed using the linear regression method and the equation:

$$\ln y = kt + b$$

where:

y – concentration of Flufenacet in soil in [$\mu\text{g/kg}$];

t – time elapsing from application in [days];

k – dissipation rate constant;

The calculated half-lives (expressed as DisT_{50} values) were:

- for the variant with winter wheat (on bare soil): $\text{DisT}_{50} = 98 \pm 5$ days;
- for variant with spring corn: $\text{DisT}_{50} = 74 \pm 4$ days;
- for variant with summer corn: $\text{DisT}_{50} = 56 \pm 3$ days.

On the basis of the obtained results it was stated that neither application rate (what was demonstrated in the separate trial) nor the crop cover had any significant influence on the rate of dissipation of Flufenacet on the trial site. The observed differences in the soil half-lives were attributed to the different environmental conditions recorded on the trial site, in particular temperature and soil microbial activity.

In the paper it was also stated that after 4 months of crop growing period following application of the test compound the rate of dissipation of Flufenacet increased, becoming greater than that predicted by the 1st order kinetics. That may indicate that the dissipation of Flufenacet on the trial site bore traits of a bi-phasic process.

RMS comments:

The obtained kinetic endpoints are compliant with those obtained for Flufenacet in regulatory studies. However, because of the method of their derivation they shall be considered only as indicative and not used as regulatory endpoints. The results of the study also clearly indicate that Flufenacet in field is confined to the top 10- to 20-cm layer and displays no tendency to move to the deeper soil layers. That statement conforms the observation made in the regulatory studies aimed on the examination of the field dissipation of that compound, that Flufenacet is not expected to dissipate from the top 30-cm soil layer by leaching to the deeper ones.

However, as RMS stated at the beginning of the whole summary of the study, presenting its evaluation, the results are only conformatory and indicative. As such they cannot be reported in the EU List of End Points.

Study 10:

Report: Rouchaud J.^{a)}, Neus O.^{a)}, Eelen H.^{b)}, Bulcke R.^{b)} (2001): “Persistence, Mobility and Adsorption of the Herbicide Flufenacet in the Soil of Winter Wheat Crops.”; Laboratory of Phytopharmacy, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium (a) and Weed Research Center, Universiteit Ghent, B-9000 Gent, Belgium; published study - published in: “The Bulletin of Environmental Contamination and Toxicology”, vol 67, 2001, pp 609 – 616.

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper;

RMS comments: The paper presents the results of the examination of persistence of Flufenacet in soil under realistic – field conditions. The compound was performed on four trial sites located in Belgium, on which winter cereals (winter wheat) were grown. The test compound – Flufenacet was applied to the soil as post-emergent pesticide, in autumn, at application rate 240 g/ha. examined for two fortification levels. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with other, regulatory field dissipation studies. Analysing its content RMS stated that it reported the results of the study that continued the research project started by the experiment described in previously summarised publications – **Study 8** and **Study 9**.

The level of detail was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below. However, RMS is of the opinion

that the results it provides may be regarded only as supplementary and conformatory to the endpoints provided by the regulatory studies submitted by the Applicant and should not be used as a source of regulatory endpoints.

Summary:

The paper contains an abstract, outlining the aims of the experiment and its key results, which was made available on-line. However, due to the copyright restrictions RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the persistence and mobility of Flufenacet in soil under realistic – field conditions and on cropped field. The experiment was performed on four trial sites in Belgium: Melle, Zingem and Zevekote, located 40 km apart, and Cortil-Noirmont, 100 km-distant from Melle. The characteristic of each trial site, as provided in the paper, is given below in the table B.8.1.1.2.2.1._CA-144.

Table B.8.1.1.2.2.1._CA-144: The brief characteristic of the trial sites.

Parameter		Trial site			
		Melle	Zingem	Zevekote	Cortil-Noirmont
Soil type		Sandy loam	Loamy sand	Clay loam	Silt loam
Particle size distribution	Sand [%]	55	79	19	11
	Silt [%]	38	11	45	75
	Clay [%]	7	10	36	14
pH value		7.0	6.4	6.6	6.7
Organic matter content (OM) [%]		1.51	1.60	2.12	1.2

The organic fertilization of soil on the trial sites was following:

- on Melle trial site no organic fertilizer was used on the year when the experiment started – 1999; before that year the trial site was fertilized every second year at spring with 40 tonnes/ha of either cow slurry or cow manure;
- on Zevekote trial site no organic fertilizer was used on the year when the experiment began – 1999; before that date the trial site was fertilized every second year, in September with 40 tonnes/ha of pig slurry or 40 tonnes/ha of cow manure;
- on Zingem trial site on the year when the experiment started – 1999, the soil was fertilized with cow manure applied at rate 40 tonnes/ha in October; in the preceding years the test field was fertilized every second year with either 40 tonnes/ha of cow manure or 40 tonnes/ha of pig slurry;
- on Cortil-Noirmont on the year when the experiment started soil was organically fertilized by incorporation of the leftovers of the preceding crop (sugar beet leaves) into the soil; in preceding years the test fields were fertilized by applying onto them 40 tonnes/ha of the cow manure every fourth year.

At the beginning of the experiment – in November 1999 test fields were tilled to prepare a seed bed and winter wheat was sown. On each test field four 6 x 10 metres plot were located at random, onto which the test substance – Flufenacet, was applied. It was applied to the soil surface of the test fields at rate 240 g/ha on the following dates:

- Melle trial site: on 25th November 1999;
- Zingem trial site: on 25th November 1999;
- Zevekote trial site: on 26th November 1999;
- Cortil-Noirmont: on 26th November 1999.

Additionally at trial sites Melle and Zingem the test compound was applied to the previously untreated plots at the same application rate in early spring of the following year : on 17th March 2000 at Melle and 4th April 2000 at Zingem.

At pre-defined intervals soil samples were taken from each treated plot of each trial site. The soil sampling procedure and subsequent processing and analysis of the collected soil samples were identical to those characterised above in the **Studies 8 and 9**.

The obtained results – concentrations of Flufenacet in soil in function of time were kinetically examined to determine its persistence by calculating the half-lives. The calculations were performed using the linear regression method and the equation:

$$\ln y = kt + b$$

where:

y – concentration of Flufenacet in soil in [$\mu\text{g/kg}$];

t – time elapsing from application in [days];

k – dissipation rate constant;

In case of autumn application the kinetic examination of the data covered 5-months period, while in case of the spring application 3.5-months period.

The numerical results of the study, individually for each trial site, are presented below in tables B.8.1.1.2.2.1._CA-145 – B.8.1.1.2.2.1._CA-148. Analysing these results RMS noticed that only those results were reported only for the autumn application of the test compound – Flufenacet, onto the trial sites. Reporting the data RMS decided not to provide the SD values that followed each mean concentration.

Table B.8.1.1.2.2.1._CA-145: The results of the study – soil concentrations of Flufenacet, obtained for the trial site Melle.

Footnotes to the table:

- 1) n. d. = not detected;
2) n. a. = not available.

RMS, analysing the data presented in the tables above, noticed significant discrepancies between the total concentrations obtained in 0-10 cm layer and those obtained in that layer when divided into 2-cm sections. That was due to the fact that the results for the whole 0-10 cm layer were reported as averages of four replicates, while those for sections 0-2 cm, 2-4 cm, 4-6 cm, 6-8 cm and 8-10 cm as averages of the two replicate samples taken independently of the whole 0-10 cm cores.

The persistence of the test compound – Flufenacet in soil on each of the trial site was determined using the data obtained in whole 0-10 cm layer. The calculated half-lives, for convenience denominated DisT₅₀ by the RMS, together with their SD values, are provided below. They were calculated using the linear regression method and assuming the CI = 95%.

The DisT₅₀ values reported in the publication were following:

- for Melle trial site soil persistence of Flufenacet expressed as DisT₅₀ = 66 ± 3.3 days;
- for Zevekote trial site soil persistence of Flufenacet expressed as DisT₅₀ = 64 ± 3.2 days;
- for Zingem trial site soil persistence of Flufenacet expressed as DisT₅₀ = 97 ± 4.9 days;
- for Cortil-Noirmont trial site soil persistence of Flufenacet expressed as site DisT₅₀ = 54 ± 2.7 days.

Analysing the obtained results the authors stated that the trial sites were selected in such way to minimise the differences of the trial-related variables, such as soil characteristic, weather patterns, field maintenance practices and application pattern of the test compound.

It was stated that the main differences between the trial sites were:

- soil texture;
- soil OM;
- recent organic fertilization.

While no significant correlation was found between variable soil properties – texture and OM content, and persistence of Flufenacet in soil of the trial sites, such correlation was stated between the persistence of the test compound and organic fertilization practices – while the DisT_{50} values were comparable on three trial sites with no fertilization with organic fertilizer of the animal origin, on the trial site on which such practice was effectuated (Zingem), the half-life of the test compound in soil lengthened by factor of 0.5.

In case of the spring application of Flufenacet to the two trial sites – Melle and Zingem, the reported soil half-lives of Flufenacet were following:

- for Melle trial site $\text{DisT}_{50} = 44 \pm 2.2$ days;
- for Zingem trial site $\text{DisT}_{50} = 66 \pm 3.9$ days.

The longer dissipation at Zingem trial site was attributed to the fertilization with organic fertilizer of the animal origin used in autumn of the year preceding application of the test compound – Flufenacet.

It was also stated that Flufenacet when applied at spring displayed lower soil persistence than when applied in autumn, what was related to the climatic conditions on the trial sites, mainly temperature – lower in autumn and winter than at spring and summer, as well as lower soil microbial activity observed in autumn-winter period.

Another factor examined in the study and reported in the paper was soil sorption of the test compound expressed as the parameters of Freundlich sorption isotherm. The analytical protocol used in this part of the study and the obtained results will be presented under the relevant point of this Renewal Assessment Report.

RMS comments:

The obtained kinetic endpoints are compliant with those obtained for Flufenacet in regulatory studies. However, because of the method of their derivation they shall be considered only as indicative and not used as regulatory endpoints. The results of the study also clearly indicate that Flufenacet in field is confined to the top 10- to 20-cm layer and displays no tendency to move to the deeper soil layers. That statement conforms the observation made in the regulatory studies aimed on the examination of the field dissipation of that compound, that Flufenacet is not expected to dissipate from the top 30-cm soil layer by leaching to the deeper ones.

RMS analysing the tabularised results noticed the inconsistencies of the reported values, mainly concerning the sampling dates expressed in absolute (day/month/year) and relative (Days After Treatment) terms. That however had no significant impact on the results.

However, as RMS stated at the beginning of the whole summary of the study, presenting its evaluation, the results are only conformatory and indicative. As such they cannot be reported in the EU List of End Points.

The key results of the three open literature field dissipation studies are presented below in the table B.8.1.1.2.2.1._CA-149. As indicated in the RMS's comments to each summarised report, these values are only informative and as such they will not be reported in the EU list of End Points nor used anyhow in the exposure/risk assessment.

Table B.8.1.1.2.2.1._CA-149: The key results obtained in the literature studies examining the field dissipation of Flufenacet.

B.8.1.1.2.2.2. – Soil residue studies

No studies were submitted in this area for the previous authorisation of Flufenacet in the EU. Instead was given the following justification for not providing them: “*Studies are neither required nor they were supplied because trigger values were not exceeded.*”. Also for the present evaluation no studies covering this data requirement were submitted and the Applicant did not justify their non-submission. However the results of the kinetic analysis of the results of soil dissipation studies, performed in line with the recommendations of FOCUS Kinetics Guideline [FOCUS; 2006], demonstrated that the justification presented in the previous Assessment Report for Flufenacet may be considered still valid.

B.8.1.1.2.2.3. – Soil accumulation studies

No studies were submitted in this area for the previous authorisation of Flufenacet in the EU. Instead was given the following justification for not providing them: “*Based on the soil dissipation studies (field) and rotational crop studies (laboratory) respective studies are not necessary and were not supplied.*”. Also for the present evaluation no studies covering this data requirement were submitted, but the Applicant provided the following justification for their non-submission: “*The accumulation potential of flufenacet was evaluated during the Annex I Inclusion. Due to the short dissipation times, soil accumulation testing is not required for flufenacet.*”

RMS is of the opinion that the justification provided by the Applicant is defensible. The results of the kinetic evaluation of the data obtained in the field dissipation trials performed by the RMS and aimed of the determination of the persistence of Flufenacet and its selected major soil degradation products in soil resulted in short dissipation times, with DT₉₀ values for Flufenacet predominantly shorter than 200 days and only in case of the trial Monheim, 30500/6, in which Flufenacet was applied in autumn (late October) to bare soil in amount 240 g/ha thbeing longer – the not normalised DT₉₀ = 226 days. Therefore it can be stated that in none of the trials was recorded the DisT₉₀ ≥ 1 year, a formal requirement for performing this type of studies set by the Commission Regulation (EU) No. 283/2013. Also in the three open-literature studies identified as relevant for the present evaluation, Flufenacet was demonstrated not to have a tendency for accumulation in soil after either autumn or spring application (please refer to the summaries of the **Studies 8-10**, presented under the point B.8.1.1.2.2.1. of this Renewal Assessment Report).

Additionally the issue of the accumulation potential for both Flufenacet and its major soil metabolites was assessed in the model soil exposure assessment presented under the point B.8.2. in the document Vol. 3. B.8_CP.

B.8.1.1.2.2.4. – Summary of the field studies.

The dissipation of Flufenacet in soil under field conditions was examined on sixteen trial sites located in the EU – in Germany, France (Northern and Southern) and Italy. The characteristic of the trial sites in presented below in the table B.8.1.1.2.2.4._CA-1. The next table – B.8.1.1.2.2.4._CA-2, provides the brief characteristic of the weather conditions recorded at each trial site during the experiment.

Table B.8.1.1.2.2.4._CA-1: The brief characteristic of field trials.

Study	Information on the trial site			Data on application		Data on crop cover

The residues of Flufenacet on the trial sites were determined by sampling, at pre-determined intervals, soil cores down to 30-cm or 50-cm depth. The number of sampling points was, depending on the trial site, eight or nine. The soil samples were dissected into 10-cm layers and analysed for the content of Flufenacet and its three major soil degradates – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The performed analysis showed that FOE Alcohol was not formed on any trial site in detectable amounts >3 µg/kg soil (LOD). Other two degradation products were detectable and, on some trial sites even quantifiable (recorded in amounts > LOQ = 10 µg/kg soil), but in none of the trials were observed in amounts higher than 30 µg/kg soil. Neither Flufenacet nor any of its degradation products were detected in deeper soil layers – below 20 cm.

The obtained results were kinetically examined in line with the recommendations of the FOCUS Work Group on the Degradation Kinetics. The results of the determination of the persistence of Flufenacet and its two quantifiable degradation products – FOE Oxalate and FOE Sulfonic acid, are presented below in three separate tables – B.8.1.1.2.2.4._CA-3 (Flufenacet), B.8.1.1.2.2.4._CA-4 (FOE Oxalate) and B.8.1.1.2.2.4._CA-5 (FOE Sulfonic acid).

The results obtained for Flufenacet and FOE Sulfonic acid were also kinetically examined with aim to derive the kinetic endpoints suitable for modelling. The kinetic analysis was performed using the inverse modelling approach. The assessment was conditionally accepted by the RMS. However, RMS decided, because of the stated deficiencies, not to use its results in the model exposure assessment, nor to report them in the List of End Points. At the same time they may be used, at zonal or MS level, as refined input parameters in Tier 2a GW exposure assessment. The results are presented below in the table B.8.1.1.2.2.4._CA-6.

Table B.8.1.1.2.2.4._CA-6: The proposed modelling kinetic endpoints for Flufenacet and FOE Sulfonic acid determined from the data obtained in field dissipation trials using the inverse modelling approach.

The soil residues studies and soil accumulation studies were not performed as the results of the field dissipation studies demonstrated that they were not required – their results clearly indicated that neither Flufenacet nor its degradation products would accumulate in soil.

Finally three relevant open-literature studies examining the dissipation of Flufenacet in soil under realistic – field conditions were identified. Their key results are presented below in the table B.8.1.1.2.2.4._CA-7.

Table B.8.1.1.2.2.4._CA-7: The key results obtained in the literature studies examining the field dissipation of Flufenacet.

B.8.1.1.3. – Summary of soil persistence (route and rate of degradation in soil)

The results of the examination of the persistence of Flufenacet in soil are presented below. The same summary is also provided in the Vol 1 and in Vol 3, B.8._CP.

1) Degradation in soil under aerobic conditions:

The route of degradation of the acetanilide herbicide Flufenacet in aerobic soil was extensively examined in eight agricultural soils – seven originating from the EU and one from US. The test compound – Flufenacet, was radiolabelled in one of the following three following positions:

- uniformly in phenyl ring – compound tested on four soils,
- position C2 in thiadiazole moiety – test performed on one soil,
- position C5 in thiadiazole moiety – examined in four soils.

These data were presented in five unpublished studies submitted specifically for the purpose of this assessment. Additionally the data relevant for determining transformation pattern of Flufenacet in aerobic soil, relevant for regulatory purposes, were found in one scientific paper, examining the degradation of Flufenacet radiolabelled uniformly in phenyl ring in two US soils. That study was based on a non-GLP regulatory study, conceived as a bridging study for laboratory and field experiments on the degradation of Flufenacet in soil. That study was verified by RMS and found acceptable. Therefore the results of the literature study based on it were included into evaluation.

The key results of the examination of transformation of Flufenacet are presented in the tabularised form below (tables B.8.1.1.3._CA-1 – B.8.1.1.3._CA-4), separately for the compound radiolabelled in phenyl ring and in thiadiazole moiety.

Table B.8.1.1.3._CA-1: The levels of mineralisation and NER fraction formed, and identified degradation products in experiments with [Phenyl-U-¹⁴C] Flufenacet.

Study	Soil		Level of mineralisation [% AR]:		Level of NER [% AR]:			Identified degradation products
	Name	Type (USDA)	After ~100 days	at the study's end	Max.	After ~100 days	at the study's end

Footnotes to the table:

- 1) Justification based on the criteria set by the Guideline SANCO/221/2000, listed under the point 4 on page 6:
“As a minimum, degradation products must be characterized and identified by the notifiers to the extent that it is technically feasible and their relevance must be assessed, if one of the following conditions applies:
a) Metabolites, which account for more than 10% of the amount of active substance added in soil at any time during the studies; or
b) which account for more than 5% of the amount of active substance added in soil in at least two sequential measurements during the studies; or
c) for which at the end of soil degradation studies the maximum of formation is not yet reached.
- 2) Compound not detected in that soil.

The transformation pattern of Flufenacet in soil was examined only on biologically viable soil. That was due to the fact that, on the basis of available results it was assumed that all transformation processes were predominantly or solely biologically-mediated. It was postulated that the initial step of the degradation was the cleavage of the test item on bridging oxygen of the thiadiazole heterocycle. The further sequence for the thiadiazole moiety is presented below:

- tautomerisation of keto-enol functional group, resulting in formation of FOE Thiadone,
- hydrolytical opening of thiadone ring and further oxidation resulting in formation of either FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA), or else simple products of mineralisation and NER fraction – ultimate transformation products;
- further transformation of FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA) to the simple products of mineralisation and NER fraction – ultimate transformation products.

In case of the moiety containing fluorophenyl ring next postulated step was the formation of the transient FOE Cysteine- or FOE Glutathione conjugates, undergoing subsequent quick transformation to FOE Methylsulfoxide, FOE Alcohol and FOE Chloroacetanilide. As possible side-processes were postulated direct formation of FOE Chloroacetanilide and FOE Alcohol. It shall be noted that FOE Chloroacetanilide may be not only a genuine degradation product, but also, and possibly to greater extent, analytical artefact. However, as the issue was not satisfactorily clarified, the RMS's proposal is to consider FOE Chloroacetanilide a genuine degradation product.

Additionally, as in course of evaluation FOE Alcohol was identified to be a potentially major degradation product, the additional assessment was performed to determine whether, in absence of data for that compound, the exposure assessment for FOE Alcohol may be considered to be covered by that for its immediate degradate – FOE Oxalate.

The Applicant in course of the discussion on the nature of FOE Alcohol made a following statement (the text is copied directly from the Applicant's e-mail; the “outdoor soil metabolism study” refers to the cited study by Shadrack and Kasper [1995]):

We cannot reconstruct what the reason for the accumulation or artificial formation of FOE alcohol (aka FOE hydroxy) was in that outdoor soil metabolism study, but we have several other laboratory studies, as well as EU and US field studies, which demonstrate, that FOE alcohol is a minor, transient metabolite, not accumulating at all, but rather being further oxidized quickly to FOE oxalate.

RMS having analysed the results provided by the study by Shadrack and Kasper [1995], reproduced in the publication by Bloomberg et al. [2002], noted that the compound was formed in greater amounts in Chualar soil, having lower OC content and slightly lower microbial activity of the two soils used in the experiment. Taking into account the fact that FOE Alcohol was also detected only in the study by Pangilinan and Smith [1994], performed on another soil having low OC content and microbial activity, but not in the study by Kelley et al [1995], all that may indicate that FOE Alcohol is indeed a transient, fast degrading compound, that would appear in higher amounts and for longer only in weak soils.

To further demonstrate that it was possible to cover the exposure assessment for FOE Alcohol with that for its immediate degradate – FOE Oxalate, RMS performed the comparative analysis by means of QSAR calculations, carried out with EPI Suite ver. 4.10 (September 2010) tool. The results of that assessment indicate that the properties of both compounds relevant for their environmental fate and behaviour are comparable. Therefore the exposure assessment performed for FOE Oxalate may be considered as covering that for FOE Alcohol.

The route of degradation of the acetanilide herbicide Flufenacet in anaerobic soil was examined in three soils – one from the US and two European. The test compound – Flufenacet, was radiolabelled in one of the following two positions:

- uniformly in phenyl ring – compound tested on one US soil,
- in position C5 of Thiadiazole moiety – examined in two EU soils.

The experiments performed to determine the transformation pattern of Flufenacet in soil under anaerobic conditions consisted of two phases – aerobic preincubation phase and anaerobic incubation phase. RMS decided to present the key results of the experiments taking into account both phases. In case of aerobic preincubation phase the results are given for the terminal time point of that phase.

The key results for the examination of transformation of Flufenacet in anaerobic soils in the area of formation of terminal degradation products – mineralisation expressed as CO₂ and NER fraction, are presented below in the table B.8.1.1.3._CA-5. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey. It shall be noted that under anaerobic conditions mineralisation, if occurred at all, was minimal. No other volatile compounds were identified during either aerobic or anaerobic phases. The level of NER formed under anaerobic conditions (net formation) was comparable to that observed in aerobic soils.

Table B.8.1.1.3._CA-5: The levels of the terminal degradation products – CO₂ and NER fraction formed in soil during examination of the transformation pattern of Flufenacet in soil under anaerobic conditions.

Study/ radiolabelling position	Soil		Results obtained for aerobic phase		Results obtained for anaerobic phase ¹⁾					
	Name	Type (USDA)	CO ₂ [%AR] – end of phase	NER [%AR] – end of phase	Mineralisation level – CO ₂ formed [% AR]			NER level [% AR]		
					Beginning of phase	Max.	Net anaero- bic ²⁾	Beginning of phase	Max.	Net anaero- bic ³⁾
Pangilinan & Smith [1994]/ ¹⁴ C-phenyl	Howe	Sandy loam	1.4 (DAT 30)	8.4 (DAT 30)	1.4 (DAT 30 DAF 0)	1.8 (DAT 210 DAF 180)	0.4	8.4 (DAT 30 DAF 0)	32.6 (DAT 210 DAF 180)	24.2 (DAT 210 DAF 180)
Heinemann [2012]/ ¹⁴ C-5- Thiadiazole	HH ⁴⁾	Silt loam	1.6 (DAT 15)	16.9 (DAT 15)	1.6 (DAT 15 DAF 0)	1.7 (DAT 105 DAF 90)	0.1	10.2 (DAT 15 DAF 0)	24.5 (DAT 135 DAF 120)	14.3 (DAT 135 DAF 120)
	DD ⁵⁾	Loam	1.9 (DAT 15)	10.1 (DAT 15)	1.8 (DAT 15 DAF 0)	1.9 (DAT 105 DAF 90)	<0.1 ⁶⁾	8.6 (DAT 15 DAF 0)	31.6 (DAT 135 DAF 120)	23.0 (DAT 135 DAF 120)

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase; in case of soils HH and DD they are different, because were available the results obtained immediately after generating the anaerobic conditions;
- 2) Net anaerobic is a difference between the total amount of CO₂ formed and that determined in aerobic traps for volatiles;
- 3) Net anaerobic is a difference between maximum determined level of NER and that measured at the beginning of anaerobic phase;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) At the time point where maximum CO₂ level of 2.0% AR was recorded, the amount recovered for aerobic volatile traps was 1.9% AR and from anaerobic volatile traps <0.1 AR; the slightly higher total amount may be due to either rounding or losses during extraction; in that soil the level of mineralization, expressed as recovered CO₂ in anaerobic phase was <0.1% AR;

The examination of the extracted fraction enabled the identification of one new degradate, not identified in aerobic soils – FOE Thioglycolate. All other identified degradation products were those already found in aerobic soils. On that basis it can be stated that the transformation pattern of Flufenacet in soil under anaerobic conditions would not differ significantly from that determined in aerobic soils. The key results of the profiling of degradation products in anaerobic soils are presented below in table B.8.1.1.3._CA-6. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey.

Table B.8.1.1.3._CA-6: The results of the profiling of Flufenacet and its degradation products.

- 2) Net anaerobic is a difference between the maximum amount determined in anaerobic phase and that at its beginning;
- 3) FOE TGS – FOE Thioglycolate sulfoxide;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) Flufenacet is the active substance, therefore not forming in soil; as a result its concentration at the end of incubation period is given to show the level of decline;
- 7) In that soil the concentrations of FOE Trifluoroethane sulfonic acid initially decreased, to increase afterwards reaching maximum on the indicated time point; it was assumed that this maximum can be attributed totally to the amount of that compound formed under anaerobic conditions;
- 8) N/A – not applicable (parent compound);

On the basis of the results of the studies examining route of degradation of Flufenacet in soil under aerobic conditions a following transformation scheme was proposed – Figure B.8.1.1.3._CA-1 (it shall be indicated that

the scheme contains also the elements of the transformation pattern under anaerobic conditions, as the two schemes were complementary):

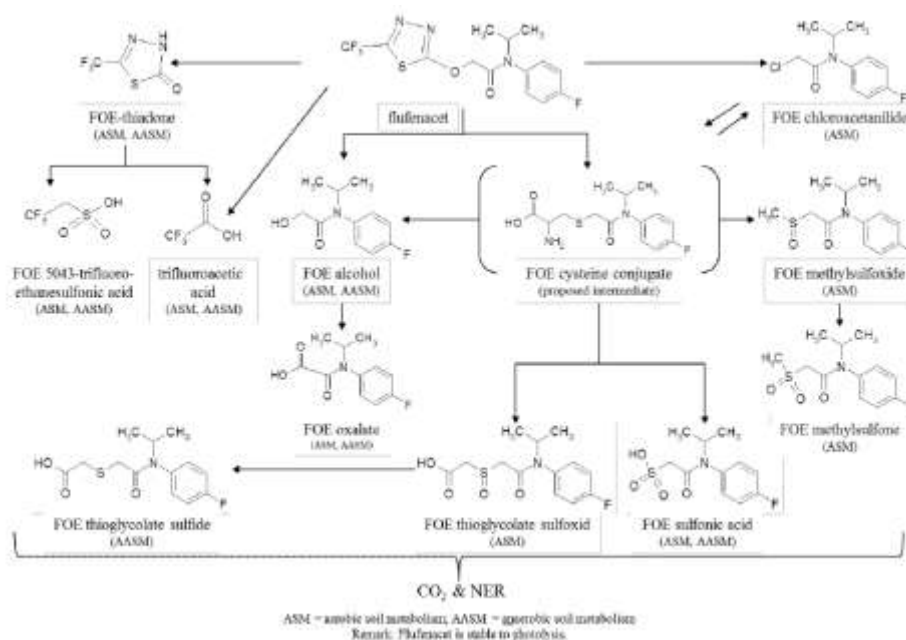

Figure B.8.1.1.3._CA-1: A postulated transformation scheme for Flufenacet in soil, as proposed by the Applicant, verified and approved by the RMS (scheme copied from the Applicant's documentation).

The degradation kinetics of Flufenacet in aerobic soil under laboratory conditions was extensively examined by the Applicant and its results presented in 26 study reports, of which 24 were found by the RMS acceptable and relevant for the current assessment. Additionally two literature studies were identified by the RMS which also provided the data on the degradation kinetics of Flufenacet in aerobic soils. These reports were found by the RMS relevant as supplementary source of data, however not suitable for deriving the regulatory endpoints.

The key results for each of the evaluated compounds are presented below, in tabularised form, individually for each of the test compounds.

a) Kinetic endpoints determined for Flufenacet:

The degradation kinetics of Flufenacet in aerobic soil was examined in ten trials using nine soils. One of the test soils – Howe, Indiana, Sandy loam soil, was used in two trials in which was used Flufenacet differently radiolabelled (either in phenyl ring or in C2 position of thiadiazole moiety), but the resulting kinetic endpoints cannot be averaged prior to calculating the overall geomean because they were derived in two separate studies, significantly differing in sample processing method.

The persistence (best-fit) kinetic endpoints obtained for Flufenacet are presented below in the table B.8.1.1.3._CA-7. The modelling endpoints are given in the table B.8.1.1.3._CA-8.

Table B.8.1.1.3._CA-7: The persistence kinetic endpoints determined for Flufenacet in aerobic soil.

For GW and SW model exposure assessment the **geomean DT₅₀ = 17.89 days** and **geomean k = 0.0387 [days⁻¹]** are the kinetic endpoints recommended as input parameters.

b) Kinetic endpoints determined for FOE Sulfonic acid:

The degradation kinetics of FOE Sulfonic acid in aerobic soil was examined in seventeen trials on the same number of the test soils. The experiments were performed in two variants – four trials with soils treated with Flufenacet (active substance) and the remaining thirteen trials with soils treated with FOE Sulfonic acid.

The performed kinetic analysis resulted in a data base consisting of twelve reliable kinetic endpoints, all determined in trials in which the test soils were treated with FOE Sulfonic acid. In case of the experiments on soils treated with Flufenacet it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Sulfonic acid in soil because decline of that compound was not observed. As a result, the default values – DT₅₀ = 1000 days and DT₉₀ > 1000 days, were proposed for these trials. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fractions for FOE Sulfonic acid, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

In case of the kinetic analysis of the data obtained in Laacherhof IIIA Silt loam soil in the study by [Hellpointner; 1996], it was not possible to obtain a reliable kinetic fit and hence kinetic endpoints. For that reason the trial was removed from both summary table presenting persistence and modelling endpoints.

The persistence (best-fit) kinetic endpoints obtained for FOE Sulfonic acid are presented below in the table B.8.1.1.3._CA-9. The modelling endpoints are given in the table B.8.1.1.3._CA-10.

Table B.8.1.1.3._CA-9: The persistence kinetic endpoints determined for FOE Sulfonic acid in aerobic soil.

Arithmetic mean for <i>ff</i> (n = 4)												0.195

Footnotes to the table:

- 1) Measured in:
 - CaCl₂/water for values marked a);
 - distilled water for results marked b);
 - (0.01M) CaCl₂ for results marked c);
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) Value not determined – the decline phase not reached;
- 4) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **geomean DT₅₀ = 45.11 days** and **geomean *k* = 0.0154 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.195** (arithmetic mean) for Flufenacet as a precursor.

c) Kinetic endpoints determined for FOE Oxalate:

The degradation kinetics of FOE Oxalate in aerobic soil was examined in four trials on the same number of the test soils. The experiments were performed with soils treated with Flufenacet (active substance).

The performed kinetic analysis resulted in a data base consisting of three reliable kinetic endpoints. In case of the experiment in Howe, Indiana, Sandy loam soil it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Oxalate because the decline of that compound was not observed. As a result, the default values – DT₅₀ = 1000 days and DT₉₀ > 1000 days, were proposed for that trial. These values, due to

their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fraction for FOE Oxalate, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

The persistence (best-fit) kinetic endpoints obtained for FOE Oxalate are presented below in the table B.8.1.1.3._CA-11. The modelling endpoints are given in the table B.8.1.1.3._CA-12.

Table B.8.1.1.3._CA-11: The persistence kinetic endpoints determined for FOE Oxalate in aerobic soil.

- 3) Value not determined – the decline phase not reached;

For GW and SW model exposure assessment the **geomean DT₅₀ = 11.08 days** and **geomean k = 0.0639 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended ff value is **ff = 0.426** (arithmetic mean) for Flufenacet as a precursor.

d) Kinetic endpoints determined for FOE Methylsulfone:

The degradation kinetics of FOE Methylsulfone in aerobic soil was examined in eleven trials using the same number of the test soils. The experiments were performed in two variants – three trials with soils treated with Flufenacet (active substance) and the remaining eight trials with soils treated with FOE Methylsulfone.

The performed kinetic analysis resulted in a data base consisting of nine reliable kinetic endpoints, one with soil treated with Flufenacet as a precursor of FOE Methylsulfone and remaining eight with soils treated with FOE Methylsulfone. In case of two trials on soils treated with Flufenacet – BBA 2.2 Loamy sand soil and Hoefchen im Tal Silt loam soil, it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Methylsulfone in soil, because decline of that compound was not observed. As a result, the default values – $DT_{50} = 1000$ days and $DT_{90} > 1000$ days, were proposed for these trials. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fractions for FOE Methylsulfone, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

The persistence (best-fit) kinetic endpoints obtained for FOE Methylsulfone are presented below in the table B.8.1.1.3._CA-13. The modelling endpoints are given in the table B.8.1.1.3._CA-14.

Table B.8.1.1.3._CP-13: The persistence kinetic endpoints determined for FOE Methylsulfone in aerobic soil.

- 4) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **median $DT_{50} = 81.70$ days** and **median $k = 0.00848$ [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended ff value is **$ff = 0.070$** (arithmetic mean) for Flufenacet as a precursor.

e) Kinetic endpoints determined for FOE Thiadone:

The degradation kinetics of FOE Thiadone in aerobic soil was examined in eight trials using the equal number of the test soils. The experiments were performed in two variants – five trials with soils treated with Flufenacet (active substance) and the remaining eight trials with soils treated with FOE Methylsulfone.

The performed kinetic analysis resulted in a data base consisting of eight reliable kinetic endpoints, four with soil treated with Flufenacet as a precursor of FOE Thiadone and three with soils treated with FOE Thiadone. In case of one trial on soil treated with Flufenacet – Howe, Indiana Sandy loam soil, it was not possible to obtain reliable fit for FOE Thiadone in combination with the parent compound. Such fit however was obtained when the data were kinetically analysed for FOE Thiadone alone using the top-down approach. That solution however implied that no reliable value for kinetic formation fraction in that trial could be obtained and reported. RMS decided not to report the default value $ff = 1.00$, proposed by the Applicant. The persistence (best-fit) kinetic endpoints obtained for FOE Thiadone are presented below in the table B.8.1.1.3._CA-15. The modelling endpoints are given in the table B.8.1.1.3._CA-16.

Table B.8.1.1.3._CA-15: The persistence kinetic endpoints determined for FOE Thiadone in aerobic soil.

- 4) Medium for measuring pH not given;
- 5) Value not available – kinetic endpoints determined using the top-down approach;
- 6) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **geomean DT₅₀ = 1.95 days** and **geomean k = 0.3557 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.570** (arithmetic mean) for Flufenacet as a precursor.

f) Kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA):

The degradation kinetics of FOE 5043-Trifluoroethanesulfonic acid (TFESA) in aerobic soil was examined in four trials using the equal number of the test soils. The experiments were performed with soils treated with Flufenacet (active substance).

The performed kinetic analysis resulted in a data base consisting of four reliable kinetic endpoints. In case of two trials – on the Dollendorf II Clay loam soil and Laacherhof Wurmwielse Loam soil it was not possible to obtain reliable kinetic fits for the whole transformation scheme, therefore the top-down approach was used. RMS however decided to keep the determined values of kinetic formation fraction *ff*. The persistence (best-fit) kinetic endpoints obtained for FOE 5043-Trifluoroethanesulfonic acid (TFESA) are presented below in the table B.8.1.1.3._CA-17. The modelling endpoints are given in the table B.8.1.1.3._CA-18.

Table B.8.1.1.3._CA-17: The persistence kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints		
Soil name	Soil type (USDA)	OC	pH ¹⁾			χ^2 error	Vis. fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]	Kinetic formation fraction <i>ff</i>
Hoefchen Am Hohenseh 4a;	Silt loam	2.5	6.7	19.1 ⁰ C; 55% MWHC	SFO	5.85	G	k	0.0761	9.10	30.23	0.264
Laacherhof AXXa;	Loamy sand	2.4	6.1	19.9 ⁰ C; 55% MWHC	SFO	18.25	G	k	0.1548	4.48	14.87	0.534
Dollendorf II;	Clay loam	5.3	7.2	19.9 ⁰ C; 55% MWHC	SFO	4.31	G	k	0.0331	20.9	69.5	0.422
Laacherhof Wurm-wiese;	Loam	2.2	5.4	19.9 ⁰ C; 55% MWHC	SFO	12.3	G	k	0.3090	2.24	7.45	0.655
Arithmetic mean for <i>ff</i> (n = 3)												0.469

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂;
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

The **DT₅₀ = 20.9 days** value, determined in Dollendorf II Clay loam soil was identified as appropriate input parameter for soil exposure assessment.

Table B.8.1.1.3._CA-18: The modelling kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints		
Soil name	Soil type (USDA)	OC	pH ¹⁾			χ^2 error	Vis. fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]	Kinetic formation fraction <i>ff</i>
<i>Hoefchen Am Hohenseh 4a;</i>	Silt loam	2.5	6.7	19.1°C; 55% MWHC	SFO	5.85	G	<i>k</i>	0.0785	8.83	29.32	0.264
<i>Laacherhof AXXa;</i>	Loamy sand	2.4	6.1	19.9°C; 55% MWHC	SFO	18.25	G	<i>k</i>	0.1579	4.39	14.57	0.534
<i>Dollendorf II;</i>	Clay loam	5.3	7.2	19.9°C; 55% MWHC	SFO	4.31	G	<i>k</i>	0.0349	19.87	66.01	0.422

Geometric mean (n = 4)									0.1082	6.41	21.30	----
									Arithmetic mean for <i>ff</i> (n = 3)		0.469	

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂;
 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

For GW and SW model exposure assessment the **geomean DT₅₀ = 6.41 days** and **geomean *k* = 0.1082 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.469** (arithmetic mean) for FOE Thiadone as a precursor.

g) Kinetic endpoints determined for Trifluoroacetic acid (TFA):

The degradation kinetics of Trifluoroacetic acid (TFA) in aerobic soil was examined in eight trials using the equal number of the test soils. The experiments were performed in two variants – four trials with soils treated with Flufenacet (active substance) and the remaining four trials with soils treated with TFA.

Due to the high persistence of the test compound – TFA, in none of the test soils it was possible to obtain the reliable kinetic endpoints. For that reason the default values were proposed.

Due to the difference between the modelling tools, for the persistence endpoints two sets of the default values were provided. For trials on test soils treated with Flufenacet as precursor of TFA, where the analysis performed by the Applicant was accepted, the default kinetic endpoints were: **DT₅₀ = 1000 days** and **DT₉₀ > 1000 days**. In case however of the trials with TFA applied as parent compound, for which RMS had to repeat the kinetic analysis, the kinetic endpoints were: **DT₅₀ = 10000 days** and **DT₉₀ > 10000 days** – the values returned by the applied tool. RMS considers these defaults to be representative for the persistence of TFA in soil, as that indicated the results of the examination of the fate of TFA in environment presented in the open-source literature.

However for modelling the recommended input value is **DT₅₀ = 1000 days**, because of the constraints of the current modelling tools. It shall be noted that due to the nature of the determined endpoint – a default value, its normalisation was not performed as not necessary.

For TFA a set for two kinetic formation fraction values were determined – one for formation of TFA from Flufenacet and the second for its formation from FOE Thiadone.

The persistence (best-fit) kinetic endpoints obtained for TFA Thiadone are presented below in the table B.8.1.1.3._CA-19. The modelling endpoints are given in the table B.8.1.1.3._CA-20.

Table B.8.1.1.3._CA-19: The persistence kinetic endpoints determined for Trifluoroacetic acid (TFA) in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints		
Soil name	Soil type (USDA)	OC	pH ¹⁾			χ^2 error	Vis. fit ¹⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]	Kinetic formation fraction $ff^{4)}$

Geometric mean (n = 8)										1000	>1000	----
Arithmetic mean for ff (n = 4)												$ff_1 = 0.430$ $ff_2 = 0.531$

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂;
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) n. d. – not determined
- 4) ff_1 – kinetic formation fraction for formation of TFA from Flufenacet; ff_2 – kinetic formation fraction for formation of TFA from FOE Thiadone.

For GW and SW model exposure assessment the default **DT₅₀ = 1000 days** is a kinetic endpoint recommended as input parameter. The corresponding recommended ff values are $ff_1 = 0.430$ (arithmetic mean) for Flufenacet as a precursor and $ff_2 = 0.531$ (arithmetic mean) for FOE Thiadone as a precursor.

The kinetic endpoints identified by RMS as appropriate to be used in model exposure assessment for soil, groundwater and surface water compartments are summarised below in the table B.8.1.1.3._CA-21. For completeness also the maximum concentrations observed in soils are provided.

Table B.8.1.1.3._CA-21: The kinetic endpoints determined in laboratory studies on aerobic soils, recommended to be used in model exposure assessment for soil, groundwater and surface water compartments.

Compound	Compartment	Recommended endpoints					
		Maximum observed in soil		Kinetic formation fraction - ff		Persistence in soil – DT ₅₀ value	
		Observed soil maximum [%]	Remark	ff	Remark	DT ₅₀ [days]	Remark
Flufenacet	Soil	Not applicable	Not applicable – parent compound	----	Not applicable – parent compound	57.6	Longest not normalised lab value
	Groundwater			----		17.89	Normalised lab geomean value
	Surface Water			----		17.89	Normalised lab geomean value
FOE Sulfonic acid	Soil	26.5	Recommended for simple modelling ¹⁾	0.195	Precursor: flufenacet; to be used in complex modelling ²⁾	318	Longest not normalised lab value
	Groundwater	----	Not applicable	0.195	Precursor: flufenacet;	45.11	Normalised lab geomean value
	Surface Water	26.5	To be used in calculations at Steps 1 and 2	0.195	Precursor: flufenacet; to be used in Step 3-4 assessment	45.11	Normalised lab geomean value
FOE Oxalate	Soil	26.3	Recommended for simple modelling ¹⁾	0.426	Precursor: flufenacet; to be used in complex modelling ²⁾	18.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.426	Precursor: flufenacet;	11.08	Normalised lab geomean value
	Surface Water	26.3	To be used in calculations at Steps 1 and 2	0.426	Precursor: flufenacet; to be used in Step 3-4 assessment	11.08	Normalised lab geomean value
FOE Methylsulfone	Soil	6.6	Recommended for simple modelling ¹⁾	0.070	Precursor: flufenacet; to be used in complex modelling ²⁾	174	Longest not normalised lab value
	Groundwater	----	Not applicable	0.070	Precursor: flufenacet;	81.70	Normalised lab median value
	Surface Water	6.6	To be used in calculations at Steps 1 and 2	0.070	Precursor: flufenacet; to be used in Step 3-4 assessment	81.70	Normalised lab median value
FOE Thiadone	Soil	5.8	Recommended for simple modelling ¹⁾	0.570	Precursor: flufenacet; to be used in complex modelling ²⁾	15.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.570	Precursor: flufenacet;	1.95	Normalised lab geomean value
	Surface Water	5.8	To be used in calculations at Steps 1 and 2	0.570	Precursor: flufenacet; to be used in Step 3-4 assessment	1.95	Normalised lab geomean value
FOE 5043-Trifluoroethane-sulfonic acid	Soil	6.0	Recommended for simple modelling ¹⁾	0.469	Precursor: Thiadone; to be used in complex modelling ²⁾	20.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.469	Precursor: Thiadone;	6.41	Normalised lab geomean value
	Surface Water	6.0	To be used in calculations at Steps 1 and 2	0.469	Precursor: Thiadone; to be used in Step 3-4 assessment	6.41	Normalised lab geomean value
Trifluoroacetic acid (TFA)	Soil	81.5	Recommended for simple modelling ¹⁾	0.430	Precursor: flufenacet; to be used in complex modelling ²⁾	10000	Longest lab value (default)
				0.531	Precursor: Thiadone; to be used in complex modelling ²⁾		
	Groundwater	----	Not applicable	0.430	Precursor: flufenacet;	1000	FOCUS default for non-degrading compounds
				0.531	Precursor: Thiadone;		
	Surface Water	81.5	To be used in calculations at Steps 1 and 2	0.430	Precursor: flufenacet; to be used in Step 3-4 assessment	1000	FOCUS default for non-degrading compounds
				0.531	Precursor: Thiadone; to be used in Step 3-4 assessment		

Footnotes to the table:

- 1) By the term “simple modelling” are understood calculations performed using simple models with metabolites applied as parent;
- 2) The term “complex models” concerns calculations performed using more sophisticated tools, e.g. ESCAPE, in which metabolites are calculated as formed from their precursor (parent compound or preceding degradation product).

Additionally the results of the determination of the rate of degradation of Flufenacet in aerobic soils incubated under controlled (laboratory) conditions were provided by two literature studies. The key results of these two studies are provided below in the table B.8.1.1.3_CA-22. These results shall be considered as indicative and for that reason were not used to derive the regulatory endpoints.

Table B.8.1.1.3_CA-22: The key results of the relevant publications examining the rate of degradation of Flufenacet in aerobic soils.

Study	Test soil	Key soil properties			Incubation conditions		Fortification level [µg a. s./g soil]	Kinetic endpoints – DT ₅₀ [days]		Method of calculation
		Soil type (USDA)	pH	OC [%]	T [°C]	Soil moisture		T=25°C; FC	T=20°C; FC	
<i>Gupta, Gajbhiye, Agnihotri [2001]</i>	Sandy loam	Sandy loam	7.1	0.34	25	FC	1	9.3	13.4	1 st order, linear regression, r =0.99
							10	13.0	20.4	1 st order, linear regression, r =0.99

	Ranchi sandy loam	US Sandy clay loam	5.54	0.04	25	FC	1	10.5	16.5	1 st order, linear regression, r =0.99
							10	21.3	33.4	1 st order, linear regression, r =0.99
	Nagpur clayey soil	US Clay	8.25	0.40	25	FC	1	31.0	48.6	1 st order, linear regression, r =0.99
							10	29.2	45.8	1 st order, linear regression, r =0.94

2) Degradation in soil under anaerobic conditions:

The route of degradation of the acetanilide herbicide Flufenacet in anaerobic soil was examined in three soils – one from the US and two European. The test compound – Flufenacet, was radiolabelled in one of the following two positions:

- uniformly in phenyl ring – compound tested on one US soil,
- in position C5 of Thiadiazole moiety – examined in two EU soils.

The experiments performed to determine the transformation pattern of Flufenacet in soil under anaerobic conditions consisted of two phases – aerobic preincubation phase and anaerobic incubation phase. RMS decided to present the key results of the experiments taking into account both phases. In case of aerobic preincubation phase the results are given for the terminal time point of that phase.

The key results for the examination of transformation of Flufenacet in anaerobic soils in the area of formation of terminal degradation products – mineralisation expressed as CO₂ and NER fraction, are presented below in the table B.8.1.1.3_CA-23. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey. It shall be noted that under anaerobic conditions mineralisation, if occurred at all, was minimal. No other volatile compounds were identified during either aerobic or anaerobic phases. The level of NER formed under anaerobic conditions (net formation) was comparable to that observed in aerobic soils.

Table B.8.1.1.3._CA-23: The levels of the terminal degradation products – CO₂ and NER fraction formed in soil during examination of the transformation pattern of Flufenacet in soil under anaerobic conditions.

Study/ radiolabelling position	Soil		Results obtained for aerobic phase		Results obtained for anaerobic phase ¹⁾					
	Name	Type (USDA)	CO ₂ [%AR] – end of phase	NER [%AR] – end of phase	Mineralisation level – CO ₂ formed [% AR]			NER level [% AR]		
					Beginning of phase	Max.	Net anaero- bic ²⁾	Beginning of phase	Max.	Net anaero- bic ³⁾
Pangilinan & Smith [1994]/ ¹⁴C-phenyl	Howe	Sandy loam	1.4 (DAT 30)	8.4 (DAT 30)	1.4 (DAT 30 DAF 0)	1.8 (DAT 210 DAF 180)	0.4	8.4 (DAT 30 DAF 0)	32.6 (DAT 210 DAF 180)	24.2 (DAT 210 DAF 180)
Heinemann [2012]/ ¹⁴C-5- Thiadiazole	HH ⁴⁾	Silt loam	1.6 (DAT 15)	16.9 (DAT 15)	1.6 (DAT 15 DAF 0)	1.7 (DAT 105 DAF 90)	0.1	10.2 (DAT 15 DAF 0)	24.5 (DAT 135 DAF 120)	14.3 (DAT 135 DAF 120)
	DD ⁵⁾	Loam	1.9 (DAT 15)	10.1 (DAT 15)	1.8 (DAT 15 DAF 0)	1.9 (DAT 105 DAF 90)	<0.1 ⁶⁾	8.6 (DAT 15 DAF 0)	31.6 (DAT 135 DAF 120)	23.0 (DAT 135 DAF 120)

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase. In case of soils HH and DD they are different, because there were available the results obtained immediately after generating the anaerobic conditions;
- 2) "Net anaerobic" is a difference between the total amount of CO₂ formed and that determined in aerobic traps for volatiles;
- 3) "Net anaerobic" is a difference between maximum determined level of NER and that measured at the beginning of anaerobic phase;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) At the time point where maximum CO₂ level of 2.0% AR was recorded, the amount recovered for aerobic volatile traps was 1.9% AR and from anaerobic volatile traps <0.1 AR. The slightly higher total amount may be due to either rounding or losses during extraction. In that soil the level of mineralization, expressed as recovered CO₂ in anaerobic phase was <0.1% AR;

The examination of the extracted fraction enabled the identification of one new degradate, not identified in aerobic soils – FOE Thioglycolate. All other identified degradation products were those already found in aerobic soils. On that basis it can be stated that the transformation pattern of Flufenacet in soil under anaerobic conditions would not differ significantly from that determined in aerobic soils. The key results of the profiling of degradation products in anaerobic soils are presented below in table B.8.1.1.3._CA-24. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey.

Table B.8.1.1.3._CA-24: The results of the profiling of Flufenacet and its degradation products.

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase. In case of soils HH and DD they are different, because were available the results obtained immediately after generating the anaerobic conditions;
- 2) "Net anaerobic" is a difference between the maximum amount determined in anaerobic phase and that at its beginning;
- 3) FOE TGS – FOE Thioglycolate sulfoxide;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) Flufenacet is the active substance, therefore not forming in soil. For that reason its concentration at the end of incubation period is given to show the level of decline;
- 7) In that soil the concentrations of FOE Trifluoroethane sulfonic acid initially decreased, to increase afterwards reaching maximum on the indicated time point. It was assumed that this maximum can be attributed totally to the amount of that compound formed under anaerobic conditions;
- 8) N/A – not applicable (parent compound);

The results of the determination of transformation pathway of Flufenacet in anaerobic soil demonstrated that it would not significantly differ, qualitatively and quantitatively, from that observed in aerobic soil.

The degradation products that may require further consideration for the risk assessment are the same as identified during examination of the degradation pattern of Flufenacet in aerobic soil: FOE Oxalate, FOE

Thiadone and Trifluoroacetic acid. The proposed whole transformation pattern determined during examination of degradation of Flufenacet in anaerobic soil, is presented below on figure B.8.1.1.3._CA-2.

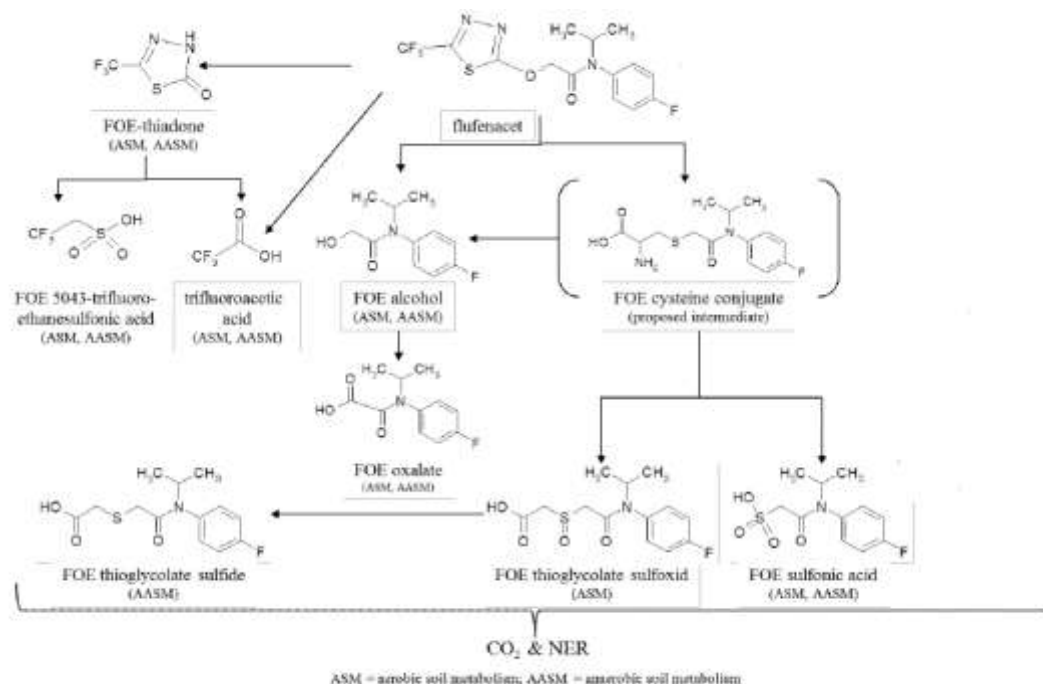

Figure B.8.1.1.3._CA-2: The proposed degradation scheme for Flufenacet in anaerobic soil, including initial aerobic stage. **ASM** stands for transformation under aerobic conditions and **AASM** for that under anaerobic conditions (scheme copied from the Applicant's documentation, modified by the RMS).

The determination of the kinetic parameters of the process of degradation of Flufenacet in anaerobic soil was performed for the results obtained in two studies, on three soils using the test compound radiolabelled in two different positions:

- uniformly in phenyl ring (one test soil);
- in C5 position of thiadiazole moiety (two test soils).

The conclusions and key results are presented below, individually for each test soil.

- The conclusions and key results obtained for Sandy loam (Howe) soil treated with Phenyl-U-¹⁴C] Flufenacet (study by [Pangilinan and Smith; 1995]):

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Oxalate and FOE Sulfonic acid, obtained for Sandy loam (Howe) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic sandy loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling. That conclusion is drawn by the RMS and is different from the Applicant's proposal – to consider the SFO kinetic model as a source of the kinetic endpoints appropriate for modelling. That conclusion is based on the fact that DFOP fit was superior to SFO both when the fitting was performed for the parent compound alone and for the parent and degradation products.
- It was not possible to obtain the reliable kinetic fit for either of the degradation products – FOE Oxalate and FOE Sulfonic acid kinetically examined together with parent. Slightly better results were obtained when the data for these two compounds were fitted alone using the top-down approach. In both cases SFO was identified as returning visually and statistically reliable fits with reliable parameters. RMS however is of the opinion that the kinetic endpoints derived from those fits should be considered indicative with regard to the persistence of both compounds in anaerobic sandy loam soil and cannot be further used to

derive any modelling endpoints. It shall be also noted that it was not possible to derive reliable kinetic formation fractions for either FOE Oxalate or FOE Sulfonic acid.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 229.63$ days, $DT_{90} = 895.64$ days, DFOP model ($k_1 = 0.9976$ days⁻¹, $k_2 = 2.416 \text{ E-}3$ days⁻¹, $g = 0.1291$);
 - Flufenacet, modelling endpoints not normalised: $k = 2.416 \text{ E-}3$ [days⁻¹], $DT_{50} = 286.90$ days, $DT_{90} = 953.06$ days, SFO (slow phase DFOP);
 - Flufenacet, modelling endpoints normalized for temperature: $k = 2.205 \text{ E-}3$ [days⁻¹], $DT_{50} = 314.35$ days, $DT_{90} = 1044.26$ days, SFO (slow phase DFOP);
 - FOE Oxalate, persistence endpoints (indicative): $DT_{50} = 311$ days, $DT_{90} = 1030$ days, SFO model – top-down approach ($k = 0.002233$ days⁻¹);
 - FOE Sulfonic acid, persistence endpoints (indicative): $DT_{50} = 352$ days, $DT_{90} = 1170$ days, SFO model – top-down approach ($k_1 = 0.001986$ days⁻¹).
- The conclusions and key results obtained for Silt loam (Hoefchen am Hohenseh 4a) soil treated with [Thiadiazole-5-¹⁴C]Flufenacet (study by [Heinemann; 2012]):

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid, obtained for Silt loam (Hoefchen am Hohenseh 4 a) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic Silt loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling.
- It was possible to obtain reliable kinetic fit and kinetic endpoints for FOE Thiadone;
- Although it was possible to obtain reliable kinetic fit for Trifluoroacetic acid, the reliable kinetic parameters describing degradation of that compound could not be derived due to the fact that the decline phase was not reached. Therefore RMS proposed to use the default DT_{50} and DT_{90} values instead of those calculated by the model;
- It was not possible to obtain the reliable kinetic fit for FOE 5043-Trifluoroethanesulfonic acid, therefore for that compound no reliable kinetic endpoints are available. RMS attributed that to the low concentrations of the compound recorded in the test system and their significant scattering, what may indicate that the compound of concern is transient and rapidly degrades in anaerobic silt loam soil.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 22.66$ days, $DT_{90} = 156.90$ days, DFOP model ($k_1 = 0.1214$ days⁻¹, $k_2 = 0.01162$ days⁻¹, $g = 0.3810$);
 - Flufenacet, modelling endpoints: $k = 0.01162$ [days⁻¹], $DT_{50} = 59.65$ days, $DT_{90} = 198.16$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
 - FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 97.04$ days, $DT_{90} = 322.30$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
 - Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
 - FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.
- The conclusions and key results obtained for Loam (Dollendorf II) soil treated with [Thiadiazole-5-¹⁴C] Flufenacet (study by [Heinemann; 2012]):

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid, obtained for Loam (Dollendorf II) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic Silt loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling.
- It was possible to obtain reliable kinetic fit and kinetic endpoints for FOE Thiadone;
- Although it was possible to obtain reliable kinetic fit for Trifluoroacetic acid, the reliable kinetic parameters describing degradation of that compound could not be derived due to the fact that the well

pronounced decline phase was not reached. Therefore RMS proposed to use the default DT_{50} and DT_{90} values instead of those calculated by the model;

- It was not possible to obtain the reliable kinetic fit for FOE 5043-Trifluoroethanesulfonic acid, therefore for that compound no reliable kinetic endpoints are available. RMS attributed that to the low concentrations of the compound recorded in the test system and their significant scattering, what may indicate that the compound of concern is transient and rapidly degrades in anaerobic silt loam soil.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 13.51$ days, $DT_{90} = 110.02$ days, DFOP model ($k_1 = 0.4756$ days⁻¹, $k_2 = 0.0167$ days⁻¹, $g = 0.3745$);
- Flufenacet, modelling endpoints not normalised: $k = 0.0167$ [days⁻¹], $DT_{50} = 41.51$ days, $DT_{90} = 137.88$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^\circ\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
- FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 97.04$ days, $DT_{90} = 322.30$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
- Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
- FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.

Additionally the results of the determination of the rate of degradation of Flufenacet in anaerobic soils incubated under controlled (laboratory) conditions were provided by two literature studies, also providing the results for aerobic soils. Below, in the table B.8.1.1.3._CA-25 are given the key results obtained in these two studies. As already indicated, these results may be considered only as indicative and were not used to derive the regulatory endpoints.

Table B.8.1.1.3._CA-25: The key results of the relevant publications examining the rate of degradation of Flufenacet in anaerobic (submerged) soils.

Study	Test soil	Key soil properties			Incubation conditions		Fortification level [µg a. s./g soil]	Kinetic endpoints – DT_{50} [days]		Method of calculation
		Soil type (USDA)	pH	OC [%]	$T [^\circ\text{C}]$	Soil moisture		$T=25^\circ\text{C};$ FC	$T=20^\circ\text{C};$ FC	
<i>Gupta, Gajbhiye, Agnihotri [2001]</i>	Sandy loam	Sandy loam	7.1	0.34	25	FC	10	22.5	35.3	1 st order, linear regression, $r = 0.99$
<i>Gupta, Gajbhiye, [2002]</i>	Dehli sandy loam	US Loamy sand	7.69	0.50	25	FC	10	22.3	35.0	1 st order, linear regression, $r = 0.99$
	Ranchi sandy loam	US Sandy clay loam	5.54	0.04	25	FC	10	24.1	37.8	1 st order, linear regression, $r = 0.99$
	Nagpur clayey soil	US Clay	8.25	0.40	25	FC	10	30.1	47.2	1 st order, linear regression, $r = 0.93$

3) Photodegradation on the soil surface:

The soil photolysis of Flufenacet was examined in one soil – US Sandy loam, using the test compound radiolabelled in one position – uniformly at phenyl ring. The experiment was performed using soil that was demonstrated to be biologically viable throughout the whole irradiation/incubation period. Samples were irradiated with artificial light (Xenon lamp) continuously for 10.25 days, corresponding to 30 days of natural summer sunlight (conditions relevant for Phoenix, Arizona, USA). The key results of the examination are presented below in the table B.8.1.1.3._CA-26

Table B.8.1.1.3._CA-26: The key results obtained for Flufenacet in soil photolysis study

Parameter		Results obtained for:	
		Irradiated sample	Dark control
Terminal transformation products	Mineralisation (CO ₂) at the end of the study	0.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	0.1% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	Max. NER level	3.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	4.4% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
Identified compounds	Flufenacet – amount at study's end	91.2 AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	87.2 AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	FOE Oxalate – max. amount	0.6% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	4.6% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	FOE Sulfonic acid – max. amount	0.4% AR; DAT ²⁾ 5.13; 15 th DNS ³⁾	2.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾

Kinetics of the process	rate constant <i>k</i> [days ⁻¹]	0.0076	0.0124
	DT ₅₀ [days]	90.72	55.90

Footnotes to the table:

- 4) N-isomer of Flufenacet (for the structural formula, please refer to the table in Appendix 1 - List of Evaluated Compounds in the Vol. 3 B.8_CA);
5) DAT stands for Days After Treatment, the real sampling point in the experiment;
6) DNS – Days of Natural Sunlight, the sampling point related to the natural summer day sunlight conditions in Tucson Arizona, USA

On the basis of these results it was stated that Flufenacet is not prone to photolytical degradation on the soil surface, therefore soil photolysis will not be a relevant degradation mechanism of Flufenacet in soil. Additionally the potential of photodegradation of FOE Thiadone on soil surface was examined. Although it was demonstrated that the process might contribute to transformation of FOE Thiadone in soil, its relevance is estimated to be minimal, also because FOE Thiadone is not expected to occur on the soil surface in significant, if any, amounts.

The photolysis of Flufenacet on the soil surface was examined in one experiment using one soil. Its results were kinetically examined, in line with the recommendations given by FOCUS [2006], by the RMS. The final set of the kinetic endpoints obtained for Flufenacet as a result of that examination is presented below in the table B.8.1.1.3._CA-27.

Table B.8.1.1.3._CA-27: The definitive set of the kinetic endpoints obtained for Flufenacet in the study examining soil photolysis of that compound.

Determined parameter	Results obtained for:		
	Dark control samples	Irradiated samples	
		Values not corrected (Suntest days)	Values corrected for summer sunlight intensity (Natural sunlight days) ¹⁾
Rate constant <i>k</i> [days⁻¹]	0.0124	0.076	0.0026
DT₅₀ [days]	55.90	90.72	265.67
DT₉₀ [days]	185.68	301.36	882.55
Kinetic model	SFO	SFO	SFO

Footnotes to the table:

- 1) values calculated for conditions representative for summer sunny day in Phoenix, AZ, USA – longitude: 33° 27' N

On their basis it can be stated that Flufenacet is not expected to degrade in soil via its photolysis on the soil surface.

The conclusion drawn by the RMS from the study on the basis of the results presented above was following: “The results clearly demonstrate that the degradation of Flufenacet was slower in irradiated samples than in the dark control. On that basis it can be stated that Flufenacet is not prone to the photolysis on the soil surface, hence soil photolysis will not be a relevant mechanism of degradation of Flufenacet in soil.”.

None of the degradation products of Flufenacet requiring further assessment were formed in that study, so the kinetic analysis for them was not performed. However, for one the major soil degradation product of Flufenacet – FOE Thiadone the photodegradation of that compound on the soil surface was examined in a separate study. The results were kinetically examined by the RMS and the definitive data set is presented below in the table B.8.1.1.3._CA-28.

Table B.8.1.1.3._CA-28: The definitive set of the kinetic endpoints obtained for FOE Thiadone in the study examining its photolysis on the soil surface.

Determined parameter	Results obtained for:	
	Dark control samples	Irradiated samples
Rate constant k [days ⁻¹]	0.1612	0.2120
DT ₅₀ [days]	4.30	3.27
DT ₉₀ [days]	14.29	10.86
Kinetic model	SFO	SFO

The results demonstrate that photolysis on the soil surface might contribute to degradation of FOE Thiadone in soil.

The net rate constant of the photolysis will be:

$$k_{\text{photolysis}} = k_{\text{irrad}} - k_{\text{dark control}} = 0.2120 - 0.1612 = 0.0508 \text{ [days}^{-1}\text{]}.$$

The resulting kinetic endpoints calculated using that value are: **DT₅₀ = 13.64 days** and **DT₉₀ = 45.33 days**.

At the same time it shall be pointed out however that the probability that that compound would be found on the soil surface in any substantial amounts is minimal. For that reason the process should be considered to have minimal relevance in the overall transformation of Flufenacet in soil.

4) Soil persistence under realistic – field, conditions:

The dissipation of Flufenacet in soil under field conditions was examined on sixteen trial sites located in the EU – in Germany, France (Northern and Southern) and Italy. The characteristic of the trial sites is presented below in the table B.8.1.1.3._CA-29. The next table – B.8.1.1.3._CA-30, provides the brief characteristic of the weather conditions recorded at each trial site during the experiment.

Table B.8.1.1.3._CA-29: The brief characteristic of field trials.

Study	Information on the trial site			Data on application		Data on crop cover

40495/0	S. Romualdo	Italy	236	Ar. Sperim. M. Marani/Ravenna	44063	407	17.0

The residues of Flufenacet on the trial sites were determined by sampling, at pre-determined intervals, soil cores down to 30-cm or 50-cm depth. The number of sampling points was, depending on the trial site, eight or nine. The soil samples were dissected into 10-cm layers and analysed for the content of Flufenacet and its three major soil degradates – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The performed analysis showed that FOE Alcohol was not formed on any trial site in detectable amounts >3 µg/kg soil (LOD). Other two degradation products were detectable and, on some trial sites even quantifiable (recorded in amounts > LOQ = 10 µg/kg soil), but in none of the trials were observed in amounts higher than 30 µg/kg soil. Neither Flufenacet nor any of its degradation products were detected in deeper soil layers – below 20 cm.

The obtained results were kinetically examined in line with the recommendations of the FOCUS Work Group on the Degradation Kinetics. The results of the determination of the persistence of Flufenacet and its two quantifiable degradation products – FOE Oxalate and FOE Sulfonic acid, are presented below in three separate tables – B.8.1.1.3._CA-31 (Flufenacet), B.8.1.1.3._CA-32 (FOE Oxalate) and B.8.1.1.3._CA-32 (FOE Sulfonic acid).

Table B.8.1.1.3._CA-31: The persistence kinetic endpoints determined for Flufenacet in field dissipation trials.

The results obtained for Flufenacet and FOE Sulfonic acid were also kinetically examined with aim to derive the kinetic endpoints suitable for modelling. The kinetic analysis was performed using the inverse modelling approach. The assessment was conditionally accepted by the RMS. However, RMS decided, because of the stated deficiencies, not to use its results in the model exposure assessment, nor to report them in the List of End Points. At the same time they may be used, at zonal or MS level, as refined input parameters in Tier 2a GW exposure assessment. The results are presented below in the table B.8.1.1.3._CA-34.

4) The DIN 19682 classification presented because the USDA classification not provided; in another report it was stated to be Sandy loam (USDA) containing 58.5% sand, 22.7% silt and 18.8% clay.

The soil residues studies and soil accumulation studies were not performed as the results of the field dissipation studies demonstrated that they were not required – their results clearly indicated that neither Flufenacet nor its degradation products would accumulate in soil.

Finally three relevant open-literature studies examining the dissipation of Flufenacet in soil under realistic – field conditions were identified. Their key results are presented below in the table B.8.1.1.3._CA-35.

B.8.1.2. – Adsorption/desorption in soil

To address the issue of sorption of Flufenacet and its major soil degradation products onto soil the Applicant submitted nine study reports, of which eight were aimed on the examination of adsorption and desorption and the additional one examined the time-dependent sorption in soil of one of the degradation products of Flufenacet – FOE Sulfonic acid. All they will be summarised below under the relevant data points.

Additionally were identified four open-source publications providing the data on sorption of Flufenacet onto soil. They will be also summarised below under the relevant data points.

B.8.1.2.1. – Adsorption and desorption

To address this data point the Applicant submitted eight studies – four for the parent compound Flufenacet and another another four for its degradation products. Their summaries are provided below under the relevant data points. Additionally the RMS identified three relevant open-literature studies on soil sorption of Flufenacet include d into the RAR

B.8.1.2.1.1. – Adsorption and desorption of the active substance

The adsorption of Flufenacet onto soil was examined in four studies, two submitted for the previous authorisation of Flufenacet in the EU (studies by [Kelley and Wood; 1992] and by [Christensen and Yen; 1994]) and two newly submitted studies ([Stupp; 2010] and [Hein; 2012]). They are summarised below as **Studies 1-4**. Additionally the RMS in course of the repeated literature search identified three papers relevant for this assessment dealing with the issue of the batch sorption of Flufenacet onto soil. They are summarised further down this section of the Report as **Studies 5 – 7**.

Study 1:

Report: Kelley I., Wood S., (1992): “Adsorption/Desorption of FOE 5043 to Soil.”; Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120, USA; Miles Study No. F3182101, Miles Report No. 103903, 30 September 1992; updated by study report: Kelley I., Wood S., (1993): Addendum to Miles Report No. 103903: Adsorption/Desorption of FOE 5043 to Soil.”; Miles Report No.103903-1, 13 September 1993; study reference number: M-002202-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines (1982), Subdivision N, Section 163-1 for adsorption/desorption of chemicals.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.1.1, in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. For the present authorisation in the EU the study was evaluated for its compliance with OECD Guideline for the Testing of Chemicals 106 – Adsorption-Desorption Using a Batch Equilibrium Method. Additionally the study was checked for its validity against the US EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1230 – Adsorption/Desorption (Batch Equilibrium) and OPPTS 835.1220 – Sediment and Soil Adsorption/Desorption Isotherm as well as SETAC Guidance Document “Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides.”. Also consulted was the Guideline which was declared in the study report to be a reference document – US EPA Guideline 163-1 for determining the adsorption/desorption of chemicals. Finally, RMS consulted the evoked above Assessment Report for Flufenacet prepared by the then RMS-France and the Review Report for the active substance Flufenacet, in particular the List of Endpoints in the area of soil sorption. That was done because of the following problems related to the study protocol were identified:

- of the five test soils used in the experiment two displayed very low OC content: Howe (IN) Loamy sand/Sandy loam (OC = 0.23%) and Vero Beach (FL) Sand (OC = 0.17%) and according to the provisions of the OECD Guideline 106 (and US EPA OPPTS

835.1220 Guideline) such soils are not recommended to be used in the examination of the soil sorption because the low OC content they display may disturb the results (correlation between adsorption and organic content); the problem and resulting acceptability of the results obtained for these two soils will be discussed in details in the summary of the study;

- in case of one of the test soils – Howe (IN) Loamy sand/Sandy loam soil its classification in the study report was changed from Loamy sand to Sandy loam on the basis of the triplicate analysis of its properties performed by the same laboratory in three consecutive years; the problem and resulting acceptability of the results obtained for that soil will be discussed in details in the summary of the study;
- in the preliminary test HgCl_2 was used as a sterilising agent; the problem will be discussed in details in the summary of the study;

In general however, despite the problems listed above, RMS found the study acceptable, and possible to be used for the regulatory purposes. The study is summarised below.

Summary:

The aim of the was to examine the process of the equilibrium sorption – adsorption and desorption, of Flufenacet onto soil. The study was performed using five test soils – four originating form the US and one European soil. Their characteristic is provided below in the table B.8.1.2.1.1._CA-1.

Table B.8.1.2.1.1._CA-1: The characteristic of soils used in the study.

Parameter		Soil				
		<i>Stanley (307)</i>	<i>Hagerstown (318)</i>	<i>Howe (395)²⁾</i>	<i>Vero Beach (396)</i>	<i>Monheim (3253)</i>
Soil origin		Kansas, USA	Maryland, USA	Indiana, USA	Florida, USA	Germany, Europe
Soil type	<i>Applicant</i>	Silt loam	Clay loam	Loamy sand	Sand	Sandy loam
	<i>RMS (USDA)</i>	Silt loam	Clay loam	Loamy sand	Sand	Sandy loam
Particle size distribution	Sand [%]	17	21	78	94	72
	Silt [%]	66	50	17	3	23
	Clay [%]	17	29	5	3	5
Soil pH		5.9	6.4	6.4	5.0	6.4
Organic matter content (OM) [%]		2.9	2.2	0.4	0.3	2.41 ³⁾
Organic carbon content (OC) [%] ¹⁾		1.68	1.28	0.23	0.17	1.4 ⁴⁾
CEC [meq/100 g]		26.0	21.0	7.4	3.8	8.0

Footnotes to the table:

- 1) recalculated by the RMS from organic matter content using the following equation: $\text{OM} = 1.724 \text{ OC}$; with exception of Monheim Sandy loam test soil;
- 2) As reported in the study report and in the Assessment Report prepared by the RMS – France for the first authorisation of Flufenacet in the EU;
- 3) Value recalculated by the RMS from OC content using the following equation: $\text{OM} = 1.724 \text{ OC}$;
- 4) Measured value.

The four US soils were selected in accordance with the US EPA Guideline 163-1, recommending that:

- the experiment should be performed on at least four soils, such as agricultural sand, sandy loam, silt loam, clay or clay loam, each having pH within the range 4-8;
- at least one of the test soils should have an organic matter content lower than or equal to 1%, and in such case sand or sandy loam is preferred;
- one of the test soils should also be used in other experiments examining the environmental fate and behaviour of the test compound, and in particular aerobic soil metabolism study; the preferred soil is sandy loam.

The test soils meet these criteria, although in case of two of them – Vero Beach Sand soil and Howe Loamy sand soil, the same cannot be stated when the acceptability criteria of the OECD 106 Guideline are applied – the OC content is lower than the recommended 0.3%.

The fifth soil, Monheim Sandy loam soil, was included into the set because it was used in one of the lysimeter studies. The soil meets all acceptability criteria listed in US EPA Guideline 163-1 and in OECD Guideline 106.

It shall be indicated that in case of the two US soils – Vero Beach Sand soil and Howe Loamy sand soil the OC content was lower than 0.3% recommended by OECD 106 Guideline as minimal soil OC content. That recommendation was explained by the fact that soils with less than 0.3% OC content may disturb correlation between OC and adsorption. For that reason the results for both soils should not be taken into consideration in calculation of the averaged sorption parameters for Flufenacet.

However, it shall be indicated that the Howe loamy sand soil was used in two studies examining the route and rate of degradation of Flufenacet in soil under aerobic conditions. Both studies were found acceptable in course

of the current evaluation, despite the deficiencies displayed by the test soil. As a result, in order to maintain the consistency of the evaluation, RMS proposes to consider the adsorption parameters obtained for Flufenacet in this soil reliable, also because the level of adsorption of Flufenacet onto this soil was higher than recommended as minimum 20%.

In case of Vero Beach Sand soil it shall be indicated that it was also used in another study, aimed on the examination of the soil sorption of several degradation products of Flufenacet – FOE Oxalate, FOE Sulfonic acid, FOE Thiadone, FOE Methylsulfoxide and FOE Alcohol. There that soil displayed similar deficiency – very low OC content. In RMS's opinion, to maintain the representativeness of the adsorption parameters determined for the metabolites listed above – the Vero Beach Sand soil was one of four test soils used in the experiment and the evoked study is a sole study examining soil sorption of the compounds listed above that was submitted for the purpose of the current evaluation, the results obtained for that soil should be kept in the data base. Therefore, to maintain the consistency of the evaluation, also for Flufenacet they should not be excluded just on the basis of soil characteristic.

In case of Howe Loamy sand soil an additional problem was identified – its proper identification with regard to the USDA textural class. The Applicant in the study report classified that soil as Loamy sand to subsequently change that classification, in the Addendum to the study issued on 13th September 1993, to Sandy loam. The proposal was based on the results of the repeated analysis of the properties of the test soil performed by two laboratories – Agvise in 1991 and 1992, and A&L Great Lakes Laboratories in 1993, demonstrating that the test soil was rather Sandy loam. However, it shall be pointed out that the results of the analysis performed in February 1992, the year in which the evaluated soil sorption study was also performed, showed that the test soil was Loamy sand. As nowhere in the study report it was stated that in the repeated analysis the same batch was subjected to characterisation, it may be assumed that the results were obtained for three different soil batches sampled on the same field and representing spatial variability of soil on the sampling area. Also assuming that the analysed sample came from the same batch as soil samples used in the examination of the soil sorption of Flufenacet, it seems appropriate to classify the test soil Howe as Loamy sand and not Sandy loam. For that reason RMS decided to keep the classification presented in the main study report and not in its amendment.

The test soils were air-dried and sieved through 2-mm sieve before being used. No other information with regard to soil sampling and handling procedure prior to the beginning of the experiment was given in the study report.

The test compound – Flufenacet, was used in two forms: as radiolabelled and as a non-radiolabelled compound.

The radiolabelled test compound was [Phenyl-¹⁴C]-Flufenacet, having a specific activity 60.0 mCi/mmol and radiochemical purity of 98%. Its structural formula, with radiolabelling position marked by an asterisk, is shown below on figure B.8.1.2.1.1._CA-1.

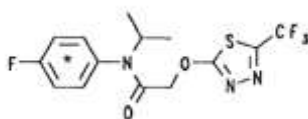

Figure B.8.1.2.1.1._CA-1: The structural formula of the test compound. The radiolabelling position is indicated by the asterisk (*) (copied from the study report).

The non-radiolabelled test substance used in the experiment had a chemical purity of 94.8%.

The water solubility of the test compound, determined for the purpose of this study was approx. 42 ppm at T = 20°C.

The experiment consisted of the following stages:

- 1) **Initial Preliminary Test**, carried out to determine the optimum soil:solution ratio and the stability of the test compound in soil;
- 2) **Second Preliminary Test** in which the equilibration time, i.e. time necessary for adsorption to reach a plateau, was determined for each test soil;
- 3) The **Definitive Test** in which the Adsorption and Desorption isotherms for Flufenacet in each test soil were determined;

The main aim of the Initial Preliminary Test was to determine the optimum soil:solution ratio at which maximum adsorption of Flufenacet onto soil occurred. Additionally the stability of the test item in soil was examined. The examination was performed using a one test soil – Stanley (307) Silt loam soil, having the highest OC content – 1.68%. The test solution was 0.01M CaCl₂ aqueous solution containing 25 ppm of the radiolabelled test item – Flufenacet. It was prepared in duplicate – one replicate containing HgCl₂ and another

without that compound. HgCl_2 was added, in amount to grant a rate of 1.8 mmol/kg soil, as soil sterilising agent. The specific activity of the test solution was 1869 dpm/ μg in case of the test solution with HgCl_2 and 2290 dpm/ μg in case of that not containing it.

The tested soil:solution ratios were: 1:5, 1:10, 1:20 and 1:50. In case of the ratios 1:5, 1:10 and 1:20 1-g portions of the test soil were used. The amounts of the test solution were: 5 mL for 1:5 ratio, 10 mL for 1:10 ratio and 20 mL for 1:20 ratio. For testing 1:50 soil:solution ratio 0.4 g portions of the test soil and 20 mL of test solution were used. The examination was performed in 20-mL culture tubes.

For each tested soil:solution ratio and test solution variant triplicate samples were prepared. They were shaken continuously for 21 hours at constant $T = 24 \pm 1^\circ\text{C}$. After that period the samples were centrifuged for 30 minutes at 4000 rpm, clear supernatants decanted into 10-mL graduated cylinders and their volume recorded. The triplicate 100- μL aliquots were taken for the determination of the radioactivity content, and then the supernatants were pooled before being further processed by extraction – transfer of the test compound to the aqueous phase before subsequent chromatographic (TLC and HPLC) analysis. At that stage of the experiment the most appropriate extraction method of the aqueous supernatant was determined. That was done in a following way:

- one portion of supernatant was extracted three times with CH_2Cl_2 ;
- another portion was extracted once with $\text{CH}_3\text{COOC}_2\text{H}_5$ (ethyl acetate);
- the third portion was passed through C_{18} SPE column and eluted with MeOH.

Organic extracts were evaporated to dryness and residues redissolved in MeOH prior to chromatographic – TLC and HPLC, analysis. The aim of the chromatographic analysis performed at that stage was to determine the extent of the would-be degradation of the test compound and identify and quantify the degradation products.

The most efficient organic extraction method identified at that stage was that with $\text{CH}_3\text{COOC}_2\text{H}_5$, subsequently used in remaining stages of the experiment.

The optimum soil:solution ratio determined at this stage of the experiment and subsequently used in the further examination of the equilibrium sorption of Flufenacet onto soil was 1:5.

The aim of the Second Preliminary Test was to determine the time required to reach the equilibrium concentration, i.e. the equilibration time after which the adsorption changed by less than 5% within 24 hours. The experiment was performed using all five test soils and the optimum soil:solution ratio determined at previous stage. For that purpose 1-g samples of test soils – 19 for each test soil, were weighed into 10-mL borosilicate glass centrifuge tubes equipped with teflon-lined caps. Soil samples were pre-equilibrated for 2 hours with the appropriate amounts of blank, sterile 0.01 M CaCl_2 solution decanted at the end of equilibration period. After that the appropriate amounts of the test solution – either blank 0.01 M CaCl_2 solution or the 0.01 M CaCl_2 solution containing 25 ppm Flufenacet, were added. All samples were then shaken for the predefined time, up to 48 hours, on a laboratory rotator at 20 rpm. The shaker was placed in the incubator set to the constant $T = 22 \pm 1^\circ\text{C}$.

The test solution containing Flufenacet was prepared in the following way: 0.06 mg of ^{14}C -Flufenacet and 6.19 mg of the non-radiolabelled Flufenacet were weighed to 250-mL volumetric flask and dissolved in small amount of CH_3CN (<1%). The solution was brought to volume with the appropriate amount of sterile 0.01M CaCl_2 aq. Then the solution was radioassayed by LSC. Its specific activity was determined to be 4059 dpm/ μg Flufenacet.

For each test soil and the solution with the test compound the samples were taken, in duplicate, after 2, 4, 8, 16 and 24 hours and after 48 hours, in triplicate. Also for each time point single samples with the blank solution were taken for analysis.

Additionally in that experiment five test vessels containing only the appropriate amount of test solution (soilless samples) were set and sampled at the same time points as above in order to determine the possible adsorption of the test compound to the vessel.

The samples were centrifuged for 30 minutes at 4300 rpm at $T = 20^\circ\text{C}$. The clear supernatants were decanted and their volume recorded. Three 200- μL aliquots of each supernatant were analysed for radioactivity content by LSC.

The supernatants of the samples collected after 48 hour of shaking were pooled, extracted three times with $\text{CH}_3\text{COOC}_2\text{H}_5$, organic extracts collected, evaporated to almost dryness and residue redissolved in 1 mL of $\text{CH}_3\text{COOC}_2\text{H}_5$ before being analysed by TLC.

The remaining soil pellets were dried under the gentle stream of N_2 and their triplicate aliquots analysed for the radioactivity content, after combustion, by LSC.

For the following three test soils: Stanley Silt loam, Howe Loamy sand and Monheim Sandy loam, the optimum equilibration time was determined to be 24 hours while for the remaining two test soils – Hagerstown Clay loam and Vero Beach Sand the optimum equilibration time was 48 hours.

The definitive test was carried out to obtain Freundlich sorption isotherms for the processes of adsorption and desorption of Flufenacet in soil and to determine Freundlich isotherm parameters for these processes: the sorption constants – $K_{F\text{ ads}}$ and $K_{F\text{ des}}$ and corresponding $1/n$ values.

The experiment was performed for all five test soils and for the following nominal concentrations of the test item – Flufenacet, in 0.01 M $\text{CaCl}_2\text{ aq}$ test solution: 0.04 ppm, 2.1 ppm, 10.5 ppm 15.8 ppm and 21 ppm.

The test solutions listed above were prepared in the following way:

- Firstly the solution having the concentration 21 ppm – stock solution, was prepared by dissolving the appropriate amount of Flufenacet in sterile 0.01 M $\text{CaCl}_2\text{ aq}$. Small amount of CH_3CN (<1%) was added to the volumetric flask to facilitate solubility and grant homogeneity of the solution. The specific radioactivity of that solution was measured by LSC and was determined to be 4770 dpm/ μg Flufenacet.
- Next the solutions having concentrations 15.8 ppm, 10.5 ppm and 2.1 ppm were prepared by diluting the stock solution in volumetric flasks with the appropriate amounts of 0.01M $\text{CaCl}_2\text{ aq}$. The dilution factors were 0.75, 0.5 and 0.1 respectively.
- The test solution having the lowest concentration of the test item – 0.04 ppm was prepared by dissolving 40 μg of [^{14}C]-Flufenacet in 1000 mL of 0.01M $\text{CaCl}_2\text{ aq}$ in a volumetric flask. The obtained solution had a specific activity, determined by LSC, of 366639 dpm/ μg Flufenacet.

The determination of Freundlich sorption isotherms was carried out in a following way:

- The examination of the adsorption began with weighing to the test vessels, of the same kind as used at preceding step (10-mL disposable borosilicate glass centrifuge tubes), 1-g samples of each test soil. Test vessels were prepared in triplicate for each combination of the test soil and test solution.
- The so prepared soil samples were pre-equilibrated with the appropriate amount of 0.01 M $\text{CaCl}_2\text{ aq}$ solution in the same manner as described for the preceding step.
- Next the appropriate test solutions were introduced to the test vessels in such amount to obtain soil:solution ratio 1:5. So prepared samples were equilibrated for either 24 hours (Stanley Silt loam, Howe Loamy sand and Monheim Sandy loam test soils) or 48 hours (Hagerstown Clay loam and Vero Beach Sand test soils), by constant rotating at 20 rpm, in the darkness and at $T = 22^\circ\text{C}$. Alongside them were equilibrated blank samples, containing each test soil and sterile 0.01M $\text{CaCl}_2\text{ aq}$ solution, and 5 tubes containing the test solutions.
- After equilibration test vessels were centrifuged for 45 min at 4300 rpm (at constant $T = 20^\circ\text{C}$). Triplicate aliquots of supernatants were analysed for radioactivity content and the pH of each supernatant was measured. Next, supernatants were decanted into graduated 5-mL centrifuge tubes, their volumes recorded and conductivity measured. Finally supernatants from replicate samples were pooled and extracted with three portions of $\text{CH}_3\text{COOC}_2\text{H}_5$. The organic extracts were processed in the same way as described for Second Preliminary Test and then analysed by TLC.
- To examine the desorption isotherm the appropriate amount of sterile blank 0.01M $\text{CaCl}_2\text{ aq}$ solution was added to each test vessel after decantation of the test solution. So prepared samples were equilibrated in the same way as described above for the adsorption phase. After that time the test vessels were centrifuged, three 200- μL aliquots of each supernatant radioassayed, pH of each supernatant determined and supernatants decanted to measure their volume. They were then processed in the same way as supernatants obtained at the step examining the adsorption.
- Soil samples left after decantation were dried under the gentle stream of N_2 , ground to a fine powder and three aliquots of each of them were analysed, after combustion, for the radioactivity content using LSC.

The LSC analyses of liquid and solid samples were performed using Packard Tri-Carb Model 4640 LS counter.

Liquid samples were analysed directly, after mixing their 100- μL or 200- μL aliquots with 15 mL of the Ultima Gold Liquid Scintillation cocktail. The parameters of the analysis were following:

- for solutions having the initial specific activity of 366639 dpm/ μg :
 - average sample counting size: 0.2 mL;
 - sample counting time: 5 min.;
 - average background: 35 cpm;
 - average counting efficiency: 95%;
 - Lowest Acceptable Gross Count Rate (LAGC): 64 cpm;
 - Lowest Acceptable Net Count Rate (LANC) – 32 cpm;
 - minimum sensitivity: $5.0 \text{ E-}4$ ppm;
 - greatest probable error (GPE): 8.8%.
- for solutions having the initial specific activity of 4769 dpm/ μg
 - average sample counting size: 0.2 mL;

- sample counting time: 5 min.;
- average background: 35 cpm;
- average counting efficiency: 95%;
- Lowest Acceptable Gross Count Rate (LAGC): 70 cpm;
- Lowest Acceptable Net Count Rate (LANC) – 35 cpm;
- minimum sensitivity: 3.9 E-2 ppm;
- greatest probable error (GPE): 8.8%.

Solid samples were analysed in a following way: the whole portion was oxidised and the evolved $^{14}\text{CO}_2$ trapped in a mixture of 6 mL Carbosorb and 15 mL Perma Fluor V. The parameters of the analysis were following:

- for samples having the initial specific activity of 366639 dpm/ μg :
 - average sample counting size: 0.1 g;
 - sample counting time: 5 min.;
 - average background: 35 cpm;
 - average counting efficiency: 95%;
 - Lowest Acceptable Gross Count Rate (LAGC): 70 cpm;
 - Lowest Acceptable Net Count Rate (LANC): 35 cpm;
 - minimum sensitivity: 1.0 E-3 ppm;
 - greatest probable error (GPE): 8.8%.
- for samples having the initial specific activity of 4769 dpm/ μg :
 - average sample counting size: 0.1 g;
 - sample counting time: 5 min.;
 - average background: 35 cpm;
 - average counting efficiency: 95%;
 - Lowest Acceptable Gross Count Rate (LAGC): 70 cpm;
 - Lowest Acceptable Net Count Rate (LANC) – 35 cpm;
 - minimum sensitivity: 7.7 E-2 ppm;
 - greatest probable error (GPE): 8.8%.

The TLC method, used to analyse the organic extracts was performed on silica gel, 0.25 mm-thick, TLC plates. The plates were developed in $\text{CHCl}_3:\text{CH}_3\text{COOC}_2\text{H}_5$ (3:1). Sample extracts were overspotted with authentic standards. Radioactive bands were detected using radio-TLC analyser Raytest Rita-6800 and the quantitative analysis was performed using the thin-layer analyser.

The HPLC analysis was performed using a Hewlett Packard 1090 chromatograph equipped with Spherisorb 3 ODS 70 x 10 mm chromatographic column and coupled to UV detector, set at wavelength $\lambda = 254$ nm, and Raytest Ramona 90 radioactivity detector. The chromatographic separation was performed in a linear gradient mode, using the mobile phase consisting of:

- water + 0.4% CH_3COOH as **Solvent A**, and
- CH_3CN + 0.4% CH_3COOH as **Solvent B**.

Gradient elution lasted 40 minutes and the gradient programme was following:

- at 0 min 10% Solvent B;
- at 25 min 100% Solvent B;
- at 40 min 100% Solvent B.

The flow rate was 1 mL/min.

Additional analytical method characterised in the study report was GC-MS, but because nowhere in the study report it was indicated to be used, RMS decided not to provide its characteristic.

Results and their discussion:

The examination of the stability of the test compound performed during Initial Preliminary Test showed that Flufenacet was stable in soil and no degradation products were detected. The same observation was made in the supernatants collected after 48-hours lasting equilibration during the Second Preliminary Test. For that reason at later stages HgCl_2 as sterilising agent was not used. The use of that compound in the Initial Preliminary Test had no influence on the obtained results because in parallel the same experiment without it was performed. Therefore it may be stated that the use of HgCl_2 in initial preliminary test had no impact on the results obtained at that stage as well as on the results of the subsequent stages of the experiment.

The results of the determination of the appropriate soil:solution ratio are presented below in the table B.8.1.2.1.1._CA-2. The reported values represent the averages of the replicate samples. They demonstrated that the highest % of adsorption was obtained for 1:5 soil:solution ratio and that ratio was selected to be used throughout the whole remaining part of the study.

Table B.8.1.2.1.1._CA-2: The results of the determination of the appropriate soil:solution ratio using Stanley Silt loam test soil.

Soil:solution ratio	Initial concentration of Flufenacet [$\mu\text{g/g}$ soil]	Concentration of Flufenacet in solution after 21-hours equilibration [$\mu\text{g/mL}$]	% Flufenacet adsorbed onto soil after 21-hours equilibration
1:5	125	14.4	47.01
1:10	250	17.2	36.36
1:20	500	19.2	26.75
1:50	1250	20.6	34.75

The results of the determination of the appropriate equilibration time for each test soil are presented below in the table B.8.1.2.1.1._CA-3.

Table B.8.1.2.1.1._CA-3: The results of the determination of the appropriate equilibration time for each test soil.

Test soil	Soil:solution ratio	Concentration of Flufenacet in solution [$\mu\text{g/mL}$] and % change/24h interval							Selected optimum equilibration time
		Initial	after 2 hours	after 4 hours	after 8 hours	after 16 hours	After 24 hours	after 48 hours	
Stanley Silt loam	1:5	25	18.0	17.8	17.8	17.5	16.9 6.1	16.6 1.8	24 hours
Hagerstown Clay loam	1:5	25	20.9	18.8	18.5	18.7	18.0 13.9	14.7 18.9	48 hours
Howe Loamy sand	1:5	25	21.2	21.2	20.2	20.7	19.7 7.1	20.2 +2.5	24 hours
Vero Beach Sand	1:5	25	21.6	22.0	21.9	21.9	22.0 +1.9	18.0 18.2	48 hours
Monheim Sandy loam	1:5	25	15.7	15.3	15.2	14.4	14.7 6.4	14.5 1.4	24 hours

The results of the determination of pH and conductivity of supernatants obtained during adsorption and desorption phases of the definitive test are presented below in the table B.8.1.2.1.1._CA-4. In the next table – B.8.1.2.1.1._CA-5 are presented the results of the determination of the distribution of Flufenacet in the test systems with each test soil and recovery at the end of the Definitive Test – determination of Freundlich Adsorption and Desorption isotherms. Finally, in the table B.8.1.2.1.1._CA-6 are presented the results of the Definitive test that were used to plot the Freundlich Adsorption and Desorption isotherms and determine Freundlich sorption isotherm parameters for adsorption and desorption processes.

Table B.8.1.2.1.1_CA-4: The conductivity and pH of the supernatants obtained during adsorption and desorption phases of the definitive test.

Test soil	Nominal initial concentration of Flufenacet the test solution [µg/mL]	Properties of the supernatant obtained during

The graphical and numerical results of the experiment – Freundlich adsorption and desorption isotherms and their parameters, are presented below individually for each test soil. On their basis it may be stated that the obtained Freundlich sorption isotherms were of good quality. However, RMS stated that in the study report the way of determination of the Freundlich adsorption constant K_f was not clearly explained, therefore it was difficult to interpret the results. That concerned in particular the values presented in the Table 13 of the study report, in which the K_d values were presented. These were most probably K_f values, but the assumption made by the RMS required verification. The headings of the graphs presenting the isotherms contained the information that they were used for the determination of $1/n$ values, what was confusing. In the body text of the study report were mentioned the K_d values, but referred to as distribution coefficients. Finally, in case of the K_{OC} values it was stated in the study report that they were determined using the OC value calculated using the equation $OC = OM/1.9$. For that reason RMS repeated the analysis using as input data presented above in the table B.8.1.2.1.1_CA-6. The input data and obtained results are presented below the results obtained by the Applicant. Reporting the Applicant's results RMS decided to maintain the format of reporting used in the original study report.

The results obtained by the Applicant:

The graphical results obtained for the experiment with Stanley Silt loam soil are presented on figure B.8.1.2.1.1_CA-2 and the Freundlich isotherm parameters for adsorption and desorption processes obtained in that soil in the table B.8.1.2.1.1_CA-7.

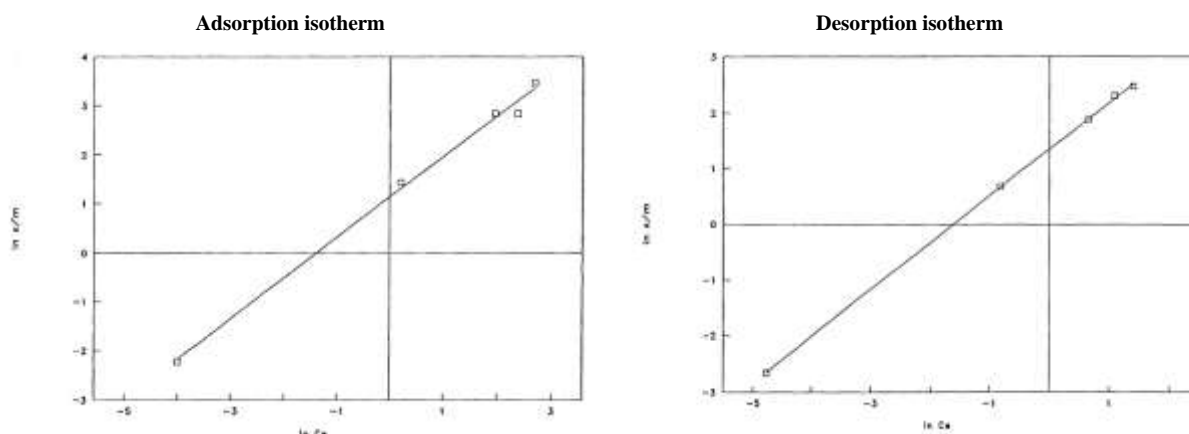

Figure B.8.1.2.1.1_CA-2: The Freundlich adsorption and desorption isotherms obtained for Flufenacet in Stanley Silt loam soil (copied from the study report).

Table B.8.1.2.1.1_CA-7: The parameters of Freundlich adsorption and desorption isotherms for Flufenacet determined in Stanley silt loam soil.

Process	Determined parameter				Correlation coefficient (r)
	K_d [mL/g]	K_{oc} [mL/g]	1/n		
			value	SD	
Adsorption	3.2	213	0.837	0.036	0.9945
Desorption	3.9	254	0.840	0.008	0.9998

The graphical results obtained for the experiment with Hagerstown Clay loam soil are presented on figure B.8.1.2.1.1_CA-3 and the Freundlich isotherm parameters for adsorption and desorption processes obtained in that soil in the table B.8.1.2.1.1_CA-8.

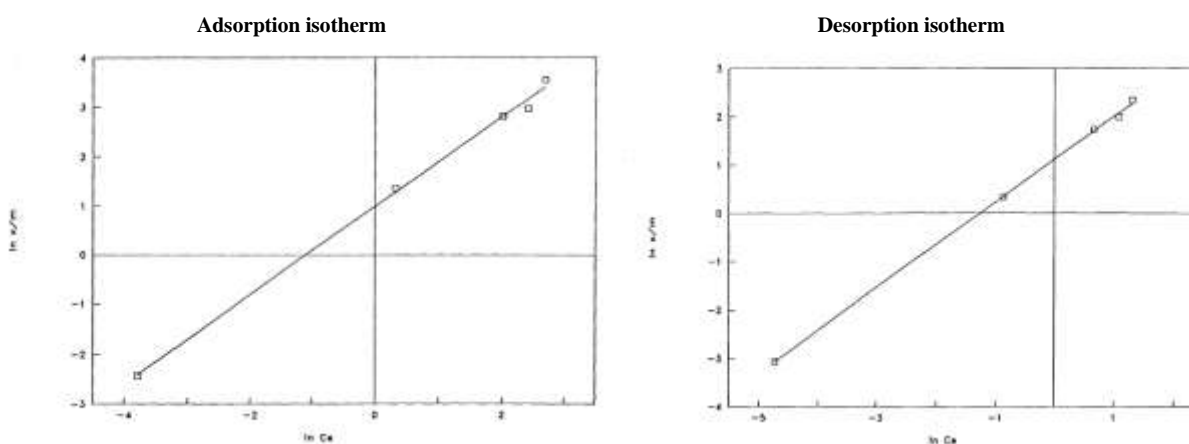

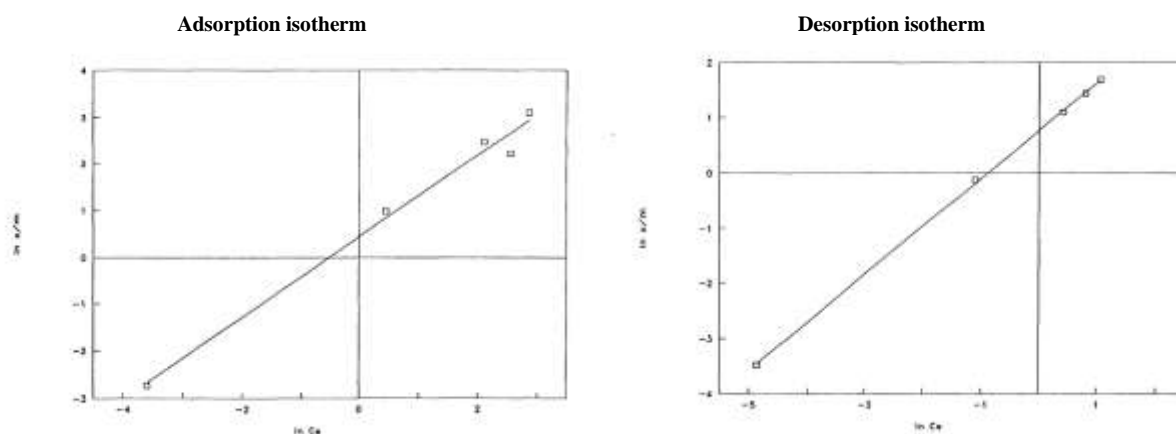

Figure B.8.1.2.1.1_CA-3: The Freundlich adsorption and desorption isotherms obtained for Flufenacet in Hagerstown Clay loam soil (copied from the study report).

Desorption	5.3	395	0.907	0.017	0.9990

The results obtained by the RMS:

Below in the table B.8.1.2.1.1_CA-12 are given the input data used in the repeated determination of Freundlich adsorption and desorption parameters performed by the RMS. To maintain the consistency and comparability with the Applicant's analysis RMS transformed the input data using the natural-logarithm transformation. Therefore the Freundlich adsorption constant was calculated using the following equation:

$$K_f = e^{\ln K}$$

Table B.8.1.2.1.1_CA-12: The input data used in the repeated determination of Freundlich adsorption and desorption isotherms performed by the RMS.

Test soil	Nominal initial concentration of Flufenacet [µg/mL]	Results obtained for adsorption phase				Results obtained for desorption phase			
		Concentrations of Flufenacet at equilibrium		Log-transformed (ln) Concentrations of Flufenacet at equilibrium		Concentrations of Flufenacet at equilibrium		Log-transformed (ln) Concentrations of Flufenacet at equilibrium	
		in solution Ce [µg/mL]	in soil x/m [µg/g]	Ln (Ce)	Ln (x/m)	in solution Ce [µg/mL]	in soil x/m [µg/g]	Ln (Ce)	Ln (x/m)

The data were fitted using the CurveExpert Professional 1.0 tool. The linear regression model was applied. The graphical and numerical results are presented below, individually for each test soil. All values were rounded to the two, and in case of 1/n three, digits after the decimal point. The correlation coefficient is reported with four digits after the decimal point

The graphical results obtained for the experiment with Stanley Silt loam soil are presented on figure B.8.1.2.1.1_CA-7 and the Freundlich isotherm parameters for adsorption and desorption processes obtained in that soil in the table B.8.1.2.1.1_CA-13.

In case of this soil it was demonstrated that level of adsorption was <20%. For that reason the determined Freundlich sorption isotherm parameters, although determined and reported in the table above, should not be used to derive the regulatory endpoints.

The graphical results obtained for the experiment with Monheim Sandy loam soil are presented on figure B.8.1.2.1.1._CA-11 and the Freundlich isotherm parameters for adsorption and desorption processes obtained in that soil in the table B.8.1.2.1.1._CA-17.

The final results of the study – Freundlich adsorption parameters for Flufenacet obtained in each test soil, are presented below in the table B.8.1.2.1.1._CA-18. RMS considers these results reliable and possible to be used to derive input parameters for modelling. It shall be noted however, that in case of Vero Beach Sand soil the level of adsorption was lower than the minimum requirement of 20%. Therefore the determined Freundlich adsorption parameters should be considered with care and RMS decided not to include these values into the data set from which the regulatory endpoints are calculated. For that reason those values, being presented in the table B.8.1.2.1.1._CA-18 below, are marked in italics.

Table B.8.1.2.1.1._CA-18: The definitive set of Freundlich adsorption parameters determined for Flufenacet in the study.

Study 2:

Report: Hein E.-M., (2012): “[Thiadiazole-5-¹⁴C] FOE 5043 (Flufenacet): Adsorption/Desorption on Five Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany; study ID M1312069-2, Report No. EnSa-12-0517; 01 October 2012; study reference number: M-439282-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for the Testing of Chemicals No. 106, Adsorption/Desorption, 2000;
- US EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835 1230, Adsorption/Desorption (Batch Equilibrium), 2008;
- Canada PMRA, Guidelines for Registration of Pesticides, Environmental Chemistry and Fate, 1987.

GLP: Yes;

RMS comments: This is a new study, submitted specifically for the purpose of the current assessment. It was evaluated for compliance with the following Guidelines:

- OECD Guideline for the Testing of Chemicals No. 106, Adsorption/Desorption, 2000;
- US EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835 1220, Sediment and Soil Adsorption/Desorption Isotherm, 1998;
- US EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835 1230, Adsorption/Desorption (Batch Equilibrium), 2008;

The following deviations were stated:

- the soil:solution ratios tested to identify the adequate soil:solution ratio were: 1:1.3, 1:2 and 1:4; the higher soil solution ratios were not tested and the Applicant provided no justification for not additionally examining at least 1:25 ratio recommended by the Guidelines;
- throughout the whole experiment HgCl_2 added to the 0.01M $\text{CaCl}_{2\text{aq}}$ in amount 50 mg/L was used to eliminate the microbial activity of the test soils and in that way grant the stability of the test compound in contact in soil; it shall be noted however that that method of sterilisation is not recommended as potentially influencing the results of the experiment - Hg^{2+} ions may competitively occupy the sorption sites on the surface of the test soil, therefore limiting the extent of the adsorption of the test compound, what in turn may result in underestimation of the adsorption parameters and Freundlich adsorption isotherm constant in particular.

RMS however decided to consider the study valid as in all other aspects it complied with the provisions of the reference Guidelines, at the same time taking into consideration the fact that the adsorption parameters may be underestimated and that the extent of that potential underestimation was not possible to be assessed.

The study is summarised below.

Summary:

The aim of the was to examine the process of the equilibrium sorption – adsorption and desorption, of Flufenacet onto soil. The study was performed using five European test soils. Their characteristic is provided below in the table B.8.1.2.1.1._CA-19. The test soils were sampled from the agriculturally used areas, from the fields covered with grass on which no pesticides were used for 5 years prior to the sampling. They were collected from the 0-20 cm layer using the shovel and transported to the test facility in plastic bags. There they were sieved through 2-mm sieve and stored in a refrigeration room until being used. The storage period was following:

- for Laacher Hof AXXa soil: 63 days;
- for Hoefchen am Hohenseh soil: 18 days;
- for Hanscheider Hof soil: 157 days;
- for Dollendorf II soil: 56 days;
- for Wurmwielse soil: 18 days.

Table B.8.1.2.1.1._CA-19: The characteristic of soils used in the study.

Parameter		Soil				
		<i>Laacher Hof AXXa (AA)</i>	<i>Hoefchen am Hohenseh (HH)</i>	<i>Hanscheider Hof (HN)</i>	<i>Dollendorf II (DD)</i>	<i>Wurmwiess (WW)</i>
Soil origin		Monheim, North Rhine- Westphalia, Germany	Burscheid, North Rhein- Westphalia, Germany	Burscheid, North Rhein- Westphalia, Germany	Blankenheim, North Rhein- Westphalia, Germany	Monheim, North Rhine- Westphalia, Germany
Soil type (USDA)		Loamy sand	Silt loam	Silt loam	Loam	Sandy loam
Particle size distribution	Sand [%]	79	15	31	37	53
	Silt [%]	16	70	54	40	30
	Clay [%]	5	15	15	23	17
Soil pH	in 0.01M CaCl ₂ (1:2)	5.8	6.5	5.3	7.3	5.1
	in water (1:1)	6.2	6.7	5.7	7.5	5.4
	in 1M KCl (1:1)	5.7	6.1	4.9	7.0	4.7
Water holding capacity	maximum, [g H ₂ O/100 g soil]	49.9	55.9	61.3	78.5	61.9
	at 0.1 bar (pF 2.0) [%]	17.2	31.7	36.7	41.1	20.1
	at 0.33 bar (pF 2.5) [%]	12.4	21.9	25.6	34.7	16.5
Organic matter content (OM) [%] ¹⁾		3.79	2.76	4.65	7.59	2.93
Organic carbon content (OC) [%]		2.2	1.6	2.7	4.4	1.7
CEC [meq/100 g]		10.0	11.6	9.6	19.2	9.9
Bulk density [g/cm ³]		1.20	1.11	1.04	0.98	1.08

Footnotes to the table:

- 1) Recalculated by the RMS from organic matter content using the following equation: OM = 1.724 OC (the values are almost identical to those reported by the Applicant, however some inaccuracies related to the rounding procedure were stated);

The test compound used in the experiment was the ¹⁴C-FOE 5043 radiolabelled in C5-thiadiazole position, as shown below on figure B.8.1.2.1.1._CA-12.

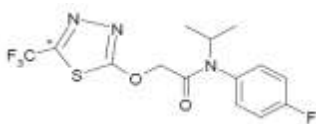

Figure B.8.1.2.1.1._CA-12.: The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 1.54 MBq/mg and its radiochemical purity, determined using both HPLC and TLC, was > 99%. Also the chemical purity of the test compound, determined using HPLC equipped with UV detector, was > 99%. It was delivered to the test facility as a vacuum-dried solid.

The whole delivered sample was used to prepare a **stock solution** by dissolving it in 17 mL of CH₃OH. The obtained solution had a nominal concentration 2 mg Flufenacet/mL and specific activity 3047 kBq/mL. It was labelled **HO58 SS** and used to prepare all other solutions containing the test compound – [¹⁴C]-Flufenacet, used in the experiment (**Application solutions**). The identity and purity of the test compound in the solution **HO58 SS** was determined using ¹H-NMR and HPLC-MS/MS methods.

The **Application solutions** were prepared as 0.01 M CaCl₂ aq (aqueous) solutions, with or without mercury (II) chloride.

The 0.01 M CaCl₂ aq solutions were prepared as follows:

- the solution of calcium chloride without mercury chloride was prepared by dissolving 2.94 g of CaCl₂ x 2 H₂O in ultrapure water in 2-L volumetric flask – **Aqueous Solution A**;
- the solution of calcium chloride with mercury chloride was prepared by dissolving 2.94 g of CaCl₂ x 2 H₂O and 100 mg of HgCl₂ in ultrapure water in 2-L volumetric flask – **Aqueous solution B**.

The application solutions containing the test item – [^{14}C]-Flufenacet, were prepared in a way characterised below.

Firstly the **Stock solution HS6006 SS1** was prepared by transferring 1.75 mL of the stock solution **HO58 SS** into a glass bottle. Next it was evaporated to dryness under the gentle stream of N_2 and residue redissolved in 350 mL of 0.01 M CaCl_2 aq solution (**Aqueous solution A**) in 15-minutes lasting sonication. The concentration of so prepared solution was determined by LSC – it was 16303.1 Bq/mL, what corresponded to 10.6 μg Flufenacet/mL. That solution was used to prepare a series of the **Application solutions**, varying in concentration of the test item and labelled **Application solution A – E**.

The **Application Solution A** was prepared by diluting the total residual volume of the **Stock solution HS6006 SS1** with 45 mL of **Aqueous solution A**. The obtained solution was analysed for its homogeneity and the radioactivity content by LSC. The determined radioactivity content was 15318 Bq/mL, what corresponded to the concentration of 9.9 mL [^{14}C]-Flufenacet/mL. That solution was used to obtain the final nominal concentration 1.0 mg Flufenacet/mL.

Other **Application solutions – B, C, D and E**, were prepared in a series of dilutions of the **Application Solution A**, in a following way:

- **Application Solution B** by diluting 15 mL of the **Application Solution A** with 35 mL of 0.01 M CaCl_2 aq with HgCl_2 – **Aqueous solution B**, to obtain 50 mL of the solution having a concentration, when determined by LSC, 4446.08 Bq/mL, corresponding to 2.9 mg Flufenacet/mL, and containing 6.447 mmole HgCl_2 . It was used to obtain the final nominal test concentration of 0.3 mg Flufenacet/mL;
- **Application Solution C** by diluting 5 mL of the **Application Solution A** with 45 mL of **Aqueous solution B**, to obtain 50 mL of the solution having a concentration, when determined by LSC, 1482.9 Bq/mL, corresponding to 1.0 mg Flufenacet/mL, and containing 8.289 mmole HgCl_2 . It was used to obtain the final nominal test concentration of 0.1 mg Flufenacet/mL;
- **Application Solution D** by diluting 1.5 mL of the **Application Solution A** with 48.5 mL of **Aqueous solution B**, to obtain 50 mL of the solution having a concentration, when determined by LSC, 453.34 Bq/mL, corresponding to 0.3 mg Flufenacet/mL, and containing 8.934 mmole HgCl_2 . It was used to obtain the final nominal test concentration of 0.03 mg Flufenacet/mL;
- **Application Solution E** by diluting 0.5 mL of the **Application Solution A** with 49.5 mL of **Aqueous solution B**, to obtain 50 mL of the solution having a concentration, when determined by LSC, 150.16 Bq/mL, corresponding to 0.1 mg Flufenacet/mL, and containing 9.118 mmole HgCl_2 . It was used to obtain the final nominal test concentration of 0.01 mg Flufenacet/mL;

The study was carried out using 42-mL Teflon centrifuge tubes with screw cap as test vessels. It consisted of the following experiments:

- **Preliminary tests**, during which were determined:
 - Stability of the test item;
 - Adsorption of the test item onto the surface of the test vessels;
 - Adequate soil:solution ratio;
 - Adequate equilibrium time for adsorption;
 - Adequate equilibrium time for desorption;
 - Mass balance of the test compound – Flufenacet;
- **Definitive test**, consisting of:
 - Determination of Freundlich adsorption isotherm and its parameters – Freundlich adsorption constant $K_{\text{F ads}}$ and corresponding $1/n$ value, in a single-step experiment;
 - Determination of Freundlich desorption isotherm and its parameters – desorption constant $K_{\text{F des}}$ and corresponding $1/n$ value, in a multi-step (three-step) experiment;

All experiments were performed in a walk-in climatic chamber, at constant temperature $T = 20 \pm 2^\circ\text{C}$. The temperature in the experimental chamber was continuously monitored and the results of that monitoring are presented in section “Results and their discussion”, further down the summary.

For agitation (shaking) of the test vessels containing test soil and test solutions the mechanical overhead shaker was used.

The general experimental procedure used in the study, common for all steps, is characterised below.

Its first step was the preparation of the test system. First the designated amounts of each test soil (dry weight) were weighed into centrifuge tubes. Next the appropriate amount of either 0.01 M CaCl_2 aq solution or 0.01 M CaCl_2 aq solution containing 50 mg/L HgCl_2 (184.2 mmole/L), was added. HgCl_2 was used as a sterilising agent, preventing the degradation of the test compound, in all experiments except that aimed on the determination of the appropriate soil:solution ratio. The amount of the solution added into the test vessel containing the test soil was always such, to obtain a total solution volume of 18 mL, taking into account the residual soil moisture.

The so prepared test vessels were sealed and pre-equilibrated for at least 12 hours in the dark by agitation at constant temperature.

After pre-equilibration 2 mL of the adequate **Application solution (A – E)**, characterised above, was added to obtain the final solution volume of 20 mL. All preliminary tests were carried out using the **Application Solution A** – the highest nominal test concentration of 1.0 mg Flufenacet/mL.

The definitive test aimed on the examination of the adsorption was carried out using all five application solutions – **Application solution A – Application solution E**, to cover the concentration range (nominal) of 0.01 – 1.0 mg Flufenacet/mL. The same concentration range was used in examination of the 1st step of desorption. The next desorption steps – 2nd and 3rd, were examined using only one – highest nominal concentration of the test item – 1.0 mg/mL.

After introduction of the test compound the test vessels were closed and the suspensions agitated for the appropriate amount of time. After that period samples were centrifuged and the supernatants decanted. Their aliquots were analysed by LSC, and the supernatants weighed and analysed using radio-HPLC. Additionally in supernatants obtained while examining adsorption in the definitive test, pH was determined.

In definitive tests after decantation of clarified supernatants the fresh 20-mL portions of **Aqueous solution B** were introduced to the test vessels and the procedure repeated to examine the desorption. In case of samples treated with the test compound at nominal concentration 1.0 mg Flufenacet/mL that procedure was repeated three times to examine three-steps desorption.

Finally, to calculate the material balance the soil samples remaining after decantation of supernatants were lyophilised, homogenised and analysed, after combustion, for radioactivity content using LSC.

Because it was demonstrated that the test compound was stable during the experiment, its partition was determined on the basis of its content in the liquid phase and the soil content was not determined.

All test were performed using the duplicate samples.

For the whole experiment the verification of the application rate was performed in a following way: 2 mL of the appropriate **Application solution** were pipetted into 10- mL or 25-mL graduated glass flask and the solution was brought to the volume with CH₃CN/H₂O 1:1. The obtained solution was quantitatively analysed by LSC. The determined radioactivity content was set to 100% AR.

The specific conditions of the performance of each experiment are presented below.

The stability of the test item was examined in the soilless test systems. To the two test vessels 18 mL of the **Aqueous solution B** (containing HgCl₂) were introduced. Next 2 mL of the **Application solution A** were added. The test vessels were sealed and agitated for 96 hours. At pre-defined time points – after 0, 6, 24, 48, 72 and 96 hours the 100-μL aliquots were taken for the LSC analysis. Additionally the samples taken at the following time points: after 0, 24 and 96 hours of equilibration, were analysed by radio-HPLC. In the same experiment was examined the adsorption of the test item – Flufenacet, to the surface of the test vessels. N.b. the samples used in that experiment contained, each, 3.3156 mmol of HgCl₂.

The adequate soil:solution ratio was determined for each test soil by examining the following ratios:

- 1:1.3 – 15 g soil (d. w.) and 20 mL solution;
- 1:2 – 10 g soil (d. w.) and 20 mL solution;
- 1:4 – 5 g soil (d. w.) and 20 mL solution;

That was done in the following way: first the appropriate portions of each test soils were weighed to the test vessels and 18 mL **Aqueous solution A** were added. So prepared test vessels were pre-equilibrated for 24 hours as described above. Next 2 mL of the **Application solution A** were added to each test vessel and they were agitated for 24 hours. After that period the samples were centrifuged for 15 minutes at 5000g, and the 100-μL aliquots of supernatants analysed by LSC.

The soil:solution ratios higher than 1:4 were not tested and the reason for that was not provided. In this test, exclusively, HgCl₂ as sterilising agent was not used.

The adequate adsorption equilibrium time was determined for all test soils. The soil:solution ratio used in this test was 1:4. The test systems were prepared in duplicate for each test soil and pre-equilibrated for 48 hours, as already described. In this test **Aqueous solution B** was used. After pre-equilibration to each sample 2 mL of the **Application solution A** were added. The samples were then agitated for up to 96 hours. At the pre-defined time points – 6, 24, 48, 72 and 96 hours after treatment, samples were centrifuged for 10 minutes at 5000g and 100-μL aliquots of clarified supernatants taken for LSC analysis. After that soil pellets were resuspended and samples returned to the agitating device. The amount of HgCl₂ in each test vessel was 3.3156 mmol.

The adequate desorption equilibrium time was not examined separately, but set to the same value as that determined for the adsorption.

The mass balance of the test item – Flufenacet, was examined in the following way: the samples were prepared in duplicate and pre-equilibrated for the 48-hours in a way described above (4 g test soil, 18 mL of **Aqueous solution B**). The selected soil:solution ratio was 1:4. After pre-equilibration 2 mL of the **Application solution A** were added to each test vessel. After application the samples were equilibrated, by agitating, for 96 hours, then centrifuged for 10 minutes at 5000g and clarified supernatants collected for analysis by LSC (500- μ L aliquots). The amount of collected supernatant for each soil was determined by weighing it.

The soils remaining in the test vessels after decantation of supernatants were extracted by shaking them with four 10-mL portions of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 1:1. Each extraction cycle (shaking) lasted 30 minutes. Samples were then centrifuged for 10 min. at 5000g, supernatants decanted and combined, and their total volume determined using the graduated cylinders. The 500- μ L aliquots of each combined extract were analysed by LSC.

The aliquots of aqueous supernatants and soil organic extracts were analysed by radio-HPLC to check the stability of the test item and determine its concentration to establish the mass balance. Aqueous extracts were examined directly and organic extracts after processing. The processing consisted on concentrating of 5-mL aliquots to which 0.1 mL of aqueous solubiliser was added, centrifugation of the concentrated extracts and analysis of the supernatants.

The definitive test aimed on the determination of Freundlich adsorption and desorption isotherms, and Freundlich sorption parameters for both processes was carried out following the procedure presented below on figure B.8.1.2.1.1_CA-13. For examining adsorption and 1st stage of desorption the following initial concentrations of the test item – [^{14}C]-Flufenacet. were used: 0.01 mg/L, 0.03 mg/L, 0.1 mg/L, 0.3 mg/L and 1.0 mg/L.

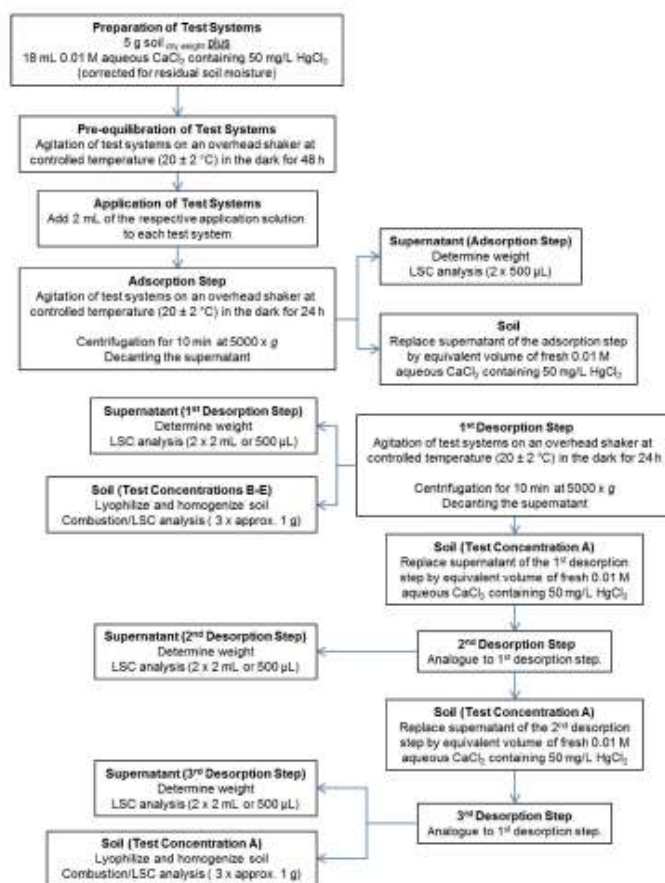

Figure B.8.1.2.1.1_CA-13: The flow chart of the experimental procedure for the definitive test (copied from the study report).

Throughout the definitive tests HgCl_2 was used as soil sterilising agent to prevent degradation of the test item – Flufenacet. As Hg^{2+} ions are known to have strong affinity to the soil organic matter, what might have

influenced the results of the experiment, RMS calculated the amount of HgCl_2 , in mmoles, present in the test systems at each stage of the definitive test. The results are presented below in the table B.8.1.2.1.1._CA-20.

Table B.8.1.2.1.1._CA-20: The amount of HgCl_2 in the test systems at each stage of the definitive test

Nominal concentration of the test item [mg/L]	Amount of HgCl_2 in the sample [mmoles]								
	Adsorption (ads)			Desorption 1 st step (des1)		Desorption 2 nd step (des2)		Desorption 3 rd step (des3)	
	Introduced at pre-equilibration	Introduced with treatment solution	Total	Introduced with solution	Total – (ads + des1)	Introduced with solution	Total – (ads + des1 + des2)	Introduced with solution	Total – (ads + des1 + des2 + des3)
1.0	3.3156	0	3.3156	3.684	6.9996	3.684	10.6836	3.684	14.3676
0.3	3.3156	0.2579	3.5735	3.684	7.2576	----	----	----	----
0.1	3.3156	0.3316	3.6472	3.684	7.3312	----	----	----	----
0.03	3.3156	0.3574	3.6730	3.684	7.3570	----	----	----	----
0.01	3.3156	0.3647	3.6803	3.684	7.3643	----	----	----	----

All liquid samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a LS6500 or LKB-Wallac 1219 Spectral counters.

The samples having volume of up to 2000 μL were analysed for the radioactivity content in mini-vials with 2 mL of Quicksafe[®] A solution containing 5% of water. The counting time was 10 min and the background 12 – 16 cpm. The analysis was performed using LS 6500 counter.

Aliquots of application solutions were analysed in maxi-vials using 7 mL of Quicksafe[®] A solution containing 5% of water. The counting time was 10 min and the background 22 – 23 cpm.

The radioactivity in solid samples – soil samples remaining after decantation of liquid phase, was determined after combustion of three 1-g aliquots of dried and homogenised material. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxsolve C400 liquid. The counting time was 10 min and the background 17 – 20 cpm and the counting instrument LKB-Wallac 1219 Spectral counter.

The instrumental limit of detection – LOD_i was set to twice maximum instrument background count rate and instrumental limit of quantitation – LOQ_i to three times maximum instrument background count rate. The maximum instrument background count rate was determined to be 0.3 – 0.5 Bq. Therefore for different types of liquid samples the instrumental LOD_i and LOQ_i were as follows:

- samples with scintillation cocktail of 2 mL Quicksafe A + 5% water, $\text{LOD}_i = 0.5$ Bq and $\text{LOQ}_i = 0.8$ Bq;
- samples with scintillation cocktail of 7 mL Quicksafe A + 5% water, $\text{LOD}_i = 0.8$ Bq and $\text{LOQ}_i = 1.2$ Bq;
- samples with scintillation cocktail of 15 mL Oxsolve C400, $\text{LOD}_i = 0.7$ Bq and $\text{LOQ}_i = 1.0$ Bq.

When calculated for different types of analysed samples, the determined LOD and LOQ values for LSC analysis were as presented below in the table B.8.1.2.1.1._CA-21:

Table B.8.1.2.1.1._CA-21: The LOD and LOQ values for different types of samples analysed using LSC.

Type of sample	max. total amount – volume or mass	min. aliquots analysed – volume or mass	LOD (worst case) expressed in:		LOQ (worst case) expressed in:	
			Bq	mass units	Bq	mass units
Supernatant (adsorption)	20 mL	0.5 mL	20	0.65 ng/mL	32	1.04 ng/mL
Supernatant (desorption)	20 mL	0.5 mL	20	0.65 ng/mL	32	1.04 ng/mL
Soil residues	5 g	0.9 g	3	0.34 ng/g	5	0.65 ng/g

The RP-HPLC analysis was performed in a gradient mode. The system consisted of HP 1100 chromatograph equipped with a binary pump, autosampler, on-line degasser, column oven and a Variable Wavelength UV detector set at $\lambda = 254$ nm, coupled with Ramona Star radioactivity detector. The chromatographic separation was performed on Purosphere Star RP 18e 250 mm * 4.6 mm * 5 μm chromatographic column. It worked in the following gradient regime:

- **Mobile phase A:** 985 mL Water + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ (5 mM NH_4COOH /265 mM HCOOH),
- **Mobile phase B:** 985 mL CH_3CN + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ (5 mM NH_4COOH /265 mM HCOOH),
- **Gradient mode:** is presented below in the table B.8.1.2.1.1._CA-22;
- Total run time was 75 minutes.

Table B.8.1.2.1.1._CA-22: The gradient mode used in the analysis.

Time [min.]		0	5	55	60	62	75
Gradient	% A	100	100	5	5	100	100
	% B	0	0	95	95	0	0

The flow rate was set to 1.0 mL/min. The chromatographic column was kept under the ambient temperature. The identification of the test compound – Flufenacet, was carried out by means of the comparison of the retention times. For Flufenacet the retention time R_t was approx. 44.6 min.

The LC-MS analysis was performed as HPLC/MS analysis. It was carried out using HP1000 HPLC system equipped with a Nucleodur Gravity C_{18} chromatographic column (250 * 2 mm, 3 μ m), UV detector followed by the Ramona Star radiodetector and LTQ Orbitrap XL mass spectrometer.

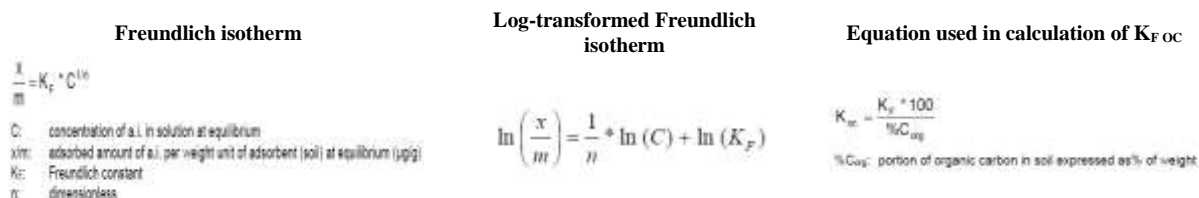

The parameters of chromatographic analysis were following:

- column temperature: 40°C,
- flow rate: 0.2 mL/min,
- elution mode: gradient,
- mobile phase:
 - Solvent A: $H_2O + 0.1\% HCOOH$,
 - Solvent B: $CH_3CN + 0.1\% HCOOH$.
- The gradient programmes used in the analysis is presented below in the table B.8.1.2.1.1._CA-23:

Table B.8.1.2.1.1._CA-23: The gradient mode used in the analysis.

Time [min.]		0	1	25	35
Gradient	% A	95	95	5	5
	% B	5	5	95	95

The calculations of the Freundlich sorption parameters were performed using the equations presented below on figure B.8.1.2.1.1._CA-14.

**Figure B.8.1.2.1.1._CA-14:** The equations used in the calculations of the Freundlich sorption parameters

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in table B.8.1.2.1.1._CA-19. It may be stated that the test soils meet the acceptability criteria with regard to their textural characteristic, pH range and OC content range.

The results of the monitoring of the temperature during the experiment are presented below on figure B.8.1.2.1.1._CA-15. On their basis it was stated that the mean $T = 19.5^\circ C$ and its range $18.9 - 20.3^\circ C$. It was therefore within the pre-defined limits of $T = 20 \pm 2^\circ C$. It may be also stated that the temperature was constant within the study period, so all thermodynamic experiments, and in particular that aimed on the determination of the sorption isotherms, returned reliable results.

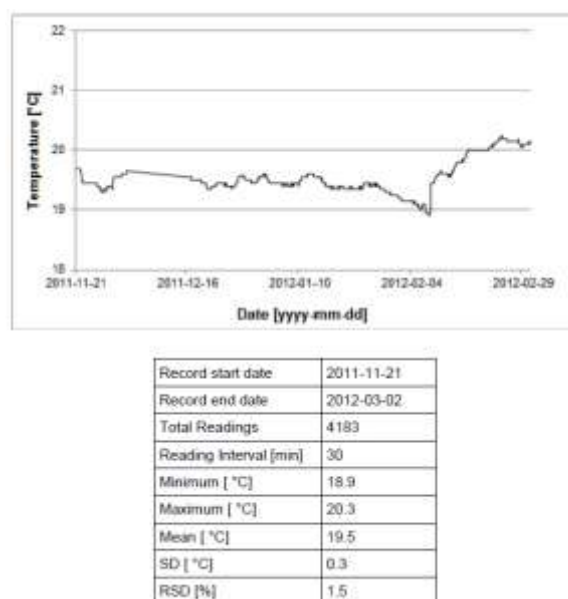

Figure B.8.1.2.1.1_CA-15: The graphical results of the monitoring of the temperature during the study (copied from the study report).

On the basis of the results of the determination of LOD and LOQ for LSC analysis and the results presented in the table B.8.1.2.1.1_CA-20 it was stated that the method was well suited for the analysis of the samples from the lowest treatment concentrations.

The graphical results of the verification of the chromatographic method used in the study – the radio-HPLC, are presented below on figure B.8.1.2.1.1_CA-16. On their basis the instrumental LOD was determined to be 2.5 Bq, equal to 0.3% AR and the LOQ was set to $3 \times \text{LOD} = 0.9\%$ AR.

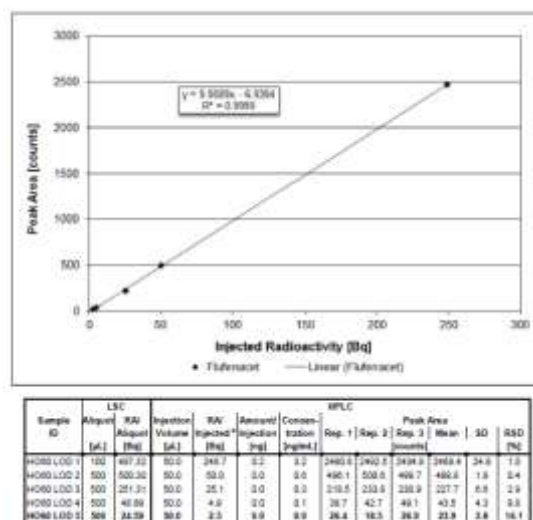

Figure B.8.1.2.1.1_CA-16: The graphical results of the verification of radio-HPLC analytical method used in the study (copied from the study report).

The numerical results of the examination of stability of the test item – Flufenacet in 0.01M CaCl_2 aq solution are presented below in the table B.8.1.2.1.1_CA-24. On their basis it was stated that the compound was stable.

Table B.8.1.2.1.1._CA-24: The results of the examination of the stability of the test item in the test solution.

I) Experimental conditions				
Amount of soil:		Test system without soil		
Amount of test solution in test vessel:		20 mL		
Concentration of the test item:		1.0 mg/L (nominal; highest concentration used in experiment)		
Equilibration time:		0 – 96 h		
II) Results				
Equilibraion time [Hours]	Replicate	Obtained results		
		Total radioactivity in the test vessel [%AR]	Radioactivity identified as Flufenacet	
			% in chromatogram	[% AR]

The results of the determination of the appropriate soil:solution ratio are presented below, in numerical form in the table B.8.1.2.1.1._CA-25 and in graphical form on figure B.8.1.2.1.1._CA-17. The abbreviations used on that graph to denominate test soils were following:

- AX for Laacher Hof AXXa soil;
- HH for Hoefchen am Hohenseh soil;
- HN for Hanscheider Hof soil;
- DD for Dollendorf II soil;
- WW for Wurmwiese soil.

Table B.8.1.2.1.1._CA-25: The numerical results of the determination of the appropriate soil:solution ratio.

Test soil	Soil solution ratio		Amount of Flufenacet remaining in solution [% AR]	Amount of Flufenacet sorbed onto soil [% AR]
	in g soil/mL solution	as ratio		
<i>Laacher Hof AXXa Loamy sand</i>	15/20	1:1.3	23.8	76.2
	10/20	1:2	33.0	67.0
	5/20	1:4	49.9	50.1
<i>Hoefchen am Hohenseh Silt loam</i>	15/20	1:1.3	27.9	72.1
	10/20	1:2	37.5	62.5
	5/20	1:4	55.6	44.4
<i>Hanscheider Hof Silt loam</i>	15/20	1:1.3	17.5	82.5
	10/20	1:2	24.6	62.5
	5/20	1:4	41.4	58.6
<i>Dollendorf II Loam</i>	15/20	1:1.3	13.4	86.6
	10/20	1:2	18.6	81.4
	5/20	1:4	32.5	67.5
<i>Wurmwiese Sandy loam</i>	15/20	1:1.3	29.1	70.9
	10/20	1:2	38.7	61.3
	5/20	1:4	57.8	42.2

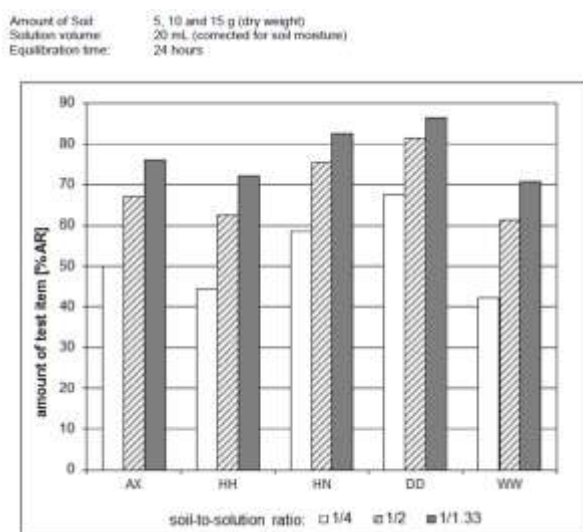

Figure B.8.1.2.1.1_CA-17: The graphical results of the determination of the appropriate soil:solution ratio – amount of Flufenacet adsorbed onto soil (copied from the study report).

On the basis of the obtained results, presented above, the soil:solution ratio 1:4 was selected to be used in further tests.

The results of the determination of the appropriate equilibration time are presented below, in numerical form in the table B.8.1.2.1.1_CA-26 and in graphical form on figure B.8.1.2.1.1_CA-18. The abbreviations used on that graph to denominate test soils were following:

- AX for Laacher Hof AXXa soil;
- HH for Hoefchen am Hohenseh soil;
- HN for Hanscheider Hof soil;
- DD for Dollendorf II soil;
- WW for Wurmwiese soil.

Table B.8.1.2.1.1_CA-26: The numerical results of the determination of the appropriate equilibration time.

Test soil	Replicate	Amount of Flufenacet adsorbed onto soil [% AR] after					
		0 hours	6 hours	24 hours	48 hours	72 hours	96 hours
Laacher Hof AXXa Loamy sand	1	1.8	45.6	49.2	50.2	50.8	50.8

The verification of the application rate of Flufenacet in the definitive test gave the following results:

- for the solution having a nominal concentration **1.0 mg Flufenacet/L** the measured concentration was **0.96 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.3 mg Flufenacet/L** the measured concentration was **0.28 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.1 mg Flufenacet/L** the measured concentration was **0.094 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.03 mg Flufenacet/L** the measured concentration was **0.028 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.01 mg Flufenacet/L** the measured concentration was **0.0095 mg Flufenacet/L**.

The results of the determination of the pH of supernatant after establishing the adsorption equilibrium in the definitive test are given below in the table B.8.1.2.1.1_CA-29. In the next table – B.8.1.2.1.1_CA-30 are presented the analogical results obtained for the desorption phase of the same test.

Table B.8.1.2.1.1_CA-29: The results of the determination of the pH of solution at equilibrium in the adsorption part of the definitive test.

Initial concentration of Flufenacet [mg/L]		Replicate	pH of the solution measured in the test system containing the test soil:

The results of the definitive phase – the concentrations of the test item – Flufenacet, at equilibrium for adsorption and desorption phases and the determined isotherms, are presented below, individually for each test soil.

a) Results obtained for the test soil Laacher Hof AXXA Loamy sand:

The numerical results obtained for the adsorption phase – concentrations of the test item in soil and solution at equilibrium and the % of the Flufenacet adsorbed onto soil, are presented below in the table B.8.1.2.1.1._CA-30.

Table B.8.1.2.1.1._CA-30: The numerical results of the experiment obtained for the adsorption phase.

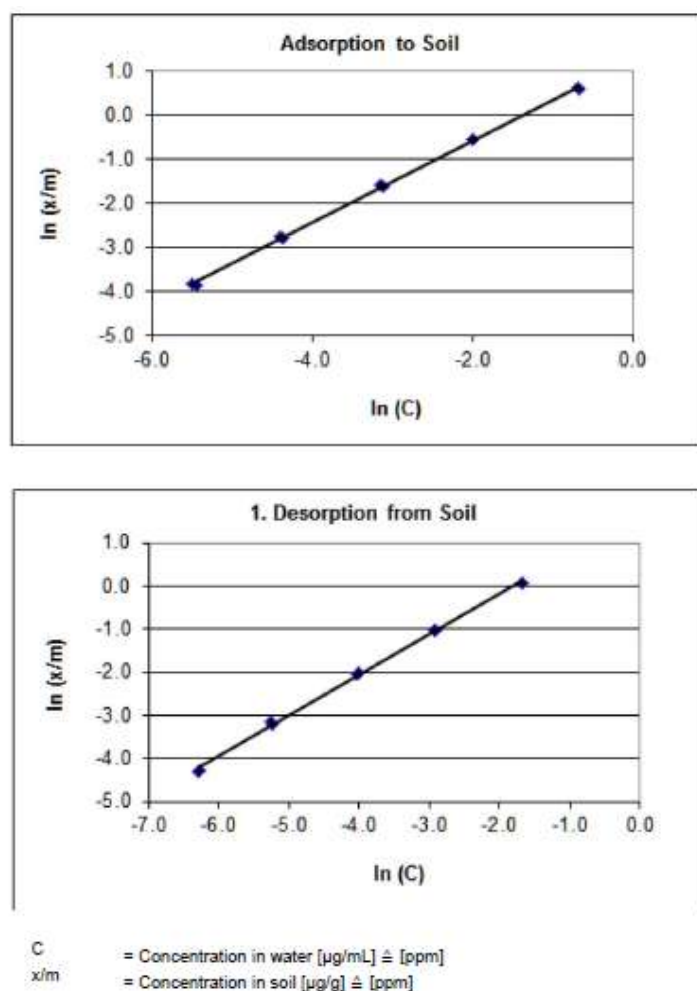

Initial concentration of Flufenacet [mg/L]		Replicate	Concentration of Flufenacet in				Amount adsorbed [% AR]
nominal	measured		Soil		Solution		
			x/m [µg/g]	Ln (x/m)	Ce [µg/mL]	Ln (Ce)	
1.0	0.96	1	1.824	0.60	0.507	-0.68	47.3
		2	1.804	0.59	0.512	-0.67	46.8
		mean	1.814	----	0.510	----	47.1
0.3	0.28	1	0.579	-0.55	0.135	-2.00	51.8
		2	0.575	-0.55	0.136	-2.00	51.5
		mean	0.577	----	0.135	----	51.6
0.1	0.094	1	0.204	-1.59	0.043	-3.15	54.3
		2	0.197	-1.63	0.045	-3.11	52.4
		mean	0.201	----	0.044	----	53.3
0.03	0.028	1	0.063	-2.76	0.012	-4.39	56.1
		2	0.062	-2.79	0.013	-4.36	54.6
		mean	0.062	----	0.013	----	55.3
0.01	0.0095	1	0.022	-3.83	0.004	-5.49	56.7
		2	0.021	-3.87	0.004	-5.45	54.8
		mean	0.021	----	0.004	----	55.8

The numerical results obtained for the desorption phase – concentration of the test item in soil and solution at equilibrium and the % of Flufenacet remaining adsorbed are presented below in the table B.8.1.2.1.1._CA-31.

Table B.8.1.2.1.1._CA-31: The numerical results of the experiment obtained for the desorption phase.

Desorption step 1 st							
Initial concentration of Flufenacet [mg/L]		Replicate	Concentration of Flufenacet in				Amount remaining adsorbed [% AR]
nominal	measured		Soil		Solution		
			x/m [µg/g]	Ln (x/m)	Ce [µg/mL]	Ln (Ce)

Final conclusion of the study:

The final results of the study – Freundlich adsorption parameters for Flufenacet obtained in each test soil, are presented below in the table B.8.1.2.1.1._CA-45. RMS considers these results reliable and possible to be used to derive input parameters for modelling.

In case of the desorption the results should be considered with care because the use of HgCl_2 as sterilising agent might have a considerable impact on them – the competitive sorption of mercury ions could possibly caused the higher desorption of the test compound.

Table B.8.1.2.1.1._CA-45: The definitive set of Freundlich adsorption parameters determined for Flufenacet in the study.

Parameter	Test soil				
	Laacher Hof AXXa Loamy sand	Hoefchen am Hohensch Silt loam	Hanscheider Hof Silt loam	Dollendorf II Loam	Wurmweise Sandy loam
$K_f [\text{mL/g}]$	3.555	3.280	5.101	7.495	3.319

Study 3:

Report: Stupp H. P. (2010): “[Phenyl-UL-¹⁴C] Flufenacet: Adsorption on Two Japanese Soils.”; Bayer CropScience AG – Development, Environmental Safety Metabolism/ADME and Environmental Fate, Alfred-Nobel-Str. 50, D-40789 Monheim am Rhein, Germany (performing laboratory) for Bayer CropScience K. K, 6-5 Marunouchi 1-chome, Chiyoda-ku, 100-8262 Tokyo, Japan; Study No. M1311954-4; Bayer Report No. MEF-10/534; 04. 08. 2010; study reference number: M-3875732-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Japanese MAFF New Test Guidelines for Supporting Registration of Pesticides, 12 Nousan 8147;
- OECD Guideline for the Testing of Chemicals No. 106, Adsorption/Desorption, 2000;

GLP: Yes;

RMS comments: This is a new study, submitted specifically for the purpose of the current assessment. It was evaluated for compliance with the following Guidelines:

- OECD Guideline for the Testing of Chemicals No. 106, Adsorption/Desorption, 2000;
- US EPA OCSPF Fate, Transport and Transformation Test Guidelines, OPPTS 835 1220, Sediment and Soil Adsorption/Desorption Isotherm, 1998;
- US EPA OCSPF Fate, Transport and Transformation Test Guidelines, OPPTS 835 1230, Adsorption/Desorption (Batch Equilibrium), 2008;

The following deviations were stated:

- Of the two test soils used in the study one – Ushiku Sandy loam soil, was of volcanic ash origin and as such not representative for the EU conditions. Also in case of that soil the history of the pesticide use on the collection site is not precise, what makes impossible to state whether Flufenacet or any plant protection product belonging to the same chemical group was used during 5 years prior to sampling.
- Test soils used in experiment were not freshly sampled, but stored after pre-processing (sieving and air-drying) for 19 months before being used. Additionally in case of Kamikawa Loam soil the date of sampling was not provided what makes impossible to estimate exact time elapsing between sampling and the beginning of storage period.
- Very atypical was soil solution ratio used in the definitive test – 3:20 when expressed in g soil:mL solution or 1:6.6667 when expressed as unitless ratio (the second ratio calculated by the RMS). Applicant however declared in the study report that that ratio was 1:7, substantially rounding the value representing the relative amount of solution in the test system. That however had only minimal influence on the obtained results.

RMS never the less decided to consider the study valid as in all other aspects it complied with the provisions of the reference Guidelines.

The study is summarised below.

Summary:

The aim of the study was to investigate soil sorption of Flufenacet onto two Japanese soils in line with the requirements of the Japanese MAFF New Test Guidelines for Supporting Registration of Pesticides. The experiment was performed according to the provisions of the OECD 106 Guideline. The test soils used in the experiment were Sandy loam soil of the volcanic ash origin (OECD type 2) and Loam soil of the alluvial origin (OECD type 4), representative for agriculturally used areas in Japan. Their brief characteristic is provided below in the table B.8.1.2.1.1_CA-46. It shall be noted that one of the test soils – Sandy loam soil, due to its origin cannot be considered representative for the EU. The test soils were collected from the top 30-cm layer using shovel, air-dried to sieve conditions, sieved through 2-mm sieve, placed in the plastic bag and transferred to the test laboratory. There they were stored for about 19 months at T = 5⁰C until being used. The Ushiku test soil was collected from turf field and Kamikawa test soil from paddy field. In case of the Ushiku soil it was stated, with regard to pesticide use history of the collection site, that it received conventional application, not explaining the meaning of the expression. For Kamikawa test soil it was stated that on the collection site no pesticides were used for 5 years prior to the sampling.

Table B.8.1.2.1.1._CA-46: The characteristic of soils used in the study.

Parameter	Soil	
	<i>Ushiku</i>	<i>Kamikawa</i>
Soil geographical origin	Ushiku, prefecture Ibaraki, Japan	Kamikawa, island of Hokkaido, Japan
Soil series	Volcanic ash (OECD type 2)	Alluvial soil (OECD type 4)
Soil type – USDA	Sandy loam	Loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	49
	Silt (2 – 50 µm) [%]	32
	Clay (< 2 µm) [%]	19
Soil pH	in CaCl ₂	4.9
	in water	5.3
	in KCl	4.4
Organic carbon content (OC) [%] ²⁾	4.3	2.1
Organic matter content (OM) [%]	7.4	3.6
Cation Exchange Capacity – CEC [mEq/100g]	15.9	12.2
Water holding capacity at 0.33 bar [% moisture]	41.9	36.5
Bulk density (disturbed) [g/cm ³]	0.78	0.97

Footnotes to the table:

1) As provided in the study report; recalculated from OM using the following equation: OC = OM/1.724.

The test compound used in the experiment was the ¹⁴C-FOE 5043 radiolabelled uniformly in phenyl ring, as shown below on figure B.8.1.2.1.1._CA-24.

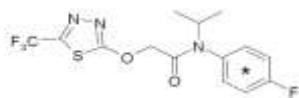

Figure B.8.1.2.1.1._CA-24: The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 6.11 MBq/mg (165.14 µCi/mg) and its radiochemical purity, determined using both HPLC and TLC, was > 99%. Also the chemical purity of the test compound, determined using HPLC equipped with UV detector, was > 99%.

The whole delivered sample was used to prepare a **stock solution**, by dissolving it in 5.5 mL of CH₃CN. The obtained solution had a nominal concentration 1 mg Flufenacet/mL and specific activity 6.132 MBq/mL. It was labelled **KR05SS** and used to prepare all other solutions containing the test compound – [¹⁴C]-Flufenacet, used in the experiment (**Application solutions**). The identity and purity of the test compound in the solution **KR05SS** was determined using ¹H-NMR and HPLC-MS/MS methods.

The **Application solutions** were prepared as aqueous solutions in 0.01 M CaCl₂ aq.

The 0.01 M CaCl₂ aq solution was prepared by dissolving 2.94 g of CaCl₂ x 2 H₂O in Milli-Q water in 2-L volumetric flask.

Five application solutions, labelled **Application solution A1 – E** and having concentrations of [¹⁴C]-Flufenacet in range 0.1 mg/L – 10.0 mg/L, were prepared.

To prepare the **Application Solution A1** 0.2 mL of the solution **KR05SS** was transferred into 20-mL volumetric flask and the solvent gently evaporated. The residue was re-dissolved in 20 mL of 0.01 M CaCl₂ aq and the so prepared solution was sonicated for 15 minutes to grant proper dissolution of the test item. The concentration of the so prepared **Application solution A1** was 10 mg/L. It was labelled **KR05APP-A1**.

To prepare the **Application Solution B** 0.06 mL of the solution **KR05SS** was transferred into 20-mL volumetric flask and the solvent gently evaporated. The residue was re-dissolved in 20 mL of 0.01 M CaCl₂ aq and the so prepared solution was sonicated for 15 minutes to grant proper dissolution of the test item. The concentration of the so prepared **Application solution B** was 3.0 mg/L. It was labelled **KR05APP-B**.

To prepare **Application Solution C** 2.0 mL of the solution **KR05APP-A1** was transferred into 20-mL volumetric flask and diluted to 20 mL with 0.01 M CaCl_2 aq. The concentration of the so prepared **Application solution C** was 1.0 mg/L. It was labelled **KR05APP-C**.

To prepare **Application Solution D** 2.0 mL of the solution **KR05APP-B** was transferred into 20-mL volumetric flask and diluted to 20 mL with 0.01 M CaCl_2 aq. The concentration of the so prepared **Application solution D** was 0.3 mg/L. It was labelled **KR05APP-D**.

To prepare **Application Solution E** 2.0 mL of the solution **KR05APP-C** was transferred into 20-mL volumetric flask and diluted to 20 mL with 0.01 M CaCl_2 aq. The concentration of the so prepared **Application solution E** was 0.1 mg/L. It was labelled **KR05APP-E**.

The study was carried out using 43-mL Teflon centrifuge tubes with screw caps as test vessels. Additionally, in the test examining the adsorption of the test item onto the surface of the test vessels the glass vessels were used as well.

The study consisted of the following experiments:

- **Preliminary tests**, during which were determined:
 - Stability of the test item;
 - Adsorption of the test item onto the surface of the test vessels;
 - Adequate soil:solution ratio;
 - Adequate equilibrium time for adsorption;
 - Mass balance of the test compound – Flufenacet;
- **Definitive test**, consisting of:
 - Determination of Freundlich adsorption isotherm and its parameters – Freundlich adsorption constant $K_{F\text{ ads}}$ and corresponding $1/n$ value, in a single-step experiment;

All experiments were performed in a walk-in climatic chamber, at constant temperature $T = 25 \pm 2^\circ\text{C}$. The temperature in the experimental chamber was continuously monitored and the results of that monitoring are presented in section “Results and their discussion”, further down the summary.

For agitation (shaking) of the test vessels containing test soil and test solutions the mechanical overhead shaker, set to 30 rpm, was used.

The test aimed on the examination of the stability of the test item and adsorption of the test item onto the surface of the test vessels was performed in the systems without soil. It was carried out using Teflon or glass test vessels containing 20 mL of the **Application solution A1** and lasted 48 hours.

All experiments with soil started with the pre-equilibration of the test systems. To do that firstly the designated amounts of each test soil (dry weight) were weighed into centrifuge tubes. Next, the appropriate amount of 0.01 M CaCl_2 aq solution was added. The volume of the added liquid was always such, to obtain a total solution volume of 18 mL, taking into account the residual soil moisture.

The so prepared test vessels were sealed and pre-equilibrated for at least 24 hours in the dark by agitation at constant temperature $T = 25^\circ\text{C}$.

After pre-equilibration 2 mL of the adequate **Application solution (A1 – E)**, characterised above, was added to obtain the final solution volume of 20 mL. All preliminary tests were carried out using the **Application Solution A1** – that having the highest nominal test concentration of 1.0 mg Flufenacet/mL.

The definitive test aimed on the examination of the adsorption was carried out using all five application solutions – **Application solution A1 – Application solution E**, to cover the concentration range (nominal) of 0.01 – 1.0 mg Flufenacet/mL.

After introduction of the test compound the test vessels were closed and the suspensions agitated for the appropriate amount of time. After that period samples were centrifuged and the supernatants decanted. Their aliquots were analysed by LSC and HPLC. Additionally the pH of the supernatants was measured.

The remaining soil samples were freeze-dried and analysed, after combustion, by LSC. That was done to calculate the mass balance.

In case of the preliminary test, aimed on the determination of Parental Mass Balance, the soil samples remaining after decantation of supernatant were also analysed (extracted and obtained organic extracts analysed by LSC and HPLC) for the content of the test compound.

All test were performed using the duplicate samples.

The specific conditions of the performance of each experiment are presented below.

The adequate soil:solution ratio was determined for both test soils by examining the following ratios:

- 1:4 – 5 g soil (d. w.) and 20 mL solution;
- 1:7 – 3 g soil (d. w.) and 20 mL solution;
- 1:20 – 1 g soil (d. w.) and 20 mL solution;

That was done in the following way: firstly the appropriate portions of each test soils were weighed to the test vessels and 18 mL 0.01 M CaCl_2 _{aq} solution were added. So prepared test vessels were pre-equilibrated for 24 hours as described above. Next 2 mL of the **Application solution A1** were added to each test vessel, vessels were sealed and agitated for 24 hours. After that period the samples were centrifuged for 10 minutes at 4000 rpm, supernatants decanted and their three 500- μL aliquots analysed by LSC.

The adequate adsorption equilibrium time was determined for all test soils. The soil:solution ratio used in this test was 1:7. The test systems were prepared in duplicate for each test soil and pre-equilibrated for 24 hours, as already described. After pre-equilibration to each sample 2 mL of the **Application solution A1** were added. The samples were then agitated for up to 48 hours. At the pre-defined time points – 6, 24 and 48 hours after treatment samples were centrifuged for 10 minutes at 4000 rpm and 500- μL aliquots of clarified supernatants taken for LSC analysis.

The mass balance of the test item – Flufenacet, was examined in the following way: the samples were prepared in duplicate and pre-equilibrated for the 48-hours in a way described above (3 g test soil, 18 mL of 0.01M CaCl_2 _{aq} solution). The selected soil:solution ratio was 1:7. After pre-equilibration 2 mL of the **Application solution A1** were added to each test vessel. After application the samples were equilibrated, by agitating, for 48 hours, then centrifuged for 10 minutes at 4000 rpm and clarified supernatants collected for analysis by LSC (50- μL aliquots) and HPLC.

The soils remaining in the test vessels after decantation of supernatants were extracted by shaking them with three 10-mL portions of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 80:20 v/v. After each extraction cycle samples were centrifuged, supernatants decanted and combined, and their total volume determined. Three 250- μL aliquots of each combined extract were analysed by LSC. Extracts were also analysed by HPLC.

The definitive test aimed on the determination of Freundlich adsorption isotherm and Freundlich sorption parameters was carried out following the the procedure preseneted below on figure B.8.1.2.1.1._CA-24. For examining it the following initial (nominal) concentrations of the test item – [^{14}C]-Flufenacet, were used: 0.01 mg/L, 0.03 mg/L, 0.1 mg/L, 0.3 mg/L and 1.0 mg/L.

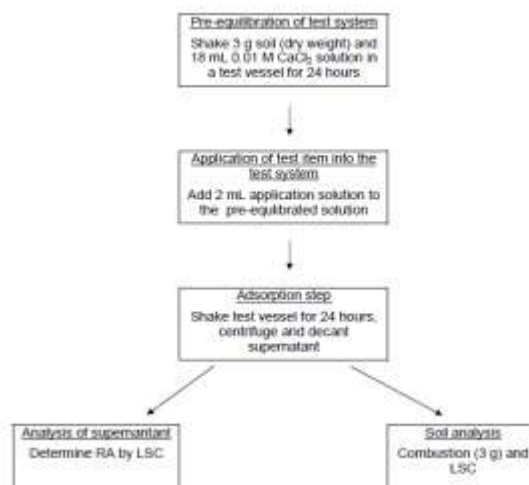

Figure B.8.1.2.1.1._CA-24: The flow chart of the experimental procedure for the definitive test (copied from the study report).

All liquid samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a LS6000LL/LS6500 or LKB-Wallac 1219 Spectral counters.

The samples having a volume up to 500 µL were analysed for the radioactivity content in mini-vials with 2 mL of Quicksafe® A solution containing 5% of water. The counting time was 10 min and the background 13 – 15 cpm. The analysis was performed using LS6000LL/LS6500 counter.

The radioactivity in solid samples – soil samples remaining after decantation of liquid phase, was determined after combustion of dried material. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxysolve C400 liquid. The counting time was 10 min and the background 18 – 20 cpm and the counting instrument LKB-Wallac 1219 Spectral counter.

The instrumental limit of detection – LOD_i was set to twice maximum instrument background count rate and instrumental limit of quantitation – LOQ_i to three times maximum instrument background count rate. The maximum instrument background count rate was determined to be 0.3 Bq. As a result the instrumental $\text{LOD}_i = 0.6 \text{ Bq}$ and $\text{LOQ}_i = 1.8 \text{ Bq}$.

The RP-HPLC analysis was performed in a gradient mode. The system consisted of Agilent 1200 Series chromatograph workstation equipped with a UV detector set at $\lambda = 254 \text{ nm}$, coupled with Ramona Star radioactivity detector. The chromatographic separation was performed on LiChrospher100 RP 18e 250 mm * 4.6 mm * 5 µm chromatographic column. It worked in the following gradient regime:

- **Mobile phase A:** water + 0.1% HCOOH,
- **Mobile phase B:** CH_3CN + 0.1% HCOOH,
- **Gradient mode:** is presented below in the table B.8.1.2.1.1._CA-47;
- Total run time was 66 minutes.

Table B.8.1.2.1.1._CA-47: The gradient mode used in the analysis.

Time [min.]		0	5	60	65	66
Gradient	% A	100	100	0	0	100
	% B	0	0	100	100	0

The flow rate was set to 1.5 mL/min. The chromatographic column was kept under the constant temperature $T = 40^\circ\text{C}$. The identification of the test compound – Flufenacet, was carried out by means of the comparison of the retention times. For Flufenacet the retention time R_t was approx. 44 min.

The LC-MS analysis was performed as HPLC/MS analysis. It was carried out using Agilent HP1100 HPLC system equipped with a Nucleodur Gravity C_{18} chromatographic column (250 * 2 mm, 3 µm), UV detector followed by the Ramona Star radiodetector and LTQ Orbitrap XL mass spectrometer.

The parameters of chromatographic analysis were following:

- column temperature: 40°C ,
- flow rate: 0.2 mL/min,
- elution mode: gradient,
- mobile phase:
 - Solvent A: H_2O + 0.1% HCOOH,
 - Solvent B: CH_3CN + 0.1% HCOOH.
- The gradient programmes used in the analysis is presented below in the table B.8.1.2.1.1._CA-48:

Table B.8.1.2.1.1._CA-48: The gradient mode used in the analysis.

Time [min.]		0	1	25	35
Gradient	% A	95	95	5	5
	% B	5	5	95	95

The calculations of the Freundlich sorption parameters were performed using the equations presented below on figure B.8.1.2.1.1._CA-25.

Freundlich isotherm	Log-transformed Freundlich isotherm	Equation used in calculation of $K_{F\text{OC}}$
$\frac{x}{m} = K_F \cdot C^{1/n}$ <p> C: concentration of a.i. in solution at equilibrium x/m: adsorbed amount of a.i. per weight unit of adsorbent (soil) at equilibrium ($\mu\text{g/g}$) K_F: Freundlich constant n: dimensionless </p>	$\ln\left(\frac{x}{m}\right) = \frac{1}{n} \cdot \ln(C) + \ln(K_F)$	$K_{oc} = \frac{K_F \cdot 100}{\%C_{oc}}$ <p>$\%C_{oc}$: portion of organic carbon in soil expressed as% of weight</p>

Figure B.8.1.2.1.1._CA-25: The equations used in the calculations of the Freundlich sorption parameters.

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in table B.8.1.2.1.1._CA-46. It may be stated that the test soils meet the acceptability criteria with regard to their textural characteristic, pH range and OC content range. However, one of the test soils – Ushiku Sandy loam soil, was of the volcanic origin. For that reason the results obtained for that soil, although partly presented in this summary (due to the fact that the results for both test soils were presented together) cannot be considered acceptable, because they are not representative for the EU conditions.

The results of the monitoring of the temperature during the experiment are presented below on figure B.8.1.2.1.1._CA-26. On their basis it was stated that the mean $T = 25.21^{\circ}\text{C}$ and its range $25.00 - 25.55^{\circ}\text{C}$. It was therefore within the pre-defined limits of $T = 25 \pm 2^{\circ}\text{C}$. It may be also stated that the temperature was constant within the study period, so all thermodynamic experiments, and in particular that aimed on the determination of the sorption isotherms, returned reliable results.

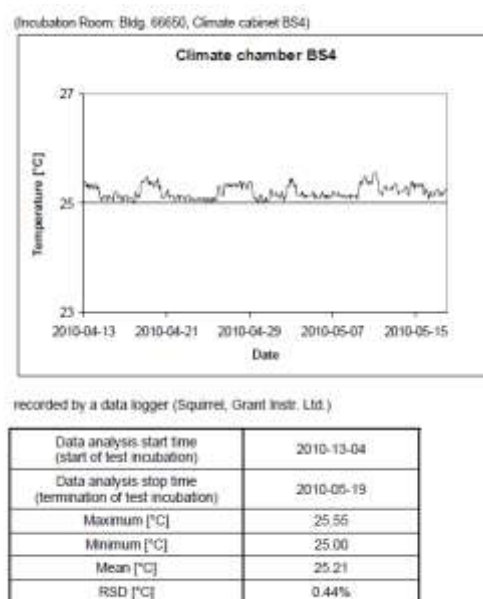

Figure B.8.1.2.1.1._CA-26: The graphical results of the monitoring of the temperature during the study (copied from the study report).

On the basis of the results of the determination of LOD and LOQ for LSC analysis it was stated that the method was well suited for the analysis of the samples from the lowest treatment concentrations.

The LOD and LOQ for the radio-HPLC method were determined to be $\text{LOD} = 0.2\% \text{ AR}$ and $\text{LOQ} = 3 \cdot \text{LOD} = 0.6\% \text{ AR}$.

The results of the examination of the test item – Flufenacet, in the test solution and its adsorption onto the surface of the test vessels are presented below in the table B.8.1.2.1.1._CA-49. On their basis it was stated that Flufenacet was stable in the test system and it did not adsorb onto the test vessels.

Table B.8.1.2.1.1._CA-49: The results of the examination of the stability of the test item in the test solution.

I) Experimental conditions				
Amount of soil:		Test system without soil		
Amount of test solution in test vessel:		20 mL

The results of the determination of the appropriate soil:solution ratio are presented below, in numerical form in the table B.8.1.2.1.1._CA-50 and in graphical form on figure B.8.1.2.1.1._CA-27. The abbreviations used on the figure stand for: U – Ushiku soil, K – Kamikawa soil.

Table B.8.1.2.1.1._CA-50: The numerical results of the determination of the appropriate soil:solution ratio.

Test soil	Soil solution ratio		Amount of Flufenacet remaining in solution [% AR]	Amount of Flufenacet sorbed onto soil [% AR]
	in g soil/mL solution	as ratio		
Ushiku	1/20	1:20	82.9	17.1
	3/20	1:7	51.1	49.0
	5/20	1:4	36.6	63.4
Kamikawa	1/20	1:20	77.8	22.2
	3/20	1:7	48.1	51.9
	5/20	1:4	33.7	66.3

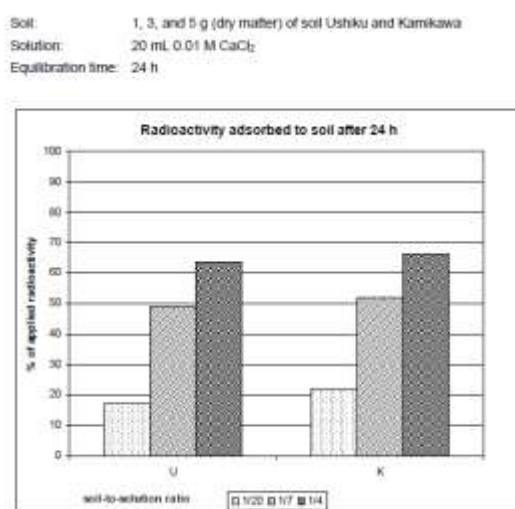

Figure B.8.1.2.1.1._CA-27: The graphical results of the determination of the appropriate soil:solution ratio – amount of Flufenacet adsorbed onto soil (copied from the study report).

On the basis of the presented above obtained results, the soil:solution ratio 1:7 (3:20) was selected to be used in further tests.

The results of the determination of the appropriate equilibration time are presented below, in numerical form in the table B.8.1.2.1.1._CA-51 and in graphical form on figure B.8.1.2.1.1._CA-28. The abbreviations used on that graph to denominate test soils were following:

- U for Ushiku Sandy loam soil;
- K for Kamikawa Loam soil.

Table B.8.1.2.1.1._CA-51: The numerical results of the determination of the appropriate equilibration time.

Test soil	Replicate	Amount of Flufenacet [% AR] after equilibration time:							
		0 hours		6 hours		24 hours		48 hours	
		in supernatant	adsorbed onto soil	in supernatant	adsorbed onto soil	in supernatant	adsorbed onto soil	in supernatant	adsorbed onto soil
<i>Ushiku Sandy loam</i>	1	78.7	21.3	50.2	49.8	44.2	55.8	41.4	58.6
	2	76.6	23.4	50.5	49.5	44.6	55.4	40.1	59.9
	mean	77.7	22.3	50.3	49.7	44.4	55.6	40.7	59.3
<i>Kamikawa Loam</i>	1	66.6	33.4	44.6	55.4	41.4	58.6	38.5	61.5
	2	65.8	34.2	43.3	56.7	41.5	58.5	38.7	61.3
	mean	66.2	33.8	44.0	56.0	41.5	58.5	38.6	61.4

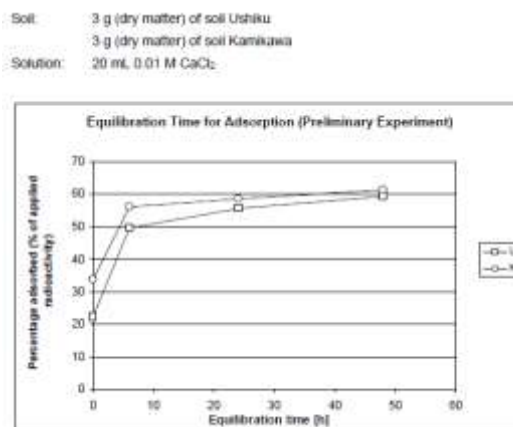

Figure B.8.1.2.1.1._CA-28: The graphical results of the determination of the appropriate equilibration time (copied from the study report).

The results of the determination of the mass balance, performed as one of the preliminary tests for each test soil, are presented below in the table B.8.1.2.1.1._CA-52. In the next table – B.8.1.2.1.1._CA-53 are presented the results of the determination of the mass balance performed for the definitive tests.

Table B.8.1.2.1.1._CA-52: The results of the determination of the mass balance carried out in Preliminary Parental Mass Balance Test.

Test soil	Radioactivity recovered (mean of two replicates) in:					
	<i>CaCl₂ solution</i>		<i>Soil organic extracts</i>		<i>Total recovered</i>	
	as Total Radioactivity [% AR]	as Flufenacet [% AR]	as Total Radioactivity [% AR]	as Flufenacet [% AR]	as Total Radioactivity [% AR]	as Flufenacet [% AR]
<i>Ushiku Sandy loam</i>	37.3	37.3	66.5	66.5	103.8	103.8
<i>Kamikawa Loam</i>	37.5	37.5	67.3	67.3	104.8	104.8

Table B.8.1.2.1.1._CA-53: The results of the determination of the recovery of radioactivity in the definitive test – after adsorption and desorption steps.

Initial (nominal) concentration of Flufenacet	Total radioactivity recovery, expressed in [% AR], in experiment with the test soil:	
	<i>Ushiku Sandy loam soil</i>	<i>Kamikawa Loam soil</i>
1.0	96.5	94.1
0.3	99.3	98.9
0.1	99.0	98.4
0.03	98.8	96.7
0.01	96.5	96.2
Mean recovery (with SD)	98.0 (1.3)	96.9 (1.7)

The verification of the application rate of Flufenacet in the definitive test gave the following results:

- for the solution having a nominal concentration **1.0 mg Flufenacet/L** the measured concentration was **1.000 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.3 mg Flufenacet/L** the measured concentration was **0.292 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.1 mg Flufenacet/L** the measured concentration was **0.087 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.03 mg Flufenacet/L** the measured concentration was **0.029 mg Flufenacet/L**;
- for the solution having a nominal concentration **0.01 mg Flufenacet/L** the measured concentration was **0.009 mg Flufenacet/L**.

The results of the determination of the pH of supernatant after establishing the adsorption equilibrium in the definitive test is given below in the table B.8.1.2.1.1._CA-54.

Table B.8.1.2.1.1._CA-54: The results of the determination of the pH of solution at equilibrium in the adsorption part of the definitive test.

Initial concentration of Flufenacet [mg/L]		Replicate	pH of the solution measured in the test system containing the test soil:

The graphical results of the experiment – Freundlich adsorption isotherms for Flufenacet in Ushiku and Kamikawa soils are presented below on figure B.8.1.2.1.1._CA-29. The numerical results – Freundlich adsorption parameters for Flufenacet in Kamikawa soil are presented in the table B.8.1.2.1.1._CA-57. The values obtained in Ushiku soil are presented for completeness. RMS however decided to mark them in italics in order to indicate that they will not be used in the subsequent assessment because of the very limited utility. That is due to the fact that Ushiku soil is of volcanic origin, therefore not representative for the EU agriculturally used areas.

C: Concentration in water in $\mu\text{g/mL}$ (ppm)
 x/m: Concentration in soil in $\mu\text{g/g}$ (ppm)

Evaluation of linear regression according to FREUNDLICH:

Soil		Ushiku	Kamikawa
Regression	R^2	0.9996	0.9973

Study 4:

Report: Christensen K. P., Yen P. Y., (1994): “FOE 5043 – determination of the Adsorption and Desorption Properties in Canadian Soils.”; Springborn Laboratories Inc., Environmental Sciences Division, 790 Main Street, Wareham, Massachusetts 02571-1075, USA (performing laboratory) for Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120, USA; Springborn Laboratories Report No #94-5-5256; Miles Inc. Study No. F3182103, Miles Inc. Report No. 106578, ; Bayer Report No. MR 106578; 12 September 1994; study reference number: M-002186-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Canadian Guidelines T-1-255 # 6.2, B-1 Adsorption/Desorption Measurements.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.1.1, in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. For the present authorisation in the EU the study was evaluated for its compliance with OECD Guideline for the Testing of Chemicals 106 – Adsorption-Desorption Using a Batch Equilibrium Method. Additionally the study was checked for its validity against the US EPA Fate, Transport and Transformation Test Guideline OPPTS 835.1220 – Sediment and Soil Adsorption/Desorption Isotherm. and SETAC Guidance Document “Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides.” It was stated that the study generally complied with the provisions of the three evoked Guidance documents. However, in the study report in section reporting the protocol deviations it was stated, as a first deviation listed, that although the study was declared to be carried out in constant temperature $T = 20 \pm 2^{\circ}\text{C}$, the temperature actually recorded during the whole study duration ranged from 15.9°C to 22.9°C . That deviation was considered by the study director to have an insignificant influence on the obtained results, but it shall be indicated that the 5°C -difference in temperature recorded during the equilibrium test aimed on the determination of the time necessary for reaching the equilibrium state may have a significant impact on the results. As a result, the RMS – Poland is of the opinion that although study generally complies with the provisions of the relevant Guidelines, it cannot be considered acceptable for the scientific reason – because of high uncertainty of the determined thermodynamical parameters, in particular Freundlich isotherm constant, due to the reported fluctuations of the temperature during the experiment. The issue is discussed in details in the brief summary provided below. Finally, it shall be stated that, because of the stated lack of reliability of the adsorption parameters determined in the study, the results of this study will not be included into the List of End Points nor used to derive the input parameters for the model GW and SW exposure assessment for Flufenacet.

Summary:

The aim of the study was to investigate soil sorption of Flufenacet onto two Canadian soils in line with the requirements of the Canadian Guideline T-1-255 #6.2, B. The test soils used in the experiment were Loam and Silt loam originating from Ontario, Canada. Their brief characteristic is provided below in the table B.8.1.2.1.1._CA-58.

Table B.8.1.2.1.1._CA-58: The characteristic of soils used in the study.

Parameter		Soil	
		Loam	Silt loam
Soil origin		Harriston, Ontario, Canada	St. George, Ontario, Canada
Soil type ¹⁾		Loam	Silt loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	42	20
	Silt (2 – 50 µm) [%]	50	56
	Clay (< 2 µm) [%]	8	24
pH (measurement medium not defined)		7.1	7.3
Organic carbon content (OC) [%] ²⁾		4.3	2.8
Organic matter content (OM) [%]		7.3	4.7
Cation Exchange Capacity – CEC [mEq/100g]		14.6	17.1
Water holding capacity	at ½ bar [g H ₂ O/100 g soil]	32.2	27.1
	at 15 bar [g H ₂ O/100 g soil]	21.0	20.1
Bulk density (disturbed) [g/cm ³]		0.91	0.96

Footnotes to the table:

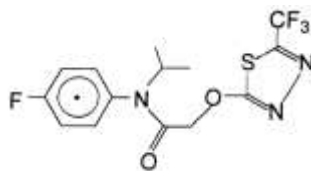

1) As declared in the study report;

2) As provided in the study report; recalculated from OM using the following equation: OC = OM/1.7.

The test soils were representative for the agricultural regions in which Flufenacet was intended to be used. They were collected from the pasture/hayfield sites in Ontario, on which no pesticides were used for 5 years prior to the sampling. Soil samples were taken from the top 15-cm layer and placed in plastic bags shipped directly to the test facility. There they were stored refrigerated until being used.

At the beginning of the experiment the test soils were sieved through 2-mm sieve to remove skeletal elements – rocks and large plant parts, and their portions were sent to the laboratory performing characterisation of soil properties. The determination of the soil moisture content was performed in the test facility at the beginning of each stage of the testing of soil equilibrium sorption of Flufenacet.

The test compound was [¹⁴C]-Flufenacet radiolabelled uniformly in fluorophenyl ring. Its declared radiochemical purity was 98.98 – 99.1% and specific activity 66.5 mCi/mmol. The structural formula is presented below on figure B.8.1.2.1.1._CA-30.

**Figure B.8.1.2.1.1._CA-30:** The structural formula of the test compound. The radiolabelling position is indicated by the asterisk (*) (copied from the study report).

Also the non-radiolabelled Flufenacet was used in the experiment. It had the chemical purity of 99.6%.

The characterised above radiolabelled test compound was used to prepare the **Stock solution** in acetonitrile, having a concentration 0.0867 mg Flufenacet/mL and radiochemical purity of 99.9%. That solution was used to prepare two **secondary stock solutions**, both containing radiolabelled and non-radiolabelled test compound.

The first of them, **fortification secondary stock solution** had concentration of the test item 14.9 mg/mL. The second, **additional secondary stock solution** was prepared by diluting the **fortification secondary stock solution** 100 times (to the concentration of the test item 0.149 mg/mL) with acetone.

The test solutions were prepared by diluting the appropriate amounts of the **Stock solutions** with 0.01 M CaCl₂ or ASTM type II water.

The examination of the soil equilibrium soil sorption of Flufenacet consisted of the following tests:

- **Screening test**, in which were determined the approximate distribution coefficients (K_d) for Flufenacet in each soil and established the soil:solution ratio optimal to provide ~50% of the applied amount of Flufenacet in the liquid phase;
- **Equilibrium test** aimed on the determination of the time necessary for reaching the equilibrium between the adsorbed and dissolved test item;
- **Isotherm determination**, in which the adsorption and desorption isotherms were determined.

The concentrations of the test compound – Flufenacet, were determined only in liquid phase by LSC and HPLC analysis. The amounts remaining in the adsorbent – soil, were calculated as a difference between the initial amount in the test system and that determined in the liquid phase at the end of each test.

The preliminary experiments showed that Flufenacet was stable in the system and did not adsorb to the test vessels. The optimum soil:solution ratio was determined to be 1:5 and the optimum equilibration time – 24 hours for Loam soil and 48 hours for Silt loam soil.

The Freundlich sorption isotherms were determined using the following initial concentrations of the test item: 0.21 mg/L, 1.0 mg/L, 5.1 mg/L and 14.2 mg/L.

In Loam soil the % of the test compound adsorbed after equilibration ranged from 46.0% to 51.9%. The three-cycle desorption resulted in desorption of the 81.1% of Flufenacet adsorbed onto soil.

In Silt loam soil the % of the test compound adsorbed after equilibration was 36.6 – 54.0%. The three-cycle desorption resulted in approx. 90.7% of the adsorbed Flufenacet being desorbed.

For each test soil the Freundlich adsorption isotherm and Freundlich desorption isotherm were determined.

Characterising the protocol deviations the Study director stated that:

- the testing was intended to be performed at $T = 20 \pm 2^{\circ}\text{C}$, in line with the recommendations of the relevant Guidelines;
- actually, the temperature during the whole testing fluctuated from $T = 15.9^{\circ}\text{C}$ to $T = 22.9^{\circ}\text{C}$, so the difference between the lowest and highest value recorded during the study was 7°C ;
- in case of the screening test the measured temperature was in range $15.9 - 22.8^{\circ}\text{C}$ (the difference 6.9°C);
- in case of the equilibrium test the measured temperature range was $17.9 - 22.9^{\circ}\text{C}$ (the difference 5.0°C);
- in case of the determination of adsorption and desorption isotherms for Flufenacet in Loam soil the measured temperature was in range $17.1 - 21.5^{\circ}\text{C}$ (the difference 4.4°C);
- in case of the determination of adsorption and desorption isotherms for Flufenacet in Silt loam the range of the measured temperature was $17.5 - 21.7^{\circ}\text{C}$ (the difference 4.2°C);
- additionally, although it was declared that the temperature records would be collected daily during the experiment, on one day it was not;
- the problems described above were attributed to the equipment malfunctioning;
- at the same time it was stated that although the overall range was relatively large, as well as that measured in the screening test, in later stages it was $\leq 1^{\circ}\text{C}$;
- as a final conclusion it was stated that “*in this case, the slight difference in temperature probably did not significantly affect the results.*”.

It shall be indicated that in the study report the detailed data on the temperature recorded during the study were not provided. As a result it is very difficult to verify some of the statements, in particular the penultimate one.

RMS does not fully agree with the final conclusion: the 4°C -difference cannot be considered a “*slight difference in temperature*”, in particular in case when the thermodynamic constants are determined, and such is the Freundlich adsorption constant. It shall be also pointed out that the significant difference in temperature recorded in the screening test might already have compromised the results, as the test was performed using the solution containing the test item. It shall be indicated that the whole experiment is based on the determination of the distribution at equilibrium of the compound in liquid and solid phases. The test item is organic compound of limited solubility in aqueous solutions ($S_{\text{aq}} = 56 \text{ mg/L}$ at $T = 20^{\circ}\text{C}$), so the temperature may be a driving factor in the experiment, especially in case it rises. Finally, aqueous solubility of the organic compound in function of time may not be linear, therefore it may be very difficult to predict how that influenced the results. Last but not least, lack of data presenting the changes of the temperature during the experiment makes it impossible to assess how the fluctuations reported above influenced the results.

All that taken into account RMS is of the opinion that due to the deviations reported above the obtained results, and in particular the determined Freundlich sorption parameters bear to significant level of uncertainty to be considered reliable.

As a result, RMS decided not to present them in the summary, include them in the List of End Points nor to use them to derive the input parameters for Flufenacet to be used in model GW and SW exposure assessment (calculation of the PEC values).

Additionally the data on the soil sorption of Flufenacet at equilibrium were provided in three open-source publications summarised below as **Studies 5-7**. It shall be indicated that two of them have already been summarised in this Renewal Assessment Report as they covered also the issue of degradation of Flufenacet in soil examined under laboratory conditions and its dissipation in soil under field conditions.

Study 5:

Report: Gupta S., Gajbhiye V. T., Agnihotri N. P. (2001): “Adsorption-Desorption, Persistence and Leaching Behavior of Flufenacet in Alluvial Soil of India.”; Division of Agricultural Chemicals, Indian Agricultural Research Institute, New Delhi 110 012, India; published study - published in: “Bulletin of Environmental Contamination and Toxicology”, vol. 66, 2001, pp 9-16.

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper

RMS comments: The paper presents the results of the examination of soil equilibrium sorption (determination of Freundlich sorption isotherms), mobility in soil profile (column leaching experiment) and persistence in aerobic and anaerobic soil, for Flufenacet. The experiments were performed using one test soil. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with the OECD 307 guideline for soil persistence, OECD 106 Guideline for examining batch sorption and OECD 312 for column leaching. The level of details was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below, in this section of the Assessment Report for its part examining the soil sorption (adsorption and desorption) of Flufenacet in soil under laboratory conditions. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and confirmatory to the endpoints provided by the regulatory studies submitted by the Applicant, and should not be used as a source of regulatory endpoints.

Summary:

The Editor has not provided the abstract for that publication. However the paper contained the introduction, clearly outlining the aims and scope of the research activity described in it, which may be considered a summary of the study. Due to the copyright restrictions, RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the mobility and persistence of Flufenacet in soil. The test soil used in the experiment was an agricultural soil, of the type of inceptisol, having the following physicochemical properties:

- **particle size distribution:** 64.7% sand, 15.6% silt and 19.7% clay;
- **soil texture class:** Sandy loam;
- **pH:** 7.1;
- **OC:** 0.34%;
- **Moisture content at FC (field capacity):** 20%.

The soil used in the experiment was freshly sampled from the top 15-cm layer of the fields of Indian Agricultural Research Institute in New Delhi, India. It was then air-dried and sieved through 2-mm mesh screen before being used.

The test compound was analytical grade Flufenacet, having a purity of > 99.5%, provided by M/s Bayer India Ltd. It was applied to the test soil in form of aqueous solution in 0.01 N (0.005 M) CaCl_2 aq, prepared from the stock solution of Flufenacet in acetone, having a concentration of 0.5 mg/mL.

The aliquot of this solution was transferred into the glass tube and left at $T = 25 \pm 2^\circ\text{C}$ to evaporate acetone. The residue was reconstituted in 0.01N (0.005 M) CaCl_2 aq. That solution was used as a treatment solution in the experiment examining batch sorption of Flufenacet.

As a first step was performed a preliminary experiment aimed on the determination of appropriate equilibration time. It was performed in glass tubes containing 10 g soil and 20 mL solution – 0.01N (0.005 M)

CaCl₂ _{aq} spiked with 0.5 mg Flufenacet. That gave the soil:solution ratio 1:2. In the paper it was not determined on what basis that ratio was selected. The so prepared samples were equilibrated for 1, 2, 4, 6 and 24 hours by shaking on horizontal shaker. After that time samples were removed, centrifuged and clear supernatants analysed for the content of the test compound – Flufenacet. It was stated that the maximum sorption occurred during the first four hours. Therefore the 4-hours equilibration time was selected as optimum for further examination.

The main test – the examination of the adsorption of Flufenacet onto soil at equilibrium in order to determine the parameters of Freundlich adsorption isotherm sorption was carried out in glass tubes containing the test soil and 0.01N CaCl₂ _{aq} solution in ratio 1:2 (10 g soil: 20 mL solution). The test compound – Flufenacet was introduced into the system in the solution. Its initial concentrations were: 0.1 mg/L, 0.5 mg/L, 1 mg/L, 2 mg/L, 5 mg/L, 10 mg/L 20 mg/L and 30 mg/L. The equilibration time was 4 hours and the temperature $T = 25 \pm 2^{\circ}\text{C}$. Samples were prepared in duplicate. After equilibration samples were centrifuged for 10 min at 2000 rpm, clarified supernatants decanted, their 10-mL aliquots diluted with saturated NaCl aqueous solution and extracted with 3 30-mL portions of CH₂Cl₂. Organic extracts were collected, combined and dried by passing through anhydrous Na₂SO₄. The combined organic extract was then evaporated to dryness, reconstituted in n-hexane and analysed by GC-ECD.

The desorption isotherm was determined in a separate study using one concentration of the test compound – 30 mg Flufenacet/L (highest concentration tested in the experiment on adsorption). The soil:solution ratio was 1:2 and the samples containing the test compound were equilibrated for 4 hours. After that time samples were centrifuged, supernatant decanted and a fresh 20-mL portion of a blank 0.01N (0.005 M) CaCl₂ _{aq} solution added. The samples were equilibrated for another 4 hours and then centrifuged and the clarified supernatants collected and processed in the same way as described for the adsorption phase. The procedure was repeated five times to obtain the data for five-step desorption process.

All samples were analysed using GC-ECD technique on Helwett Packard 5890 Gas Chromatograph equipped with ⁶³Ni electron capture detector. The separation was performed on megabore HP-1 capillary GC column, 10-metres long, 0.53-mm of internal diameter and having 2.65 µm-thick film. The GC oven was programmed at initial temperature of $T = 160^{\circ}\text{C}$ lasting for 9 minutes, then increasing at rate $30^{\circ}\text{C}/\text{min}$ to $T = 260^{\circ}\text{C}$, held at that level for 3 minutes. The carrier gas was N₂ administered at a rate 15 mL/min.

For Flufenacet the $R_t = 7.4$ min. The LOQ = 0.005 µg/g for both soil and aqueous matrices.

The numerical results of the examination of adsorption at equilibrium are presented below in the table B.8.1.2.1.1._CA-59. Analysing these results RMS stated that in case of the concentration of Flufenacet adsorbed probably the units were wrongly reported - µg/mL instead of µg/g.

Table B.8.1.2.1.1._CA-59: The numerical results of the examination of adsorption at equilibrium.

Initial concentration of Flufenacet in solution [µg/mL]	Concentration of Flufenacet at equilibrium:		Distribution coefficient - K_d
	In solution – C_e [µg/mL]	In soil (adsorbed) – C_s [µg/mL]	
0.1	0.06	0.09	1.57
0.5	0.24	0.51	2.11
1.0	0.42	1.15	2.72
2.0	0.88	3.91	4.43
5.0	2.29	5.43	2.38
10.0	4.86	10.29	2.12
20.0	9.84	20.33	2.07
30.0	16.66	26.69	1.60

To determine the Freundlich adsorption isotherm the presented above concentrations at equilibrium were logarithmically transformed using Log₁₀-transformation and then fitted to the equation representing the linearised form of Freundlich isotherm:

$$\text{Log } C_s = \text{Log } K + 1/n \text{ Log } C_e$$

The determined parameters were following:

- $\text{Log } K = 0.3545$
- $1/n = 0.988$
- $r = 0.99$

When recalculated Freundlich adsorption constant $K_{f \text{ ads}} = 2.26$ mL/g. The calculated $K_{f \text{ OC}} = 664.71$ mL/g, indicating strong sorption of the test compound to the test soil.

The calculated change of the free energy of adsorption $\Delta G = -3.317$ Kcal/mol, indicating that the process of the adsorption was spontaneous and that its nature was physisorption.

RMS comments:

The study protocol indicates that it was in line with the provisions of the OECD 106 Guideline. However, the fact that the test soil was a non-EU soil that was not well characterised and the problems revealed during the analysis of the data lead to the conclusion that the adsorption parameters determined in it cannot be used to derive the EU regulatory endpoints. The results may be therefore considered solely as indicative.

Study 6:

Report: Gajbhiye V. T., Gupta S. (2001): “Adsorption-desorption behaviour of flufenacet in five different soils of India.”; Division of Agricultural Chemicals, Indian Agricultural Research Institute, New Delhi 110 012, India; published study - published in: “Pest Management Science”, vol 57, 2001, pp 633 – 639.

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper.

RMS comments: The paper presents the results of the examination of soil equilibrium sorption (determination of Freundlich adsorption and desorption isotherms) for Flufenacet. The experiment was performed using five test soils. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied OECD 106 Guideline. The level of details was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and confirmatory to the endpoints provided by the regulatory studies submitted by the Applicant, and should not be used as a source of regulatory endpoints.

Summary:

The paper contains an abstract, outlining the aims of the experiment and its key results, which was made available on-line. However, due to the copyright restrictions RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS. For the same reason RMS could not present the graphical results of the experiment and in particular the determined adsorption isotherms.

Extended summary prepared by RMS:

The aim of the study was to examine the sorption (adsorption and desorption) of Flufenacet in soil at equilibrium by determining the parameters of the adsorption and desorption isotherms. Also examined was the mechanism of the adsorption and its correlation with key soil properties, such as soil pH, soil OC/OM content and soil clay content. The whole experiment was performed at ambient temperature, most probably at $T = 25^{\circ}\text{C}$ (the indicator for that was the declared temperature for which the change of free Gibbs energy – ΔG , was determined).

The experiment was carried out on five Indian agricultural soils, coming from different geographic and climatic regions of the country. Their characteristic provided below in the table B.8.1.2.1.1._CA-60. The soils were sampled from the top 0-15 cm layer (plough layer) from the agriculturally used fields on which Flufenacet was not used prior to the sampling. The soils were air-dried, ground and passed through 2-mm sieve before being used. They were characterised for their physicochemical properties using the methodology in line with that described by Day P. R. in “*Methods of Analysis*” Part I, ed. by Black CA, 1965 on pp. 545 – 567, and by Jackson M. L. in “*Soil Chemical Analysis*”, Prentice Hall of India Pvt Ltd, New Delhi, 1973.

Table B.8.1.2.1.1_CA-60: The characteristic of soils used in the study.

Parameter		Soil				
		<i>Delhi</i>	<i>Ranchi</i>	<i>Nagpur</i>	<i>Kerala</i>	<i>Assam</i>
Soil origin		Northern plains, India	Eastern plateau, India	Deccan plateau, India	Western ghats, India	Assam plains, India
Climate type		Semi-arid with cold winter	Subhumid	Semi-arid with mild winter	Coastal	Humid
Soil type		Inceptisol	Ultisol	Vertisol	Alfisol	Oxisol
Soil textural type (reported in the study)		Sandy loam	Sandy loam	Clayley	Loam	Loamy sand
Soil textural type – USDA (determined by RMS)		Loamy sand	Sandy clay loam	Clay	Sandy clay loam	Silt loam
Particle size distribution	Sand [%]	77.5	60.0	40.0	50.0	45.8
	Silt [%]	17.5	8.8	16.3	25.0	51.7
	Clay [%]	5.0	31.2	43.7	25.0	2.5
Soil pH (medium not determined)		7.69	5.54	8.35	4.45	6.87
Organic matter content (OM) [%]		0.864	0.072	0.688	0.786	0.553
Organic carbon content (OC) [%]		0.501	0.042	0.399	0.456	0.321
CEC [meq/100 g]		6.95	3.86	13.69	20.20	14.00

The test compound was analytical grade Flufenacet, having a purity of > 99.5%, provided by M/s Bayer India Ltd. It was used to prepare the stock solutions in acetone, first having a concentration 1000 mg Flufenacet/L and the second, diluted, having a concentration of 100 mg Flufenacet/L.

All experiments were performed using aqueous solutions of Flufenacet – in 0.01M CaCl_2 aq. The aqueous stock solution of Flufenacet, having a concentration of 30 mg/L was prepared from the diluted acetone stock solution, having a concentration of 100 mg Flufenacet/L. To do that the appropriate aliquot of the diluted acetone stock solution was transferred to the volumetric flask and left to evaporate acetone. The residue was reconstituted in 0.01M CaCl_2 aq. In order to grant proper dissolution of the test compound the flask was shaken for 2 hours on mechanical shaker. That solution was used to prepare other treatment solutions used in the experiment examining batch sorption of Flufenacet.

As a first step was performed a preliminary experiment aimed on the determination of appropriate equilibration time. It was performed in 50-mL glass-joint test tubes containing 10 g soil and 20 mL solution – 0.01M CaCl_2 aq containing 10 mg/L Flufenacet. That gave the soil:solution ratio 1:2. In the paper it was not determined on what basis that ratio was selected. The so prepared samples were equilibrated for 1, 2, 4, 6, 12 and 24 hours by shaking on a mechanical shaker. At designated time points (listed above) samples were removed, centrifuged and clear supernatants analysed for the content of the test compound – Flufenacet. It was stated that the maximum sorption occurred during first 2-4 hours, depending on the test soil. Therefore the 4-hours equilibration time was selected as optimum for further examination.

The main test – the examination of the adsorption of Flufenacet onto soil at equilibrium in order to determine the parameters of Freundlich adsorption isotherm was carried out in glass tubes containing the test soil and 0.01M CaCl_2 aq solution in ratio 1:2 (10 g soil: 20 mL solution). The test compound – Flufenacet was introduced into the system in the solution. Its initial concentrations were: 0.0 mg/L, 0.1 mg/L, 0.5 mg/L, 1 mg/L, 2 mg/L, 5 mg/L, 10 mg/L 20 mg/L and 30 mg/L. The equilibration time was 4 hours at room temperature. Samples were prepared in duplicate. After equilibration samples were centrifuged for 10 min at 2000 rpm, clarified supernatants decanted and their 5-mL aliquots diluted with 5 mL of saturated NaCl aqueous solution, then extracted with three 20-mL portions of CH_2Cl_2 . Organic extract was collected, combined and dried by passing through anhydrous Na_2SO_4 . It was then evaporated to dryness, reconstituted in n-hexane and analysed by GC-ECD.

The desorption isotherm was determined in a separate study using one concentration of the test compound – 30 mg Flufenacet/L (highest concentration tested in the experiment on adsorption). The soil:solution ratio was 1:2 and the samples containing the test compound were equilibrated for 4 hours. After that time samples were centrifuged, supernatant decanted and a fresh 20-mL portion of a blank 0.01M CaCl_2 aq solution added. The samples were equilibrated for another 4 hours and then centrifuged and the clarified supernatants collected and processed in the same way as described for the adsorption phase. The procedure was repeated five times to obtain the data for five-step desorption process.

All samples were analysed using GC-ECD technique on Helwett Packard 5890 Gas Chromatograph equipped with ^{63}Ni electron capture detector. The separation was performed on megabore HP-1 capillary GC column, 10-metres long, 0.53-mm of internal diameter and having 2.65 μm -thick film. The GC oven was programmed at initial temperature of $T = 160^\circ\text{C}$ lasting for 9 minutes, then increasing at rate $30^\circ\text{C}/\text{min}$ to $T = 260^\circ\text{C}$, held at that level for 3 minutes. The carrier gas was N_2 administered at a rate 15 mL/min. For Flufenacet the $R_t = 7.4$ min.

The numerical results of the experiment presenting the concentrations of Flufenacet in solution and that adsorbed onto soil were not provided. Instead in the paper were presented the results of the determination of the distribution coefficients for Flufenacet in each test soil and for each initial concentration in solution. They are presented below in the table B.8.1.2.1.1._CA-61.

Table B.8.1.2.1.1._CA-61: The adsorption distribution coefficients – K_d , determined for Flufenacet in each test soil.

Initial (nominal) concentration of Flufenacet [mg/L]	The K_d [mL/g] values determined for Flufenacet in the test soil:				
	<i>Delhi</i> (Loamy sand)	<i>Ranchi</i> (Sandy clay loam)	<i>Nagpur</i> (Clay)	<i>Kerala</i> (Sandy clay loam)	<i>Assam</i> (Silt loam)
0.1	1.57	2.44	0.99	5.69	0.90
0.5	2.11	2.88	2.98	2.76	0.88
1.0	2.72	4.05	3.54	4.89	0.74
2.0	2.52	6.58	3.62	2.88	0.53
5.0	2.38	5.76	3.89	4.76	0.68
10.0	2.12	4.70	3.87	5.24	0.58
20.0	2.07	3.21	3.84	5.21	1.08
30.0	1.60	2.74	3.57	4.73	0.77
<i>average K_d</i>	<i>2.14</i>	<i>4.05</i>	<i>3.29</i>	<i>4.52</i>	<i>0.77</i>

In the paper there were presented the adsorption isotherms determined in each soil for the not transformed equilibrium concentrations of Flufenacet in soil and solution (they are not presented here due to the copyright restrictions; to see them the readers are kindly asked to refer to the original paper). In case of the four isotherms – those obtained in Delhi Loamy sand soil, Ranchi Sandy clay loam soil, Nagpur Clay soil and Kerala Sandy clay loam soil, the shape of the isotherms complied with the model Freundlich sorption isotherm (Linear or Type I isotherm, in the paper named “C” type isotherm). In case however of Assam soil, the isotherm acquired a different shape – sigmoidal (Type V isotherm), therefore more appropriate model describing adsorption in that soil seems to be BET isotherm.

The concentrations at equilibrium, for both adsorption and desorption, were logarithmically transformed (Log_{10} -transformation) in order to determine Freundlich sorption isotherms in their linearised form and Freundlich sorption parameter for adsorption and desorption processes. The resulting linear regression equations and corresponding correlation coefficients are presented below in the table B.8.1.2.1.1._CA-62. In case of Assam soil the regression equations and corresponding correlation coefficients are given in italics, because the shape of the adsorption isotherm indicate that they may not well comply with the Freundlich model.

Table B.8.1.2.1.1._CA-62: The regression equation for linearised Freundlich adsorption and desorption isotherms obtained for Flufenacet in each test soil.

Test soil	Isotherms determined for the process of:			
	<i>Adsorption</i>		<i>Desorption</i>	
	Regression equation	Correlation coefficient r	Regression equation	Correlation coefficient r
<i>Delhi (Loamy sand)</i>	$\text{Log}(C_s) = 0.3230 + 0.9963 \text{ Log}(C_e)$	0.99	$\text{Log}(C_s) = 1.2954 + 0.1205 \text{ Log}(C_e)$	0.94
<i>Ranchi (Sandy clay loam)</i>	$\text{Log}(C_s) = 0.5588 + 0.9812 \text{ Log}(C_e)$	0.98	$\text{Log}(C_s) = 0.8086 + 0.4358 \text{ Log}(C_e)$	0.91
<i>Nagpur (Clay)</i>	$\text{Log}(C_s) = 0.5056 + 1.2213 \text{ Log}(C_e)$	0.99	$\text{Log}(C_s) = 1.1621 + 0.4430 \text{ Log}(C_e)$	0.85
<i>Kerala (Sandy clay loam)</i>	$\text{Log}(C_s) = 0.6429 + 1.0151 \text{ Log}(C_e)$	0.99	$\text{Log}(C_s) = 1.5380 + 0.0856 \text{ Log}(C_e)$	0.97
<i>Assam (Silt loam)</i>	$\text{Log}(C_s) = -0.1206 + 0.985 \text{ Log}(C_e)$	0.99	$\text{Log}(C_s) = 0.6015 + 0.4395 \text{ Log}(C_e)$	0.96

The determined parameters of the Freundlich adsorption isotherm, including the change in free Gibbs energy - ΔG in function of the organic matter content, are presented below in the table B.8.1.2.1.1._CA-63. RMS decided not to present the parameters of the Freundlich desorption isotherm as from the paper it was not clear how that isotherm was experimentally determined. RMS decided not to present the results obtained in Assam Silt loam soil.

Table B.8.1.2.1.1._CA-63: The determined Freundlich adsorption parameters for Flufenacet in each test soil

Test soil	OM content [%]	Freundlich isotherm parameters				Thermodynamic effect - ΔG_{OM}
		K_F [mL/g]	K_{FOM} [mL/g]	K_{FOC} [mL/g]	1/n	
<i>Delhi</i> (Loamy sand)	0.864	2.10	243.06	419.16	0.996	-3.27
<i>Ranchi</i> (Sandy clay loam)	0.072	3.62	5027.78	8619.05	0.981	-5.08
<i>Nagpur</i> (Clay)	0.688	3.20	465.12	802.00	1.221	-3.66
<i>Kerala</i> (Sandy clay loam)	0.786	4.39	558.52	962.72	1.015	-3.77

Additionally for the adsorption process the effect of different physico-chemical soil properties – soil pH, OM content and clay content, on the phenomenon was determined. That was done by calculating the multiple regression equation between soil properties and the Freundlich adsorption constant – K_F . The calculated equation was following:

$$K_F = 4.27 + 1.3248 (\% \text{ OM}) + 0.0644 (\% \text{ clay}) - 0.5511 \text{pH}$$

with correlation coefficient $r = 0.95$.

The results of the examination of the multi-step desorption using a single, highest, concentration are presented below in the table B.8.1.2.1.1._CA-64.

Table B.8.1.2.1.1._CA-64: The results of the determination of multi-step desorption.

Test soil	Flufenacet adsorbed at equilibrium [mg/kg soil]	% of initially adsorbed flufenacet desorbed at:				
		Step 1	Step 2	Step 3	Step 4	Step 5
<i>Delhi</i> (Loamy sand)	26.69	4.20	1.13	9.90	8.40	8.30
<i>Ranchi</i> (Sandy clay loam)	24.92	16.40	13.70	7.60	4.50	2.60
<i>Nagpur</i> (Clay)	41.00	7.34	7.15	6.70	3.86	3.24
<i>Kerala</i> (Sandy clay loam)	42.18	3.40	2.10	1.73	1.26	0.86
<i>Assam</i> (Silt loam)	16.62	5.16	13.50	9.70	6.40	3.20

Conclusions drawn from the study were following:

- Flufenacet was moderately to strongly adsorbed to all test soils;
- The adsorption was only partly reversible and the release by desorption was expected to be slow;
- The process was spontaneous and its mechanism was predominantly a physisorption;
- It was strongly and positively correlated with soil organic matter content, while the correlation with soil pH was negative;
- The influence of the soil clay content on the adsorption of Flufenacet onto the test soils did not play a significant role;
- At the same time it was stated that none of the soil properties individually were highly correlated with the process, but the high correlation was observed for the combination of all three of them;
- At least in four of five test soils the adsorption was in good agreement with the assumed model – Freundlich isotherm.

RMS comments:

The study protocol indicates that it was in line with the provisions of the OECD 106 Guideline. However, the fact that the test soil was a non-EU soils and some stated limitations of the study itself and the reporting of its results (e. g. concentrations at equilibrium for the adsorption phase not reported) lead to the conclusion that the adsorption parameters determined in it cannot be used to derive the EU regulatory endpoints. The results may be

therefore considered solely as indicative. It is worth noting that the study confirms the observation made in the previously summarised study that the adsorption is spontaneous and predominantly is physical in its nature.

Study 7:

Report: Rouchaud J.^{a)}, Neus O.^{a)}, Eelen H.^{b)}, Bulcke R.^{b)} (2001): “Persistence, Mobility and Adsorption of the Herbicide Flufenacet in the Soil of Winter Wheat Crops.”; Laboratory of Phytopharmacy, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium (a) and Weed Research Center, Universiteit Ghent, B-9000 Gent, Belgium; published study - published in: “The Bulletin of Environmental Contamination and Toxicology”, vol 67, 2001, pp 609 – 616.

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper;

RMS comments: The paper presents the results of the examination of persistence of Flufenacet in soil under realistic – field conditions. The compound was performed on four trial sites located in Belgium, on which winter cereals (winter wheat) were grown. The test compound – Flufenacet was applied to the soil as post-emergent pesticide, in autumn, at application rate 240 g/ha. examined for two fortification levels. Although in the paper it was not indicated that the part of the experiment aimed on the determination of adsorption parameters was performed line with any relevant guidelines, it can be stated that the study protocol generally seems to comply with the provisions of the OECD 106 Guideline. However only the final results of the examination – Freundlich isotherm adsorption parameters were reported. For that reason, although the level of detail enabled the evaluation of the study for its validity (the study may be considered valid, and therefore is summarised below), RMS is of the opinion that the results it provides may be regarded only as supplementary and confirmatory to the endpoints provided by the regulatory studies submitted by the Applicant and should not be used as a source of regulatory endpoints.

Summary:

The paper contains an abstract, outlining the aims of the experiment and its key results, which was made available on-line. However, due to the copyright restrictions RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the persistence and mobility of Flufenacet in soil under realistic – field conditions and on cropped field. The experiment was performed on four trial sites in Belgium: Melle, Zingem and Zevekote, located 40 km apart, and Cortil-Noirmont, 100 km-distant from Melle. The characteristic of each trial site, as provided in the paper, is given below in the table B.8.1.2.1.1._CA-65.

Table B.8.1.2.1.1._CA-65: The brief characteristic of the trial sites.

Parameter		Trial site			
		Melle	Zingem	Zevekote	Cortil-Noirmont
Soil type		Sandy loam	Loamy sand	Clay loam	Silt loam
Particle size distribution	Sand [%]	55	79	19	11
	Silt [%]	38	11	45	75
	Clay [%]	7	10	36	14
pH value		7.0	6.4	6.6	6.7
Organic matter content (OM) [%]		1.51	1.60	2.12	1.2

The organic fertilization of soil on the trial sites was following:

- on Melle trial site no organic fertilizer was used on the year when the experiment started – 1999; before that year the trial site was fertilized every second year at spring with 40 tonnes/ha of either cow slurry or cow manure;

- on Zevekote trial site no organic fertilizer was used on the year when the experiment began – 1999; before that date the trial site was fertilized every second year, in September with 40 tonnes/ha of pig slurry or 40 tonnes/ha of cow manure;
- on Zingem trial site on the year when the experiment started – 1999, the soil was fertilized with cow manure applied at rate 40 tonnes/ha in October; in the preceding years the test field was fertilized every second year with either 40 tonnes/ha of cow manure or 40 tonnes/ha of pig slurry;
- on Cortil-Noirmont on the year when the experiment started soil was organically fertilized by incorporation of the leftovers of the preceding crop (sugar beet leaves) into the soil; in preceding years the test fields were fertilized by applying onto them 40 tonnes/ha of the cow manure every fourth year.

At the beginning of the experiment – in November 1999, test fields were tilled to prepare a seed bed and winter wheat was sown. On each test field four 6 x 10 metres plot were located at random, onto which the test substance – Flufenacet, was applied. It was applied to the soil surface of the test fields at rate 240 g/ha on the following dates:

- Melle trial site: on 25th November 1999;
- Zingem trial site: on 25th November 1999;
- Zevekote trial site: on 26th November 1999;
- Cortil-Noirmont: on 26th November 1999.

Additionally at trial sites Melle and Zingem the test compound was applied to the previously untreated plots at the same application rate in early spring of the following year : on 17th March 2000 at Melle and 4th April 2000 at Zingem.

One day before the autumn application of the test compound – Flufenacet onto the soil on each of the trial sites, from each test field soil samples were taken from the 0-10 cm layer. The sampled soils were used in the experiment aimed on the examination of the soil sorption of Flufenacet. This was a supplementary experiment aimed on the identification of the factors other than climatic conditions, such as bioavailability of the test compound, that possibly influenced the rate of degradation of Flufenacet under realistic – field conditions.

The equilibrium sorption was examined in the test system with soil solution ratio 1:2 (100 g soil and 200 mL 0.01M CaCl₂ _{aq} solution containing the appropriate amount of Flufenacet). The selected equilibration time was 24 hours. The experiments were performed in the dark at constant temperature T = 20°C. The test compound – Flufenacet was administered in form of the aqueous solutions in 0.01M CaCl₂. The initial concentrations of the test item selected for the experiment were: 20, 50, 100 and 200 µg/kg water (solution?).

After equilibration the test vessels were centrifuged for 10 minutes at 3500 rpm and the liquid – clear supernatant, and solid – remaining soil, phases analysed separately for the content of Flufenacet. The analytical procedure has already been described in the summary of the same study (**Study 10**) provided under the point B.8.1.1.2.2.1._CA of this renewal assessment report. The determined parameters of the Freundlich adsorption isotherm for Flufenacet in each test soil are presented below in the table B.1.2.1.1._CA-66.

Table B.8.1.2.1.1._CA-66: The parameters of the Freundlich adsorption isotherm determined for Flufenacet in each test soil.

Test soil	Freundlich adsorption isotherm parameters		
	K _F [mL/g]	1/n	K _{F OC} [mL/g]
<i>Melle (Sandy loam)</i>	16	0.89	1802
<i>Zingem (Loamy sand)</i>	43	0.91	4602
<i>Zevekote (Clay loam)</i>	15	0.93	1231
<i>Cortil-Noirmont (Silt loam)</i>	9	0.94	1257

RMS comments:

The study protocol indicates that it was in line with the provisions of the OECD 106 Guideline. However, due to the deficiencies displayed by the study protocol – the description of the experiment was very brief, as well as the fact that the examination of the adsorption was only a supplementary experiment carried out with aim to explain what are the possible mechanisms influencing the rate of degradation of Flufenacet in soil under realistic – field conditions, RMS is of the opinion that that the adsorption parameters determined in it cannot be used to derive the EU regulatory endpoints.

Summary: the sorption of Flufenacet onto soil at equilibrium

The Applicant submitted four studies examining the sorption of Flufenacet onto soil at equilibrium – two “existing” studies, evaluated for the previous authorisation of Flufenacet in the EU, and two new studies. Their evaluation carried out for the purpose of the present assessment showed that one “existing” study cannot be considered acceptable because the equilibrium sorption was examined at variable temperature (the differences were up to 7°C).

Three remaining studies were considered acceptable, although the determined Freundlich adsorption isotherm parameters cannot be considered reliable for all test soils (those obtained in two of twelve test soils had to be rejected because one of them was found not representative and the other had too low OC content to consider the adsorption parameters fully reliable). The reliable results are presented below in the table B.8.1.2.1.1._CA-67. On their basis it can be stated that Flufenacet displays medium to low mobility in soil. It was also stated that the adsorption of Flufenacet onto soil is not a pH-dependent process.

Table B.8.1.2.1.1._CA-67: The final results of the determination of the adsorption of Flufenacet onto soil at equilibrium – the reliable parameters of the Freundlich adsorption isotherm.

Soil name	Soil properties			Adsorption distribution coefficients		Freundlich adsorption isotherm parameters			
	Soil type (USDA)	pH	OC [%]	K_d [mL/g]	$K_{d\text{OC}}$ [mL/g]	K_f [mL/g]	$K_{f\text{OC}}$ [mL/g]	1/n	R^2
Stanley (307)	Silt loam	5.9	1.68	----	----	3.18	189.28	0.848	0.9971

Arithmetic mean (n = 10)						----	----	0.916	----
pH dependence						No		----	

The additional pieces of information on the soil sorption of Flufenacet at equilibrium were provided by three open-literature scientific papers. The key results obtained in them are presented below in the table B.8.1.2.1.1._CA-68. The values reported below may be considered as indicative and should not be used to derive the regulatory endpoints characterising soil sorption of Flufenacet.

Table B.8.1.2.1.1._CA-67: The results of the determination of the adsorption of Flufenacet onto soil at equilibrium obtained in the open-source literature scientific papers.

Study	Soil name	Soil properties			Freundlich adsorption isotherm parameters

Footnotes to the table:

1) OM content reported, no values for OC content

In the studies by [Gupta, Gajbhiye and Agnihotri; 2001] and [Gajbhiye and Gupta; 2001] for adsorption of Flufenacet onto test soil the value of the free Gibbs energy of adsorption – ΔG , was determined. It was in range $\Delta G = (-3.27) - (-5.08)$ [Kcal/mol], indicating that adsorption of Flufenacet onto soil was a spontaneous process and mechanistically it was predominantly physisorption. It was also demonstrated, in the study by [Gupta, Gajbhiye and Agnihotri; 2001], that the soil sorption of Flufenacet was strongly positively correlated with soil OC/OM content. As the results obtained in these two studies are in line with those obtained in reliable regulatory studies, that conclusion may be considered to be a general conclusion with regard to the adsorption of Flufenacet onto soil.

Additionally all results of the examination of the adsorption of Flufenacet onto soil at equilibrium considered relevant for the regulatory purpose are presented below in format recommended for reporting the EU end points.

Soil adsorption active substance (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.3.1.1 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.2.1)

B.8.1.2.1.2. – Adsorption and desorption of the metabolites

The Applicant submitted four study reports presenting the results of the examination of the equilibrium sorption of the degradation products of Flufenacet onto soil. Of them one is existing study, evaluated for the previous authorisation of the active substance in Europe and the remaining three are the new studies, submitted to address the issue of the soil sorption of three degradation products not previously identified as major soil and/or aquatic degradation products. They are summarised below as **Studies 1-4**. Additionally the already summarised in its part related to the degradation in soil under aerobic soil study on the long-term of FOE Sulfonic acid provides the data that may be used to estimate the approximate parameters of the Freundlich sorption isotherm for that compound. The RMS decided to present these data in the study summary as **Study 5**. However, in RMS's opinion these results should be considered as conformatory only and not to be used to derive the regulatory endpoints. Finally, for FOE Methylsulfide – the major aquatic degradation product of Flufenacet RMS determined the adsorption constant using QSAR method. The results are presented in the short report under the heading **Study 6**.

The repeated open literature search did not result in identification of any publications examining the adsorption of the degradation products of Flufenacet.

The examination of fate and behaviour of Flufenacet in aquatic environment (aerobic water/sediment system studies) resulted in identification of an additional degradation product not found in soil – FOE Methylsulfide. As for that degradation products no study examining its sorptive behaviour was submitted by the Applicant, RMS decided to estimate its adsorption parameters – the would be adsorption constant K_{OC} , using QSAR methods. The calculations are briefly characterised under this data point as **Study 6**, while the full report of QSAR estimation, performed using EPISuite tool, is provided in the Appendix 3 to this Assessment Report.

Study 1:

Report: Blumhorst M. R., Yen P. Y., Marlow V. A. (1994): "Soil Adsorption/Desorption of FOE 5043 Degradates: FOE Sulfonic acid, FOE Methyl Sulfoxide, FOE Oxalate, FOE Alcohol and Thiadone."; EPL Bio-analytical Services, Inc. (EPL-BAS), P. O. Box 109, 395N. Memorial Parkway, Harristown IL 62537, USA (performing laboratory) for Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, MO 64120- 0013, USA; EPL-BAS study No. 122S19, study report (Miles) No. MR 106598; 26 September 1994; study reference number: M-002185-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 163-1, Adsorption/Desorption.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.1.1, in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. For the present authorisation in the EU the study was evaluated for its compliance with OECD Guideline for the Testing of Chemicals 106 – Adsorption-Desorption Using a Batch Equilibrium Method. Additionally the study was checked for its validity against the US EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1230 – Adsorption/Desorption (Batch Equilibrium) and OPPTS 835.1220 – Sediment and Soil Adsorption/Desorption Isotherm as well as SETAC Guidance Document "Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides.". Also consulted was the Guideline which was declared in the study report to be a reference document – US EPA Guideline 163-1 for determining the adsorption/desorption of chemicals. The following deviations from the main Guideline – OECD 106, were stated:

- The pH of the test soils, measured in water, was too narrow, being in range 5.8 – 6.6, and therefore not covering at all the range for alkaline soils and narrowly that for acidic soils. Taking into account however the sorptive properties of the test compounds it may be stated that it will not have a significant influence on the conclusions of the study. That is because all degradation products, which are n.b. rather strong organic acids, are weakly sorbed onto soil and the would-be pH-dependence of the adsorption would probably not significantly alter the Freundlich adsorption constants.

- Of the four test soils one – Vero Beach Sand soil displayed lower than recommended OC content – 0.27%. It shall be indicated however that in light of the provisions of the Guideline declared as a reference for this study – US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 163-1, Adsorption/Desorption, that test soil was selected correctly.
- The definitive experiment – the determination of Freundlich sorption isotherms and Freundlich parameters for adsorption and desorption processes, was carried out using only four concentrations of the test items, while OECD 106 Guideline recommends to use for that purpose five. However such solution was in line with the recommendations of the evoked US EPA Guidelines and SETAC Guidelines, therefore it may be considered acceptable.
- The amount of the test items sorbed onto soil during the preliminary tests was lower than the recommended 20% in case of either some test soils – the problem observed for FOE Methyl Sulfoxide, FOE Alcohol and FOE Thiadone, or all soils – as stated for FOE Sulfonic acid and FOE Oxalate. For that reason the soil solution ratio used in the experiment was 3:10, corresponding to 1:3.333. In such cases the best solution, recommended by OECD 106 Guideline, would be to use 1:1 soil:solution ratio. However, due to the fact that the compounds displayed consistently low adsorption onto soil, that deviation had, in RMS's opinion, not very significant impact on the outcome of the study.

In general, despite the problems listed above, RMS found the study acceptable, and possible to be used for the regulatory purposes. The study is summarised below.

Summary:

The aim of the study was to examine soil sorption – adsorption and desorption, and determine Freundlich sorption isotherm parameters Freundlich adsorption/desorption constants and corresponding $1/n$ values, for five degradation products of Flufenacet – FOE Sulfonic acid, FOE Methyl Sulfoxide, FOE Oxalate, FOE Alcohol and FOE Thiadone. The experiment was carried out on four test soils, characterised below in the table B.8.1.2.1.2_CA-1.

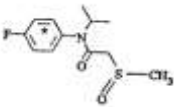

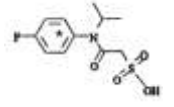

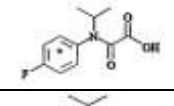

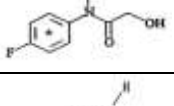

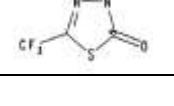

Table B.8.1.2.1.2_CA-1: The characteristic of soils used in the study.

Parameter		Soil			
		<i>Winder (396)</i>	<i>Shipshe (411)</i>	<i>Drummer (413)</i>	<i>Oska-Martin (414)</i>
Soil origin		Vero Beach, FL, USA	Howe, IN, USA	Champaign, IL, USA	Stilwell, KS, USA
Soil textural class (USDA)		Sand	Sandy loam	Silty clay loam	Silty clay
Particle size distribution	Sand [%]	92.5	68.5	11.1	3.1
	Silt [%]	1.3	17.6	54.1	47.1
	Clay [%]	6.3	13.9	34.8	49.8
Soil pH (in water)		5.8	6.3	6.6	6.0
Organic matter content (OM) [%]		0.5	1.3	3.7	2.1
Organic carbon content (OC) [%]		0.27	0.75	2.13	1.21
CEC [meq/100 g]		3.3	7.9	22.4	29.3
Moisture content @ $\frac{1}{3}$ bar [%]		5.0	8.3	24.8	28.1

No information concerning the sampling procedures of the test soils was provided in the study report.

The study was performed using the test compounds in radiolabelled and non-radiolabelled form (technical-grade test items). The characteristic of the radiolabelled test compounds is provided below in the table B.8.1.2.1.2_CA-2. The structural formulas reported in the table are copied from the study report and the radiolabelling position is indicated with an asterisk (*). Below that table are provided the key parameters characterising their non-radiolabelled (technical-grade) equivalents. The structural formulas of the test items are not provided as they would be identical to those presented in the preceding table.

Table B.8.1.2.1.2._CA-2: The characteristic of the radiolabelled test compounds used in the experiment (structural formulas copied from the study report).

Test compound			Properties of the compound			
Name	Empirical formula	Structural formula (radiolabelling position marked with asterisk – *)	Purity [%]	Specific activity		Solvent
				expressed in [mCi/mmol]	expressed in [μCi/mg]	
FOE Methylsulfoxide	C ₁₂ H ₁₆ O ₂ SNF		98.8	21.0	81.7	CH ₃ CH ₂ OH
FOE Sulfonic acid	C ₁₁ H ₁₄ O ₄ SNF		99.3	21.0	76.4	CH ₃ CN/H ₂ O
FOE Oxalate	C ₁₁ H ₁₂ O ₃ NF		98.0	50.2	222.9	CH ₃ CN
FOE Alcohol	C ₁₁ H ₁₄ O ₂ NF		97.0	115.8	549	CH ₃ CN
FOE Thiadone	C ₃ HOSN ₂ F ₃		99.7	57	335	(CH ₃) ₂ O

The non-radiolabelled, technical grade FOE Methylsulfoxide was delivered as a liquid sample, having a purity of 93.1%. The technical grade (non-radiolabelled) FOE Sulfonic acid was delivered as a solid sample having a purity of 98.5%. The technical grade (non-radiolabelled) FOE Oxalate was delivered in form of a solid sample having a purity of 98.8%. The technical (non-radiolabelled) FOE Alcohol was delivered as solid sample having a purity of 99.4%. The technical (non-radiolabelled) FOE Thiadonewas delivered in form of a solid sample having a purity of 97.5%.

The radiolabelled test items and their non-radiolabelled counterparts were used to prepare stock solutions, separate for each test compound, subsequently used to prepare treatment solutions used at each step of the experiment.

The stock solutions were prepared by dissolving the appropriate amounts of the given technical-grade and radiolabelled test item in 5 mL of solvent. In case of FOE Sulfonic acid the solvent was CH₃CN/H₂O. The stock solutions of the remaining four test compounds were prepared in CH₃CN.

The processes of adsorption of the test compounds onto soil and their desorption were examined using the 0.01N CaCl₂ aq as the liquid phase. The blank 0.01N CaCl₂ aq was sterilised prior to use by filter-sterilisation (by passing through 0.2-μm filter).

The whole experiment consisted of the following stages:

- **First preliminary study** in which the most appropriate soil:solution ratio was determined and the possible adsorption of the test item to the test vessels was monitored;
- **Second preliminary study** aimed on the determination of the time required for adsorption equilibrium to be achieved;
- **The definitive test** in which Freundlich adsorption and Freundlich desorption isotherms were determined and their parameters derived.

All experiments were performed in glass centrifuge tubes sealed with Teflon-lined caps.

The **First preliminary study** was carried out using a treatment solutions prepared from a stock solutions by dissolving them in appropriate amount of blank sterilised 0.01N CaCl₂ aq to obtain 1000 mL of solutions having a concentration of 5 μg test item/mL. For each test compound an individual treatment solution was prepared.

For each test compound the appropriate amounts of each test soils were weighed into the test tubes and then 25 mL of treatment solution were added to obtain the following soil:solution ratios (determined on the basis of soil dry weight and assumed solution density 1 g/cm³):

- for FOE Methylsulfoxide and FOE Sulfonic acid the tested soil:solution ratios were: 1:5, 1:10, 1:20 and 1:50;
- for FOE Oxalate, FOE Alcohol and FOE Thiadone the tested soil:solution ratios were: 1:3, 1:5, 1:10 and 1:20.

In case of the three later compounds initially it was planned to test the same ratios as for FOE Methylsulfoxide and FOE Sulfonic acid, but because in the experiments with those two compounds the determined level of adsorption was relatively low, it was decided to change the examined ratios.

For each test compound and tested soil:solution ratio the samples were prepared in duplicate. Additionally for each test compound a control sample (in replicate) was prepared. The control sample contained only treatment solution of the given test compound (soilless samples).

After introduction of the treatment solution into the test vessels the test vessels were sealed with Teflon caps and shaken for 24 hours in the dark at constant temperature $T = 23.5 \pm 1.5^{\circ}\text{C}$. After that period the samples were centrifuged and from each three 1-mL aliquots of supernatant analysed by LSC.

Next test – the **Second preliminary study**, carried out to determine the optimal equilibration time, was performed using the treatment solution prepared in the same way as described above for the **First preliminary test**. The target concentration of that solution was also 5 μg test item/mL. The soil:solution ratio used in this experiment (approximate) was 1:3. To obtain it to the test vessels 6-g portions of the given test soil were weighed and 20 mL of the treatment solution containing the given test compound added (n.b. RMS on the basis of this description stated that the exact soil:solution ratio was not 1:3 but 1:3.3333). After introduction of the treatment solutions the test vessels were sealed with Teflon –lined caps and placed on the shaker to be equilibrated for up to 72 hours in the darkness and at constant temperature $T = 23.5 \pm 1.5^{\circ}\text{C}$. At pre-defined time points – 2, 8, 24, 48 and 72 hours after initiation of the experiment, duplicate samples were taken for analysis – the vessels were centrifuged and three 1-mL aliquots of the supernatant analysed by LSC for the content of the test item. Additionally the samples collected after 72 hours of equilibration were analysed by radio-HPLC to determine the stability of the test item.

For each test compound were set two control, soilless, samples, equilibrated for 72 hours and analysed after that time.

The definitive study, aimed on the determination of Freundlich adsorption and desorption isotherms and their parameters, was carried out for each test compounds using four initial concentrations: 0.04 mg/L, 0.2 mg/L, 1.0 mg/L and 5.0 mg/L.

The treatment solutions used in the experiment were prepared in the following way: firstly the stock solution of the technical grade substance was prepared in 5.0 mL of CH_3CN or $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ solution. From it on the day of initiation of the experiment the treatment solution, having a concentration approx. 5 μg test compound/mL, was prepared. This was done by transferring 0.5 mL of the characterised above stock solution and the appropriate amount of radiolabelled test substance (in less than 0.5 mL solvent) to 100-mL volumetric flask. The solution was brought to the volume with 0.01N CaCl_2 aq to obtain a treatment solution having the highest concentration – 5.0 mg/L. Next treatment solutions, having lower concentrations, were prepared by diluting that treatment solution with appropriate amount of 0.01N CaCl_2 aq in a serial-dilution procedure. The concentration of each treatment solution was verified by LSC.

Next, to examine the adsorption at equilibrium, to each pre-weighed test vessel 6-g portion of the appropriate test soil was weighed and 20 mL of appropriate treatment solution added. pH of each so prepared sample was determined, the test vessels sealed with Teflon-lined caps and placed on a shaker to be equilibrated for 24 hours in the dark at constant temperature $T = 23.5 \pm 1.5^{\circ}\text{C}$. After that time samples were centrifuged for 15 minutes at 2000 rpm, clarified supernatants collected, their volume measured and 5-mL aliquots analysed using LSC and radio-HPLC.

After removal of supernatant the test vessels with moist soil were weighed to determine the mass of the remaining soil. The volume of solution in the test vessels was brought to 20 mL using blank 0.01N CaCl_2 aq solution and so prepared samples were equilibrated for 24 hours in the same conditions as for examining the adsorption phase. After 24-hours equilibration samples were processed in the same manner as described above for the examination of the adsorption. The whole procedure was repeated three times to obtain three-step desorption.

After the last step of desorption the test vessels with remaining soil were weighed to determine the amount of the moist soil. Next the amount of the radioactivity retained by each test soil after desorption was determined. For that purpose four subsamples of each soil sample were oxidised using Harvey Model OX-550 oxidizer and generated $^{14}\text{CO}_2$ quantified by LSC. That value was subsequently used, together with the values determined in solution during the examination of adsorption and desorption, to calculate the mass balance.

All samples were quantitatively analysed by LSC. The method was not characterised, only the LOD values were reported. That parameter was determined in background checks and was defined to be $3 \times \text{SD}$ (SD = Standard Deviation). It was in range 3.2 – 9.1 dpm.

The supernatants obtained in samples equilibrated for 72 hours in the **Second preliminary study** and all supernatants obtained in **The definitive study** were examined by radio-HPLC.

The chromatographic analysis was performed in a gradient mode using Spherisorb ODS-2 chromatographic column (250 * 4.6 mm; 5 μm) maintained in a constant temperature $T = 40^\circ\text{C}$. The elution lasted for 50 minutes, of which 30 minutes was gradient elution and the remaining 20 elution in isocratic mode. The solvent system consisted of:

- **Solvent A:** 1% CH_3COOH in CH_3CN ;
- **Solvent B:** 1% CH_3COOH in H_2O

The elution programme, in relation to **Solvent A**, was following: at $t = 0.1 \text{ min}$ (beginning of chromatographic analysis) 0% **Solvent A**, linear gradient until $t = 30 \text{ min}$, at $t = 30 \text{ min}$ 100% **Solvent A**, then isocratic elution for next 20 minutes with 100% **Solvent A** until $t = 50 \text{ min}$, at $t = 50 \text{ min}$ end of chromatographic analysis. The flow rate of the solvent system was set to 1 mL/min.

The detection was performed by means of UV detection using UV detector with wavelength set to $\lambda = 230 \text{ nm}$ and LSC detector set in line after UV detector.

The identification of the test compounds was performed by means of the comparison of retention times R_t with those of the known standards. The approximate R_t values for each test compound were following:

- FOE Methylsulfoxide: $R_t = \sim 22 \text{ min}$;
- FOE Sulfonic acid: $R_t = \sim 15 \text{ min}$;
- FOE Oxalate: $R_t = \sim 16 \text{ min}$;
- FOE Alcohol: $R_t = \sim 24 \text{ min}$;
- FOE Thiadone: $R_t = \sim 20 \text{ min}$;

The results of the study are presented and discussed below.

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in the table B.8.1.2.1.2._CA-1. On their basis it may be stated that while three test soils – Shpshe sandy loam soil, Drummer Silty clay loam soil and Oska-Martin Silty clay soil fully meet the acceptability criteria set by the OECD 106 Guideline, Winder Sand soil displays lower than recommended OC content – only 0.27% instead of at least 0.3%. At the same time it shall be indicated that that soil fully meets the acceptability criteria set by the reference Guidance document for this study available at the moment of its performance – the US EPA 163-1 Guideline. Therefore it should be also considered acceptable, as well as the results obtained for that soil, although they should be considered with care. RMS noticed that the pH range of the test soils was narrow, covering only slightly acidic and neutral soils. However, taking into account the fact that the compounds display low adsorption potential onto soil, that narrow range is not expected to have a significant impact on the conclusions drawn from the study.

The results of the determination of the soil:solution ratio – the first preliminary study, are presented below, individually for each test compound, in tables B.8.1.2.1.2._CA-3 – B.8.1.2.1.2._CA-8. In the first table – B.8.1.2.1.2._CA-3 are provided the results of the determination of the concentration of the treatment solution for each test compound. The results of the determination of the soil:solution ratio are presented in the tables B.8.1.2.1.2._CA-4 – B.8.1.2.1.2._CA-8. In case in the source tables the negative values were reported for the % adsorbed, RMS replaced them with the value 0%. Such values are indicated with an asterisk – *).

On the basis of the obtained results it was stated that none of the test compound displayed significant affinity to the test vessels. The selected appropriate soil:solution ratio was 1:3.

Table B.8.1.2.1.2._CA-3: The results of the determination of concentration of test compounds in treatment solutions.

Code of treatment solution	Test compound	Specific activity of radiolabelled compound [$\mu\text{Ci}/\text{mg}$]	Concentration of the test compound in solution [$\mu\text{g}/\text{mL}$]			Specific activity of treatment solution [$\mu\text{Ci}/\text{mg}$]
			Radiolabelled	Technical grade	Total

The results of the determination of the appropriate equilibration time – the **Second preliminary study**, are presented below, individually for each test compound, in tables B.8.1.2.1.2._CA-9 – B.8.1.2.1.2._CA-15. In the first table – B.8.1.2.1.2._CA-9 are provided the results of the determination of the concentration of the treatment solution for each test compound. The results of the determination of the appropriate equilibration time are presented in the tables B.8.1.2.1.2._CA-10 – B.8.1.2.1.2._CA-14. Finally the table B.8.1.2.1.2._CA-15 presents the results of the determination of the stability of test compounds after 72-hours lasting equilibration. In case in the source tables the negative values were reported for the % adsorbed, RMS replaced them with the value 0%. Such values are indicated with an asterisk – *).

On the basis of the obtained results it was stated that the optimum equilibration time varied between substances, but in general for all them no significant change was observed for equilibration time between 24 and 72 hours. At the same time it was stated that for FOE Sulfonic acid in Drummer Silty clay loam there was a significant degradation of the test compound. As a result, the 24-hours equilibration time was proposed to be used in the definitive study for all test compounds and all test soils.

It was also demonstrated that, as in previous experiment, none of the test compound displayed significant affinity to the test vessels.

Table B.8.1.2.1.2._CA-9: The results of the determination of concentration of test compounds in treatment solutions.

Code of treatment solution	Test compound	Specific activity of radiolabelled compound [$\mu\text{Ci}/\text{mg}$]	Concentration of the test compound in solution [$\mu\text{g}/\text{mL}$]			Specific activity of treatment solution [$\mu\text{Ci}/\text{mg}$]
			Radiolabelled	Technical grade	Total	
WG1-2	FOE Methylsulfoxide	82	0.148	5.00	5.15	2.35
WE1-2	FOE Sulfonic acid	76	0.311	4.90	5.21	4.56

The numerical results of experiment examining the adsorption of FOE Methylsulfoxide onto test soils are presented below in the table B.8.1.2.1.2._CA-17. The results of the experiment examining its desorption are presented in the table B.8.1.2.1.2._CA-18. The graphical results of the experiment – the adsorption and desorption isotherms determined for each test soil, are presented on figure B.8.1.2.1.2._CA-1. The key numerical results are provided in the table B.8.1.2.1.2._CA-19. Analysing these results RMS stated that it was not possible to interpret them appropriately as the Applicant did not distinguish the isotherms representing adsorption and desorption. For that reason it was also not possible to verify the correctness of the determined parameters of each isotherm. For that reason RMS decided to repeat the determination of the isotherms using the same data as presented in tables B.8.1.2.1.2._CA-17 and B.8.1.2.1.2._CA-18 – the log-transformed data. The adsorption and desorption isotherms were determined separately. The tool used in that exercise was CurveExpert ver 1.40. The graphical results are presented on two figures – B.8.1.2.1.2._CA-2 for adsorption and B.8.1.2.1.2._CA-3 for desorption. The corresponding numerical results are provided in the table B.8.1.2.1.2._CA-20. Performing the fitting the RMS used the data for the replicates not averaging them, as had done the Applicant.

Table B.8.1.2.1.2._CA-17: The results of the examination of the adsorption of FOE Methylsulfoxide onto test soils to determine Freundlich adsorption isotherm.

Test soil	Initial concentration of the solution [µg/mL]	Replicate	Results of the experiment:

	Desorption	0.786	6.109	504.88	0.921	0.0149	0.9998

Conclusions of the experiment:

The comparison of the results presented in the study report and those obtained by the RMS showed that the parameters of the adsorption and desorption isotherms obtained by the Applicant and RMS were almost identical. At the same time RMS stated that the determined adsorption isotherms displayed, except that determined for Winder Sand soil, good conformity with the experimental results. That conformity was not so good in case of the desorption isotherms, especially in case of Winder Sand soil and Shipshe Sandy loam soil, but that in turn may be partly attributed to low level of adsorption recorded in these two soils. The 1/n values for the adsorption isotherms were in range 0.893 – 1.059, indicating that the isotherms well complied with the assumed model. In case of the results obtained in Winder Sand soil it was stated that the adsorption isotherm was robust and well complied with the model – Freundlich sorption isotherm. For that reason RMS decided to include the results into the data set, even though the OC content was lower than the recommended minimum – 0.3%.

The definitive set of the results from this experiment is presented below in the table B.8.1.2.1.2._CA-21. RMS decided to present the values determined as a result of the repeated analysis of the data set.

Table B.8.1.2.1.2._CA-21: The definitive set of Freundlich adsorption and desorption parameters determined for FOE Methylsulfoxide.

Test soil – USDA type (name)	Key soil properties		Freundlich adsorption isotherm parameters			Freundlich desorption isotherm parameters		
	pH ¹⁾	OC [%]	K _F [mL/g]	K _{F OC} [mL/g]	1/n	K _F [mL/g]	K _{F OC} [mL/g]	1/n
<i>Sand (Winder)</i>	5.8	0.27	0.133	49.26	1.059	0.084	31.11	0.630
<i>Sandy loam (Shipshe)</i>	6.3	0.75	0.349	46.53	0.900	0.287	38.27	0.938
<i>Silty clay loam (Drummer)</i>	6.6	2.13	2.042	95.87	0.893	2.576	120.94	0.890
<i>Silty clay (Oska-Martin)</i>	6.0	1.21	5.598	462.64	0.914	6.109	504.88	0.921

Footnotes to the table:

1) Measured in water;

b) Results obtained for FOE Sulfonic acid:

The results of the determination of the concentrations of the test compound in treatment solutions used in the experiment are presented below in the table B.8.1.2.1.2._CA-22.

Table B.8.1.2.1.2._CA-22: The results of the verification of the concentration of treatment solutions used in the Definitive Study for FOE Sulfonic acid.

Test soil	Treatment solution code	Theoretical concentration of the test item [µg/mL]	Measured concentration of the test item [µg/mL]		
			Radiolabelled test item	Technical grade test item	Total concentration of the test item

	WE3-7	0.2	0.080	0.12	0.200
	WE4-7	0.04	0.016	0.024	0.0410

The numerical results of experiment examining the adsorption of FOE Sulfonic acid onto test soils are presented below in the table B.8.1.2.1.2._CA-23. The results of the experiment examining its desorption are presented in the table B.8.1.2.1.2._CA-24. The results obtained during examination of the adsorption showed that the adsorption of the test compound onto soil was very low, generally below 10%. For that reason the results of the desorption bear a significant level of uncertainty as the initial concentrations of the test compound retained by soil were very low. RMS decided to report the results presented by the Applicant noticing at the same time that they should be considered with extreme care, as in many instances the reported level of desorption is either above 100%, or a negative value, what is due to the fact that the concentrations were determined at levels close to LOQ.

For that reason the Applicant decided not to determine the desorption isotherms (the available data base did not enable doing that). The graphical results of the experiment – the adsorption isotherms reported in the study report, are given on figure B.8.1.2.1.2._CA-4 and in numerical form in the table B.8.1.2.1.2._CA-25. RMS decided to verify them using the values presented in the table B.8.1.2.1.2._CA-21 – the log-transformed concentrations in soil and solution at equilibrium. The results are provided on figure B.8.1.2.1.2._CA-5 and in numerical form in the table B.8.1.2.1.2._CA-26. The tool used in that exercise was CurveExpert ver. 1.4. Performing the fitting the RMS used the data for the replicates not averaging them, as had done the Applicant.

Table B.8.1.2.1.2._CA-23: The results of the examination of the adsorption of FOE Sulfonic acid onto test soils to determine Freundlich adsorption isotherm.

Test soil	Initial concentration of the solution [µg/mL]	Replicate	Results of the experiment:					
			Concentration at equilibrium				Amount adsorbed onto soil	
			in solution		in soil		in [µg]	in [%]

Footnotes to the table:

- 1) n. c. = not calculated;
- 2) n. r. = not reported, probably not determined;
- 3) all values as reported in the study report;
- 4) all values as reported in the study report.

The graphical results of the experiment presented in the study report are given below on figure B.8.1.2.1.2._CA-4 and in numerical form in the table B.8.1.2.1.2._CA-25.

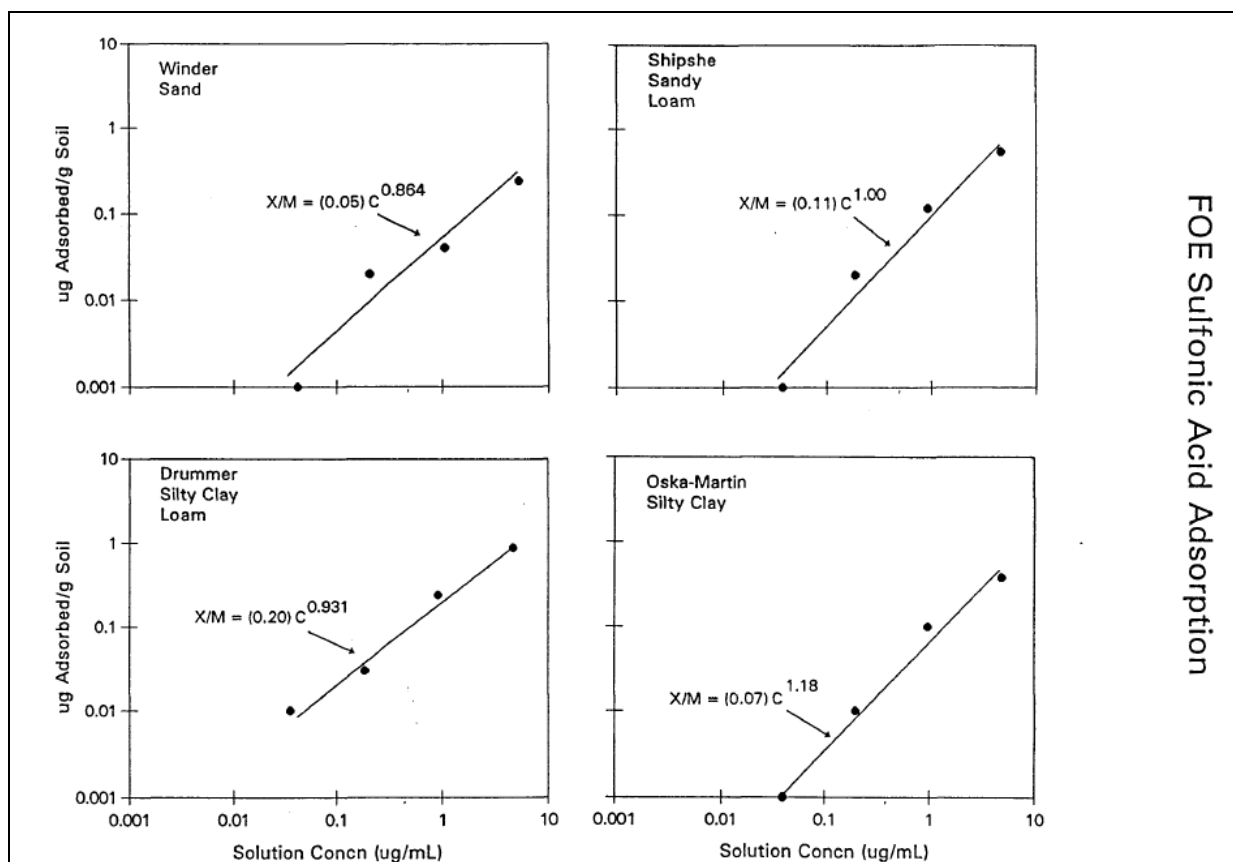

Figure B.8.1.2.1.2._CA-4: The adsorption isotherms for FOE Sulfonic acid provided by the Applicant (copied from the study report).

Table B.8.1.2.1.2._CA-25: The key numerical results of the experiment presented in the study report – parameters of Freundlich adsorption isotherm for FOE Sulfonic acid, including the correlation coefficient r

Test soil	Parameters of Freundlich adsorption isotherm					Parameters of Freundlich desorption isotherm				
	$\text{Log } K_{f \text{ ads}}$	$K_{f \text{ ads}} [\text{mL/g}]$	$1/n$	$K_{fOC \text{ ads}} [\text{mL/g}]$	r	$\text{Log } K_{f \text{ des}}$	$K_{f \text{ des}} [\text{mL/g}]$	$1/n$	$K_{fOC \text{ des}} [\text{mL/g}]$	r
Winder Sand soil	-1.30	0.05	0.864	19	0.973	Not determined				
Shipshe Sandy loam soil	-0.950	0.11	1.000	15	0.992	Not determined				
Drummer Silty clay loam soil	-0.689	0.20	0.931	10	0.970	Not determined				
Oska-Martin Silty clay soil	-1.14	0.07	1.180	6	0.988	Not determined				

The graphical and numerical results of the repeated analysis, performed by the RMS, of the data from the table B.8.1.2.1.2._CA-23 (for adsorption) are presented below on figure B.8.1.2.1.2._CA-5 and in the table B.8.1.2.1.2._CA-26.

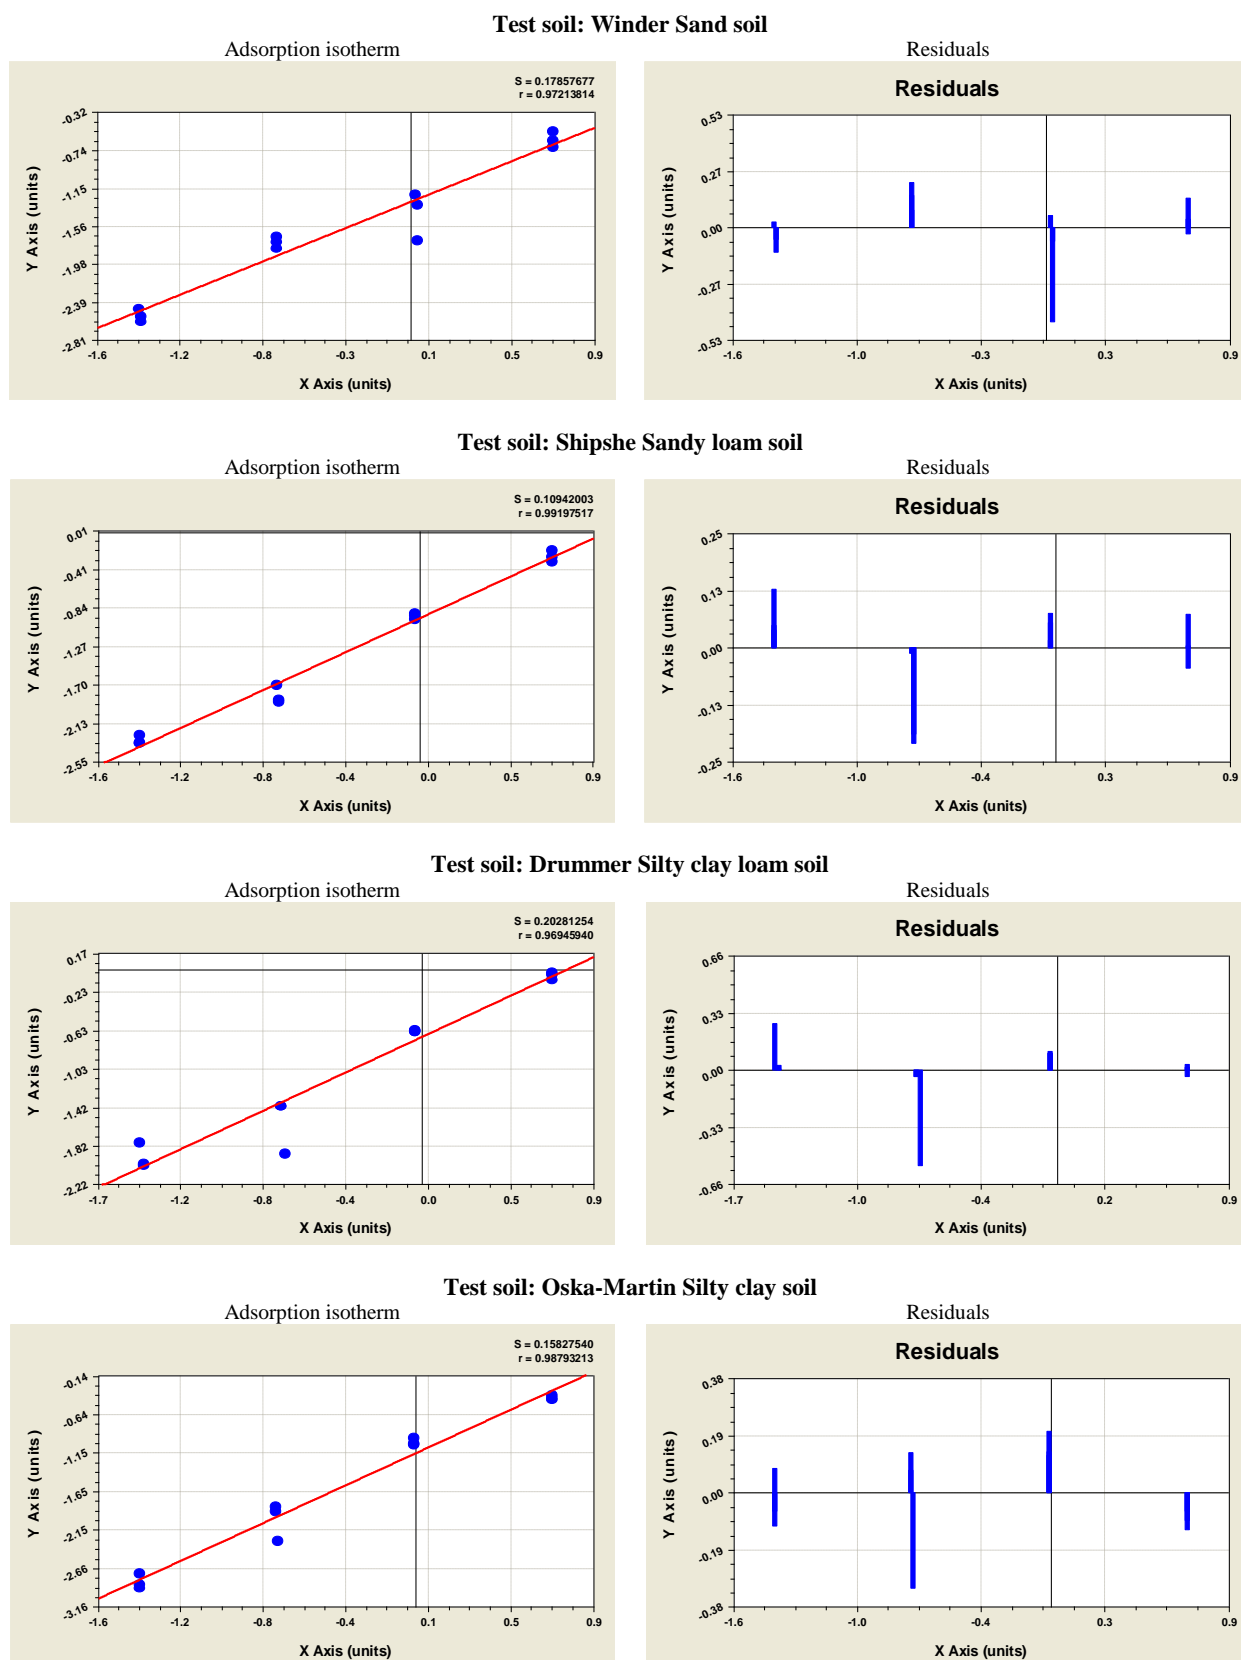

Figure B.8.1.2.1.2._CA-5: The adsorption isotherms for FOE Sulfonic acid determined by the RMS.

Table B.8.1.2.1.2._CA-26: The parameters of the Freundlich adsorption isotherm determined for FOE Sulfonic acid by the RMS

Test soil	Process	Parameters of isotherm				Statistical evaluation	
		Log K _F	K _F [mL/g]	K _{F OC} [mL/g]	1/n	SD	Correlation coefficient <i>r</i>
<i>Winder, Sand soil</i>	Adsorption	-1.294	0.051	18.88	0.865	0.1786	0.9721
<i>Shipshe, Sandy loam soil</i>	Adsorption	-0.974	0.106	14.13	1.002	0.1094	0.9920
<i>Drummer, Silty clay loam soil</i>	Adsorption	-0.690	0.204	9.58	0.931	0.2028	0.9695
<i>Oska-Martin, Silty clay soil</i>	Adsorption	-1.145	0.072	5.95	1.183	0.1583	0.9879

Conclusions of the experiment:

The comparison of the results presented in the study report and those obtained by the RMS showed that the parameters of the adsorption isotherms obtained by the Applicant and RMS were very similar. At the same time RMS stated that the determined adsorption isotherms displayed good conformity with the experimental results. It was not possible to determine the desorption isotherms. That was due to the fact that because of low level adsorption of FOE Sulfonic acid onto every test soil used in the experiment, the results obtained for the desorption bore very high level of uncertainty. The 1/n values for the adsorption isotherms were in range 0.865 – 1.183, indicating that the isotherms generally well complied with the assumed model. However, in case of the isotherm determined for Oska-Martin Silty clay soil the that value was close to 1.2, indicating that the mechanism other than that described by Freundlich equation may also be involved. This is not a definitive conclusion, because the high 1/n value may also be due to generally low level of adsorption and resulting preferential occupation of the sorption sites.

In case of the results obtained in Winder Sand soil it was stated that the adsorption isotherm was robust and well complied with the model – Freundlich sorption isotherm. For that reason RMS decided to include the results into the data set even though the OC content was lower than the recommended minimum – 0.3%.

The definitive set of the results from this experiment is presented below in the table B.8.1.2.1.2._CA-27. RMS decided to present the values determined as a result of the repeated analysis of the data set.

Table B.8.1.2.1.2._CA-27: The definitive set of Freundlich adsorption parameters determined for FOE Sulfonic acid.

Test soil – USDA type (name)	Key soil properties		Freundlich adsorption isotherm parameters			Freundlich desorption isotherm parameters		
	pH ¹⁾	OC [%]	K _F [mL/g]	K _{F OC} [mL/g]	1/n	K _F [mL/g]	K _{F OC} [mL/g]	1/n
<i>Sand (Winder)</i>	5.8	0.27	0.051	18.88	0.865	Not determined		
<i>Sandy loam (Shipshe)</i>	6.3	0.75	0.106	14.13	1.002	Not determined		
<i>Silty clay loam (Drummer)</i>	6.6	2.13	0.204	9.58	0.931	Not determined		
<i>Silty clay (Oska-Martin)</i>	6.0	1.21	0.072	5.95	1.183	Not determined		

Footnotes to the table:

1) Measured in water;

c) Results obtained for FOE Oxalate:

The results of the determination of the concentrations of the test compound in treatment solutions used in the experiment are presented below in the table B.8.1.2.1.2._CA-28.

Table B.8.1.2.1.2._CA-28: The results of the verification of the concentration of treatment solutions used in the Definitive Study for FOE Oxalate.

Test soil	Treatment solution code	Theoretical concentration of the test item [µg/mL]	Measured concentration of the test item [µg/mL]		
			Radiolabelled test item	Technical grade test item	Total concentration of the test item
<i>Winder Sand soil</i>	WI1-3	5.0	0.718	4.4	5.12
	WI2-3	1.0	0.143	0.88	1.02

	WI3-5	0.2	0.029	0.176	0.205
	WI4-5	0.04	0.006	0.0352	0.0410
<i>Oska-Martin Silty clay soil</i>	WI1-6	5.0	0.735	4.4	5.14
	WI2-6	1.0	0.147	0.88	1.03
	WI3-6	0.2	0.029	0.176	0.205
	WI4-6	0.04	0.006	0.0352	0.0412

The numerical results of experiment examining the adsorption of FOE Oxalate onto test soils are presented below in the table B.8.1.2.1.2._CA-29. The results of the experiment examining its desorption are presented in the table B.8.1.2.1.2._CA-30. The results obtained during examination of the adsorption showed that the adsorption of the test compound onto soil was very low, generally below 10%. For that reason the results of the desorption bear a significant level of uncertainty as the initial concentrations of the test compound retained by soil were very low. RMS decided to report the results presented by the Applicant noticing at the same time that they should be considered with extreme care, as in many instances the reported level of desorption is either above 100%, or a negative value, what is due to the fact that the concentrations were determined at levels close to LOQ.

For that reason the Applicant decided not to determine the desorption isotherms (the available data base did not enable doing that). The graphical results of the experiment – the adsorption isotherms reported in the study report, are given on figure B.8.1.2.1.2._CA-6 and in numerical form in the table B.8.1.2.1.2._CA-31. RMS decided to verify them using the values presented in the table B.8.1.2.1.2._CA-29 – the log-transformed concentrations in soil and solution at equilibrium. The results are provided on figure B.8.1.2.1.2._CA-7 and in numerical form in the table B.8.1.2.1.2._CA-32. The tool used in that exercise was CurveExpert ver. 1.4. Performing the fitting the RMS used the data for the replicates not averaging them, as had done the Applicant.

Table B.8.1.2.1.2._CA-29: The results of the examination of the adsorption of FOE Oxalate onto test soils to determine Freundlich adsorption isotherm.

Test soil	Initial concentration of the solution [µg/mL]	Replicate	Results of the experiment:

Footnotes to the table:

- 1) n. c. = not calculated;
- 2) n. r. = not reported, probably not determined;
- 3) all values as reported in the study report;
- 4) all values as reported in the study report.

The graphical results of the experiment presented in the study report are given below on figure B.8.1.2.1.2._CA-6 and in numerical form in the table B.8.1.2.1.2._CA-31.

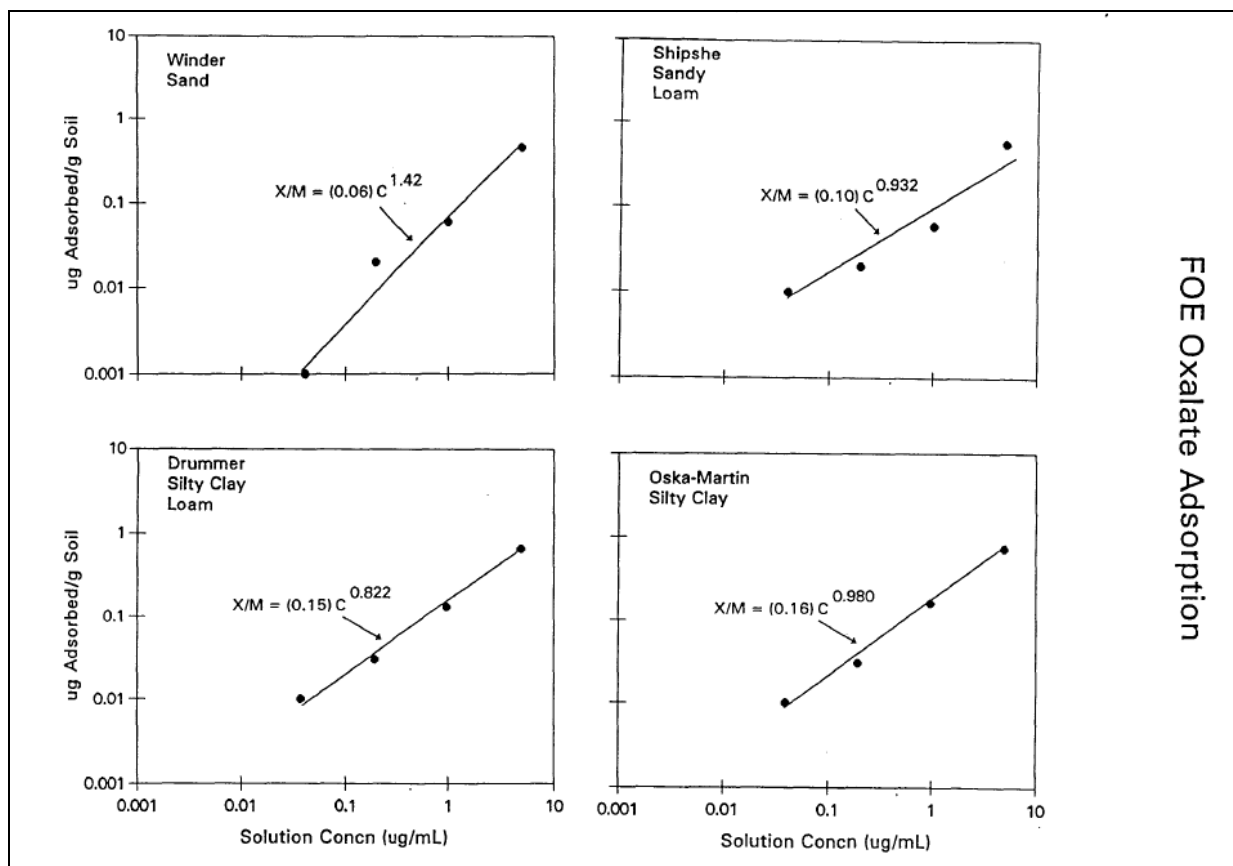

Figure B.8.1.2.1.2_CA-6: The adsorption isotherm for FOE Oxalate provided by the Applicant (copied from the study report).

Table B.8.1.2.1.2_CA-31: The key numerical results of the experiment presented in the study report – parameters of Freundlich adsorption isotherm for FOE Oxalate, including the correlation coefficient r

Test soil	Parameters of Freundlich adsorption isotherm					Parameters of Freundlich desorption isotherm				
	$\text{Log } K_{f \text{ ads}}$	$K_{f \text{ ads}} [\text{mL/g}]$	$1/n$	$K_{f \text{ OC ads}} [\text{mL/g}]$	r	$\text{Log } K_{f \text{ des}}$	$K_{f \text{ des}} [\text{mL/g}]$	$1/n$	$K_{f \text{ OC des}} [\text{mL/g}]$	r
Winder Sand soil	-1.22	0.06	1.42	23	0.923	Not determined				
Shipshe Sandy loam soil	-1.02	0.10	0.932	13	0.981	Not determined				
Drummer Silty clay loam soil	-0.816	0.15	0.822	7	0.989	Not determined				
Oska-Martin Silty clay soil	-0.806	0.16	0.980	13	1.00	Not determined				

The graphical and numerical results of the repeated analysis, performed by the RMS, of the data from the table B.8.1.2.1.2_CA-29 (for adsorption) are presented below on figure B.8.1.2.1.2_CA-7 and in the table B.8.1.2.1.2_CA-32.

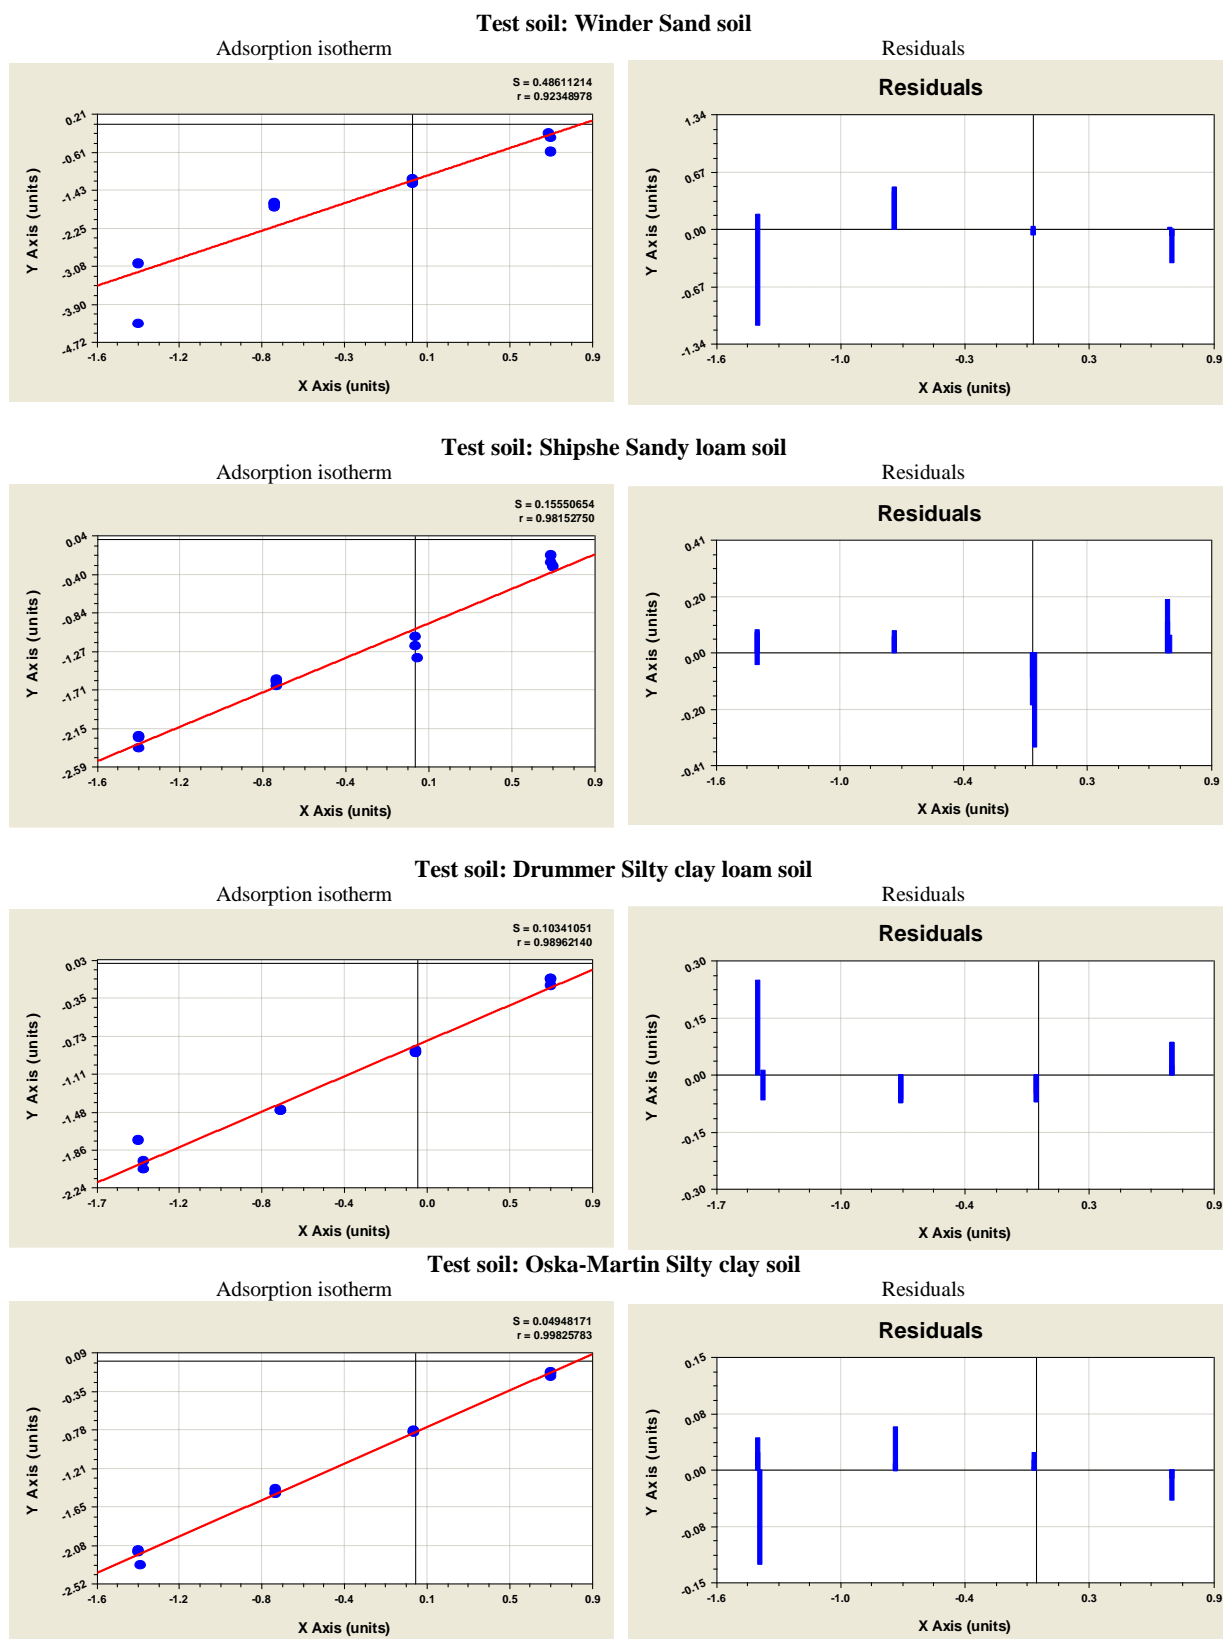

Figure B.8.1.2.1.2._CA-7: The adsorption isotherms for FOE Oxalate determined by the RMS.

Table B.8.1.2.1.2._CA-32: The parameters of the Freundlich adsorption isotherm determined for FOE Oxalate by the RMS

Test soil	Process	Parameters of isotherm				Statistical evaluation	
		Log K _F	K _F [mL/g]	K _{F OC} [mL/g]	1/n	SD	Correlation coefficient <i>r</i>
<i>Winder, Sand soil</i>	Adsorption	-1.214	0.061	22.59	1.423	0.4861	0.9230
<i>Shipshe, Sandy loam soil</i>	Adsorption	-1.018	0.096	12.80	0.933	0.1555	0.9815
<i>Drummer, Silty clay loam soil</i>	Adsorption	-0.814	0.153	7.18	0.824	0.1034	0.9896
<i>Oska-Martin, Silty clay soil</i>	Adsorption	-0.805	0.157	12.97	0.978	0.0495	0.9983

Conclusions of the experiment:

The comparison of the results presented in the study report and those obtained by the RMS showed that the parameters of the adsorption isotherms obtained by the Applicant and RMS were very similar. At the same time RMS stated that the determined adsorption isotherms displayed good conformity with the experimental results. It was not possible to determine the desorption isotherms. That was due to the fact that because of low level adsorption of FOE Oxalate onto every test soil used in the experiment, the results obtained for the desorption bore very high level of uncertainty. The 1/n values for the adsorption isotherms were in range 0.824 – 1.423, with the highest value obtained for Winder Sand soil. In case of three remaining soil the 1/n were in range 0.824 – 0.978, indicating that for these three soils the isotherms well complied with the assumed model. In case of the isotherm determined for Winder Sand soil the high 1/n value of 1.423 may indicate that the mechanism other than that described by Freundlich equation could also be involved. This however is not a definitive conclusion, because the high 1/n value may also be due to generally low level of adsorption and resulting preferential occupation of the sorption sites.

However, because of high 1/n value, indicating the adsorption mechanism other than that described by Freundlich isotherm, and also due to the fact that the OC = 0.27% was below the recommended lowest level of 0.3%, the parameters of Freundlich adsorption isotherm obtained in Winder Sand soil cannot be considered reliable. For that reason RMS decided not to include these results into the final data set.

The definitive set of the results from this experiment is presented below in the table B.8.1.2.1.2._CA-33. RMS decided to present the values determined as a result of the repeated analysis of the data set.

Table B.8.1.2.1.2._CA-33: The definitive set of Freundlich adsorption and desorption parameters determined for FOE Oxalate.

Test soil – USDA type (name)	Key soil properties		Freundlich adsorption isotherm parameters			Freundlich desorption isotherm parameters		
	pH ¹⁾	OC [%]	K _F [mL/g]	K _{F OC} [mL/g]	1/n	K _F [mL/g]	K _{F OC} [mL/g]	1/n
<i>Sandy loam (Shipshe)</i>	6.3	0.75	09.096	12.80	0.933	Not determined		
<i>Silty clay loam (Drummer)</i>	6.6	2.13	0.153	7.18	0.824	Not determined		
<i>Silty clay (Oska-Martin)</i>	6.0	1.21	0.157	12.97	0.978	Not determined		

Footnotes to the table:

1) Measured in water;

d) Results obtained for FOE Alcohol:

The results of the determination of the concentrations of the test compound in treatment solutions used in the experiment are presented below in the table B.8.1.2.1.2._CA-34.

Table B.8.1.2.1.2._CA-34: The results of the verification of the concentration of treatment solutions used in the Definitive Study for FOE Alcohol.

Test soil	Treatment solution code	Theoretical concentration of the test item [µg/mL]	Measured concentration of the test item [µg/mL]

	WL4-6	0.04	0.002	0.0384	0.0407

The numerical results of experiment examining the adsorption of FOE Alcohol onto test soils are presented below in the table B.8.1.2.1.2._CA-35. The results of the experiment examining its desorption are presented in the table B.8.1.2.1.2._CA-36. The graphical results of the experiment – the adsorption and desorption isotherms determined for each test soil, are presented on figure B.8.1.2.1.2._CA-8. The key numerical results are provided in the table B.8.1.2.1.2._CA-37. Analysing these results RMS stated that it was not possible to interpret them appropriately as the Applicant did not distinguish the isotherms representing adsorption and desorption. For that reason it was also not possible to verify the correctness of the determined parameters of each isotherm. For that reason RMS decided to repeat the determination of the isotherms using the same data as presented in tables B.8.1.2.1.2._CA-35 and B.8.1.2.1.2._CA-36 – the log-transformed data. The adsorption and desorption isotherms were determined separately. The tool used in that exercise was CurveExpert ver 1.40. The graphical results are presented on two figures – B.8.1.2.1.2._CA-9 for adsorption and B.8.1.2.1.2._CA-10 for desorption. The corresponding numerical results are provided in the table B.8.1.2.1.2._CA-38. Performing the fitting the RMS used the data for the replicates not averaging them, as had done the Applicant.

Table B.8.1.2.1.2._CA-35: The results of the examination of the adsorption of FOE Alcohol onto test soils to determine Freundlich adsorption isotherm.

The graphical and numerical results of the repeated analysis, performed by the RMS, of the data from the tables B.8.1.2.1.2_CA-35 (for adsorption) and B.8.1.2.1.2_CA-36 (for desorption) are presented below on figures B.8.1.2.1.2_CA-9 (adsorption) and B.8.1.2.1.2_CA-10 (desorption) and in the table B.8.1.2.1.2_CA-38.

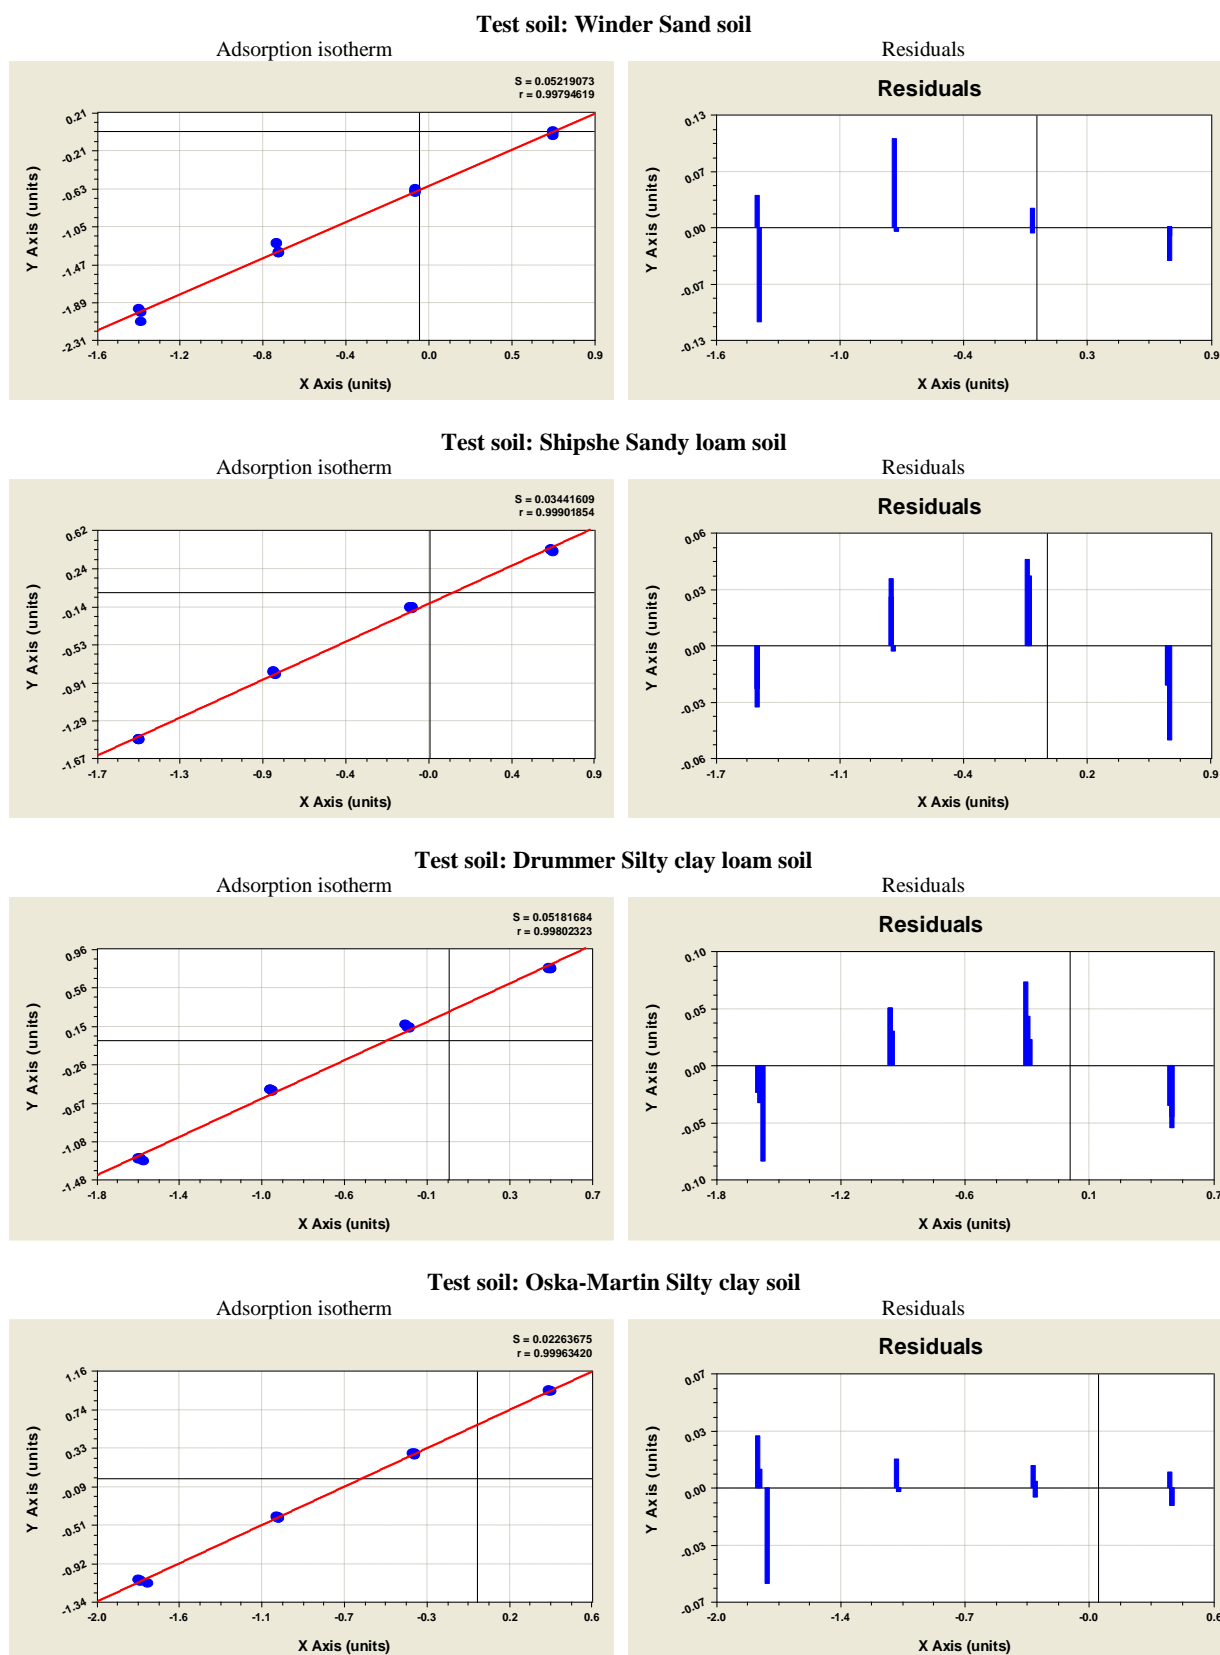

Figure B.8.1.2.1.2._CA-32: The adsorption isotherms for FOE Alcohol determined by the RMS.

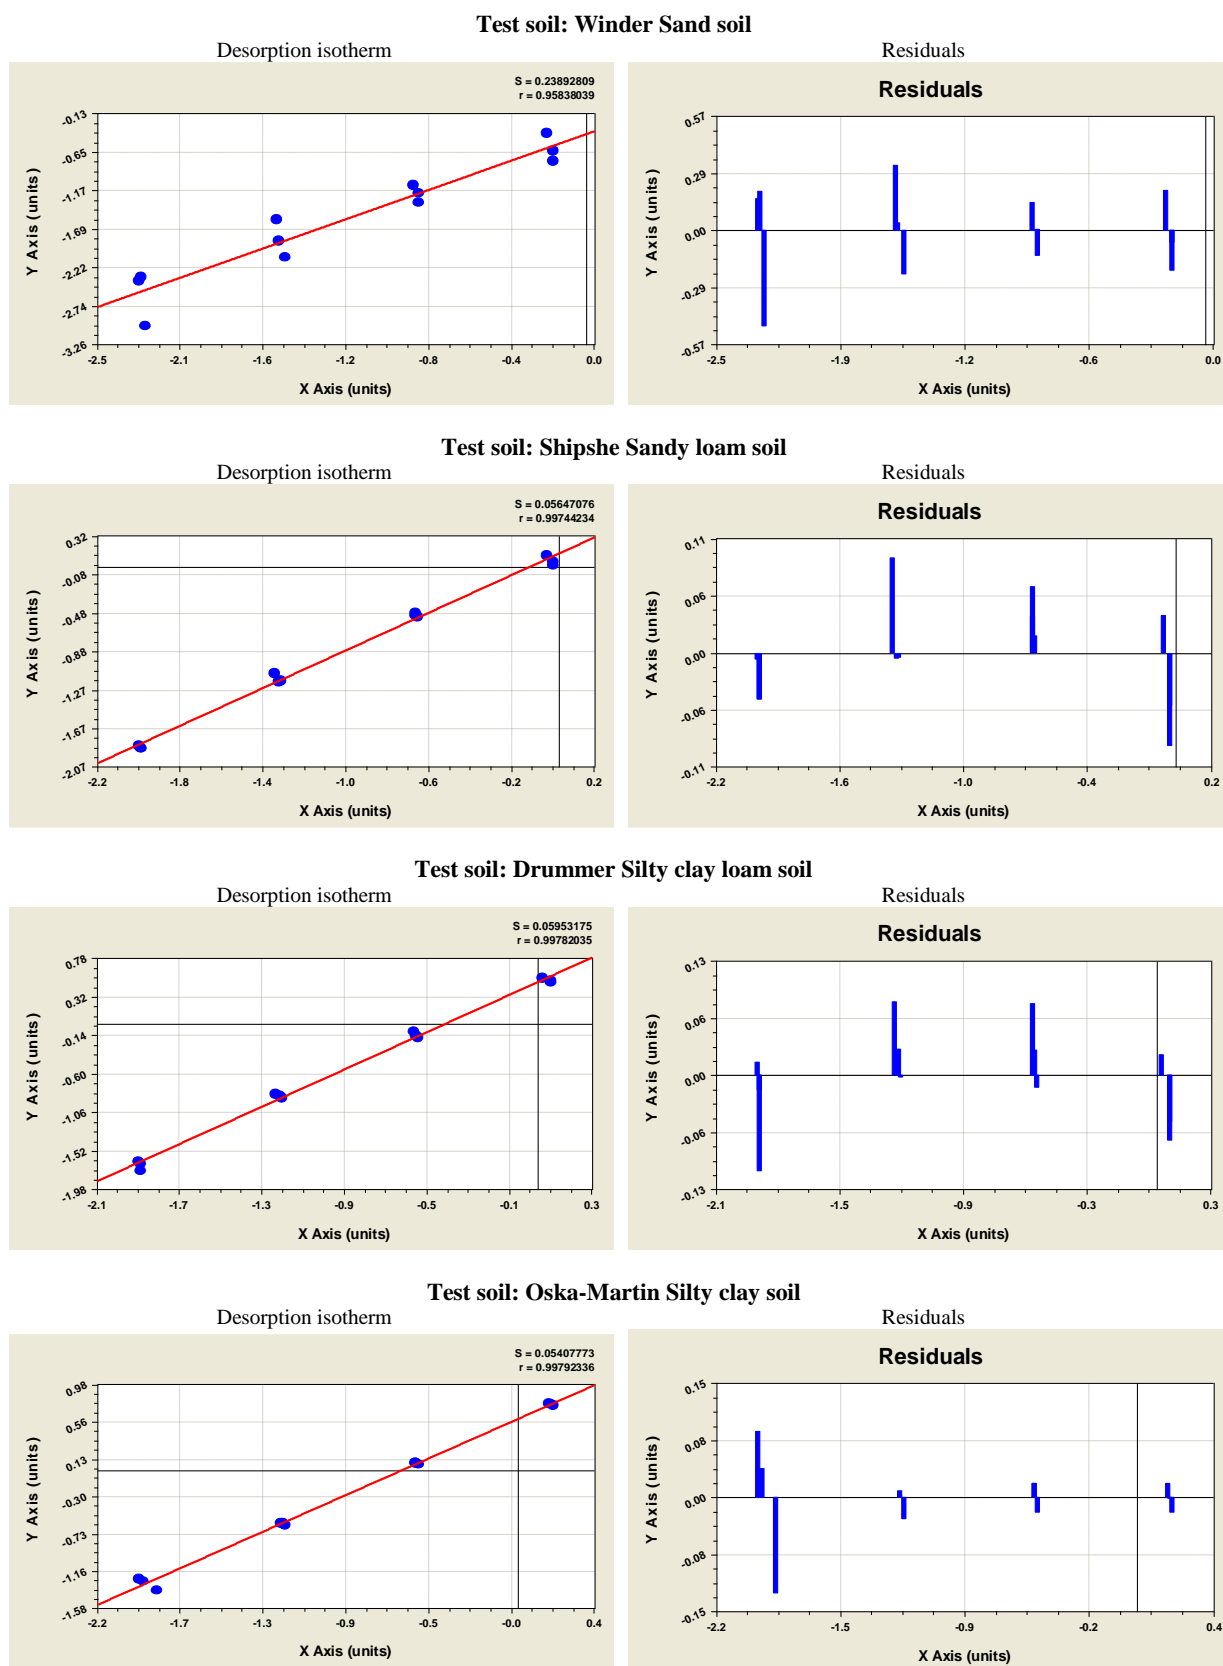

Figure B.8.1.2.1.2_CA-33: The desorption isotherms for FOE Alcohol determined by the RMS.

Table B.8.1.2.1.2._CA-38: The parameters of the Freundlich adsorption and desorption isotherms determined for FOE Alcohol by the RMS

Test soil	Process	Parameters of isotherm				Statistical evaluation	
		Log K _F	K _F [mL/g]	K _{F OC} [mL/g]	1/n	SD	Correlation coefficient <i>r</i>
<i>Winder, Sand soil</i>	Adsorption	-0.645	0.226	83.70	0.947	0.0522	0.9979
	Desorption	-0.403	0.395	52.67	0.946	0.2389	0.9584
<i>Shipshe, Sandy loam soil</i>	Adsorption	-0.108	0.780	104.00	0.887	0.0344	0.9990
	Desorption	0.141	1.384	184.53	0.970	0.0565	0.9974
<i>Drummer, Silty clay loam soil</i>	Adsorption	0.305	2.018	94.74	0.940	0.0518	0.9980
	Desorption	0.504	3.191	149.81	1.142	0.0595	0.9978
<i>Oska-Martin, Silty clay soil</i>	Adsorption	0.580	3.802	314.21	0.950	0.0226	0.9996
	Desorption	0.593	3.917	323.72	0.986	0.0541	0.9979

Conclusions of the experiment:

The comparison of the results presented in the study report and those obtained by the RMS showed that the parameters of the adsorption and desorption isotherms obtained by the Applicant and RMS were almost identical. At the same time RMS stated that the determined adsorption isotherms displayed very good conformity with the experimental results. That conformity was also good in case of the desorption isotherms.

The 1/n values for the adsorption isotherms were in range 0.887 – 0.950, indicating that the isotherms well complied with the assumed model. In case of the results obtained in Winder Sand soil it was stated that the adsorption isotherm was robust and well complied with the model – Freundlich sorption isotherm. For that reason RMS decided to include the results into the data set even though the OC content was lower than the recommended minimum – 0.3%.

The definitive set of the results from this experiment is presented below in the table B.8.1.2.1.2._CA-39. RMS decided to present the values determined as a result of the repeated analysis of the data set.

Table B.8.1.2.1.2._CA-39: The definitive set of Freundlich adsorption and desorption parameters determined for FOE Alcohol.

Test soil – USDA type (name)	Key soil properties		Freundlich adsorption isotherm parameters			Freundlich desorption isotherm parameters		
	pH ¹⁾	OC [%]	K _F [mL/g]	K _{F OC} [mL/g]	1/n	K _F [mL/g]	K _{F OC} [mL/g]	1/n
<i>Sand (Winder)</i>	5.8	0.27	0.226	83.70	0.947	0.395	52.67	0.946
<i>Sandy loam (Shipshe)</i>	6.3	0.75	0.780	104.00	0.887	1.384	184.53	0.970
<i>Silty clay loam (Drummer)</i>	6.6	2.13	2.018	94.74	0.940	3.191	149.81	1.142
<i>Silty clay (Oska-Martin)</i>	6.0	1.21	3.802	314.21	0.950	3.917	323.72	0.986

Footnotes to the table:

1) Measured in water;

e) Results obtained for FOE Thiadone:

The results of the determination of the concentrations of the test compound in treatment solutions used in the experiment are presented below in the table B.8.1.2.1.2._CA-40.

Table B.8.1.2.1.2._CA-40: The results of the verification of the concentration of treatment solutions used in the Definitive Study for FOE Thiadone.

Test soil	Treatment solution code	Theoretical concentration of the test item [µg/mL]	Measured concentration of the test item [µg/mL]		
			Radiolabelled test item	Technical grade test item	Total concentration of the test item

The numerical results of experiment examining the adsorption of FOE Thiadone onto test soils are presented below in the table B.8.1.2.1.2._CA-41. The results of the experiment examining its desorption are presented in the table B.8.1.2.1.2._CA-42. The graphical results of the experiment – the adsorption and desorption isotherms determined for each test soil, are presented on figure B.8.1.2.1.2._CA-11. The key numerical results are provided in the table B.8.1.2.1.2._CA-43. Analysing these results RMS stated that it was not possible to interpret them appropriately as the Applicant did not distinguish the isotherms representing adsorption and desorption. For that reason it was also not possible to verify the correctness of the determined parameters of each isotherm. For that reason RMS decided to repeat the determination of the isotherms using the same data as presented in tables B.8.1.2.1.2._CA-41 and B.8.1.2.1.2._CA-42 – the log-transformed data. The adsorption and desorption isotherms were determined separately. The tool used in that exercise was CurveExpert ver 1.40. The graphical results are presented on two figures – B.8.1.2.1.2._CA-12 for adsorption and B.8.1.2.1.2._CA-13 for desorption. The corresponding numerical results are provided in the table B.8.1.2.1.2._CA-44. Performing the fitting the RMS used the data for the replicates not averaging them, as had done the Applicant.

Table B.8.1.2.1.2._CA-41: The results of the examination of the adsorption of FOE Thiadone onto test soils to determine Freundlich adsorption isotherm.

Test soil	Initial concentration of the solution [µg/mL]	Replicate	Results of the experiment:

Conclusions of the experiment:

The comparison of the results presented in the study report and those obtained by the RMS showed that the parameters of the adsorption isotherms obtained by the Applicant and RMS were very similar. In case however of the desorption isotherms the obtained results displayed some differences. That was stated in particular for Winder Sand soil and Shipshe Sandy loam soil.

RMS also stated that the determined adsorption isotherms displayed good conformity with the experimental results. Similar statement can be made in case of the desorption isotherms.

The 1/n values for the adsorption isotherms were in range 0.672 – 0.806, indicating that the isotherms complied to the acceptable degree with the assumed model. In case of the results obtained in Winder Sand soil it was stated that the adsorption isotherm was robust and well complied with the model – Freundlich sorption isotherm. For that reason RMS decided to include the results into the data set even though the OC content was lower than the recommended minimum – 0.3%.

The definitive set of the results from this experiment is presented below in the table B.8.1.2.1.2._CA-45. RMS decided to present the values determined as a result of the repeated analysis of the data set.

Table B.8.1.2.1.2._CA-45: The definitive set of Freundlich adsorption and desorption parameters determined for FOE Thiadone.

Test soil – USDA type (name)	Key soil properties		Freundlich adsorption isotherm parameters			Freundlich desorption isotherm parameters

Final conclusions of the study:

The examination of the soil sorption of five degradation products of Flufenacet – FOE Methylsulfoxide, FOE Sulfonic acid, FOE Oxalate, FOE Alcohol and FOE Thiadone was carried out using four different agricultural US soils. The test soils had representative range of OC content, but relatively narrow range of pH – one of them was acidic, the remaining three neutral. That relatively narrow range of soil pH does not enable to make a definitive conclusion concerning the would-be pH-dependence of the adsorption, but generally low level of adsorption indicates that that phenomenon, if occurs, may not have a significant influence on the sorption properties of the test compounds.

It was stated that the test compounds were weakly to moderately sorbed onto soil, what was correlated with their properties, such as acidity (e.g. FOE Sulfonic acid and FOE Oxalate are relatively strong organic acid, in soil expected to be present in dissociated state) or water solubility.

In general FOE Sulfonic acid and FOE Oxalate were weakly sorbed onto soil and the process was fully reversible. FOE Methylsulfoxide, FOE Alcohol and FOE Thiadone were sorbed onto soil more strongly, although they should be classified in general as weakly to moderately sorbed onto soil, and the adsorption was to the significant degree reversible.

In case of four test compounds – FOE Methylsulfoxide, FOE Sulfonic acid, FOE Alcohol and FOE Thiadone, it was possible to determine reliable Freundlich isotherm adsorption parameters in all four test soils. In case of FOE Oxalate reliable Freundlich isotherm adsorption parameters were determined for three test soils, all having pH in neutral range (between 6.0 and 6.6), what limits the possibility of the examination of the pH-dependence of the soil sorption for that compound. On the other hand, the analysis of the physicochemical properties of that compound, and in particular its acidity, may indicate that that phenomenon may play only minor role in its sorptive behaviour in soil.

The definitive results of the study – the Freundlich adsorption parameters for each test compound, are presented below in reporting format recommended for EU-agreed List of End Points.

Soil adsorption transformation products (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.3.1.2 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.2.1)

Study 2:

Report: Hein W., (2011): “[Phenyl-UL-¹⁴C] BCS-CO62475: Adsorption/Desorption in Five Different Soils.”; RLP AgroScience GmbH, Breitenweg 71, 67435 Neustadt a. d. Weinstrasse, Germany (performing laboratory) for Bayer CropScience Aktiengesellschaft, Development, Environmental Safety Metabolism/ADME and Environmental Fate, Alfred Nobel Str. 50, D-40789 Monheim, Germany; Study number (RLP AgroSciences GmbH) AS158; Bayer Report No. M-411141-01-1; 30 June 2011; study reference number: M-411141-01-1.

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for Testing of Chemicals No 106 “Adsorption/Desorption”, Jan. 21, 2000;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835. 1220 Sediment and Soil Adsorption/Desorption Isotherm;
- Canada Pest Management Regulatory Agency (PMRA), Environmental Chemistry and Fate, Guidelines for Registration of Pesticides in Canada, 1987.

GLP: Yes;

RMS comments: This is a newly submitted study, aimed on the examination of the soil sorption of FOE Methylsulfone – one of the major soil degradation products of Flufenacet. For the purpose of the current assessment it was evaluated for compliance with the following Guidelines:

- OECD Guideline for Testing of Chemicals No 106, Adsorption – Desorption Using a Batch Equilibrium Method, adopted 21st January 2000;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1220, Sediment and Soil Adsorption/Desorption Isotherm, January 1998;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1230, Adsorption/Desorption (Batch Equilibrium), October 2000;

It was stated that the study complied with the provisions of the evoked Guidelines. However, the RMS examining the study report stated that the Freundlich adsorption and desorption isotherms were determined using the averaged equilibrium data for each initial concentration of the test compound, although the values for each replicate were reported. Additionally the linearised Freundlich adsorption and desorption isotherms for the given test soil were presented on the same graph and they were not clearly distinguished, what caused problems with the interpretation of the results. For that reason RMS decided to repeat the fitting of the data using the replicates as individual input data and separating adsorption and desorption isotherms. The study is summarised below.

Summary:

The aim of the study was to examine the adsorption and desorption of FOE Methylsulfone (for the purpose of this study bearing a codename BCS-CO62475) – a major soil degradation product of Flufenacet, onto soil. The examination was performed using five test soils, three EU and two US soils. Their characteristic is provided below in the table B.8.1.2.1.2._CA-46.

The test soils were sampled from the agriculturally used areas. In case of the EU soils, they were sampled from fields on which no pesticides were used for at least 5 years prior to the sampling. They were collected from the 0-20 cm layer using the shovel. The soil samples were air-dried and sieved through 2-mm sieve before being delivered to the test facility. There they were stored first in ambient conditions and then at T = 0-10°C until being used.

One of the US soils was sampled from the field on which different pesticides used on cabbage, broccoli and lettuce were applied until December 2007. After that, until sampling in March 2009 (for approx. 15 consecutive months), no use of any plant protection products was recorded. The second US soil was sampled from the field on which no pesticides were used for at least three consecutive years before sampling. Soil samples were collected by shovel from the top 6- to 8-inch layer (corresponding to the soil depth of 0-15 cm or 0-20 cm). The soil samples were air-dried and sieved through 2-mm sieve before being delivered to the test facility. There they were stored first in ambient conditions and then at T = 0-10°C until being used.

The storage period was following:

- for the EU soils: 740 days after delivery to the test facility;
- for the US soils: 718 days after delivery to the test facility.

Table B.8.1.2.1.2._CA-46: The characteristic of soils used in the study.

Parameter	Soil				
	<i>Wurmwiese</i>	<i>Höfchen am Hohenseh 4a</i>	<i>Dollendorf II</i>	<i>Guadalupe CA</i>	<i>Springfield NE</i>

CEC [meq/100 g]	10.8	13.9	21.9	16.1	16.1

The test compound used in the experiment was the ¹⁴C-FOE Methylsulfone uniformly radiolabelled in phenyl ring, as shown below on figure B.8.1.2.1.2._CA-14.

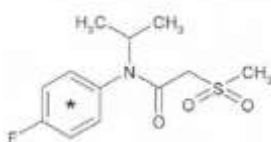

Figure B.8.1.2.1.2._CA-14: The structural formula of the radiolabelled FOE Methylsulfone (BCS-CO62475) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The test compound had specific activity of 3.26 MBq/mg (88 µCi/mg), radiochemical purity (determined by HPLC) of > 98% and chemical purity (also determined by HPLC) of > 98%. It was delivered to the test facility as a transparent, vacuum-dried solid. It was stored in the test facility at $T \leq -18^{\circ}\text{C}$ until being used.

The whole delivered sample was used to prepare the **Standard Stock Solution I**, bearing the code-name **SSL I**. That was done by transferring the whole amount of the radiolabelled test compound into a 10-mL volumetric flask and dissolving it in CH₃CN added up to calibration mark. The so prepared stock solution was analysed for its concentration of the test item by LSC. That was done using two 0.1-mL aliquots of the stock solution diluted 50 times before being analysed.

The so determined concentration of the test item in the standard solution was 0.537 mg/mL. Additionally the radiopurity of the solution was determined using radio-HPLC. It was > 98.5%.

Additionally, as a reference compound for chromatography, the non-radiolabelled FOE Methylsulfone was used in the experiment. It was delivered to the test facility as a white solid, having a chemical purity of 97.2%. It was used to prepare the **Standard Stock Solution II** by weighing 3.6 mg of it and dissolving it in 3.6 mL CH₃CN.

The whole experiment was carried out using 0.01M CaCl₂ aq solution, prepared by dissolving 2.94 g CaCl₂ x 2 H₂O in 2 litres of distilled water. The so prepared solutions were used throughout the whole study. Their pH was in range 6.57 – 6.77. They were generally labelled **Stock Solution I_{Bio}** (**SL I_{Bio}**) and as such used to prepare the treatment solutions used in the experiment.

The whole study consisted of three steps, further called experiments:

- the **Preliminary Test I**, aimed on the determination of the appropriate soil:solution ratio for each test soil, stability of the test item in 0.01M CaCl₂ aq solution and its potential adsorption to the test vessels; the experiment was performed using a single initial concentration of the test item – 1.00 mg/L (highest concentration of FOE Methylsulfone used in the study);

- the **Preliminary Test II**, in which was determined the appropriate equilibration time and parental mass balance in order to demonstrate the stability of the test compound during incubation for determining sorption isotherms; the experiment was performed using a single initial concentration of the test item – 1.00 mg/L (highest concentration of FOE Methylsulfone used in the study);
- the **Definitive Test**, aimed on the determination of the Freundlich adsorption and desorption isotherm and calculation of their parameters - K_F and $1/n$ values; at this stage five different nominal initial concentrations of the test compound – FOE Methylsulfone, were used: 0.01 mg/L, 0.03 mg/L, 0.10 mg/L, 0.30 mg/L and 1.00 mg/L.

The test compound was administered in form of the application solutions prepared from the **Standard Stock Solution I (SSL I)** as aqueous solutions in 0.01M $\text{CaCl}_{2\text{aq}}$.

In case of the **Preliminary Test I** the application solution was prepared by transferring 0.745 mL of the solution **SSL I** into the appropriate flask. The organic solvent was evaporated under the gentle stream of N_2 and residue redissolved in 40 mL of **SL I_{Bio}** solution. The so prepared solution was then analysed by LSC for concentration of the test item and by radio-HPLC for its radiopurity.

In case of the **Preliminary Test II** the application solution was prepared by transferring 2.7 mL of the solution **SSL I** into the appropriate flask. The organic solvent was evaporated under the gentle stream of N_2 and residue redissolved in 145 mL of **SL I_{Bio}** solution. The so prepared solution was then analysed by LSC for concentration of the test item and by radio-HPLC for its radiopurity.

The application solutions for the **Definitive Test** were prepared by a serial dilution of the solution **SSL I**. As a first step the **Solution A**, having a nominal concentration 10 mg/L, was prepared from a solution **SSL I**. That was done by transferring 0.838 mL of the solution **SSL I** into the appropriate flask. The organic solvent was evaporated under the gentle stream of N_2 and the residue redissolved in 45 mL of **SL I_{Bio}** solution. The so prepared solution was then analysed by LSC for concentration of the test item and by radio-HPLC for its radiopurity. Next, the four remaining application solutions, marked **B**, **C**, **D** and **E** were prepared by diluting the **Solution A** with the **SL I_{Bio}** solution. The procedure looked as follows:

- the **Solution B**, having a nominal concentration of 3.0 mg/L, was prepared by transferring 7.50 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution;
- the **Solution C**, having a nominal concentration of 1.0 mg/L, was prepared by transferring 2.50 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution;
- the **Solution D**, having a nominal concentration of 0.30 mg/L, was prepared by transferring 0.75 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution;
- the **Solution E**, having a nominal concentration of 0.10 mg/L, was prepared by transferring 0.25 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution.

The so prepared solutions were then analysed by LSC for concentration of the test item and by radio-HPLC for their radiopurity.

The measured concentrations of the so prepared application solutions were following:

- **Solution A** (nominal concentration 10.0 mg/L): 9.90 mg/L;
- **Solution B** (nominal concentration 3.00 mg/L): 2.95 mg/L;
- **Solution C** (nominal concentration 1.00 mg/L): 0.98 mg/L;
- **Solution D** (nominal concentration 0.30 mg/L): 0.29 mg/L;
- **Solution E** (nominal concentration 0.10 mg/L): 0.10 mg/L;

Their radiopurity was > 98%.

The study was performed using the following general conditions:

- all experiments were performed in the darkness and at constant temperature $T = 20 \pm 2^\circ\text{C}$;
- test vessels were borosilicate glass centrifuge tubes with Teflon lined screw caps;
- the **Preliminary Test I** and the **Definitive Test** were carried out in 42-mL test vessels using the total volume of solution (not corrected for the soil residual moisture content) of 20 mL;
- the **Preliminary Test II** was performed in 83-mL test vessels using the total volume of solution (not corrected for the soil residual moisture content) of 50 mL;
- equilibration was performed by shaking the test vessels for the pre-defined amount of time on the horizontal overhead shaker at ~20 rpm;
- at the end of equilibration samples containing soil were centrifuged for about 10 minutes at ~5000 rpm (~4200 g) to separate liquid and solid phases;

- in all experiments with the test soils the samples were pre-equilibrated for at least 16 hours before introduction of the test compound; the pre-equilibration procedure is characterised in details for each experiment, as they differed due to the different amounts of solution used.

The **Preliminary Test I** was aimed on the determination of the appropriate soil:solution ratio for each test soil and the stability of the test compound in 0.01M CaCl₂ _{aq} solution.

The examination of the stability of FOE Methylsulfone in 0.01M CaCl₂ _{aq} solution was carried out in soilless systems. First two 42-mL test vessels were filled each with 18 mL of **SL I_{Bio}** solution. Next, to each of them 2 mL of the **Solution A** were added to obtain the final volume of 20 mL and the concentration of the test item (nominal) 1.0 mg/L. So prepared test vessels were capped and equilibrated for up to 96 hours. At pre-defined time points – 24 hours, 48 hours, 72 hours and 96 hours of shaking, aliquots of each test solution were analysed by LSC and HPLC.

The experiment aimed on the determination of the appropriate soil:solution ratio began by weighing 2-g, 10-g and 20-g portions of each test soil into 42-mL test vessels. All samples were prepared in duplicate. Next, to each test vessel 18 mL of **SL I_{Bio}** solution were added, test vessels capped and so prepared samples pre-equilibrated overnight (for ≥16 hours). After pre-equilibration samples were centrifuged for 5 minutes at 1000 rpm and 2 mL of the **Solution A** were added to obtain the final volume of 20 mL and the concentration of the test item (nominal) 1.0 mg/L. So prepared samples were then equilibrated, by shaking on horizontal shaker, for 24 hours. After that period samples were centrifuged and radioactivity content in supernatants determined by LSC. Additionally, for each test soil and each tested soil:solution ratio, pH of the supernatants was determined using one of the replicates.

The appropriate soil:solution ratio was determined on the basis of the results of LSC analysis of supernatants after equilibration and in comparison to the initial measured concentration of the test item in solution, which was 1.018 mg/L.

The **Preliminary Test II** was aimed on the determination of the appropriate equilibration time and the stability of the test compound in the test system.

The experiment was performed using 83-mL test vessels and the total volume of the solution (not corrected for residual soil moisture content) of 50 mL. It was carried out using the soil:solution ratio determined individually for each test soil at preceeding step.

The experiment was initiated by weighing the appropriate amount of the test soil into the test vessels. For each test soil five replicates were prepared. Next, to each test vessel 45 mL of **SL I_{Bio}** solution were added, test vessels capped and so prepared samples pre-equilibrated overnight (for ≥16 hours). After pre-equilibration 5 mL of the **Solution A** were added to obtain the final volume of 50 mL and the concentration of the test item (nominal) 1.0 mg/L. So prepared samples were then equilibrated, by shaking on horizontal shaker, for up to 120 hours. At pre-defined time points – after 2 hours, 4 hours, 6 hours 24 hours, 30 hours, 48 hours, 72 hours 96 hours and 120 hours of shaking, samples were taken for analysis. The sampling procedure, as characterised in the study report, is presented below on figure B.8.1.2.1.2._CA-15.

Sampling Procedure for the Determination of Adsorption Equilibrium Times and Matrix Stability Analysis per Soil:

Time	2 h	4 h	6 h	24 h	30 h	48 h	72 h	96 h	120 h
Rep 1		X		○					
Rep 2			X	X		○			
Rep 3	X		X			X	○		
Rep 4	X				X		X	○	
Rep 5		X			X			X	○

X =

- 1) Removed from shaker
- 2) Centrifuged, 10 min, 5000 rpm = 4200^g, 20°C
- 3) An aliquot of the supernatant was taken and afterwards analysed by LSC
- 4) Return to shaker

○ =

- 1) Centrifuged (Conditions see above)
- 2) Complete removal of supernatant
- 3) LSC and HPLC supernatant
- 4) Extracted soil and analyzed by HPLC
- 5) Combustion of soil residue and LSC-measurement

At each sampling interval the mentioned test vessels were centrifuged and aliquots of 100 µL were taken from the supernatants for LSC.

Figure B.8.1.2.1.2._CA-15: The sampling procedure used in the **Preliminary Test II** (copied from the study report).

The soil extraction was a 4-step cold-extraction process. At each step soil was extracted for 30 minutes with 40 mL of CH₃CN/H₂O 1:1 (v:v) solution. The extracts were combined and analysed by LSC for radioactivity content and by radio-HPLC to determine the nature of the extracted radioactivity.

The **Definitive Test** was carried out using the the procedure presented below on figure B.8.1.2.1.2._CA-16. The experiment was performed in 42-mL test vessels and using 20 mL of the test solution. The nominal initial concentrations of the test item – FOE Methylsulfone, used in the experiment were following: 1.00 mg/L, 0.30 mg/L, 0.10 mg/L, 0.03 mg/L and 0.01 mg/L. The measured initial concentrations of the test item in solution were calculated using the actual volume of the solution, corrected by addition of the residual soil moisture content. The resulting total volume of the solution in the test system were:

- **20.13 mL** for Wurmwiese Loam soil (the determined residual soil moisture content was 0.13 mL);
- **20.18 mL** for Höfchen am Hohenseh Silt loam soil (the determined residual soil moisture content was 0.18 mL);
- **20.27 mL** for Dollendorf II Clay loam soil (the determined residual soil moisture content was 0.27 mL);
- **20.24 mL** for Guadalupe Sandy loam soil (the determined residual soil moisture content was 0.24 mL);
- **20.07 mL** for Springfield Silt loam soil (the determined residual soil moisture content was 0.07 mL).

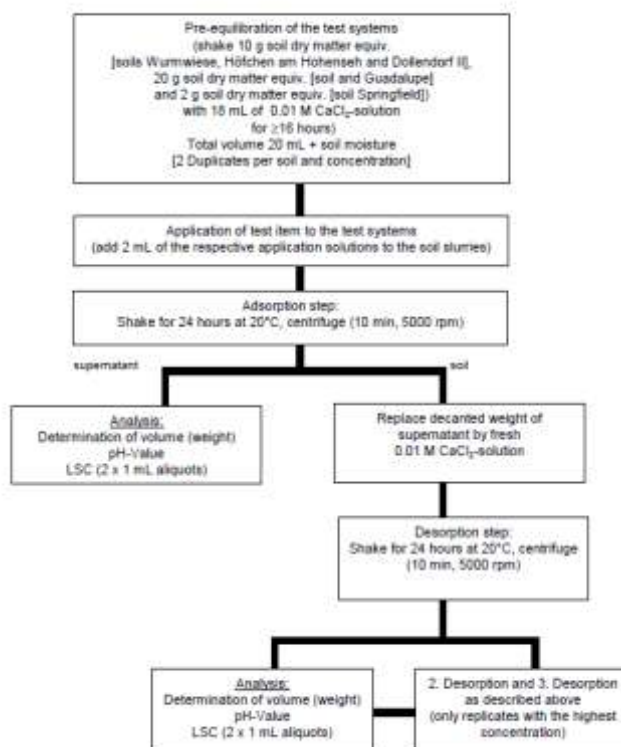

Figure B.8.1.2.1.2._CA-16: The conceptual scheme of the experimental procedure used in the **Definitive Test** (copied from the study report).

The examination of the 1st step of desorption was carried out for all five nominal concentrations of the test item, in order to determine the Freundlich desorption isotherms. The next steps – 2nd and 3rd, were examined using the samples with the highest initial (nominal) concentration of the test item – 1.00 mg/L.

In all samples left after the examination of the desorption the mass balance was established. That was done by mixing the remaining soil sample with cellulose added in amount 0.4 g/g soil. So prepared samples were air-dried, homogenised and analysed after combustion by LSC. In case of Wurmwiese, Höfchen am Hohenseh, Dollendorf II and Guadalupe test soils the aliquots of the soil samples were taken for analysis, while the samples of the Springfield test soil were analysed entirely.

All liquid samples were analysed for their radioactivity content using LSC method. The analysis was carried out using TRI-CARB 2800 TR or TRI-CARB 2300 TR liquid scintillation counters. Samples were analysed in Ultima Gold LS cocktail. The counting time was usually 10 minutes. The background was determined using

blank samples and automatically subtracted from the analysed samples during the LSC analysis. Also automatically, by the instrument, was performed quench and counting efficiency correction for transformation of gross count (cpm) into dmp.

The solid samples used to determine the mass balance were oxidised using Sample Oxidiser OX 500. Generated $^{14}\text{CO}_2$ was absorbed in Oxisolve C-400 or CarboSorb-E/Permafluor E+ LS cocktail and analysed using TRI-CARB 2800 TR or TRI-CARB 2300 TR liquid scintillation counters.

The chromatographic analysis was performed in a gradient mode using Jasco HPLC system equipped with radio-HPLC detector and UV detector set at $\lambda = 210$ nm. The chromatographic separation was carried out on Nucleodur C18 Gravity (125 x 4 mm; 5 μm) chromatographic column, preceded by LiChroCart 4-4 LiChrospher 100-RP-18 (5 μm) per-column. The chromatographic column was kept in HPLC oven set at a constant temperature $T = 20^\circ\text{C}$. The elution was performed in one of the two gradient modes (**Gradient 1** and **Gradient 2**), characterised below in the table B.8.1.2.1.2._CA-47. The solvent system used in elution consisted of:

- **Solvent A:** bidistilled water + 0.2% H_3PO_4 (85%),
- **Solvent B:** CH_3CN .

The flow rate was set to 1.5 mL/min. The retention time of the test item – [^{14}C] FOE Methylsulfone was $R_t = \text{approx } 18$ min.

Table B.8.1.2.1.2._CA-47: The gradient modes used in the HPLC analysis of samples collected during the study.

Gradient 1			Gradient 2		
Time [minutes]	Solvent system		Time [minutes]	Solvent system	
	% Solvent A	% Solvent B		% Solvent A	% Solvent B
0	100	0	0	100	0
5	100	0	5	100	0

40	0	100	20	0	100
42	100	0	23	0	100
45	100	0	25	100	0
			28	100	0

The calculations of the Freundlich sorption parameters were performed using the equations presented below on figure B.8.1.2.1.2._CA-17.

Freundlich isotherm	Log-transformed Freundlich isotherm	Equation used in calculation of $K_{F,OC}$
$x/m = K_F \cdot c_e^{1/n}$ <p> K_F = Freundlich coefficient x/m = Equilibrium concentration of adsorbed test item in $\mu\text{g/g}$ dry weight soil c_e = Equilibrium concentration of test item in solution $\mu\text{g/mL}$ $1/n$ = Constant </p>	$\log\left(\frac{x}{m}\right) = \frac{1}{n} \cdot \log c_e + \log K_F$	$K_{F,OC} = \frac{K_F \cdot 100}{\% \text{ org. C}}$ <p> $K_{F,OC}$ = Adsorption coefficient related to organic carbon $\% \text{ org. C}$ = portion of organic carbon in soil expressed as % of weight </p>

Figure B.8.1.2.1.2._CA-17: The equations used in the calculations of the Freundlich sorption parameters (copied from the study report).

The results of the study are presented and discussed below.

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in table B.8.1.2.1.2._CA-46. On their basis it may be stated that all test soils fully meet the acceptability criteria set by the OECD 106 Guideline.

The results of the monitoring of the temperature during the definitive test are presented below on figure B.8.1.2.1.2._CA-18. On their basis it was stated that the mean $T = 19.9^{\circ}\text{C}$ and its range $19.1 - 20.6^{\circ}\text{C}$. It was therefore within the pre-defined limits of $T = 20 \pm 2^{\circ}\text{C}$.

Figure B.8.1.2.1.2._CA-18: The graphical results of the monitoring of the temperature during the study (copied from the study report).

The numerical results of the examination of stability of the test item – FOE Methylsulfone in 0.01M CaCl_2 aq solution are presented below in the table B.8.1.2.1.2._CA-48. On their basis it was stated that the compound was stable.

Table B.8.1.2.1.2._CA-48: The results of the examination of the stability of the test item in the test solution.

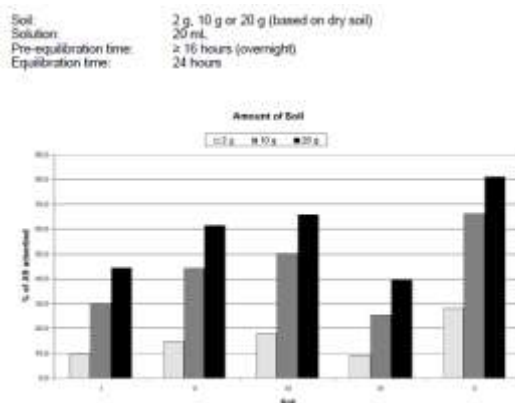

I) Experimental conditions				
Amount of soil:		Test system without soil		
Amount of test solution in test vessel:		20 mL		
Concentration of the test item:		1.001 mg/L (measured highest concentration used in experiment)		
Equilibration time:		0 – 96 h		
II) Results				
Equilibraion time [Hours]	Replicate	Obtained results		
		Total radioactivity in the test vessel in [Bq/20 mL]	Total radioactivity in the test vessel [%AR]	Amount of the test item [%]
0		65257.5	100%	99.5

The results of the determination of the appropriate soil:solution ratio are presented below, in numerical form in the table B.8.1.2.1.2._CA-49 and in graphical form on figure B.8.1.2.1.2._CA-197. The symbols used on that graph to denominate test soils were following:

- I for Wurmwiess test soil;
- II for Höfchen am Hohenseh test soil;
- III for Dollendorf II test soil;
- IV for Guadalupe test soil;
- V for Springfield test soil.

Table B.8.1.2.1.2._CA-49: The numerical results of the determination of the appropriate soil:solution ratio.

Test soil	Soil solution ratio		Amount of FOE Methylsulfone remaining in solution [% AR]	Amount of FOE Methylsulfone sorbed onto soil [% AR]
	in g soil/mL solution	as ratio		
<i>Wurmwiese</i> <i>Loam soil</i>	2/20	1:10	90.4	9.6
	10/20	1:2	69.9	30.1
	20/20	1:1	55.7	44.3
<i>Höfchen am Hohenseh</i> <i>Silt loam soil</i>	2/20	1:10	85.4	14.6
	10/20	1:2	55.9	44.1
	20/20	1:1	38.6	61.4
<i>Dollendorf II</i> <i>Clay loam soil</i>	2/20	1:10	82.2	17.8
	10/20	1:2	49.9	50.1
	20/20	1:1	34.2	65.8
<i>Guadalupe</i> <i>Sandy loam soil</i>	2/20	1:10	91.0	9.0
	10/20	1:2	74.6	25.4
	20/20	1:1	60.4	39.6
<i>Springfield</i> <i>Silt loam soil</i>	2/20	1:10	72.0	28.0
	10/20	1:2	33.7	66.3
	20/20	1:1	18.9	81.1

**Figure B.8.1.2.1.2._CA-19:** The graphical results of the determination of the appropriate soil:solution ratio – amount of FOE Methylsulfone adsorbed onto soil (copied from the study report).

On the basis of the obtained results, presented above, the following soil:solution ratios were selected to be used in further tests:

- for Wurmwiese Loam soil: 1:2;
- for Höfchen am Hohenseh Silt loam soil: 1:2;
- for Dollendorf II Clay loam soil: 1:2;
- for Guadalupe Sandy loam soil: 1:1;
- for Springfield Silt loam soil: 1:10.

The results obtained during the **Preliminary Test II** are presented below in numerical and graphical form. In the table B.8.1.2.1.2._CA-50 are provided the numerical results of the determination of the appropriate equilibration time. These results are also given in graphical form on figure B.8.1.2.1.2._CA-20. Below them, in the table B.8.1.2.1.2._CA-51 are presented the results of the determination of the mass balance aimed on the determination of the stability of the test item – FOE Methylsulfone in the test system containing soil during the equilibration period. On the basis of these results the selected appropriate equilibration time was 24 hours. It was also stated that the recovery of radioactivity and the test item was > 90% during the whole incubation period indicating that FOE Methylsulfone was stable in the test system for up to 120 hours.

Table B.8.1.2.1.1._CA-26: The numerical results of the determination of the appropriate equilibration time.

Equilibration time [hours]	Results									
	Concentration of applied radioactivity in the test system with soil Wurmwiese, expressed as:		Concentration of applied radioactivity in the test system with soil Höfchen am Hohenseh, expressed as:		Concentration of applied radioactivity in the test system with soil Dollendorf II, expressed as:		Concentration of applied radioactivity in the test system with soil Guadalupe, expressed as:		Concentration of applied radioactivity in the test system with soil Springfield, expressed as:

The results of the **Definitive Test** are presented below. The verification of the application rate of FOE Methylsulfone in the **Definitive Test** gave the following results:

- for the solution having a nominal concentration **1.0 mg FOE Methylsulfone/L** the measured concentration was **0.99 mg FOE Methylsulfone/L**;
- for the solution having a nominal concentration **0.30 mg FOE Methylsulfone/L** the measured concentration was **0.29 mg FOE Methylsulfone/L**;
- for the solution having a nominal concentration **0.10 mg FOE Methylsulfone/L** the measured concentration was **0.10 mg FOE Methylsulfone/L**;
- for the solution having a nominal concentration **0.03 mg Flufenacet/L** the measured concentration was **0.03 mg FOE Methylsulfone/L**;
- for the solution having a nominal concentration **0.01 mg Flufenacet/L** the measured concentration was **0.01 mg FOE Methylsulfone/L**.

The results of the determination of the recovery of applied radioactivity are presented below in the table B.8.1.2.1.2._CA-52.

Table B.8.1.2.1.2._CA-52: The results of the determination of the recovery of radioactivity in the **Definitive Test** – after adsorption and desorption steps.

Initial (measured) concentration of FOE Methylsulfone	Replicate	Total radioactivity recovery, expressed in [% AR], in experiment with the test soil:				
		<i>Wurmwiese Loam soil</i>	<i>Höfchen am Hohenseh Silt loam soil</i>	<i>Dollendorf II Clay loam soil</i>	<i>Guadalupe Sandy loam soil</i>	<i>Springfield Silt loam soil</i>
0.99 mg/L	1	100.6	98.6	98.6	99.4	98.6
	2	99.6	96.6	98.9	99.0	98.5

		2	5.52	6.83	6.84	6.79	6.68

The results of the definitive phase – the concentrations of the test item – FOE Methylsulfone, at equilibrium for adsorption and desorption phases, used by the Applicant to determine the Freundlich adsorption and desorption isotherms, are presented below in two tables – B.8.1.2.1.2._CA-55 for adsorption phase and B.8.1.2.1.2._CA-56 for the desorption phase. The Applicant used mean values to determine the isotherms.

Table B.8.1.2.1.2._CA-55: The results of the examination of the adsorption of FOE Methylsulfone onto test soils to determine Freundlich adsorption isotherm.

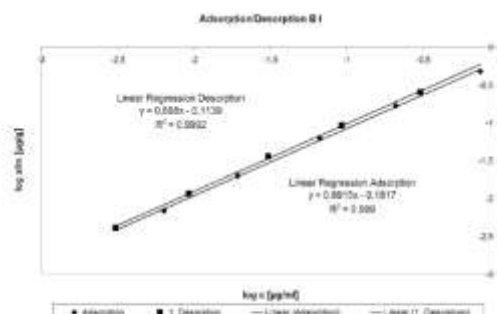

Test soil	Initial concentration of the solution [µg/mL]	Results of the experiment:				
		Concentration at equilibrium				Amount adsorbed onto soil in [%]
		in solution		in soil		
		Ce [µg/mL]	Log Ce	x/m [µg/g]	Log (x/m)

	0.01	0.002	-2.6185	0.017	-1.7576	51.7 ± 0.4

On the basis of the results presented in the tables below the adsorption and desorption isotherms for FOE Methylsulfone in each test soil were determined. They are presented below on figure B.8.1.2.1.2._CA-21. Additionally, in the table B.8.1.2.1.2._CA-56, are presented the Freundlich isotherm parameters obtained for the adsorption and desorption in each test soil.

The adsorption and desorption isotherms obtained in Wurmwiese test soil

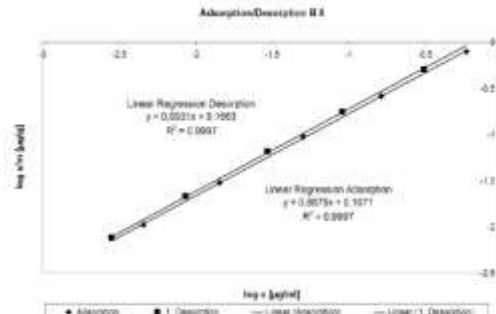

Evaluation of linear regression according to FREUNDLICH:

Regression	R ²	Adsorption	1 st Desorption
Slope	1/n	0.9991	0.9992
Interception	Log K _d	-0.8915	-0.8900
		-0.1817	-0.1139

C: Concentration in water in µg/mL (ppm)
X/m: Concentration in soil in µg/g (ppm)

The adsorption and desorption isotherms obtained in Höfchen am Hohenseh test soil

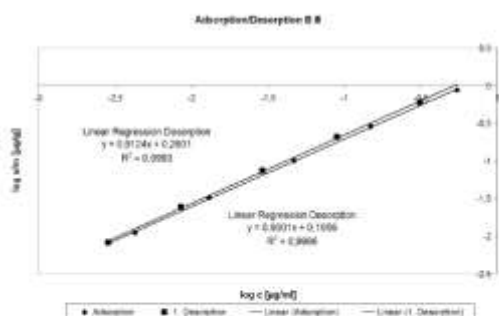

Evaluation of linear regression according to FREUNDLICH:

Regression	R ²	Adsorption	1 st Desorption
Slope	1/n	0.9997	0.9997
Interception	Log K _d	0.9975	0.9971
		-0.1971	-0.1993

C: Concentration in water in µg/mL (ppm)
X/m: Concentration in soil in µg/g (ppm)

The adsorption and desorption isotherms obtained in Dollendorf II test soil

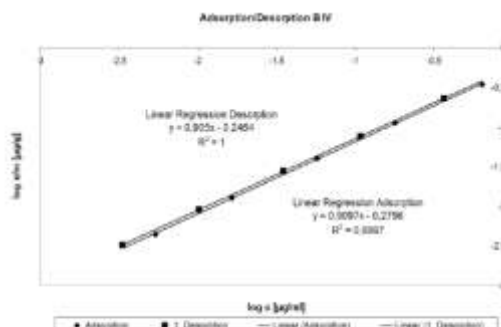

Evaluation of linear regression according to FREUNDLICH:

Regression	R ²	Adsorption	1 st Desorption
Slope	1/n	0.9996	0.9993
Interception	Log K _d	0.9171	0.9124
		0.1996	0.2831

C: Concentration in water in µg/mL (ppm)
X/m: Concentration in soil in µg/g (ppm)

The adsorption and desorption isotherms obtained in Guadelupe test soil

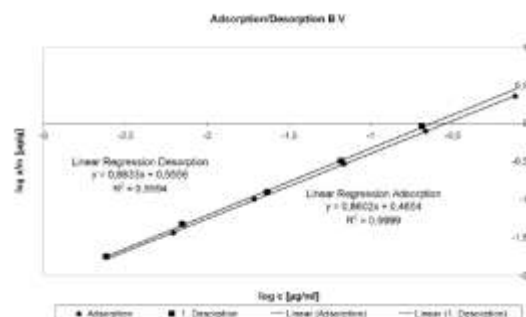

Evaluation of linear regression according to FREUNDLICH:

Regression	R ²	Adsorption	1 st Desorption
Slope	1/n	0.9997	1.0000
Interception	Log K _d	-0.2796	-0.2484

C: Concentration in water in µg/mL (ppm)
X/m: Concentration in soil in µg/g (ppm)

The adsorption and desorption isotherms obtained in Springfield test soil

Evaluation of linear regression according to FREUNDLICH:

Regression	R ²	Adsorption	1 st Desorption
Slope	1/n	0.9999	0.9994
Interception	Log K _d	0.8602	0.8633
		0.4654	0.5556

C: Concentration in water in µg/mL (ppm)
X/m: Concentration in soil in µg/g (ppm)

Figure B.8.1.2.1.2._CA-21: The Freundlich adsorption and desorption isotherms determined for FOE Methylsulfone in each test soil (copied from the study report).

Table B.8.1.2.1.2._CA-56: The key numerical results of the experiment presented in the study report – parameters of Freundlich adsorption and 1st desorption isotherms for FOE Methylsulfone, as reported by the Applicant.

Test soil	Parameters of Freundlich adsorption isotherm					Parameters of Freundlich 1 st desorption isotherm				
	$\text{Log } K_{f\text{ ads}}$	$K_{f\text{ ads}} [\text{mL/g}]$	$1/n$	$K_{f\text{OC ads}} [\text{mL/g}]$	R^2	$\text{Log } K_{f\text{ des}}$	$K_{f\text{ des}} [\text{mL/g}]$	$1/n$	$K_{f\text{OC des}} [\text{mL/g}]$	R^2
Wurmwiese Loam soil	-0.1817	0.6582	0.8915	37.4	0.9990	-0.1139	0.7693	0.8980	43.7	0.9992
Höfchen am Hohenseh Silt loam soil	0.1071	1.2797	0.8875	52.9	0.9997	0.1663	1.4666	0.8931	60.6	0.9997
Dollendorf II Clay loam soil	0.1956	1.5688	0.9001	33.2	0.9996	0.2601	1.8200	0.9124	38.6	0.9993
Guadalupe Sandy loam soil	-0.2796	0.5253	0.9097	75.0	0.9997	-0.2464	0.5671	0.9050	81.0	1.0000
Springfield Silt loam soil	0.4654	2.9201	0.8602	171.8	0.9999	0.5556	3.5944	0.8833	211.4	0.9994

The Applicant also presented the results of the determination of Freundlich isotherms for serial desorption of FOE Methylsulfone from five test soils. The isotherms were determined for the experiment with highest initial concentration tested – 0.99 mg/L. The graphical results – isotherms in their linearised form, are presented below on figure B.8.1.2.1.2.-CA-22. The numerical results of the experiment – the determined Freundlich parameters (K_f , $K_{f\text{OC}}$ and $1/n$ values) are presented in the table B.8.1.2.1.2._CA-57. Analysing the isotherms RMS noticed that they were determined using four experimental points. It may be assumed that while three of them represent the concentrations at equilibrium after each desorption step, the remaining fourth is for concentrations at equilibrium determined during examining the adsorption process.

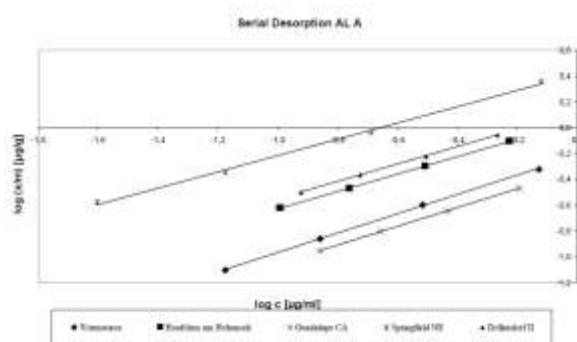

Figure B.8.1.2.1.2._CA-22: Freundlich isotherms for serial desorption of FOE Methylsulfone from the tes soils (copied from the study report)

Table B.8.1.2.1.2._CA-56: The key numerical results of the determination of the Freundlich isotherm for a serial desorption of FOE Methylsulfone from test soils, as reported by the Applicant

Test soil	Parameters of Freundlich serial desorption isotherm			
	$K_{f\text{ des}} [\text{mL/g}]$	$1/n$	$K_{f\text{OC des}} [\text{mL/g}]$	R^2
Wurmwiese Loam soil	0.6027	0.7455	34.2	0.9998
Höfchen am Hohenseh Silt loam soil	1.1029	0.6744	45.8	0.9999
Dollendorf II Clay loam soil	1.3210	0.6723	28.0	0.9999
Guadalupe Sandy loam soil	0.4711	0.7268	67.3	0.9999
Springfield Silt loam soil	2.6021	0.6313	153.1	0.9967

Because of the stated difficulties in the interpretation of the results obtained by the Applicant – the adsorption and desorption isotherms were presented on the same graph, as well as because to determine the isotherms the averaged values were used instead of those for the individual replicates, RMS decided to verify the results of the determination of adsorption and 1st desorption Freundlich isotherms. The results of this exercise, together with input data used in it, are presented below, individually for each test soil. To maintain the consistency with the Applicant's analysis the data used to plot the isotherms were logarithmically transformed to Log₁₀ values. The isotherms were plotted using the CurveExpert Pro 1.0 tool.

a) Results obtained for Wurmwiese Loam soil:

The input data used to determine Freundlich adsorption isotherm are presented below in the table B.8.1.2.1.2._CA-57. The next table – B.8.1.2.1.2._CA-58 presents the input data used to determine Freundlich desorption isotherm. For the purpose of the reporting all values were rounded to the four digits after the decimal point to maintain the consistency with the source data – amounts in soil and in solution at equilibrium, provided in the study report.

The graphical results of the fitting – linearised Freundlich adsorption and desorption isotherms are presented on figure B.8.1.2.1.2._CA-23. Finally, the table B.8.1.2.1.2._CA-59 provides the numerical results of the fitting – the parameters of Freundlich sorption isotherms together with their statistical evaluation.

Table B.8.1.2.1.2._CA-57: The results of the examination of the adsorption of FOE Methylsulfone onto test soil *Wurmwiese (Loam)* used by the RMS to determine Freundlich adsorption isotherm.

Soil mass <i>m</i> , solution volume <i>V</i>	Initial concentration of the solution [μg/mL]	<i>Rep.</i>	Results of the experiment:						<i>Amount adsorbed onto soil in [%]</i>
			<i>In soil at equilibrium</i>			<i>In solution at equilibrium</i>

c) Results obtained for Dollendorf II Clay loam soil:

The input data used to determine Freundlich adsorption isotherm are presented below in the table B.8.1.2.1.2._CA-63. The next table – B.8.1.2.1.2._CA-64 presents the input data used to determine Freundlich desorption isotherm. For the purpose of the reporting all values were rounded to the four digits after the decimal point to maintain the consistency with the source data – amounts in soil and in solution at equilibrium, provided in the study report.

The graphical results of the fitting – linearised Freundlich adsorption and desorption isotherms are presented on figure B.8.1.2.1.2._CA-25. Finally, the table B.8.1.2.1.2._CA-65 provides the numerical results of the fitting – the parameters of Freundlich sorption isotherms together with their statistical evaluation.

Table B.8.1.2.1.2._CA-63: The results of the examination of the adsorption of FOE Methylsulfone onto test soil *Dollendorf II (Clay loam)* used by the RMS to determine Freundlich adsorption isotherm.

Guadalupe Sandy loam soil	-0.2464	0.5671	0.9050	81.0	1.0000	-0.2467	0.5666	0.9048	80.94	0.9992
Springfield Silt loam soil	0.5556	3.5944	0.8833	211.4	0.9994	0.5585	3.6183	0.8833	212.84	0.9995

The comparative analysis of the results presented above showed that the differences between K_f and K_{fOC} calculated by the Applicant and RMS for the adsorption process were not significant. Also not very substantial were the differences between calculated $1/n$ values.

In case of the desorption parameters the significant difference was found in case of the constants obtained in Höfchen am Hohenseh test soil. The possible reason for that was not identified, as the raw data used by the RMS and the Applicant were the same.

Final conclusion:

The Freundlich adsorption parameters obtained by the Applicant can be considered fully reliable to be reported in the EU List of Endpoints and to be used in GW and SW model exposure assessment. They are presented below, in form recommended for reporting the EU-agreed endpoints.

Soil adsorption transformation products (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.3.1.2 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.2.1)

Study 3:

Report: Moendel M., Hein W., (2011): “[1-¹⁴C] BCS-AZ56567: Adsorption/Desorption in Five Different Soils.”; RLP AgroScience GmbH, Breitenweg 71, 67435 Neustadt a. d. Weinstrasse, Germany (performing laboratory) for Bayer CropScience Aktiengesellschaft, Development, Environmental Safety Metabolism/ADME and Environmental Fate, Alfred Nobel Str. 50, D-40789 Monheim, Germany; Study number (RLP AgroSciences GmbH) AS155; Bayer Report No. M-406740-01-1; 07 April 2011; study reference number: M-406740-01-1.

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for Testing of Chemicals No 106 “Adsorption/Desorption”, Jan. 21, 2000;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835. 1220 Sediment and Soil Adsorption/Desorption Isotherm;
- Canada Pest Management Regulatory Agency (PMRA), Environmental Chemistry and Fate, Guidelines for Registration of Pesticides in Canada, 1987.

GLP: Yes;

RMS comments: This is a newly submitted study, aimed on the examination of the soil sorption of Trifluoroacetic acid (TFA) – one of the major soil degradation products of Flufenacet. For the purpose of the current assessment it was evaluated for compliance with the following Guidelines:

- OECD Guideline for Testing of Chemicals No 106, Adsorption – Desorption Using a Batch Equilibrium Method, adopted 21st January 2000;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1220, Sediment and Soil Adsorption/Desorption Isotherm, January 1998;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1230, Adsorption/Desorption (Batch Equilibrium), October 2000;

It was stated that the study complied with the provisions of the evoked Guidelines. As a result, it was found acceptable and is summarised below.

Summary:

The aim of the study was to examine the adsorption and desorption in soil of Trifluoroacetic acid - TFA (for the purpose of this study bearing a codename BCS-AZ565697), a major soil degradation product of Flufenacet. The examination was performed using five test soils – three EU and two US soils. Their characteristic is provided below in the table B.8.1.2.1.2._CA-75.

Table B.8.1.2.1.2._CA-75: The characteristic of soils used in the study.

Parameter		Soil				
		<i>Wurmwiese</i>	<i>Höfchen am Hohenseh 4a</i>	<i>Dollendorf II</i>	<i>Guadalupe CA</i>	<i>Springfield NE</i>

CEC [meq/100 g]		10.8	13.9	21.9	16.1	16.1

The test soils were sampled from the agriculturally used areas. In case of the EU soils, they were sampled from fields on which no pesticides were used for at least 5 years prior to the sampling. They were collected from the 0-20 cm layer using the shovel. The soil samples were air-dried and sieved through 2-mm sieve before being

delivered to the test facility. There they were stored first in ambient conditions and then at $T = 0-10^{\circ}\text{C}$ until being used.

One of the US soils was sampled from the field on which different pesticides used on cabbage, broccoli and lettuce were applied until December 2007. After that, until sampling in march 2009 (for approx. 15 consecutive months), no use of any plant protection products was recorded. The second US soil was sampled from the field on which no pesticides were used for at least three consecutive years before sampling. Soil samples were collected by shovel from the top 6- to 8-inch layer (corresponding to the soil depth of 0-15 cm or 0-20 cm). The soil samples were air-dried and sieved through 2-mm sieve before being delivered to the test facility. There they were stored first in ambient conditions and then at $T = 0-10^{\circ}\text{C}$ until being used.

The storage period was following:

- for the EU soils: 587 days after delivery to the test facility;
- for the US soils: 565 days after delivery to the test facility.

The test compound used in the experiment was the ^{14}C -TFA (Trifluoroacetic acid), shown below on figure B.8.1.2.1.2._CA-27.

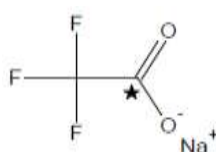

Figure B.8.1.2.1.2._CA-27: The structural formula of the radiolabelled TFA (BCS-AZ56567) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The test compound had specific activity of 3.48 MBq/mg (94.04 $\mu\text{Ci/mg}$) and radiochemical purity, determined by HPLC, > 98%. It was delivered to the test facility as a colourless, vacuum-dried solid. It was stored in the test facility in cold until being used.

The delivered sample was used to prepare the **Standard Stock Solution I**, bearing the code-name **SSL I**. That was done by dissolving 5.66 mg of the radiolabelled test with 5 mL of bi-distilled water. The so prepared stock solution was analysed for its concentration of the test item by LSC. That was done using two 0.1-mL aliquots of the stock solution diluted 50 times before being analysed.

The so determined concentration of the test item in the standard solution was 0.566 mg/mL. The radiopurity of the solution, determined using radio-HPLC, was > 99%.

Additionally, as a reference compound for chromatography, the non-radiolabelled TFA was used in the experiment. It was delivered to the test facility as a colourless liquid, having a chemical purity of 99.9%. It was used to prepare the **Standard Stock Solution II** by dissolving 6.5 mg of it in 6.5 mL CH_3CN .

The whole experiment was carried out using 0.01M CaCl_2 _{aq} solution, prepared by dissolving 2.94 g $\text{CaCl}_2 \times 2 \text{H}_2\text{O}$ in 2 litres of distilled water. The so prepared solutions were used throughout the whole study. Their pH was in range 6.92 – 6.96. It was generally labelled **Stock Solution I_{Bio}** (**SL I_{Bio}**) and as such used to prepare the treatment solutions used in the experiment.

The whole study consisted of three steps, further called experiments:

- the **Preliminary Test I**, aimed on the determination of the appropriate soil:solution ratio for each test soil, stability of the test item in 0.01M CaCl_2 _{aq} solution and its potential adsorption to the test vessels; the experiment was performed using a single initial concentration of the test item – 1.00 mg/L (highest concentration of Trifluoroacetic acid – TFA, used in the study);
- the **Preliminary Test II**, in which was determined the appropriate equilibration time and parental mass balance in order to demonstrate the stability of the test compound during incubation for determining sorption isotherms; the experiment was performed using a single initial concentration of the test item – 1.00 mg/L (highest concentration of Trifluoroacetic acid – TFA, used in the study);
- the **Definitive Test**, aimed on the determination of the Freundlich adsorption and desorption isotherm and calculation of their parameters - K_F and $1/n$ values; at this stage five different nominal initial concentrations of the test compound – Trifluoroacetic acid (TFA), were used: 0.01 mg/L, 0.03 mg/L, 0.10 mg/L, 0.30 mg/L and 1.00 mg/L (**N. b.** RMS noticed that due to the low level of adsorption determined in both **Preliminary tests** only the experiment aimed on the determination of adsorption isotherm was carried out.

The test compound was administered in form of the application solutions prepared from the **Standard Stock Solution I (SSL I)** as aqueous solutions in 0.01M CaCl_2 aq.

In case of the **Preliminary Test I** the application solution was prepared by transferring 0.883 mL of the solution **SSL I** into the appropriate flask. The solution was brought to volume by addition of 50 mL **SL I_{Bio}** solution. The so prepared solution was then analysed by LSC for concentration of the test item and by radio-HPLC for its radiopurity.

In case of the **Preliminary Test II** the application solution was prepared by transferring 3.54 mL of the solution **SSL I** into the appropriate flask. The solution was then brought to volume by addition of 200 mL of **SL I_{Bio}** solution. The so prepared solution was then analysed by LSC for concentration of the test item and by radio-HPLC for its radiopurity.

The application solutions for the **Definitive Test** were prepared by a serial dilution of the solution **SSL I**. As a first step the **Solution A**, having a nominal concentration 10 mg/L was prepared from a solution **SSL I**. That was done by transferring 0.883 mL of the solution **SSL I** into the appropriate flask. The solution was then brought to volume with 50 mL of **SL I_{Bio}** solution. The so prepared solution was analysed by LSC for concentration of the test item and by radio-HPLC for its radiopurity. Next the four remaining application solutions, marked **B**, **C**, **D** and **E** were prepared by diluting the **Solution A** with the **SL I_{Bio}** solution. The procedure looked as follows:

- the **Solution B**, having a nominal concentration of 3.0 mg/L, was prepared by transferring 7.50 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution;
- the **Solution C**, having a nominal concentration of 1.0 mg/L, was prepared by transferring 2.50 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution;
- the **Solution D**, having a nominal concentration of 0.30 mg/L, was prepared by transferring 0.75 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution;
- the **Solution E**, having a nominal concentration of 0.10 mg/L, was prepared by transferring 0.25 mL of the **Solution A** into 25-mL volumetric flask and filling it to the volume with **SL I_{Bio}** solution.

The so prepared solutions were then analysed by LSC for concentration of the test item and by radio-HPLC for their radiopurity.

The measured concentrations of the so prepared application solutions were following:

- **Solution A** (nominal concentration 10.0 mg/L): 10.38 mg/L;
- **Solution B** (nominal concentration 3.00 mg/L): 3.10 mg/L;
- **Solution C** (nominal concentration 1.00 mg/L): 1.04 mg/L;
- **Solution D** (nominal concentration 0.30 mg/L): 0.31 mg/L;
- **Solution E** (nominal concentration 0.10 mg/L): 0.10 mg/L;

Their radiopurity was > 99%.

The study was performed using the following general conditions:

- all experiments were performed in the darkness and at constant temperature $T = 20 \pm 2^\circ\text{C}$;
- test vessels were borosilicate glass centrifuge tubes with Teflon lined screw caps;
- the **Preliminary Test I** and the **Definitive Test** were carried out in 42-mL test vessels using the total volume of solution (not corrected for the soil residual moisture content) of 20 mL;
- the **Preliminary Test II** was performed in 83-mL test vessels using the total volume of solution (not corrected for the soil residual moisture content) of 50 mL;
- equilibration was performed by shaking the test vessels for the pre-defined amount of time on the horizontal overhead shaker at ~20 rpm;
- at the end of equilibration samples containing soil were centrifuged for about 10 minutes at ~5000 rpm (~4200 g) to separate liquid and solid phases;
- in all experiments with the test soils the samples were preequilibrated for at least 16 hours before introduction of the test compound; the pre-equilibration procedure is characterised in details for each experiment, as they differed due to the different amounts of solution used.

The **Preliminary Test I** was aimed on the determination of the appropriate soil:solution ratio for each test soil and the stability of the test compound in 0.01M CaCl_2 aq solution.

The examination of the stability of Trifluoroacetic acid (TFA) in 0.01M CaCl_2 aq solution was carried out in soilless systems. First, two 42-mL test vessels were filled each with 18 mL of **SL I_{Bio}** solution. Next, to each of them 2 mL of the **Solution A** were added to obtain the final volume of 20 mL and the concentration of the test

item (nominal) 1.0 mg/L. So prepared test vessels were capped and equilibrated for up to 96 hours. At pre-defined time points – 24 hours, 48 hours, 72 hours and 96 hours of shaking, aliquots of each test solution were analysed by LSC and HPLC. In this experiment the measured initial concentration of the test item in solution was 0.994 mg/L.

The experiment aimed on the determination of the appropriate soil:solution ratio began by weighing 2-g, 10-g and 20-g portions of each test soil into 42-mL test vessels. All samples were prepared in duplicate. Next, to each test vessel 18 mL of **SL I_{Bio}** solution were added, test vessels capped and so prepared samples pre-equilibrated overnight (for ≥ 16 hours). After pre-equilibration samples were centrifuged for 5 minutes at 1000 rpm and 2 mL of the **Solution A** were added to obtain the final volume of 20 mL and the concentration of the test item (nominal) 1.0 mg/L. So prepared samples were then equilibrated, by shaking on horizontal shaker, for 24 hours. After that period samples were centrifuged and radioactivity content in supernatants determined by LSC. Additionally, for each test soil and each tested soil:solution ratio, pH of the supernatants was determined using one of the replicates.

The appropriate soil:solution ratio was determined on the basis of the results of LSC analysis of supernatants after equilibration and in comparison to the initial measured concentration of the test item in solution, which was 0.989 mg/L.

The **Preliminary Test II** was aimed on the determination of the appropriate equilibration time and the stability of the test compound in the test system.

The experiment was performed using 83-mL test vessels and the total volume of the solution (not corrected for residual soil moisture content) of 50 mL. It was carried out using the soil:solution ratio determined at preceding step.

The experiment was initiated by weighing the appropriate amount of the test soil into the test vessels. For each test soil five replicates were prepared. Next, to each test vessel 45 mL of **SL I_{Bio}** solution were added, test vessels capped and so prepared samples pre-equilibrated overnight (for ≥ 16 hours). After pre-equilibration 5 mL of the **Solution A** were added to obtain the final volume of 50 mL and the concentration of the test item (nominal) 1.0 mg/L. So prepared samples were then equilibrated, by shaking on horizontal shaker, for up to 120 hours. At pre-defined time points – after 2 hours, 4 hours, 6 hours 24 hours, 30 hours, 48 hours, 72 hours 96 hours and 120 hours of shaking, samples were taken for analysis. The sampling procedure, as characterised in the study report, is presented below on figure B.8.1.2.1.2._CA-28.

Sampling Procedure for the Determination of Adsorption Equilibrium Times and Matrix Stability Analysis per Soil:

Time	2 h	4 h	6 h	24 h	30 h	48 h	72 h	96 h	120 h
Rep 1		X		O					
Rep 2			X	X		O			
Rep 3	X		X			X	O		
Rep 4	X				X		X	O	
Rep 5		X			X			X	O

X = 1) Removed from shaker
2) Centrifuged, 10 min, 5000 rpm = 4200^g, 20°C
3) An aliquot of the supernatant was taken and afterwards analysed by LSC
4) Return to shaker

O = 1) Centrifuged (Conditions see above)
2) Complete removal of supernatant
3) LSC and HPLC supernatant
4) Extracted soil and analyzed by HPLC
5) Combustion of soil residue and LSC-measurement

At each sampling interval the mentioned test vessels were centrifuged and aliquots of 100 μ L were taken from the supernatants for LSC.

Figure B.8.1.2.1.2._CA-28: The sampling procedure used in the **Preliminary Test II** (copied from the study report).

The soil extraction was a 5-step cold-extraction process. At each step soil was extracted for 30 minutes with 40 mL of distilled H₂O. The extracts were combined and analysed by LSC for radioactivity content and by radio-HPLC to determine the nature of the extracted radioactivity.

The **Definitive Test** was carried out using the the procedure presented below on figure B.8.1.2.1.2._CA-29. The experiment was performed in 42-mL test vessels and using 20 mL of the test solution. The nominal initial concentrations of the test item – Trifluoroacetic acid (TFA), used in the experiment were following: 1.00 mg/L, 0.30 mg/L, 0.10 mg/L, 0.03 mg/L and 0.01 mg/L. The measured initial concentrations of the test item in solution were calculated using the actual volume of the solution, corrected by addition of the residual soil moisture content.

The resulting total volume of the solution in the test system were:

- **20.25 mL** for Wurmwiese Loam soil (the determined residual soil moisture content was 0.25 mL);
- **20.36 mL** for Höfchen am Hohenseh Silt loam soil (the determined residual soil moisture content was 0.36 mL);
- **20.56 mL** for Dollendorf II Clay loam soil (the determined residual soil moisture content was 0.56 mL);
- **20.27 mL** for Guadalupe Sandy loam soil (the determined residual soil moisture content was 0.27 mL);
- **20.80 mL** for Springfield Silt loam soil (the determined residual soil moisture content was 0.80 mL).

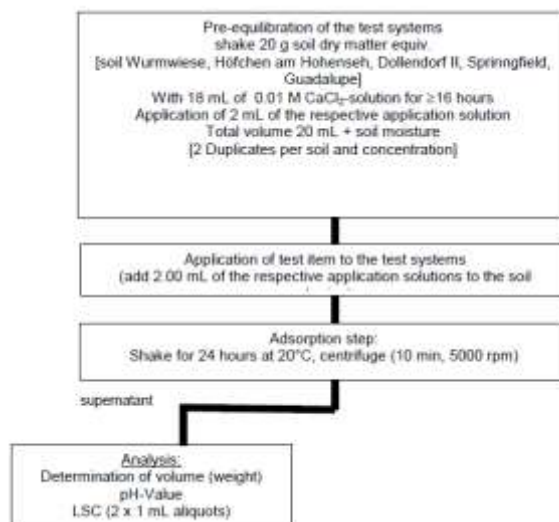

Figure B.8.1.2.1.2._CA-29: The conceptual scheme of the experimental procedure used in the **Definitive Test** (copied from the study report).

The examination of the 1st step of desorption was carried out for all five nominal concentrations of the test item, in order to determine the Freundlich desorption isotherms. The next steps – 2nd and 3rd, were examined using the samples with the highest initial (nominal) concentration of the test item – 1.00 mg/L.

In all samples left after the examination of the desorption the mass balance was established. That was done by mixing the remaining soil sample with cellulose added in amount 0.4 g/g soil. So prepared samples were air-dried, homogenised and their four 300-mg aliquots (for each test soil) were analysed after combustion by LSC.

All liquid samples were analysed for their radioactivity content using LSC method. The analysis was carried out using TRI-CARB 2800 TR or TRI-CARB 2300 TR liquid scintillation counters. Samples were analysed in Ultima Gold LS cocktail. The counting time was usually 10 minutes. The background was determined using blank samples and automatically subtracted from the analysed samples during the LSC analysis. Also automatically, by the instrument, was performed quench and counting efficiency correction for transformation of gross count (cpm) into dmp.

The solid samples used to determine the mass balance were oxidised using Sample Oxidiser OX 500. Generated ¹⁴CO₂ was absorbed in Oxisolve C-400 and analysed using TRI-CARB 2800 TR or TRI-CARB 2300 TR liquid scintillation counters.

The chromatographic analysis was performed in a gradient mode using Jasco HPLC system equipped with radio-HPLC detector and conductivity detector. The chromatographic separation was carried out on Sequant ZIC-HILIC (150 x 4.6 mm; 5 µm) chromatographic column. The elution was performed in a gradient mode characterised below in the table B.8.1.2.1.2._CA-76. The solvent system used in elution consisted of:

- **Solvent A:** Water + 0.2% H₃PO₄ (85%),
- **Solvent B:** CH₃CN.

The flow rate was set to 1.0 mL/min. The retention time of the test item – [¹⁴C] Trifluoroacetic acid (TFA) was R_t = approx 11 min.

Table B.8.1.2.1.2._CA-76: The gradient mode used in the HPLC analysis of samples collected during the study.

Time [minutes]	Solvent system	
	% Solvent A	% Solvent B
0	0	100
5	0	100
10	100	0
15	0	100
20	0	100

The calculations of the Freundlich sorption parameters were performed using the equations presented below on figure B.8.1.2.1.2._CA-30.

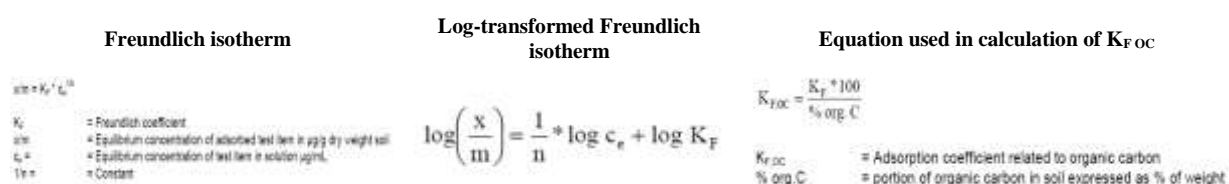

Figure B.8.1.2.1.2._CA-30: The equations used in the calculations of the Freundlich sorption parameters (copied from the study report).

The results of the study are presented and discussed below.

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in the table B.8.1.2.1.2._CA-75. On their basis it may be stated that all test soils fully meet the acceptability criteria set by the OECD 106 Guideline.

The results of the monitoring of the temperature during the definitive test are presented below on figure B.8.1.2.1.2._CA-31. On their basis it was stated that the mean $T = 20.4^{\circ}\text{C}$ and its range $20.3 - 21.0^{\circ}\text{C}$. It was therefore within the pre-defined limits of $T = 20 \pm 2^{\circ}\text{C}$.

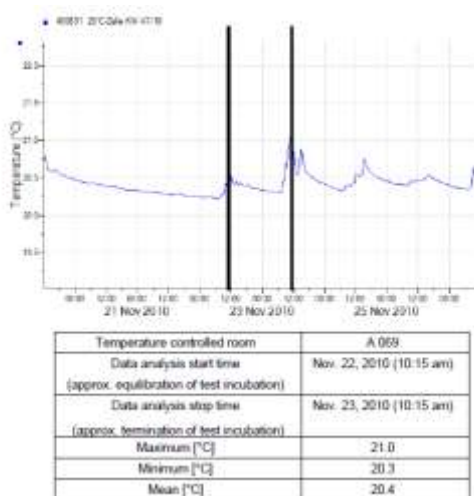

Figure B.8.1.2.1.2._CA-31: The graphical results of the monitoring of the temperature during the study (copied from the study report).

The numerical results of the examination of stability of the test item – Trifluoroacetic acid (TFA) in 0.01M CaCl_2 aq solution, are presented below in the table B.8.1.2.1.2._CA-77. On their basis it was stated that the compound was stable.

Table B.8.1.2.1.2._CA-77: The results of the examination of the stability of the test item in the test solution.

I) Experimental conditions

The results of the determination of the appropriate soil:solution ratio are presented below, in numerical form in the table B.8.1.2.1.2._CA-78 and in graphical form on figure B.8.1.2.1.2._CA-32. The symbols used on that graph to denominate test soils were following:

- I for Wurmwiese test soil;
- II for Höfchen am Hohenseh test soil;
- III for Dollendorf II test soil;
- IV for Guadalupe test soil;
- V for Springfield test soil.

Table B.8.1.2.1.2._CA-78: The numerical results of the determination of the appropriate soil:solution ratio.

Test soil	Soil solution ratio		Amount of Trifluoroacetic acid (TFA) remaining in solution [% AR]	Amount of Trifluoroacetic acid (TFA) sorbed onto soil [% AR]
	in g soil/mL solution	as ratio		
<i>Wurmwiese Loam soil</i>	2/20	1:10	100.5	-0.5
	10/20	1:2	101.8	-1.8
	20/20	1:1	106.0	-6.0

Figure B.8.1.2.1.2._CA-32: The graphical results of the determination of the appropriate soil:solution ratio – amount of Trifluoroacetic acid (TFA) adsorbed onto soil (copied from the study report).

On the basis of the obtained results the soil:solution ratio selected to be used in further tests was 1:1.

The results obtained during the **Preliminary Test II** are presented below in numerical and graphical form. In the tables B.8.1.2.1.2._CA-79 and B.8.1.2.1.2._CA-80 are provided the numerical results of the determination of the the appropriate equilibration time. These results are also given in graphical form on figure B.8.1.2.1.2._CA-33. On the basis of the obtained results the selected appropriate equilibration time was 24 hours. It was also stated that the recovery of radioactivity and the test item was > 90% during the whole incubation period, indicating that Trifluoroacetic acid was stable in the test system for up to 120 hours. The declared initial concentration of the test item was 0.994 mg/L

Table B.8.1.2.1.1._CA-79: The numerical results of the determination of the appropriate equilibration time.

1) n. a. = not available - no reliable data due to the breakage of the test vessels;

**Figure B.8.1.2.1.2._CA-33:** The graphical results of the determination of the appropriate equilibration time (copied from the study report).

The results of the **Definitive Test** are presented below. The verification of the application rate of Trifluoroacetic acid (TFA) in the **Definitive Test** gave the following results:

- for the solution having a nominal concentration **1.0 mg TFA/L** the measured concentration was **1.04 mg TFA/L** and the applied amount of radioactivity was 72248.0 Bq/test vessel;
- for the solution having a nominal concentration **0.30 mg TFA/L** the measured concentration was **0.31 mg TFA/L** and the applied amount of radioactivity was 21602.5 Bq/test vessel;
- for the solution having a nominal concentration **0.10 mg TFA/L** the measured concentration was **0.10 mg TFA/L** and the applied amount of radioactivity was 7213.7 Bq/test vessel;
- for the solution having a nominal concentration **0.03 mg TFA/L** the measured concentration was **0.03 mg TFA/L** and the applied amount of radioactivity was 2161.5 Bq/test vessel;
- for the solution having a nominal concentration **0.01 mg TFA/L** the measured concentration was **0.01 mg TFA/L** and the applied amount of radioactivity was 711.1 Bq/test vessel.

The results of the determination of the recovery of applied radioactivity are presented below in the table B.8.1.2.1.2._CA-81.

Table B.8.1.2.1.2._CA-81: The results of the determination of the recovery of radioactivity in the **Definitive Test**.

Initial (measured) concentration of Trifluoroacetic acid (TFA)	Replicate	Total radioactivity recovery, expressed in [% AR], in experiment with the test soil:

	0.010	0.010	-1.9843	----	----	-5.5 ± 0.3

On the basis of the results presented above it was stated that there was no adsorption of the test item – Trifluoroacetic acid, on any test soil. It was indicated that the negative level of adsorption was recorded in majority of cases, but without any attempt to explain that phenomenon. As a result it was stated that it was not possible to determine the adsorption isotherms.

In the study report it was stated that the experiment examining 1st desorption step was carried out, but its results were the same as for adsorption, therefore the results were not presented in the study report.

The final outcome of the study – the proposed parameters for adsorption and desorption (RMS's) proposal, are presented below in table B.8.1.2.1.2._CA-84. The proposed K_{fOC} and $1/n$ values are defaults presented with aim to be used as recommended in GW and SW modelling assessment.

Table B.8.1.2.1.2._CA-84: The key numerical results of the experiment – parameters of Freundlich adsorption and desorption isotherms for Trifluoroacetic acid (TFA); RMS's proposal.

Test soil	Parameters of Freundlich adsorption isotherm					Parameters of Freundlich desorption isotherm				
	Log $K_{f ads}$	$K_{f ads}$ [mL/g]	1/n	$K_{fOC ads}$ [mL/g]	R^2	Log $K_{f des}$	$K_{f des}$ [mL/g]	1/n	$K_{fOC des}$ [mL/g]	R^2
Wurmwiese Loam soil	n. d. ¹⁾	0.0	1.0	0.0001 ²⁾	n. d. ¹⁾	n. d. ¹⁾	0.0	1.0	0.0	n. d. ¹⁾

Footnotes to the table:

1) n. d. = not determined as it was not possible to determine the isotherm;

2) default value proposed to be used in GW and SW modelling;

Final conclusion:

The examination of the adsorption of Trifluoroacetic acid (TFA) onto soil at equilibrium showed that the test compound did not sorb onto soil to any extent (in most cases adsorption at equilibrium was shown to be negative). Therefore it was proposed to use for TFA the value of $K_f = 0$ mg/L and consider the adsorption process as fully linear, hence $1/n = 1.0$. The proposed outcome of the study – reliable endpoint values for the adsorption process, are presented below, in form recommended for reporting the EU-agreed endpoints.

Soil adsorption transformation products (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.3.1.2 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.2.1)

Study 4:

Report: Traub M., (2013): “Determination of the Adsorption/Desorption behaviour of FOE 5043-trifluoroethanesulfonic acid in five Soils.”; Eurofins Agrosience Services EcoChem GmbH, Eutinger Strasse 24, 75223 Niefern-Öschelbronn, Germany (performing laboratory) for Bayer CropScience AG, 40789 Monheim, Germany; Study number (Eurofins) S11-03923; Report No. MEFOP017; 18. 02. 2013; study reference number (Bayer): M-449893-01-1.

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for Testing of Chemicals No 106 “Adsorption/Desorption”, Jan. 21, 2000;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1230, Adsorption/Desorption (Batch Equilibrium), October 2000.

GLP: Yes;

RMS comments: This is a newly submitted study, aimed on the examination of the soil sorption of Trifluoroacetic acid (TFA) – one of the major soil degradation products of Flufenacet. For the purpose of the current assessment it was evaluated for compliance with the following Guidelines:

- OECD Guideline for Testing of Chemicals No 106, Adsorption – Desorption Using a Batch Equilibrium Method, adopted 21st January 2000;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1220, Sediment and Soil Adsorption/Desorption Isotherm, January 1998;
- US. EPA Fate, Transport and Transformation Test Guidelines OPPTS 835.1230, Adsorption/Desorption (Batch Equilibrium), October 2000;

It was stated that the study complied with the provisions of the evoked Guidelines. As a result, it was found acceptable and is summarised below.

Summary:

The aim of the study was to examine the adsorption and desorption in soil of FOE 5043-Trifluoroethanesulfonic acid - TFESA (for the purpose of this study bearing a codename BCS-CU62474), a major soil degradation product of Flufenacet. The examination was performed using five EU test soils. Their characteristic is provided below in the table B.8.1.2.1.2._CA-85.

Table B.8.1.2.1.2._CA-85: The characteristic of soils used in the study.

Parameter		Soil				
		<i>Laacher Hof AXXa (AX)</i>	<i>Höfchen am Hohenseh 4a (HaH)</i>	<i>Hansheider Hof (HH)</i>	<i>Dollendorf II (DD)</i>	<i>Wurmwiese (WW)</i>
Soil origin		Monheim, North Rhine- Westphalia, Germany	Burscheid, North Rhein- Westphalia, Germany	Burscheid, North Rhein- Westphalia, Germany	Blankenheim, North Rhein- Westphalia, Germany	Monheim, North Rhine- Westphalia, Germany

Bulk density [g/cm ³]		1.27	1.10	1.04	1.00	1.13

The test soils were sampled from the agriculturally used areas, from fields covered with grass, on which no pesticides were used for at least 5 years prior to the sampling. They were collected from the 0-20 cm layer using the shovel. The soil samples were air-dried, sieved through 2-mm sieve and stored at $T = 20^{\circ}\text{C}$ until being used.

The test compound used in the experiment was the non-radiolabelled FOE 5043-Trifluoroethanesulfonic acid – TFESA, in form of its sodium salt, shown below on figure B.8.1.2.1.2._CA-34.

Figure B.8.1.2.1.2._CA-34: The structural formula of the test compound – FOE Trifluoroethanesulfonic acid (FOE TFESA; BCS-CU62474), used in the experiment (copied from the study report).

The test compound, having a chemical purity of 99.4%, was delivered to the test facility as a white solid. It was stored in the test facility at $T = 10 - 30^{\circ}\text{C}$ until being used.

The delivered sample was used to prepare the **Stock Solution**, bearing the code-name **S1000**. That was done by dissolving the appropriate amount of the TFESA in acetonitrile to obtain a solution having a concentration of 1000 mg/L. That solution was subsequently used to prepare set of application solutions, having concentration of the test item in range 0.1 mg/L – 10 mg/L, in 0.01 M CaCl_2 aq.

The whole experiment was carried out using 0.01M CaCl_2 aq solution, prepared by dissolving 2.94 g $\text{CaCl}_2 \times 2 \text{H}_2\text{O}$ in 2 litres of distilled water. The so prepared solutions were used throughout the whole study.

The whole study consisted of two sets of experiments:

b) the **Preliminary Tests** aimed on:

- determination of the stability of the test item in matrix solution;
- examination of the potential of adsorption of the test item onto the test vessels;
- determination of the optimal soil:solution ratio for each test soil;
- determination of the appropriate equilibration time for adsorption;
- determination of the appropriate equilibration time for desorption;
- determination of the parental mass balance;

c) the **Definitive Test**, aimed on the determination of the Freundlich adsorption and desorption isotherm and calculation of their parameters - K_F and $1/n$ values; at this stage five different nominal initial concentrations of the test compound – FOE 5043-Trifluoroethanesulfonic acid (TFESA), were used: 0.01 mg/L, 0.03 mg/L, 0.10 mg/L, 0.30 mg/L and 1.00 mg/L;

The test compound was administered in form of the application solutions prepared from the **Stock Solution S1000** as aqueous solutions in 0.01M CaCl_2 aq. This was done using the procedure of serial dilution aimed on obtaining the solutions having the concentrations presented above in the paragraph characterising the stages of the experiment (characterisation of the definitive study). The whole procedure is characterised below in the table B.8.1.2.1.2._CA-86. Within that procedure an additional application solution, having the concentration 0.01 mg/L was prepared to examine the recoveries at the LOQ level. The application solutions were prepared freshly before application of the test item.

Table B.8.1.2.1.2._CA-86: The characterisation of the prepared application solutions.

Application solution ID	Nominal concentration of the test item [mg/L]	Final volume of the solution [mL]	Main solvent	Application solution prepared from solution:			Application solution used in/for:
				ID of the solution	Nominal concentration of the test item [mg/L]	Volume used [mL]	
S10	10	250	0.01M CaCl ₂ aq	S1000	1000	2.5	Preliminary and Definitive Tests
S3	3	250	0.01M CaCl ₂ aq	S1000	1000	0.75	Definitive Tests
S1	1	250	0.01M CaCl ₂ aq	S1000	1000	0.25	Definitive Tests
S0.3	0.3	250	0.01M CaCl ₂ aq	S3	3	25	Definitive Tests
S0.1	0.1	250	0.01M CaCl ₂ aq	S10	10	2.5	Definitive Tests
S0.01	0.01	----	0.01M CaCl ₂ aq	----	----	----	Examination of recoveries at LOQ

The **Stock Solution S1000** was also used to prepare a series of **Calibration Standard Solutions**, used in analysis of the samples. These were prepared by diluting the appropriate amounts of the **S1000** solution with 0.01M CaCl₂ aq. These, freshly prepared solutions were used to construct the calibration curve covering the concentrations range (nominal) 0.02 ng/mL – 100 ng/mL. Eight **Calibration Standard Solutions** were prepared, having the following concentrations of the test item: 0.02 ng/mL, 0.1 ng/mL, 0.5 ng/mL, 1.0 ng/mL, 5 ng/mL, 10 ng/mL, 50 ng/mL and 100 ng/mL.

Finally, the 0.01M CaCl₂ aq solution was used to prepare **Soil Blank Matrix** solutions for each test soil. For that purpose 1 kg of the given test soil was agitated overnight – for at least 12 hours, on a flat bed shaker with 1 L of 0.01M CaCl₂ aq solution (soil:solution ratio was 1:1). After that time soil suspension was centrifuged at 1295g and the supernatant collected to be used as the soil matrix for the given soil. The solutions were stored at $T = 20 \pm 2^{\circ}\text{C}$.

The study was performed using the following general conditions:

- all experiments were performed in the darkness and at constant temperature $T = 20 \pm 2^{\circ}\text{C}$;
- test vessels were glass vessels with PTFE screw caps, having a volume of 100 mL;
- the final volume of liquid used throughout the study was constant – 50 mL;
- equilibration was performed by shaking the test vessels for the pre-defined amount of time on the horizontal overhead shaker at ~130 rpm;
- at the end of equilibration samples containing soil were centrifuged for about 4 minutes at 1295 g to separate liquid and solid phases;
- in all experiments with the test soils the samples were preequilibrated for at least 12 hours before introduction of the test compound using the appropriate soil sample and the constant volume of blank CaCl₂ aq solution – 45 mL;
- the volume of application solutions introduced to each sample at the beginning of each test was also constant – 5 mL;
- all tests were carried out in duplicate for each kind of samples;
- all samples were analysed using HPLC-MS/MS method characterised further down the summary.

All **Preliminary Tests** were carried out using the highest nominal concentration of the test item in solution – 1 mg/L, applied as application solution **S10**.

The examination of the stability of the test item – FOE 5043-Trifluoroethanesulfonic acid (TFESA), in solution and its affinity to the test vessels was carried out using soil blank matrix solutions of each test soil. For that purpose to the vessels containing 45 mL of the given soil blank matrix solution 5 mL of the solution **S10** were introduced and so prepared samples equilibrated by agitating for 96 hours. After that period the supernatants were analysed for the content of the test item using HPLC-MS/MS method.

The determination of the appropriate soil:solution ratio was carried out using all five test soils. The examined soil:solution ratios were:

- 1:1 – the test vessels contained 50 g of the given test soil and 50 mL of the solution (final volume);
- 1:2 – the test vessels contained 25 g of the given test soil and 50 mL of the solution (final volume);
- 1:5 – the test vessels contained 10 g of the given test soil and 50 mL of the solution (final volume).

The experiment was performed in the following way: after pre-equilibration of the test vessels containing the appropriate amount of the test soil and 45 mL of blank 0.01M CaCl_2 _{aq} solutions, to each test vessel 5mL of **S10** solution were added to obtain the final volume of 50 mL. So prepared samples were equilibrated for 24 hours. After that period liquid phase was separated from solid by centrifugation, supernatants collected and analysed by HPLC-MS/MS.

The determination of the appropriate equilibration time for the adsorption process was carried out for all test soils using the appropriate soil:solution ratio determined in the test characterised above. After pre-equilibration the solution in each test vessels was brought to the final volume of 50 mL by addition of 5 mL of the application solution **S10**. So prepared test vessels were equilibrated for up to 96 hours. The concentration of the test item in solution was measured at pre-defined time points: 0, 6 24, 48, 72 and 96 hours after initiation of the experiment, as described above.

The determination of the appropriate equilibration time for desorption process was not performed as the results of the previous experiments demonstrated that virtually no adsorption of the test item onto soil occurred.

The **Definitive Test** aimed on the determination of the Freundlich adsorption isotherm and its parameters was carried out in the same manner as characterised above for preliminary test. The soil:solution ratio used in this experiment was 1:1 and the equilibration time was 96 hours. To the pre-equilibrated samples containing the appropriate amount of the test soil and 45 mL of blank 0.01M CaCl_2 _{aq} solution, 5 mL of the appropriate application solution – **S10**, **S3**, **S1**, **S0.3**, or **S0.1**, were added to obtain the final volume of the solution of 50 mL and the nominal concentration of the test item 1 mg/L, 0.3 mg/L, 0.1 mg/L 0.03 mg/L or 0.01 mg/L respectively. After application of the test item test vessels were sealed, placed on the horizontal shaker and equilibrated by agitation for the appropriate amount of time.

Because it was stated that virtually no adsorption onto any test soil was observed in this experiment the desorption at equilibrium was not examined.

All samples containing soil were after the end of equilibration period processed in the manner presented below on figure B.8.1.2.1.2._CA-35.

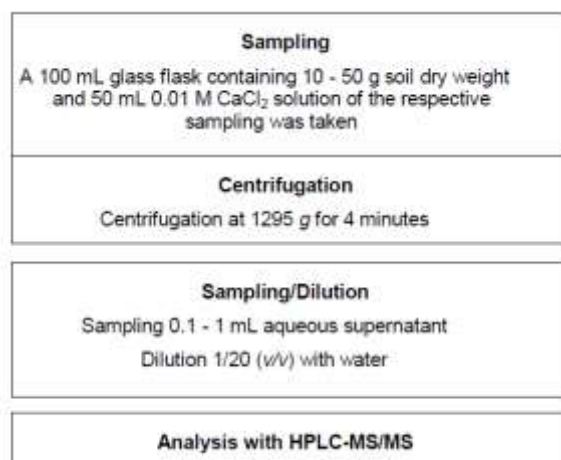

Figure B.8.1.2.1.2._CA-35: The scheme of the sample processing used in the study (copied from the study report).

The chromatographic analysis was performed in a gradient mode using Agilent HPLC system with autosampler coupled with Sciex API5000 MS/MS detector. The chromatographic separation was carried out on Phenomenex Synergi 4 μ Hydro-RP 80A (150 x 3 mm; 4 μ m) chromatographic column preceded by 4-mm guard column. The chromatographic column was kept in chromatographic oven set to constant temperature $T = 40^\circ\text{C}$. The elution was performed in a gradient mode presented below in the table B.8.1.2.1.2._CA-87. The solvent system used in elution consisted of:

- **Solvent A:** Water + 0.1% CH_3COOH ,
- **Solvent B:** CH_3CN + 0.1% CH_3COOH .

The flow rate was set to 0.5 mL/min. The retention time of the test item – FOE 5043-Trifluoroethanesulfonic acid (TFESA) was R_t = approx 2.5 min.

Table B.8.1.2.1.2._CA-87: The gradient mode used in the HPLC analysis of samples collected during the study.

Time [minutes]	Solvent system	
	% Solvent A	% Solvent B
0.00	90	10
4.00	35	65
4.01	10	90
5.00	10	90
5.01	90	10
6.00	90	10

The MS/MS detector used in the study was Sciex API5000 device, working in ESI ionisation mode with negative polarity of the source and at $T = 400^{\circ}\text{C}$.

Identification and quantitation of the test compound – FOE 5043-Trifluoroethanesulfonic acid (TFESA) was performed using the following signals:

- $m/z = 162.9$ – signal of parent compound;
- $m/z = 142.8$ – quantifier;
- $m/z = 122.8$ – qualifier 1;
- $m/z = 79.8$ – qualifier 2.

The example mass spectrum of the test item – FOE 5043-Trifluoroethanesulfonic acid (TFESA), is shown below on figure B.8.1.2.1.2._CA-36

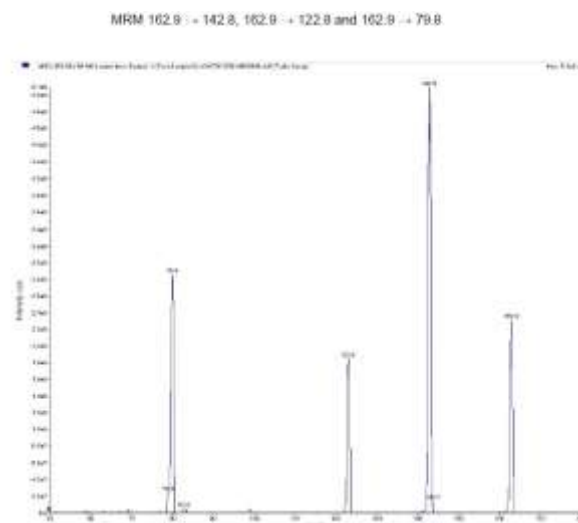

Figure B.8.1.2.1.2._CA-36: The example mass spectrum of FOE 5043-Trifluoroethanesulfonic acid (copied from the study report).

The quantitative analysis was carried out by means of calibration curve.

The whole analytical method was validated by determining the following parameters:

- LOD (Limit Of Detection) and LOQ (Limit Of Quantitation) of the method and its linearity;
- accuracy and repeatability of the analytical method;
- effect of the soil matrix on the linearity of the calibration curve;
- recovery levels of the test item.

The linearity of the whole method was determined on the basis of the calibration curve. The effect of the soil matrix on the calibration curve was examined by comparison of the mass spectra of pure 0.01M $\text{CaCl}_{2\text{aq}}$ solution and **Soil Blank Matrix** solutions, both diluted 10 times with water.

The LOD and LOQ of the method were determined when the calibration curve was constructed. The principle used here was that the LOD was the lowest measurable concentration for which signal:noise ratio was ≥ 3 . The linearity range of the calibration curve and of the method was determined analysing the constructed curve.

To determine the recovery level of the test substance – FOE 5043-Trifluoroethanesulfonic acid (TFESA), as well as the accuracy and repeatability of the analytical method, **Soil Blank Matrix** solutions for each test soil were fortified at two levels: LOQ and 1000-fold LOQ and then analysed by HPLC-MS/MS.

The results of the validation of analytical method are presented in section “Results and their discussion”.

The calculations of the Freundlich sorption parameters were performed using the equations presented below on figure B.8.1.2.1.2._CA-37.

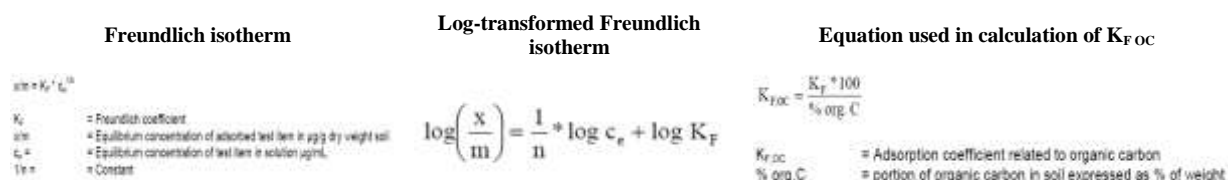

Figure B.8.1.2.1.2._CA-37: The equations used in the calculations of the Freundlich sorption parameters (copied from the study report).

The results of the study are presented and discussed below.

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in table B.8.1.2.1.2._CA-85. On their basis it may be stated that all test soils fully meet the acceptability criteria set by the OECD 106 Guideline.

The results of the monitoring of the temperature during the preliminary and definitive tests are presented below on figure B.8.1.2.1.2._CA-38. On their basis it was stated that:

- during the preliminary tests the mean $T = 20.3^{\circ}\text{C}$ and its range $19.1 - 20.9^{\circ}\text{C}$;
- during the definitive tests the mean $T = 20.2^{\circ}\text{C}$ and its range $19.3 - 20.9^{\circ}\text{C}$.

It was therefore during the whole experiment within the pre-defined limits of $T = 20 \pm 2^{\circ}\text{C}$.

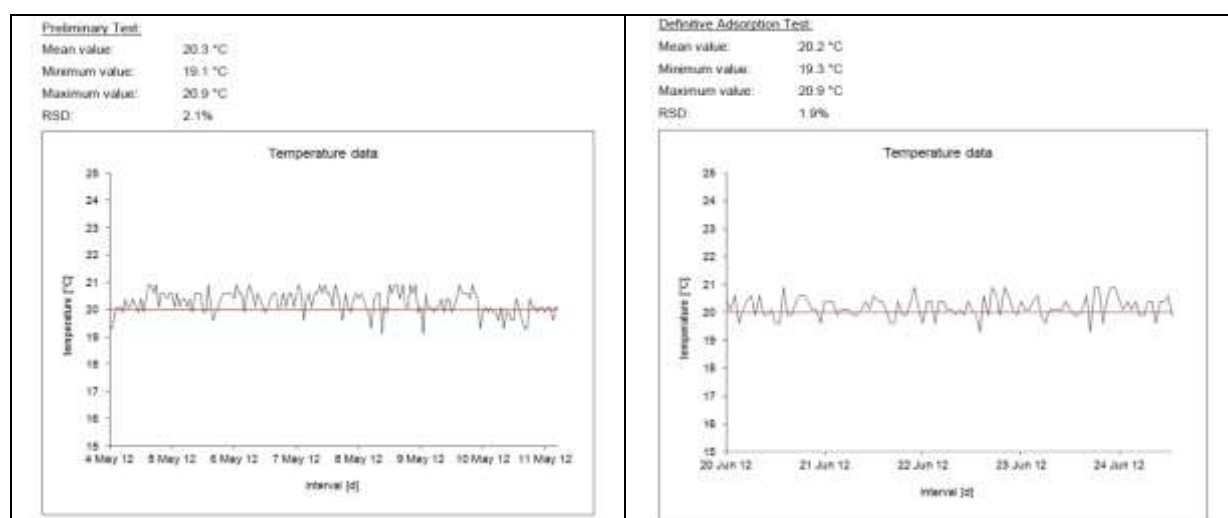

Figure B.8.1.2.1.2._CA-37: The graphical results of the monitoring of the temperature during the study (copied from the study report).

The results of the determination of linearity of analytical method and its LOD and LOQ are presented below on figure B.8.1.2.1.2._CA-38. On their basis it was stated that the method was linear in concentration range 0.02 ng/mL – 100.0 ng/mL. The determined LOQ = 0.1 ng/mL and the LOD was set to $\frac{1}{5}$ LOQ – LOQ = 0.02 ng/mL. That concentration was declared to be two orders of magnitude lower than the lowest nominal concentration of the test item used in the definitive test – 0.01 mg/L (equal to 10 ng/mL). Also at LOD level the signal to noise ratio was ≥ 3 .

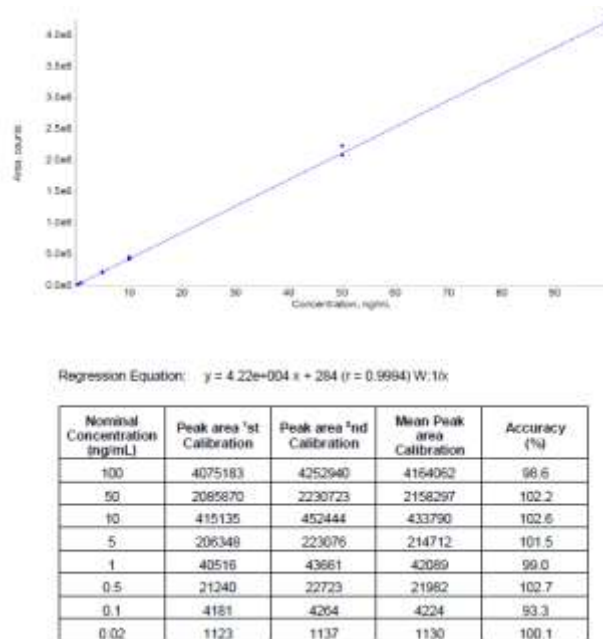

Figure B.8.1.2.1.2._CA-38: The results of the determination of linearity of analytical method (copied from the study report).

The analysis of the matrix effect on the calibration curve showed that:

- for Laacher Hof AXXa soil the matrix effect was 4%;
- for Dollendorf II soil the matrix effect was 8%;
- for Höfchen am Hohenseh 4a soil the matrix effect was 1%;
- for Hansheider Hof soil the matrix effect was 10%;
- for Wurmweise soil the matrix effect was 9%.

On that basis it was stated that there was no need to take the matrix effect into account constructing calibration curves and all calibration curves were constructed using the solutions of the test compound in pure 0.01M CaCl_2 aq.

The results of the determination of the recovery, accuracy and precision of the analytical method were following:

- for Laacher Hof AXXa soil the mean recovery at LOQ level (0.001 mg/L) was 100% (range 85 – 110%; $n = 5$) with RSD = 9%, at 1000 LOQ (1.00 mg/L) it was 108% (range 106 – 110%, $n = 5$) with RSD = 1%; the overall mean recovery was 104% with RSD = 7%;
- for Dollendorf II soil the mean recovery at LOQ level (0.001 mg/L) was 106% (range 96 – 114%; $n = 5$) with RSD = 7%, at 1000 LOQ (1.00 mg/L) it was 110% (range 108 – 113%, $n = 5$) with RSD = 2%; the overall mean recovery was 108% with RSD = 5%;
- for Höfchen am Hohenseh 4a soil the mean recovery at LOQ level (0.001 mg/L) was 95% (range 87 – 100%; $n = 5$) with RSD = 6%, at 1000 LOQ (1.00 mg/L) it was 103% (range 100 – 106%, $n = 5$) with RSD = 2%; the overall mean recovery was 99% with RSD = 6%;
- for Hansheider Hof soil the mean recovery at LOQ level (0.001 mg/L) was 109% (range 108 – 111%; $n = 5$) with RSD = 1%, at 1000 LOQ (1.00 mg/L) it was 110% (range 109 – 111%, $n = 5$) with RSD = 1%; the overall mean recovery was 110% with RSD = 1%;

- for Wurmwiese soil the mean recovery at LOQ level (0.001 mg/L) was 109% (range 103 – 116%; n = 5) with RSD = 5%, at 1000 LOQ (1.00 mg/L) it was 109% (range 107 – 112%, n = 5) with RSD = 2%; the overall mean recovery was 109% with RSD = 3%.

On the basis of these results it was stated that because the mean recoveries were in range 70-110% and RSD below 20%, therefore in line with the requirements of SANCO/3029/00, the accuracy and precision of the analytical method were considered acceptable.

Additionally the values of the blank samples were <20% LOQ in all five soils.

As a result the developed analytical method was considered suitable and specific for the test item – FOE 5043-Trifluoroethanesulfonic acid (TFESA).

The results of the determination of the initial concentration of the test item during the Preliminary Test are presented below in the table B.8.1.2.1.2._CA-88. These values were subsequently referred to as 100% AA (Applied Amount) throughout the Preliminary Test.

Table B.8.1.2.1.2._CA-88: The measured initial concentrations of the test item in the Preliminary Test.

Nominal concentration of TFESA [mg/L]	Replicate	Measured concentration of the test item – TFESA, [mg/L] in samples containing the test soil:				
		<i>Laacher Hof AXXa (AX)</i>	<i>Dollendorf II (DD)</i>	<i>Höfchen am Hohenseh 4a (HaH)</i>	<i>Hansheider Hof (HH)</i>	<i>Wurmwiese (WW)</i>
1.0	1	0.992	0.992	1.082	0.958	1.022
	2	0.960	0.988	1.066	0.930	0.992
	<i>Mean value</i>	<i>0.976</i>	<i>0.990</i>	<i>1.074</i>	<i>0.944</i>	<i>0.972</i>

The examination of the stability of the test item – FOE 5043-Trifluoroethanesulfonic acid (TFESA) in soil blank matrices showed lack of degradation during 96-hours lasting incubation. Therefore the test item was considered to be stable in the test systems for at least 96 hours.

The results of the determination of the adsorption of the test item to the test vessels, obtained for each type of the blank soil matrix, are presented below in the table B.8.1.2.1.2._CA-89. On their basis it was stated that the test compound did not display significant potential of the adsorption/adhesion onto the test vessels.

Table B.8.1.2.1.2._CA-89: The results of the determination of the adsorption/adhesion potential of the test item onto the test vessels.

Nominal concentration of TFESA [mg/L]	Replicate	% Adsorption of the test item onto the test vessels in samples containing blank control matrix of the test soil:				
		<i>Laacher Hof AXXa (AX)</i>	<i>Dollendorf II (DD)</i>	<i>Höfchen am Hohenseh 4a (HaH)</i>	<i>Hansheider Hof (HH)</i>	<i>Wurmwiese (WW)</i>
1.0	1	-1.4	2.4	2.6	3.8	4.1

			2	-5.6
			mean	-2.3
	10/50	1:5	1	-2.7
			2	-1.9
			mean	-2.3

On the basis of the obtained results the soil:solution ratio selected to be used in further tests was 1:1.

The results obtained during the determination of the appropriate equilibration time are presented below in numerical form in the table B.8.1.2.1.2_CA-91 and in graphical form on figure B.8.1.2.1.2_CA-39. On their basis the selected appropriate equilibration time was 96 hours.

Table B.8.1.2.1.1._CA-91: The numerical results of the determination of the appropriate equilibration time.

Equilibration time [hours]	Replicate	% Adsorption of the test item onto the test soil:				
		<i>Laacher Hof AXXa (AX)</i>	<i>Dollendorf II (DD)</i>	<i>Höfchen am Hohenseh 4a (HaH)</i>	<i>Hansheider Hof (HH)</i>	<i>Wurmwiese (WW)</i>

**Figure B.8.1.2.1.2._CA-39:** The graphical results of the determination of the appropriate equilibration time (copied from the study report).

The results of the **Definitive Test** are presented below, in tabularised form (tables B.8.1.2.1.2._CA-92 – B.8.1.2.1.2._CA-96), separately for each test soil. Presenting the results of the examination of adsorption at equilibrium – the amounts of the TFESA in supernatant expressed in % of Applied Amount ([%AA]), the Applicant provided an explanation that they were presented in relation to the corresponding mean values in matrix control samples, defined as 100% AA. The values were verified by the RMS and corrected when necessary. In case the values were corrected, those provided in the study report are given in brackets after the correct values calculated by the RMS. Calculating the values expressed as [%AA], in case of the mean values RMS calculated those values from the corresponding mean concentrations and not as a mean of calculated [%AA] for the two replicates.

Additionally the Applicant stated that although some mean values (RMS noticed that that concerned also the individual replicates) determined in supernatants at equilibrium were higher than 110% when referred to the respective application rate in control samples, that did not influence the validity of the experiment. It was explained that these exceedances were due, most probably, to the analytical variation, possibly also increased by low to no adsorption onto soil.

RMS, in principle agreeing with the explanation provided by the Applicant concerning the validity of the study, is of the opinion, that such phenomenon may indicate that systematic error occurred during application. Therefore the control of the amount applied should have been, rather, carried out in test samples immediately after application, using the small amounts of the solution, in order to limit the uncertainty related to the obtained results.

Table B.8.1.2.1.2._CA-92: The results of the **Definitive Test** – amounts of the test item (TFESA) in supernatant at equilibrium (after 96-hours equilibration) obtained in test soil **Laacher Hof AXXa**.

Nominal concentration of the test item [mg/L]	Replicate	Measured concentration of the test item – amount in the Matrix Control Samples		Amount in solution (supernatant) at equilibrium (after 96 hours)

On the basis of the results presented above it was stated that there was no adsorption of the test item – FOE 5043-Trifluoroethanesulfonic acid, on any test soil. It was indicated that the negative level of adsorption was recorded in majority of cases. As a result it was stated that it was not possible to determine the adsorption isotherms.

In the study report it was stated that the experiment examining the desorption was not carried out because the level adsorption was low or not it was not observed.

The final outcome of the study – the proposed parameters for adsorption and desorption (RMS's) proposal, are presented below in table B.8.1.2.1.2._CA-97. The proposed K_{fOC} and $1/n$ values are defaults presented with aim to be used as recommended in GW and SW modelling assessment.

Table B.8.1.2.1.2. CA-97: The key numerical results of the experiment – parameters of Freundlich adsorption isotherm for Trifluoroethanesulfonic acid (TFESA); RMS's proposal.

Test soil	Parameters of Freundlich adsorption isotherm				
	$\log K_{fads}$	$K_{fads} [mL/g]$	$1/n$	$K_{fOCads} [mL/g]$	R^2
Laacher Hof AXXa; Loamy sand	n. d. ¹⁾	0.0	1.0	0.0001 ²⁾	n. d. ¹⁾
Dollendorf II; Loam	n. d. ¹⁾	0.0	1.0	0.0001 ²⁾	n. d. ¹⁾
Höfchen am Hohenseh 4a; Silt loam	n. d. ¹⁾	0.0	1.0	0.0001 ²⁾	n. d. ¹⁾
Hanscheider Hof; Silt loam	n. d. ¹⁾	0.0	1.0	0.0001 ²⁾	n. d. ¹⁾
Wurmweise; Sandy loam	n. d. ¹⁾	0.0	1.0	0.0001 ²⁾	n. d. ¹⁾

Footnotes to the table:

- 1) n. d. = not determined as it was not possible to determine the isotherm;
 2) default value proposed to be used in GW and SW modelling;

Final conclusion:

The examination of the adsorption of FOE 5043-Trifluoroethanesulfonic acid (TFESA) onto soil at equilibrium showed that the test compound did not sorb onto soil to any extent (in most cases adsorption at equilibrium was shown to be negative). Therefore it was proposed to use for TFESA the value of $K_f = 0$ mg/L and consider the adsorption process as fully linear, hence $1/n = 1.0$. The proposed outcome of the study – reliable endpoint values for the adsorption process, are presented below, in form recommended for reporting the EU-agreed endpoints.

Soil adsorption transformation products (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.3.1.2 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.2.1)

FOE 5043-Trifluoroethanesulfonic acid (TFESA)							
Soil Type (USDA)	OC %	Soil pH ^{a)}	K_d (mL/g)	K_{doc} (mL/g)	K_F (mL/g)	K_{Foc} (mL/g)	$1/n$

^{a)} All values measured in water;

The Applicant also submitted the study examining the time-dependent sorption of FOE Sulfonic acid onto soil. The study has already been used to derive the kinetic endpoints for the process of degradation of that compound in aerobic soil and as such summarized in this Renewal Assessment Report as **Study 10** under the point B.8.1.1.2.1.1. – Aerobic degradation (on pages 290 – 301). Analysing the study report RMS noticed that it contained the data enabling to determine the Freundlich sorption isotherms for FOE Sulfonic acid in soil. Due to the specific design of the study, it is not possible to precisely define the would-be isotherms, but in RMS's opinion they may be representative rather for adsorption than desorption process. However, due to that uncertainty RMS is of the opinion that they should be considered only as supplementary and the resulting Freundlich isotherm parameters should not be included into the set of EU-agreed endpoints for FOE Sulfonic acid in the area of the soil sorption for that compound.

The study was presently evaluated for its compliance with OECD 106 Guideline. It is summarised below.

Study 5:

Report: Hellpointner E., (2003): "Time-Dependent Sorption of FOE5043-Sulfonic Acid in Soil."; Bayer Crop Science AG, Development – Global Regulatory Affairs, D-40789 Monheim, Germany; unpublished study Report No. MEF-229/03; 2003-10-13; study reference number: M-111445-01-1;

Guidelines: Due to the aims of the study – examination of the time-dependent sorption of FOE Sulfonic acid, it was declared to be performed in such way, to comply with the following Guidelines:

- examination of soil sorption of the test compound: OECD Guideline for Testing of Chemicals No. 106, Adsorption and Desorption;
- in the area of incubation of the test flasks – ageing and processing of test soils:
 - BBA Guidelines for the Official Testing of Plant Protectants, Part IV, 4-1 (1986);
 - SETAC-Europe Procedures for Assessing the Environmental Fate and Ecotoxicology of Pesticides (*ed.* Mark Lynch), March 1995;
 - US. EPA Guideline 162-1 Aerobic Soil Metabolism (supplemental);

GLP: Yes

RMS comments: This is a newly submitted study. Its was to examine the time-dependent sorption of FOE Sulfonic acid in soil. The study had already been evaluated, and found acceptable, with regard to its aspects aimed on the examination of the rate of degradation of the test compound in aerobic soils. At present the study was evaluated for its compliance with the following guideline:

- OECD Guideline for Testing of Chemicals No. 106, Adsorption and Desorption; to determine its suitability for the determination of Freundlich sorption isotherm for FOE Sulfonic acid in each test soil.

It was verified by the RMS and found acceptable in the area of the examination of the equilibrium sorption of FOE Sulfonic acid onto soil. It is summarised below. The summary is extended summary of that presented on pp. 290-301 as **Study 10**, containing elements strictly related to the examination of the soil sorption at equilibrium. The numbering of the figures and graphs is continuous in relation to this section of the Assessment Report.

Summary:

The aim of the study was to examine the phenomenon of the time-dependent sorption, i.e. increase with time of the K_{OC} value, of FOE Sulfonic acid onto soil. That was done in order to clarify the reasons for the observed discrepancies of the results of different studies, namely:

- high mobility and leaching potential of FOE Sulfonic acid in soil, demonstrated by the results of the batch equilibrium sorption studies – average K_{OC} = 12.5 mL/g, and modelling GW exposure assessment, with PEC_{GW} for cereals in range of 3.1 – 9.2 µg/L;
- moderate concentrations of the compound in lysimeter studies – up to 1.69 µg/L in the average 1st year leachates when the compound was applied twice in the same year;
- the fact stated in the regulatory study by Hellpointner [1999], examining the degradation of FOE Sulfonic acid in soil (summarised under the point B.8.1.1.2.1.1. as **Study 9**), that the compound was not as easily extracted from soil, especially at later time points, as it might be suggested by its K_{OC} value.

The experiment was performed using the [Phenyl-U-¹⁴C] FOE Sulfonic acid in form of ammonium salt. Its structural formula is presented below on figure B.8.1.2.1.2._CA-40. The specific activity of the test compound was 2.66 MBq/mg (21.0 mCi/mMole) and its radiochemical purity was 98%.

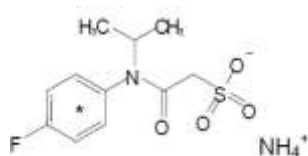

Figure B.8.1.2.1.2._CA-40: The structural formula of the test compound (copied from the study report).

The test compound was used to prepare the **Stock solution**, subsequently used in the experiment to treat the test soil. That solution was prepared by dissolving the whole delivered amount of radiolabelled FOE Sulfonic acid in 1 mL of CH₃CN and 19 mL of H₂O. Next, the concentration of the test compound in the solution was determined. For that purpose five 50-μL aliquots of the **Stock solution** were radioassayed. The concentration of the test compound, expressed as radioactivity, was determined to be 9706.3 kBq/20 mL (9.7063 MBq/20 mL), corresponding to 0.1824 mg FOE Sulfonic acid/mL. The radiochemical purity of the solution, determined by TLC, was ~98%. The **Stock solution** was used directly to treat the test soils.

Two test soils were used in the study. The soil were freshly sampled, shortly before the beginning of the experiment, from the 0-20 cm layer. Their characteristic is presented below in the table B.8.1.2.1.2._CA-98.

Table B.8.1.2.1.2._CA-98: The characteristic of soils used in the study.

Parameter		Soil	
		<i>Laacherhof AXXa</i>	<i>Laacherhof AIII</i>
Soil origin		Monheim, Germany	Monheim, Germany
Soil type (USDA)		Sandy loam	Silt loam
Particle size distribution	Sand (50 μm – 2 mm) [%]	72.4	36.9
	Silt (2 – 50 μm) [%]	22.6	51.1
	Clay (< 2 μm) [%]	5.0	12.0
pH value in CaCl ₂		6.3	6.8
pH value in H ₂ O		6.9	7.6
pH value in KCl		6.3	7.2
Organic carbon content (OC) [%]		1.47	0.88
Organic matter content (OM) [%]		2.53	1.51
Cation Exchange Capacity – CEC [mEq/100g]		10.3	9.8
Water holding capacity	Max. [g H ₂ O/100 g soil]	34.42	36.40
	In air-dried and sieved soil [%]	8.62	7.22
Bulk density [g/cm ³]		2.5	2.55
Soil microbial biomass [mg microbial C/kg soil]	At start of incubation period – DAT 0	242	275
	At the end of incubation period – DAT 100	209	195
Soil microbial biomass [% OC] ¹⁾	At start of incubation period – DAT 0	1.65	3.13
	At the end of incubation period – DAT 100	1.42	2.22

Footnotes to the table:

1) Value calculated by the RMS.

In the laboratory the test soils were air-dried and sieved to a particle size ≤ 2 mm. Then the soil moisture content was measured in sieved soil by drying it at 105°C and determining the loss of weight.

Next, 100-g (d.w.) portions of air-dried and sieved test soils (109.43 g in case of Laacherhof AXXa soil and 107.78 g in case of Laacherhof AIII soil) were weighed into 1000-mL centrifuge tubes and brought to 40% MWHC by the addition of the appropriate amount of distilled water – 4.33 g/vessel for Laacherhof AXXa soil and 6.78 g/vessel for Laacherhof AIII. The test vessels were then closed with cotton-wool plugs and pre-incubated for about one week in the darkness and at constant T = 20°C.

At the beginning of the whole experiment the soils in the test vessels were treated with the test compound applied as already described **Stock Solution** in amount 73 μL/vessel, using a 100- μL Eppendorf pipette. That gave the treatment dose of 35.5 kBq/vessel when expressed in terms of radioactivity, corresponding to the application dose of 13 μg FOE Sulfonic acid/100 g soil. It was declared in the study report that such application dose corresponded to the lowest concentration of the test compound – 0.13 μg/g soil, used in the study examining adsorption of FOE Sulfonic acid onto soil.

RMS recalculated that application dose to obtain the theoretic application rate expressed in g/ha. Standard assumptions were used: soil density $d = 1.5 \text{ g/cm}^3$ and the depth of the soil layer $l = 5 \text{ cm}$. The resulting application rate was **A = 99.70 g FOE Sulfonic acid/ha**. It corresponds to ~41% highest application rate of Flufenacet proposed in the current EU-representative GAP – 240 g/ha.

When the experimentally determined soil bulk density values were used, the calculated theoretic application rates were as follows:

- in Laacherhof AXXa soil (bulk density $d = 2.5 \text{ g/cm}^3$) application rate **A = 162.50 g FOE Sulfonic acid/ha**;
- in Laacherhof AIII soil (bulk density $d = 2.55 \text{ g/cm}^3$) application rate **A = 165.75 g FOE Sulfonic acid/ha**.

After treatment of the test soils with the test compound several test were performed, aimed on the determination of adsorption parameters. All they were performed in the same way as typical batch sorption tests described in OECD 106 Guidance document. The main test was performed with treated soil aged for the determined amount of days before the adsorption was examined. All test are briefly characterised, in form of a table copied from the study report, on figure B.8.1.2.1.2._CA-41 below.

Table 2 Applications with each approx. 35.5 kBq of test item

Test	Tubes/soil	Investigations
a) DAT-0: Soil treated prior to shaking	1	Samples taken after 1, 3, 7 and 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant
b) DAT-0: Solution treated prior to shaking	1	Samples taken after 1, 3, 7 and 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant
c) DAT-0: Reference solution: soil not treated during shaking	1	Processing after 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution, then treatment of decanted aqueous 0.01 M CaCl_2 filled into a new empty tube and shaking for 24 hrs, LSC and TLC of solution and LSC of tube extract ^{a)}
d) DAT-0: soil treated prior to shaking	1	Processing after 24 hrs of shaking with 333 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant and soil extract combustion of soil solids
e) DAT-0: Control without soil Solution treated prior to shaking	1	Samples taken after 1, 3, 7 and 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant and LSC of tube extract ^{a)}
Main Test: DAT-X: soil treated then aged prior to shaking	14	Processing after 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution, LSC and TLC of supernatant and soil extract, combustion of soil solids

^{a)}: In order to get information on the sorption of radioactivity onto the walls of the testing tubes. The tube was washed (extracted) as it is described for test a or d.

Figure B.8.1.2.1.2._CA-41: The table listing and briefly characterising tests performed in the experiment (copied from the study report).

The tests a) – e) are the equivalents of the preliminary tests in the typical experiment on the batch sorption equilibrium performed in line with OECD 106 Guideline.

All they were carried out using the 0.01M CaCl_2 _{aq} solution prepared by dissolving 2.94 g of $\text{CaCl}_2 \times \text{H}_2\text{O}$, pre-weighed into measuring flask, in 2 L of Milli-Q water. The pH of so prepared solutions was in range of 5.5 – 6.2.

The **test a)** was performed in order to establish the equilibration time for the soil:solution system in case when the test item was introduced by direct application to the soil surface, before the addition of the solution. For that purpose single vessels containing 100-g (d. w.) portions of each test soil were treated with 73 μL of characterised above **Stock Solution**, applied to the soil surface. The soil moisture of each test soil was then adjusted to 40% MWHC, 100 mL of blank 0.01M CaCl_2 _{aq} solution added to obtain the soil:solution ratio 1:1. So prepared samples were incubated for up to 24 hours, by shaking, in the darkness at constant temperature $T = 20^\circ\text{C}$. At pre-designated time points – after 1, 3 and 7 hours of shaking, 1-mL aliquots of clarified supernatant (obtained by 10-min centrifugation) were taken to analysis by LSC. At the last time point – after 24 hours of shaking, the whole test vessels were centrifuged for 15 min, clarified supernatants decanted and weighed in order to determine their volume. Then 1-mL aliquots were analysed by LSC for radioactivity content.

The **test b)** was performed in order to establish the equilibration time for the soil:solution system in case when the test item was introduced the with the 0.01M CaCl_2 _{aq} solution. For that purpose to the single vessels containing 100-g (d.w.) portions of each pre-equilibrated test soils (100 g d.w.) were added 100-mL portions of 0.01M CaCl_2 _{aq} solution treated with 73 μL of characterised above **Stock Solution**, to obtain the soil:solution ratio 1:1. The so prepared samples incubated for up to 24 hours, by shaking, in the darkness at constant

temperature $T = 20^{\circ}\text{C}$. At pre-designated time points – after 1, 3 and 7 hours of shaking, 1-mL aliquots of clarified supernatant (obtained by 10-min centrifugation) were taken to analysis by LSC. At the last time point – after 24 hours of shaking, the whole test vessels were centrifuged for 15 min, clarified supernatants decanted and weighed in order to determine their volume. Then 1-mL aliquots were analysed by LSC for radioactivity content.

The **test c)** was performed in order to determine the affinity of the test item to the test vessel. For that purpose the in single vessels 100-g (d. w.) portions of each pre-equilibrated test soil were shaken for 24 hours with 100 mL of blank 0.01M CaCl_2 aq solution (soil:solution ratio was 1:1). After that period samples were centrifuged for 15 minutes, clear supernatants decanted to empty test vessels and treated with 73 μL of characterised above **Stock Solution**. So prepared samples were then equilibrated, by shaking in the darkness at $T = 20^{\circ}\text{C}$, for another 24 hours. After that time vessels were centrifuged, supernatants collected and weighed in order to determine their amount, and 1-mL aliquots analysed by LSC to determine the radioactivity content. The empty test vessels remaining after centrifugation were washed with organic solvents in the same manner as was used in the main test in organic extraction step of test soils.

The **test d)** was performed in order to establish the equilibration time for the soil:solution system in case when the test item was introduced by direct application to the soil surface, before the addition of the solution. Therefore it looked similarly to characterised above **test a)**, except that the tested soil:solution ratio was 1:3 – the amount of blank 0.01M CaCl_2 aq solution was 333 mL.

The last of the preliminary experiments – **test e)**, had the same aim as **test b)**. The main difference between the two consisted in that it was performed in soilless system, therefore the preliminary step – equilibration of blank 0.01M CaCl_2 aq solution with 100-g portions of test soil, was omitted.

The procedure used in the **main test** is characterised below.

For each test soil 14 pre-incubated test vessels were treated with the test compound applied to the soil surface as **Stock solution** in amount 73 μL /vessel, to obtain the application dose of 0.13 mg/kg, corresponding to the theoretic application rate **A = 99.7 g/ha**. Then the test vessels were closed with cotton-wool plugs and all, except DAT-0 samples were placed in the darkness in the temperature-controlled room and incubated for up to 100 days at $T = 20^{\circ}\text{C}$.

For each test soil duplicate samples were removed for further processing at the following time points: DAT 0, DAT 3, DAT 7, DAT 14, DAT 28, DAT 56 and DAT 100. The samples removed from the incubation room were further processed following their procedure presented below on figure B.8.1.2.1.2._CA-42.

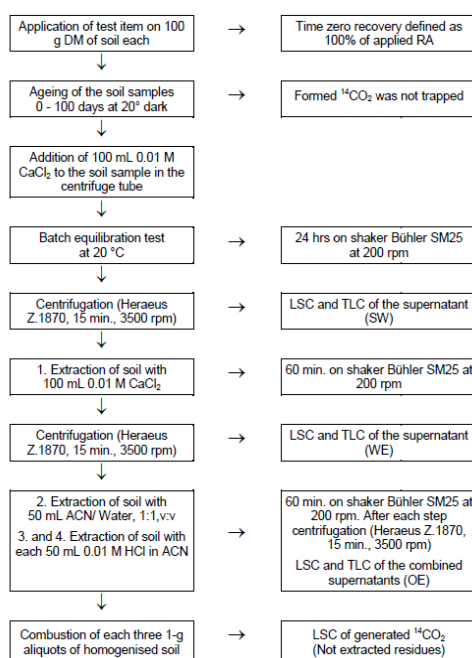

Figure B.8.1.2.1.2._CA-42: The flow chart of the processing of samples during the main test of the experiment (copied from the study report).

The 0.01M CaCl_2 solution used at the first stage of extraction, named on the flow chart “batch equilibration test”, was prepared by dissolving 2.94 g of $\text{CaCl}_2 \times \text{H}_2\text{O}$ in 2 L of deionised (Milli-Q) water. Three such solutions were prepared for the purpose of the experiment, having a pH ranging from 5.5 to 6.2. The same solution was also used at 1st step of extraction.

The clear supernatants obtained at each step after centrifugation were collected and their volume determined by weighing. The acetonitrile extracts ($\text{CH}_3\text{CN}/\text{H}_2\text{O}$ and 0.01N $\text{HCl}_{\text{aq}}/\text{CH}_3\text{CN}$ extracts) were combined.

The supernatant obtained during batch equilibration test was further called **Supernatant**, that obtained after extraction with 100 mL of 0.01 M CaCl_2 – **water extract**, while combined supernatants obtained after extraction with solutions containing CH_3CN – **organic extract**.

The extracts were not further processed but their three 200- μL aliquots analysed for radioactivity content using LSC.

The extracts were also analysed using radio-TLC. For that purpose the following amounts of each fraction were used:

- in case of **Supernatant** one 100- μL aliquot;
- in case of **Water extract** one 200- μL aliquot;
- in case of **Organic extract** one 500- μL aliquot

The extracted soil pellets were air-dried, homogenised and analysed for the content of NER fraction. For that purpose their three 1-g aliquots were combusted in oxidiser and generated $^{14}\text{CO}_2$ quantified using LSC.

The LSC analysis of the liquid samples (200- μL aliquots) was performed in 2-mL Quicksafe-A scintillation liquid containing 5% of water. The measurements were done on LS 6500 or LS 6000LL counters. Sample counting time was 10 minutes, average counting efficiency ~91% and the background 14-16 cpm.

The $^{14}\text{CO}_2$ generated during the oxidative combustion of the extracted soil pellets was absorbed in Oxysolve C-400 scintillation cocktail and analysed by LSC.

The TLC analysis was performed on crude solutions of each extract in order to determine the concentration of the test compound in each of the fractions. The analysed samples were not enriched or preconditioned prior to the analysis.

The TLC analysis was performed on 200 x 200 mm silica gel Si60 TLC plates. Chromatograms were developed in glass chamber using the following solvent system: $\text{CH}_3\text{CN}/\text{CH}_3\text{CHOHCH}_3/\text{CH}_3\text{COOC}_2\text{H}_5/\text{H}_2\text{O}$ 60:9:6:3 (v/v/v/v) solution ($\text{CH}_3\text{CHOHCH}_3$ stands for 2-propanol and $\text{CH}_3\text{COOC}_2\text{H}_5$ for ethyl acetate).

The identification of the test compound was performed by means of the comparison of the R_f values for the analysed samples with those of the known standards.

The quantitative analysis – radioactivity counting, was performed using BIO imaging analyser (Fuji Co.). The LOD (determination limit) for a single peak was 0.5% AR. That value however significantly depended on the volume of sample introduced on the plate.

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in table B.8.1.2.1.2._CA-98. On that basis it may be stated that both test soils fully meet the acceptability criteria set by the OECD 106 Guideline.

The temperature in incubation chamber was demonstrated to be constant during the whole incubation period, and maintained at the designated level $T = 20 \pm 1^\circ\text{C}$. The mean temperature during incubation was $T = 19.9^\circ\text{C}$ ranging from 19.8°C to 20.35°C .

The graphical presentation of the changes of incubation temperature are presented below on figure B.8.1.2.1.2._CA-44.

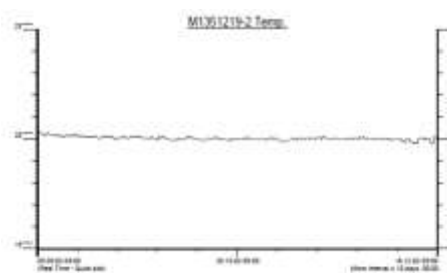

Figure B.8.1.2.1.2._CA-44: Temperature recorded in incubation chamber during the experiment (copied from the study report).

The results of the primary tests – **test a)** – **test e)**, are presented below, in tabularised form in tables B.8.1.2.1.2._CA-99 for **test a)** and **test b)**, table B.8.1.2.1.2._CA-100 for **test c)** and table B.8.1.2.1.2._CA-101 for **test e)**. The Applicant decided not to present the results of the **test d)**, as they were declared to be similar to those obtained in **test a)**.

Table B.8.1.2.1.2._CA-99: The numerical results of the **test a)** and **test b)**, aimed on the determination of the appropriate equilibration time.

Equilibration time [hours]	Radioactivity (RA) [Bq] in supernatants in vessels with the test soil: Laacher Hof AXXa, Sandy loam				Radioactivity (RA) [Bq] in supernatants in vessels with the test soil: Laacher Hof AIII, Silt loam

The total amount of radioactivity recovered in supernatants was 34312 Bq for Replicate 1, 34445 Bq for Replicate 2 and 34379 Bq on average. The amount of radioactivity washed from vessels with organic extrahents was 1763 Bq for Replicate 1, 1661 Bq for Replicate 2 and 1712 Bq on average. Given that the total radioactivity applied was 36090 Bq (100%) the average amount of radioactivity in supernatants was 95.26% and that adhered/adsorbed to the test vessels – 4.74%.

On the basis of the results presented above it was stated that the most appropriate equilibration time was 24 hours. Analysing the results presented in the table B.8.1.2.1.2._CA-99 RMS noticed that there was little difference in the radioactivity content in supernatants obtained from systems with treated soil and treated solution. That may indicate that in the definitive test the results of the batch equilibration test may be representative rather for adsorption than the desorption process.

The results of the **test c)** and **test e)** clearly demonstrated that the level of adsorption of the test item to the test vessels was very low. Additionally the results of the **test c)** demonstrated that the test item – FOE Sulfonic acid, was stable in the test system during the equilibration period.

Below are presented the results obtained during the main test.

The total recoveries of Applied Radioactivity in DAT-0 samples were as follows:

- for Laacherhof AXXa soil: **34.152 kBq**, subsequently used as a reference 100% AR value; it corresponded to 12.23 µg FOE Sulfonic acid/100 g soil;
- for Laacherhof AIII soil: **34.840 kBq**, subsequently used as a reference 100% AR value; it corresponded to 12.40 µg FOE Sulfonic acid/100 g soil.

In the study report it was stated that both soils were microbiologically viable and that the microbial biomass was within the usual range expected for soils sampled from agricultural fields.

RMS stated that the microbial biomass was above the minimal level recommended by OECD 307 Guideline – 1% OC throughout the whole study duration. It was also noted that, as expected, higher decrease in microbial biomass was observed in soil having lower OC content, but that parameter at the end of the study was still on such level that the test soil may be considered fully viable.

The results of the qualitative and quantitative analysis of the radioactivity in both test systems are presented below. Because of the design of the incubation vessels – the traps for the volatile compounds were not set, it was not possible to determine the level of mineralisation and hence it was also not possible to determine the mass balance.

RMS also noticed that the way the results were reported in the study report made them not fully transparent with regard to their further use in kinetic analysis. In particular, the results of the determination of radioactivity in each fraction was given in [Bq] for individual replicates. When transformed to % AR the values were given as averages of the two replicates.

The concentrations of FOE Sulfonic acid in different fractions at each time point determined by TLC, were expressed as % radioactivity in analysed sample. Only for extracts obtained in Laacherhof AIII soil were given the values for %AR in given fraction, enabling the calculation of the concentration of FOE Sulfonic acid expressed as % AR.

As a result, RMS decided to recalculate all the results provided in the study report in order to:

- a) obtain the results of the quantitation of radioactivity in each fraction, on each time point and for each replicate, expressed as %AR;
- b) obtain the concentrations of FOE Sulfonic acid in each replicate at each time point expressed as %AR.

The repeated calculations were carried out using the raw results presented in the study report. These are shown below, as tables copied from the study report, on figures B.8.1.2.1.2._CA-45 and B.8.1.2.1.2._CA-46. On figure B.8.1.2.1.2._CA-45 are reproduced the results of the determination of radioactivity in each fraction. For calculations were used the values marked bold – amount of radioactivity in the whole sample expressed in [Bq]. The reference value, defined as 100% AR, was “Avg. DAT-0” value reported at the bottom of each table.

On the next figure – B.8.1.2.1.2._CA-46 are presented the raw results of the analysis of each fraction by TLC. The following abbreviations were used by the Applicant in the reproduced tables to characterise fractions:

- SW for **Supernatant**;
- WE for **Water extract**;
- OE for **Organic extract**.

The numerical, re-formatted results of the experiment are given in two tables – B.8.1.2.1.2._CA-102 for Laacherhof AXXa soil and B.8.1.2.1.2._CA-103 for Laacherhof AIII soil. Presenting them the RMS decided to provide the average values for concentration of radioactivity in fractions at each sampling point as they were given in the study report. Also the concentrations of the test compound – FOE Sulfonic acid, expressed in [µg/100 g soil] are taken from the study report.

To maintain the coherence of the reported results RMS decided to present them all in format of a single digit after the decimal point. The only exception was made when the average concentrations of FOE Sulfonic acid in [µg/100 g soil], reproduced from the study report, were reported – the format used in the study report was kept.

Such approach may possibly result in small discrepancies between the averages reported by the Applicant and those calculated by the RMS, but such differences are estimated to be negligible.

In addition to numerical results RMS presented the graphical results of the determination of the distribution of radioactivity between extractable and non-extractable phases, reproduced from the study report (figure B.8.1.2.1.2._CA-47).

Finally RMS decided to provide the estimates of the mineralisation level. That was done assuming the theoretical total recovery level of AR at each time point and for each replicate equal to 100% and subtracting from that value the experimentally determined total radioactivity recovered. The resulting value was considered to represent the approximate level of mineralisation. RMS noticed that the obtained values were in line with those obtained in the study by [Hellpointner; 1999] (Study 9, point B.8.1.1.2.1.1.).

The results of the determination Freundlich sorption isotherms for FOE Sulfonic acid in Laacherhof AXXa and Laacherhof AIII test soils are presented below, in graphical form on figure B.8.1.2.1.2._CA-48 and in numerical form in the table B.8.1.2.1.2._CA-105.

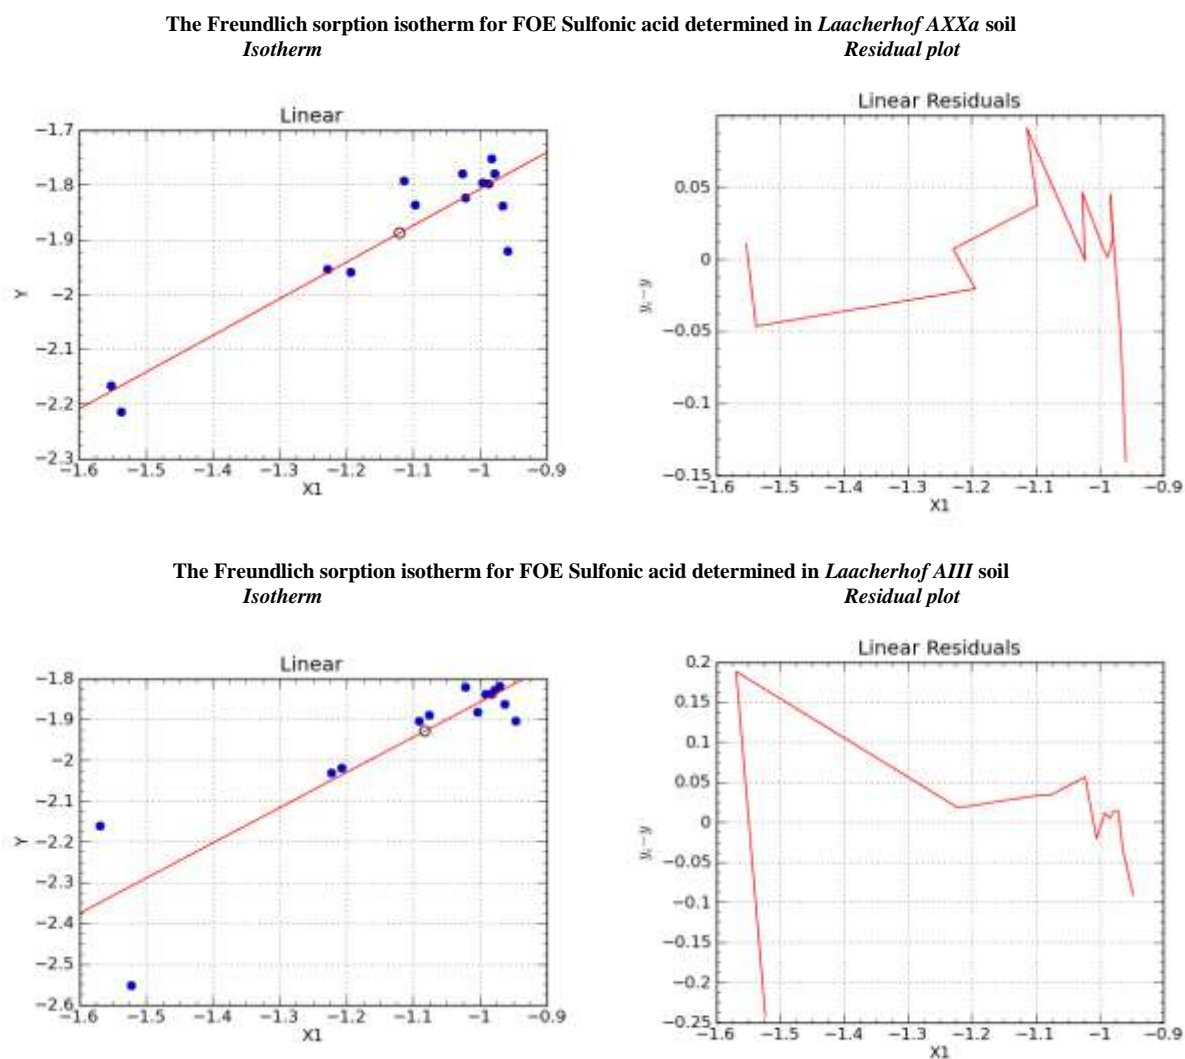

Figure B.8.1.2.1.2._CA-48: The graphical results of the determination of the Freundlich sorption isotherms for FOE Sulfonic acid in Laacherhof AXXa and Laacherhof AIII test soils.

Table B.8.1.2.1.2._CA-104: The numerical results of experiment – the parameters of the Freundlich sorption isotherm for FOE Sulfonic acid in the test soils, determined by the RMS.

Test soil	Parameters of isotherm				Statistical evaluation	
	Log K_F	K_F [mL/g]	$K_{F OC}$ [mL/g]	1/n	SD	Determination coefficient R^2
<i>Laacherhof AXXa</i> <i>Sandy loam</i>	-1.1389	0.073	10.73	0.6693	0.0573	0.8552
<i>Laacherhof AIII</i> <i>Silt loam</i>	-0.9940	0.101	11.48	0.8639	0.0963	0.7830

As indicated at the beginning of the summary the calculated Freundlich sorption isotherm parameters should be considered indicative and not included into the set of EU-agreed endpoints for FOE Sulfonic acid. That is also due to the fact that the quality of the determined isotherms is not fully satisfying.

However, on the basis of these results it may be stated that the adsorption of FOE Sulfonic acid onto soil is not expected to be pH-dependent.

The open-literature search performed by the Applicant and repeated by the RMS did not return any relevant publications in the area of the examination of the Freundlich sorption of the degradation products of Flufenacet onto soil.

As a result of the examination of the fate and behaviour of Flufenacet in the aquatic environment – in aerobic water/sediment systems, an additional degradation product was identified – FOE Methylsulfide. That metabolite was solely aquatic degradation product, not found in any of the experiments examining the transformation of Flufenacet in soil. Probably for that reason in the documentation submitted for evaluation there was no study examining its sorptive behaviour. However, because that degradation product was demonstrated to be a major aquatic metabolite, it is necessary to estimate its adsorption constant for the purpose of the modelling exposure assessment performed for SW compartment.

The Applicant in the study report presenting the substance-specific input parameters used in calculations of PEC_{SW}/PEC_{SED} values for Flufenacet and its major degradation products, proposed the K_{OC} value for FOE Methylsulfide that was determined using PCKOCWIN tool. The reference was provided to the source study report, but the report itself was not submitted for the evaluation. As a result it was not possible to verify the correctness of the determined value.

For that reason RMS decided to perform own estimation of K_{OC} for FOE Methylsulfide using the QSAR methods. The calculations are presented below, in form of a brief summary, as **Study 6**. The full, report of the calculations, provided by the modelling tool used in the estimation – EPISuite, can be found in the Appendix 3 to this Assessment Report

Study 6:

Report: RMS (2016): “Estimation of K_{OC} value for FOE Methylsulfide – a major aquatic metabolite of Flufenacet, using EPISuite tool”; RMS’s internal report;

Guidelines: not applicable.

GLP: No, not applicable (modelling exercise);

RMS comments: not applicable

Summary:

The aim of this study was to estimate the K_{OC} value for FOE Methylsulfide – a major aquatic degradation product of Flufenacet, to be subsequently used as a surrogate input value in the SW/SED modelling exposure assessment. The estimation was performed using KOCWIN, a part of EPISuite 4.1 modelling tool.

The estimation was performed for the following SMILES code created for FOE Methylsulfide:

The results of the calculations, as returned by the modelling tool, are presented below

On the basis of the results presented above the RMS selected the **K_{OC} = 598 L/kg** as a surrogate value to be used as an input parameter for FOE Methylsulfide in SW/SED modelling exposure assessment.

That value is also proposed to be introduced as a surrogate value for FOE Methylsulfide into the List of EndPoints.

Summary: the sorption of the degradation products of Flufenacet onto soil at equilibrium

To cover this data requirement the Applicant submitted four study reports, of which one had already been evaluated for the previous authorisation of Flufenacet in the EU and the remaining three were newly submitted studies. For the purpose of the current assessment these studies were evaluated for their compliance with the provisions of the current Guidelines, in particular the OECD 106 Guideline. All studies were found acceptable, despite the deficiencies they displayed.

The adsorption of FOE Oxalate, FOE Alcohol, FOE Sulfonic acid, FOE Methylsulfoxide and FOE Thiadone onto soil was examined in four US soil. The analysis of their properties showed that in case of one of them – Vero Beach Sand, the OC content was slightly lower than the recommended 0.3% (0.27%). However, it was decided to consider the parameters of the Freundlich sorption isotherms determined in that soil, valid, unless other factors indicated that the isotherm should not be considered reliable. The key results are presented below, individually for each test compound. On their basis it was stated that, according to Briggs' classification, FOE Oxalate and FOE Sulfonic acid should be classified as very mobile/mobile in soil while FOE Thiadone, FOE Alcohol and FOE Methylsulfoxide as intermediately mobile in the same compartment.

The sorption of FOE Methylsulfone onto soil was examined in a separate, newly submitted study, using five test soils – three European and two US soil. The key results of that experiment are presented below in a separate table. On their basis it may be stated that, according to Briggs' classification FOE Methylsulfone displays intermediate mobility in soil.

The soil sorption of Trifluoroacetic acid was examined in another newly submitted study, also using five test soils (three EU and two US soils). The results of that study showed that the compound adsorbed only very weakly, or not at all, onto soil, therefore it is expected to be highly mobile in that compartment. The key results of that experiment are presented in a separate table.

Finally, in the separate, newly submitted, study was examined the sorption of FOE 5043-Trifluoroethane-sulfonic acid. The experiment was performed using five test soils, all originating in the EU. The results of that study showed that also that compound adsorbed only very weakly, or not at all, onto soil, therefore it is expected to be highly mobile in that compartment. The key results of that experiment are presented in a separate table.

Additionally RMS used the results obtained in the study examining time-dependent sorption of FOE Sulfonic acid onto two soils to determine Freundlich sorption isotherms and in that way possibly extend the available data base for that compound. Due to the inadequate quality of the isotherms, the results should only be considered indicative, but the obtained Freundlich sorption constants were in line with those determined for the same compound in the other evaluated study.

Finally, the obtained results demonstrated that for none of the test compounds the soil sorption was pH-dependent.

Table B.8.1.2.1.2._CA-105: The definitive set of Freundlich adsorption and desorption parameters determined for FOE Methylsulfoxide.

1) Measured in water;

Additionally the surrogate K_{OC} value was estimated for FOE Methylsulfide – an aquatic major degradation product of Flufenacet. That was done using KOCWIN tool – a part of the EPISuite 4.1 tool. The estimated value (determined by RMS) is **K_{OC} = 598 L/kg**. That value is proposed to be used as an input parameter in the SW/SED model exposure assessment and to be reported in the EU-agreed List of EndPoints as a surrogate value for that compound.

B.8.1.2.2. – Aged sorption

The Applicant submitted one study report addressing the problem of aged sorption in soil. The report examined the phenomenon of the aged sorption of FOE Sulfonic acid – one of the major degradation products of Flufenacet in aerobic soil. The results of that study have already been used twice in this Renewal Assessment Report – as the data enabling the determination of the degradation kinetics of FOE Sulfonic acid in aerobic soils (**Study 10** and **Study 13** summarised under the point B.8.1.1.2.1.1) and to estimate Freundlich adsorption parameters in alkaline soils (**Study 5** under the point B.8.1.2.1.2). For that reason RMS decided not to provide its extended summary. Instead, in the short summary provided below are presented its key results – the determined K_d and K_{dOC} values in function of time.

Study 1:

Report: Hellpointner E., (2003): “Time-Dependent Sorption of FOE5043-Sulfonic Acid in Soil.”; Bayer Crop Science AG, Development – Global Regulatory Affairs, D-40789 Monheim, Germany; unpublished study Report No. MEF-229/03; 2003-10-13; study reference number: M-111445-01-1;

Guidelines: Due to the aims of the study – examination of the time-dependent sorption of FOE Sulfonic acid, it was declared to be performed in such way, to comply with the foillowing Guidelines:

- examination of soil sorption of the test compound: OECD Guideline for Testing of Chemicals No. 106, Adsorption and Desorption;
- in the area of incubation of the test flasks – ageing and processing of test soils:
 - BBA Guidelines for the Official Testing of Plant Protectants, Part IV, 4-1 (1986);
 - SETAC-Europe Procedures for Assessing the Environmental Fate and Ecotoxicology of Pesticides (*ed.* Mark Lynch), March 1995;
 - US. EPA Guideline 162-1 Aerobic Soil Metabolism (supplemental);

GLP: Yes

RMS comments: This is a newly submitted study. Its was to examine the time-dependent sorption of FOE Sulfonic acid in soil. The study had already been evaluated, and found acceptable, with regard to its aspects aimed on the examination of the rate of degradation of the test compound in aerobic soils. At present the study was evaluated for its compliance with the following guideline:

- OECD Guideline for Testing of Chemicals No. 106, Adsorption and Desorption; to determine its suitability for the determination of Freundlich sorption isotherm for FOE Sulfonic acid in each test soil.

It was verified by the RMS and found acceptable in the area of the examination of the equilibrium sorption of FOE Sulfonic acid onto soil. Its extended summary in the area of the examination of soil sorption at equilibrium was presented above, under the point B.8.1.2.1.2. as **Study 5**. Therefore this summary contains only brief characteristic of the soils used in the experiment, test item, and the key results regarding soil sorption – the K_d and K_{dOC} values in function of time. The numeration of the figures and graphs is continuous in relation to this section of the Assessment Report.

Summary:

The aim of the study was to examine the phenomenon of the time-dependent sorption, i.e. increase with time of the K_{OC} value, of FOE Sulfonic acid onto soil. That was done in order to clarify the reasons for the observed discrepancies of the results of different studies, namely:

- high mobility and leaching potential of FOE Sulfonic acid in soil, demonstrated by the results of the batch equilibrium sorption studies – average K_{OC} = 12.5 mL/g, and modelling GW exposure assessment, with PEC_{GW} for cereals in range of 3.1 – 9.2 µg/L;
- moderate concentrations of the compound in lysimeter studies – up to 1.69 µg/L in the average 1st year leachates when the compound was applied twice in the same year;
- the fact stated in the regulatory study by Hellpointner [1999], examining the degradation of FOE Sulfonic acid in soil (summarised under the point B.8.1.1.2.1.1. as **Study 9**), that the compound was not as easily extracted from soil, especially at later time points, as it might be suggested by its K_{OC} value.

The experiment was performed using the [Phenyl-U-¹⁴C] FOE Sulfonic acid in form of ammonium salt. Its structural formula is presented below on figure B.8.1.2.2._CA-1. The specific activity of the test compound was 2.66 MBq/mg (21.0 mCi/mMole) and its radiochemical purity was 98%.

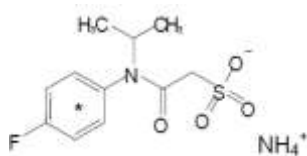

Figure B.8.1.2.2._CA-1: The structural formula of the test compound (copied from the study report).

Two test soils were used in the study. The soil were freshly sampled, shortly before the beginning of the experiment, from the 0-20 cm layer. Their characteristic is presented below in the table B.8.1.2.2._CA-1.

Table B.8.1.2.2._CA-1: The characteristic of soils used in the study.

Parameter		Soil	
		<i>Laacherhof AXXa</i>	<i>Laacherhof AIII</i>
Soil origin		Monheim, Germany	Monheim, Germany
Soil type (USDA)		Sandy loam	Silt loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	72.4	36.9
	Silt (2 – 50 µm) [%]	22.6	51.1
	Clay (< 2 µm) [%]	5.0	12.0
pH value in CaCl ₂		6.3	6.8
pH value in H ₂ O		6.9	7.6
pH value in KCl		6.3	7.2
Organic carbon content (OC) [%]		1.47	0.88
Organic matter content (OM) [%]		2.53	1.51
Cation Exchange Capacity – CEC [mEq/100g]		10.3	9.8
Water holding capacity	Max. [g H ₂ O/100 g soil]	34.42	36.40
	In air-dried and sieved soil [%]	8.62	7.22
Bulk density [g/cm ³]		2.5	2.55
Soil microbial biomass [mg microbial C/kg soil]	At start of incubation period – DAT 0	242	275
	At the end of incubation period – DAT 100	209	195
Soil microbial biomass [% OC] ¹⁾	At start of incubation period – DAT 0	1.65	3.13
	At the end of incubation period – DAT 100	1.42	2.22

Footnotes to the table:

1) Value calculated by the RMS.

In the laboratory the test soils were air-dried and sieved to a particle size ≤ 2 mm. Then the soil moisture content was measured in sieved soil by drying it at 105⁰C and determining the loss of weight.

The whole analytical procedure has been characterised when the study was summarised under the point B.8.1.2.1.2. of this Renewal Assessment Report as **Study 5**. That summary can be found on pages 961 – 973 of the Report.

Results and their discussion:

The detailed results of the study and their discussion were presented when it was summarised under the point B.8.1.2.1.2. of this Renewal Assessment Report as **Study 5**. That summary can be found on pages 961 – 973 of the Report.

The key results of the examination of time-dependent sorption of FOE Sulfonic acid onto the test soils are presented below in two tables – B.8.1.2.2._CA-2 for the test soil Laacherhof AXXa and B.8.1.2.2._CA-3 for the test soil Laacherhof AIII.

The Applicant calculated the increase factor for K_{d OC} during ageing period. In case of the experiment carried out with Laacherhof AXXa soil this factor was 2, while for the experiment on the Laacherhof AIII soil it was 1.5. At the same time it was stated that although the increase of the sorption strength was observed, the obtained sorption coefficients indicate that the classification of test compound – FOE Sulfonic acid, with regard to its mobility in soil remains unchanged – the compound should be classified as mobile according to Briggs' and Verdam et al.'s classification criteria.

The corresponding kinetic endpoints determined for FOE Sulfonic acid in each test soil, reported for completeness, are following:

- in Laacherhof AXXa Sandy loam soil: the not normalised (persistence) DT₅₀ = 62.31 days and the normalised (modelling) DT₅₀ = 49.85 days;
- in Laacherhof AIII Silt loam soil: the not normalised (persistence) DT₅₀ = 60.26 days and the normalised (modelling) DT₅₀ = 40.37 days.

B.8.1.2.3. – Summary: adsorption and desorption in soil

The sorption of Flufenacet onto soil at equilibrium was extensively examined in four studies using fourteen test soils. The results of that examination were used to obtain Freundlich sorption isotherms for adsorption and desorption processes and to derive Freundlich sorption isotherm parameters. In case of adsorption reliable parameters of Freundlich isotherm were obtained for ten test soils, while for desorption the reliable Freundlich parameters were derived using nine test soils. They are presented below in two tables: B.8.1.2.3._CA-1 for adsorption and B.8.1.2.3._CA-2 for desorption. The results obtained for adsorption indicate that Flufenacet is moderately to strongly sorbed onto soil and that the process is not preferential. It was also determined that it was not pH-dependent.

Table B.8.1.2.3._CA-1: The results of the determination of the adsorption of Flufenacet onto soil at equilibrium – the reliable parameters of the Freundlich adsorption isotherm.

Soil name	Soil properties			Adsorption distribution coefficients		Freundlich adsorption isotherm parameters

pH dependence						No			----

The additional information on the soil sorption of Flufenacet at equilibrium were provided by three open-literature scientific papers. The key results obtained in them are presented below in the table B.8.1.2.3._CA-3. The values reported below may be considered as indicative and should not be used to derive the regulatory endpoints characterising soil sorption of Flufenacet.

Table B.8.1.2.3._CA-3: The results of the determination of the adsorption of Flufenacet onto soil at equilibrium obtained in the open-source literature scientific papers.

Study	Soil name	Soil properties			Freundlich adsorption isotherm parameters			
		Soil type	pH	OC [%]	K_f [mL/g]	K_{foc} [mL/g]	1/n	r

Footnotes to the table:

1) OM content reported, no values for OC content

In the studies by [Gupta, Gajbhiye and Agnihotri; 2001] and [Gajbhiye and Gupta; 2001] for adsorption of Flufenacet onto test soil the value of the free Gibbs energy of adsorption – ΔG , was determined. It was in range $\Delta G = (-3.27) - (-5.08)$ [Kcal/mol], indicating that adsorption of Flufenacet onto soil was a spontaneous process and mechanistically it was predominantly physisorption. It was also demonstrated, in the study by [Gupta, Gajbhiye and Agnihotri; 2001], that the soil sorption of Flufenacet was strongly positively correlated with soil OC/OM content. As the results obtained in these two studies are in line with those from reliable regulatory studies, that conclusion may be considered to be a general conclusion with regard to the adsorption of Flufenacet onto soil.

Also examined was sorption onto soil at equilibrium of major soil degradation products of Flufenacet: FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid (FOE TFESA) and Trifluoroacetic acid (TFA). The key results – Freundlich sorption parameters, are presented below, individually for each test compound.

For FOE Oxalate the reliable Freundlich isotherm parameters for adsorption were determined in three test soils. The desorption was not examined because of the low level of adsorption onto soil. The results are presented below in the table B.8.1.2.3._CA-4.

Table B.8.1.2.3._CA-4: The Freundlich adsorption and desorption parameters determined for FOE Oxalate.

Test soil – USDA type (name)	Key soil properties		Freundlich adsorption isotherm parameters			Freundlich desorption isotherm parameters

pH dependence			No					

Footnotes to the table:

1) Measured in water;

The results showed that FOE Methylsulfone and FOE Thiadone were moderately sorbed onto soil. FOE Oxalate and FOE Sulfonic acid were only weakly sorbed onto soil, while FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid were practically not sorbed onto soil. No pH-dependence of the adsorption was stated for any of the degradation products, but in case of FOE Thiadone, FOE Sulfonic acid and FOE Oxalate that may be due to the limited number of soils used in the experiment as well as their narrow pH range.

Additionally for FOE Methylsulfide – major aquatic degradation product of Flufenacet, the K_{OC} value was estimated using KOCWIN – a part of EPISuite 4.1 modelling tool. The estimated value is **K_{OC} = 598 L/kg** and is recommended to be used as an input value in SW/SED model exposure assessment.

For FOE Sulfonic acid the additional examination of the soil sorption in function of time – time-dependent sorption, was performed. The key results of that examination – adsorption parameters in function of time, are provided below in the table B.8.1.2.3._CA-10.

Table B.8.1.2.3._CA-10: The key results of the examination of the time-dependent sorption of FOE Sulfonic acid onto soil.

The calculated adsorption coefficient increase factor was **2** for Laacherhof AXXa test soil and **1.5** for Laacherhof AIII test soil, indicating that the compound became more strongly sorbed onto soil with elapsing time. However that increase did not strongly influenced the mobility of FOE Sulfonic acid in soil, which remained very mobile, as indicated K_d and K_{d OC} values.

B.8.1.3. – Mobility in soil

The evaluation for Flufenacet in this area covers the following issues:

- column leaching, based on open literature studies,
- aged residue column leaching,
- lysimeter studies,
- determination of the Plant Uptake Factor – PUF, as “Other studies”

These issues are covered below, under the relevant data points.

B.8.1.3.1. – Column leaching studies

No study reports were submitted to address this issue for the first authorisation of Flufenacet in the EU. Instead the following rationale for the non-submission was provided (the text copied from the DAR prepared by the RMS – France): “No column leaching studies were performed. However this requirement is covered by adsorption studies with the active ingredient and relevant metabolites (section 7.2.1) as well as by aged residue column leaching, which is described below (section 7.2.3.)”. Also for the current evaluation the Applicant has not submitted studies addressing the column leaching of Flufenacet. Although in the MII document for Flufenacet, summarising the findings of the examination of fate and behaviour of Flufenacet in soil it is stated that there is a study addressing the issue of the column leaching of the active substance (point CA 7.1.4.1.1) it shall be indicated that the study, evaluated for the previous approval of Flufenacet in the EU, was in fact aimed on the examination of the leaching of aged residues of Flufenacet through the soil columns. Therefore it shall be stated that there is no study to address the issue of column leaching of Flufenacet through soil columns. RMS performing the repeated literature search for Flufenacet identified two publications addressing the problem of the mobility of Flufenacet through soil columns. They are summarised in this section of the Renewal Assessment Report as **Study 2** and **Study 3**.

The Applicant submitted one study report that covers the issue of the column leaching. The study was aimed on the examination of the leaching of one of the degradation products of Flufenacet – Trifluoroacetic acid (TFA), through the soil column. It is summarised below as **Study 1**.

Study 1:

Report: Hein E. –M., (2014): “[1-¹⁴C]trifluoroacetate: Soil column Leaching”; Bayer CropScience AG, BCS-D-EnSa Testing, 40789 Monheim, Germany; study No. M1212045-5; Report No. EnSa-14-0050; 2014-02-20; study reference number: M-477737-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Test Guideline No 312, Leaching in Soil Columns, April 2004;
- US. EPA OCSPP Test Guideline No 835.1240, Leaching Studies, October 2008;

GLP: Yes;

RMS comments: This is a new study, submitted specifically for the purpose of the current evaluation in order to refine the findings concerning the adsorption potential of TFA onto soil. It was evaluated for its compliance with the OECD 312 Guideline and found acceptable. It is summarised below.

Summary:

The aim of the study was to examine the mobility and leaching potential of Trifluoroacetic acid in soil. The study’s design was such to enable the determination of K_d and K_{dOC} values for the test item, because in the batch equilibrium sorption study TFA was demonstrated to display a virtually no adsorption potential. The experiment was performed on four test soils. Their characteristic is provided below in the table B.8.1.3.1._CA-1.

Table B.8.1.3.1._CA-1: The characteristic of soils used in the study.

The test soils used in the experiment were sampled in June 2011 from the sites covered with grass on which no pesticides were used for 5 consecutive years before sampling. The soil samples were taken with shovel from the top 20-cm layer, placed in either plastic bag or bucket and shipped to the laboratory where it was air-dried, sieved through a 2-mm sieve and stored at $T = 20 \pm 2^{\circ}\text{C}$ until being used.

The test compound used in the study was [¹⁴C] Trifluoroacetic acid, in form of sodium salt, radiolabelled in carboxyl group. It had a specific activity of 3.48 MBq/mg and radiochemical purity, determined by HPLC, >98%. Its structural formula is presented below on figure B.8.1.3.1._CA-1. It was delivered to the test facility in form of a vacuum-dried solid.

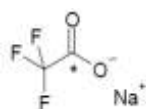

Figure B.8.1.3.1._CA-1: The structural formula of the test item – [¹⁴C]-TFA. Radiolabelling position is indicated by an asterisk (*); (copied from the study report).

The whole delivered sample of the test compound was dissolved in water to obtain a stock solution labelled **KOE7801 ST**, having a nominal concentration of 3480 kBq/mL, corresponding to 1.0 mg/mL. Its concentration was verified by the LSC and determined to be 3477.336 kBq/mL (1.0 mg/mL). The identity of the test item in the solution was confirmed by IC-MS/MS. That solution was subsequently used to prepare the application solutions of the test item, labelled **Ja64AS1** and **Ja64AS1a**. Prior to that the stock solution was stored in refrigerator in the dark.

In the study two other radiolabelled compounds were used. One of them was [¹⁴C]-atrazine, uniformly radiolabelled in triazole ring, having a specific activity of 160 mCi/mmol, corresponding to ~27.4 MBq/mg, and radiochemical and chemical purity, determined by HPLC, of 99%, used as a reference item. It was delivered to the test facility as either solid sample or MeOH-solution. Depending on the form in which it was delivered, it was used to prepare two stock solutions in water – stock solution **Ja66 SS Atr** prepared from the solid sample and stock solution **I12999-SS** prepared from MeOH-solution.

The stock solution **Ja66 SS Atr** was prepared by gradual dissolving of the whole delivered solid sample of [¹⁴C]-atrazine in water to the final volume of 10 mL. So prepared solution had a concentration, determined by LSC, of 84238 Bq/mL, corresponding to 3.10 µg/mL. The identity of the compound in the solution was confirmed by HPLC-MS/MS. That solution was used to prepare the application solution **Ja64 AS2** and until then was stored refrigerated in the darkness.

The stock solution **I12999-SS** was prepared by gradual diluting the whole amount of the delivered MeOH-solution of [^{14}C]-atrazine – 0.75 mL (having a nominal concentration of 0.1 mCi/mL, corresponding to 3.7 MBq/mL), with 6.75 mL of water. The so prepared solution had a concentration, determined by LSC, of 412 kBq/mL, corresponding to 15.0 $\mu\text{g/mL}$. The identity of the compound in the solution was confirmed by HPLC-MS/MS. That solution was used to prepare the application solution **Ja64 AS2a** and until then was stored refrigerated in the darkness.

The structural formula of the reference item is presented below on figure B.8.1.3.1._CA-2.

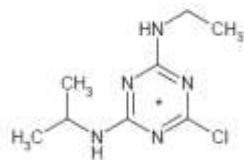

Figure B.8.1.3.1._CA-2: The structural formula of [^{14}C]-atrazine used as reference compound. Radiolabelling position is indicated by the asterisk (*); (copied from the study report).

Second additional compound used in the study was tritiated water, radiolabelled with [^3H], having a specific activity of 1 mCi/mL, corresponding to ~37 MBq/mL. That compound was used as a tracer (control item). It was used to prepare a stock solution labelled **Ja64 SS TW**. For that purpose 0.25-mL aliquot of the delivered sample was diluted with 24.75 mL of deionised water to obtain a solution having a nominal specific activity (concentration of $^3\text{H}_2\text{O}$) of 370 kBq/mL. The measured specific activity, determined by LSC, was 623.702 kBq/mL. That solution was used to prepare application solutions containing the tracer. Until being used it was stored refrigerated in the darkness. The structural formula of the control item (tracer) is presented below on figure B.8.1.3.1._CA-3.

Figure B.8.1.3.1._CA-3: The structural formula of [^3H]-water used as the control item (tracer). The radiolabelling position is indicated by the asterisk (*); (copied from the study report).

The characterised above stock solutions of the test compound, reference compound and the tracer were used to prepare four following application solutions:

- **Ja 64 AS1**, containing the test compound and the tracer;
- **Ja64 AS1a**, containing the test compound and the tracer;
- **Ja64 AS2**, containing the reference compound and the tracer;
- **Ja64 AS2a**, containing the test compound and the tracer.

The application solution **Ja64 AS1** was prepared by mixing 0.22 mL of the stock solution **KOE7801 ST** with 1.6 mL of the stock solution **Ja64 SS TW**. The solution was then brought to the volume of 10 mL with deionised water. The final concentration of the constituents of that solution, determined by LSC was 75907.2 Bq/mL (21.8 $\mu\text{g/mL}$) for the test compound (TFA) and 104747.6 Bq/mL for the tracer. The radiochemical purity of the test item – TFA, in that solution was demonstrated to be 100%.

The application solution **Ja64 AS1a** was prepared by mixing 0.33 mL of the stock solution **KOE7801 ST** with 2.4 mL of the stock solution **Ja64 SS TW**. The solution was then brought to the volume of 15 mL with deionised water. The final concentration of the constituents of that solution, determined by LSC, was 77966.8 Bq/mL (22.4 $\mu\text{g/mL}$) for the test compound (TFA) and 101473.4 Bq/mL for the tracer. The radiochemical purity of the test item – TFA, in that solution was demonstrated to be 100%.

The application solution **Ja64 AS2** was prepared by mixing 8.4 mL of the stock solution **Ja66 SS Atr** with 1.6 mL of the stock solution **Ja64 SS TW**. The final concentration of the constituents of that solution, determined by LSC, was 75756.0 Bq/mL (2.8 $\mu\text{g/mL}$) for the reference compound (atrazine) and 110100.8 Bq/mL for the tracer. The radiochemical purity of the reference item – atrazine, in that solution was demonstrated to be 97.8%.

The application solution **Ja64 AS2a** was prepared by mixing 2.79 mL of the stock solution **I12999-SS** with 2.4 mL of the stock solution **Ja64 SS TW**. The solution was then brought to the volume of 15 mL with deionised water. The final concentration of the constituents of that solution, determined by LSC, was 75181.6 Bq/mL (2.7 µg/mL) for the reference compound (atrazine) and 106626.6 Bq/mL for the tracer. The radiochemical purity of the reference item – atrazine, in that solution was demonstrated to be 98.2%.

The solution used for equilibration of the columns containing test soils and for leaching was artificial rain – 0.01M CaCl_2 _{aq} solution, prepared by dissolving 2.94 g $\text{CaCl}_2 \cdot 2 \text{H}_2\text{O}$ with deionised water in 2-L volumetric flask.

The experiment was performed using the glass columns, 45-cm long and having 5 cm of the inner diameter, filled with the test soils to ~30-cm height. They were prepared in the following way: firstly the lower, conical section of the column, was filled with a layer of a quartz wool followed by a layer of washed sea sand to retain the test soil within it. Next, the column was dry-packed with the given air-dried test soil up to its height of ~30 cm, while gently vibrating it. The amount of the test soil used per column was 675 – 856 g. So prepared columns were equilibrated to the study conditions in the darkness and at constant temperature $T = 20 \pm 2^\circ\text{C}$. That was done by saturation the soil in the columns with 400 mL 0.01M CaCl_2 _{aq} solution (artificial rain) administered from the bottom of the column to minimise air entrapment in soil pores. That resulted in 10-20 mm layer of the solution above the soil surface. The saturated columns were left for 16 hours, then drained, bringing the solution to the soil surface level. The volume of the removed supernatant was measured and the saturation volume of each soil column calculated. As in some columns soil swelled during saturation, the height of the soil column was measured again.

Next, the columns were allowed to drip off for ~5 hours and the liquid, defined as dripping volume or excess volume, was collected and measured. It was used to determine the void volume of the soil column, defined as a difference between the saturation volume and the excess volume.

Finally the columns were once again saturated with 0.01M CaCl_2 _{aq} administered from the bottom until the soil surface was covered. So prepared test columns were used in the leaching experiment. The soil columns were prepared in duplicate for each variant of the experiment

The leaching experiment was performed in two different variants – as **Study design A** and **Study design B**. The **Study design A** provided the information on the distribution of the test item in the leachate and soil column, while **Study design B** only on that of the test item in leachate.

The detailed characteristic of the **Study design A**, as provided by the Applicant in the study report, is presented on figure B.8.1.3.1._CA-4. The next two figures – B.8.1.3.1._CA-5 and B.8.1.3.1._CA-6 present soil column parameters. In a similar way are presented the detailed characteristic of the **Study design B** – on figure B.8.1.3.1._CA-7 and the parameters of the soil column – on figure B.8.1.3.1._CA-8. The values presented in tables reproduced on figures B.8.1.3.1._CA-5, B.8.1.3.1._CA-6 and B.8.1.3.1._CA-8 were used to calculate the sorption parameters – K_d and K_{dOC} values for TFA in each test soil.

Parameters	Description		
Test apparatus	Glass tubes (45 x 5 cm [length x diameter]), connected to a reservoir of artificial rain via a peristaltic pump. Flow was regulated via a post-column peristaltic pump. Leachates were collected by a programmable fraction collector.		
Test item application to soil columns			
• Identity of application solvent	Ja64 AS1, Ja64 AS1a and Ja64 AS2: water Ja64 AS2a: water with approx. 2% methanol (v/v)		
• Application volume per treatment	500 µL for all application solutions		
• Identity of application solution applied to the respective soil columns	Ja64 AS1 Ja64 DD1 / DD2 / WW1 / WW2 Ja64 AS1a Ja64LH1a / LH2a / HH1a / HH2a Ja64 AS2 Ja64 DD3 / DD4 / WW3 / WW4 Ja64 AS2a Ja64 LH3a / LH4a / HH3a / HH 4a		
• Applied radioactivity per soil column	Soil Column ID	TFA	³ H ₂ O
	Ja64 DD1 / DD2 / WW1 / WW2	36925 Bq	51996 Bq
	Ja64 LH1a / LH2a / HH1a / HH2a	39203 Bq	51625 Bq
	Soil Column ID	atrazine	³ H ₂ O
	Ja64 DD3 / DD4 / WW3 / WW4	37175 Bq	54730 Bq
	Ja64 LH3a / LH4a / HH3a / HH4a	37755 Bq	53943 Bq
• Application method	Small droplets on top of the soil column using a pipette.		
• Evaporation of application solvent	No		
Indication of test item adsorption to walls of test apparatus	No		
Number of soil columns / replicates	test item + tracer: two soil columns per soil (total 8) reference item + tracer: two soil columns per soil (total 8)		
Soil column dimensions	height: 30 to 32.5 cm diameter: 5 cm		
Weight of soil per column	699 to 856 g (dry weight)		
Soil condition	Sieved to 2 mm, air-dried		
Column packing and wetting technique	Columns were dry-packed uniformly under gentle vibration. Afterwards, soils were saturated with 0.01 M CaCl ₂ solution from bottom to top, and equilibrated for approx. 16 hours.		
Leaching solution	0.01 M CaCl ₂ solution		
Experimental conditions			
• Delivery of leaching solution to column	Delivery to open column top by peristaltic pump, maintaining a supernatant of approx. 10-20 mm above soil level.		
• Flow rate, conditions and control	Constant saturated flow of 8.2 mL/h; pressureless, with effluent control by peristaltic pump.		
• Total irrigation volume	392 mL (equal to constant rainfall of 200 mm)		
• Temperature	20.1 °C (19.8 to 20.4 °C)		
• Continuous darkness	Yes		
• Sampling time / volume per fraction	6 h / approx. 50 mL		
• Total sampling time	48 hours		
• Number / height of soil column segments	5 segments of approx. 6 cm

Figure B.8.1.3.1._CA-8: The soil column parameters for the soil columns treated with the test compound – TFA, and the tracer in the **Study design B**, as provided by the Applicant (copied from the study report).

At the beginning of the leaching experiment 0.5 mL of the appropriate application solution was introduced onto the headspace of each test column. In case of the test compound the application dose was 11 µg/g soil column, what corresponded to the field application rate of Flufenacet equal to 250 g/ha, assuming the conversion factor Flufenacet → TFA of 0.75 and a ratio $M_{TFA}/M_{Flufenacet} = 0.3$.

After application a glass funnel with a glass frit attached to it was placed upside down in the top section of each column, above the soil surface. The columns were then attached to the artificial rain container, two peristaltic pumps set to obtain the pre-defined flow rate and the fractions collector. The whole experimental set-up is presented below on figure B.8.1.3.1._CA-9.

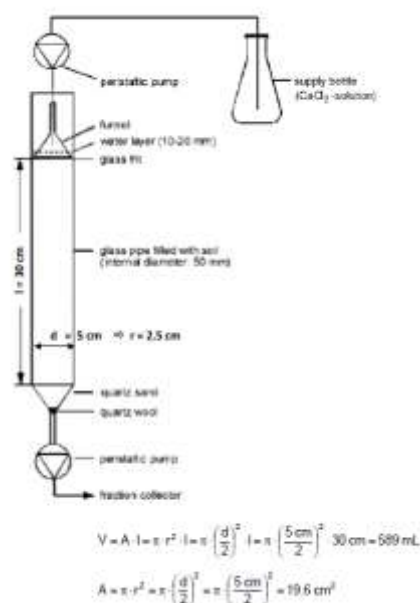

Figure B.8.1.3.1_CA-9: The schematic presentation of the test column set-up (copied from the study report).

The columns were kept throughout the whole experiment in the darkness and under the constant temperature $T = 20 \pm 2^\circ\text{C}$.

In case of the **Study design A** the leaching lasted 48 hours – the time required for the passing through the column 392 mL of the artificial rain administered at a rate 8.2 mL/h, the amount corresponding to 200 mm of the continuous rainfall. The fractions of the leachate were collected in 6-hours intervals, rendering the volume collected in each fraction of approx. 50 mL. The volume of each collected fraction was measured. Each fraction was characterised for its pH immediately after collection, and for the content of radioactivity, by LSC, within three days after collection. Afterwards the collected fractions were stored refrigerated in the darkness until being further analysed. The soil columns after draining were deep-frozen and divided into 6-cm segments for further analysis. The whole applied sample-processing procedure is presented below on figure B.8.1.3.1_CA-10.

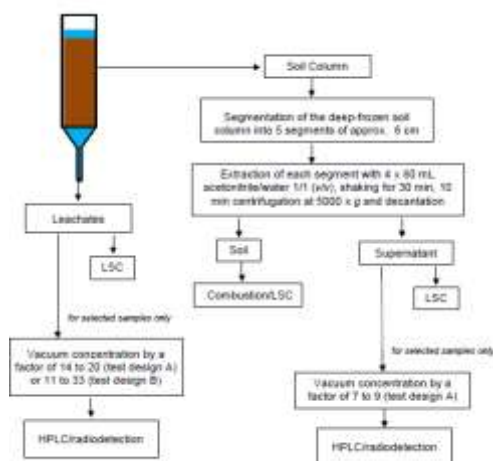

Figure B.8.1.3.1_CA-10: The schematic presentation of the sample processing procedure used in the study (copied from the study report).

In case of the **Study design B** the leaching lasted 120 hours – the time required for the passing through the column 984 mL of the artificial rain administered at a rate 8.2 mL/h, the amount corresponding to 502 mm of the

continuous rainfall. The fractions of the leachate were collected in either 6-hours intervals (approx. 50-mL fractions), or 12-hours intervals (approx. 100-mL fractions). The volume of each collected fraction was measured. Each fraction was characterised for its pH immediately after collection, and for the content of radioactivity, by LSC, within three days after collection. Afterwards the collected fractions were stored refrigerated in the darkness until being further analysed. The soil columns after draining were deep-frozen. They were however not analysed as all radioactivity introduced in form of the test item was recovered in leachates. Therefore, the whole applied sample-processing procedure was identical to that presented on figure B.8.1.3.1._CA-10, except that the recovered soil columns were not analysed.

The LSC analysis was performed using LS 6500 or LKB-Wallac 1219 Spectral counters. The radioactivity (^3H and $^3\text{H} + ^{14}\text{C}$ in parallel) in liquid samples – leachates, soil extracts, application solutions, was determined in maxi vials using the aliquots up to 2 mL and 10 mL of Quicksafe A + 5% water LS cocktail. The average sample counting time was 10 minutes, background for ^3H : 2.0 – 2.8 cpm and background for ^{14}C : 15.5 – 17.2 cpm.

Radioactivity in stock solutions was determined in mini-vials using the aliquots up to 1 mL and 2 mL of Quicksafe A + 5% water LS cocktail. The average sample counting time was 10 minutes and the background 13 cpm.

The $^{14}\text{CO}_2$ generated during combustion of the extracted soil samples was absorbed in 15 mL of Oxsolve C400 LS cocktail and analysed by LSC. The average sample counting time was 10 minutes and the background 19.1 – 19.6 cpm.

The instrumental LOD and LOQ values for the LSC analysis were determined individually for ^{14}C and ^3H measurements. They are presented below in the table B.8.1.3.1._CA-2. These values were used to calculate the LOD and LOQ values for each type of sample analysed by LSC. The obtained values – worst case LOD and LOQ for each type of analysed sample, are presented in the table B.8.1.3.1._CA-3

Table B.8.1.3.1._CA-2: The instrumental LOD and LOQ values for LSC analysis of various types of samples.

Measurement	Sample type	Scintillation cocktail	Scintillator No.	LOD _{instrumental}	LOQ _{instrumental}
^{14}C -measurement	Stock solutions	5 mL Quicksafe A + 5% water	1	0.4 Bq	0.7 Bq
	Leachate fractions and soil extracts	10 mL Quicksafe A + 5% water	2	0.6 Bq	0.9 Bq
	^{14}C from soil combustion	15 mL Oxsolve C400	3	0.7 Bq	1.0 Bq
^3H -measurement	Leachate fractions and soil extracts	10 mL Quicksafe A + 5% water	1	0.1 Bq	0.1 Bq

Table B.8.1.3.1._CA-2: The LOD and LOQ values for LSC analysis of various types of samples.

Measurements	Scintillator No.	Sample type	Volume/mass of the sample		LOD (worst case)	LOQ (worst case)
			Total (max.)	Aliquot (min.)		
^{14}C	1	Leachate fractions	104 mL/ 54 mL	2 mL/ 1 mL	298.Bq (<0.1% AR)	44.7 Bq (0.1% AR)
	1	Soil extracts	365 mL	1 mL	209.3 Bq (0.6% AR)	313.9 Bq (0.8% AR)
	2	Soil column segments (^{14}C formed during combustion)	194.2 g	0.9 g	141.0 Bq (0.4% AR)	211.5 Bq (0.6% AR)
^3H	1	Leachate fractions	104 mL/ 51 mL	2 mL/ 1 mL	4.9 Bq (<0.1% AR)	4.9 Bq (<0.1% AR)
	2	Soil extracts	365 mL	1 mL	51.1 Bq (<0.1% AR)	51.1 Bq (<0.1% AR)

The selected leachates and soil extracts were analysed using RP-HPLC method with radioactivity detection. The RP-HPLC analysis was performed in a gradient mode. The system consisted of HP 1200 chromatograph equipped with a quaternary pump, autosampler, on-line degasser, column oven and a Variable Wavelength UV detector set at $\lambda = 254$ nm, coupled with Ramona Star radioactivity detector equipped with a 370 μL glass solid phase scintillator flowcell. The chromatographic separation was performed on Purosphere Star RP 18e 250 mm * 4.6 mm, 5 μm , chromatographic column preceded by Purosphere Star RP 18e 4 mm * 4 mm, 5 μm , guard column.

It worked in the following gradient regime:

- **Mobile phase A:** 985 mL Water + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ (5 mM NH_4COOH /265 mM HCOOH);

- **Mobile phase B:** 985 mL CH₃CN + 10 mL HCOOH + 5 mL NH₄COOH_(aq) (5 mM NH₄COOH/265 mM HCOOH);
- **Gradient mode:** is shown below in the table B.8.1.3.1._CA-4;
- Total run time was 70 minutes.

The flow rate was set to 1.0 mL/min. The chromatographic column was kept under the constant temperature T = 40°C.

Table B.8.1.3.1._CA-4: The gradient mode used in the radio-HPLC analysis

Elution time [min]		0	5	55	60	62	70
Composition of the mobile phase	Solvent A [%]	100	100	5	5	100	100
	Solvent B [%]	0	0	95	95	0	0

The retention times (R_t) for the chromatographed compounds were following:

- for TFA R_t ≈ 7.4 min.;
- for atrazine R_t ≈ 37.5 min.;

The total LOD values calculated for the HPLC analysis were following:

- for leachate fractions max total LOD = 0.2% AR;
- for soil extracts max. total LOD = 1.4 % AR.

Values representing the LOQ were not provided.

Selected samples were also analysed using LC-MS/(MS) techniques – either HPLC-MS/(MS) or IC-MS/(MS) method. The analysis was carried out in order to confirm the identity of the test compound – TFA.

The HPLC-MS/(MS) analysis was performed using HP 1100 instrument equipped with Nucleodur C18 Gravity 250 • 2 mm, 5 µm, chromatographic column and UV detector, coupled to Ramona Star radioactivity detector and Q-Exactive XL MS detector. The chromatographic analysis was performed in a gradient mode using a gradient programme presented below in the table B.8.1.3.1._CA-5. The flow rate was 0.2 mL/min and elution lasted for 35 minutes. The chromatographic column was kept in a chromatographic oven set to T = 40°C. The changes in the gradient of mobile phase were linear.

Table B.8.1.3.1._CA-5: The gradient mode used in the HPLC-MS/(MS) analysis.

Time [min]	Solvent ratio	
	Solvent A – Water + 0.1% HCOOH	Solvent B – CH ₃ CN + 0.1% HCOOH
0	95	5
5	95	5
25	5	95
35	5	95

The IC-MS/(MS) analysis was performed using Dionex-ICS-5000 instrument equipped with AS20 250 • 2 mm column and conductivity detector coupled to radioactivity detector and MS detector (specification of none of them provided in the study report). The column was kept under the constant temperature T = 30°C. Elution was performed in isocratic mode using 20 mM KOH aqueous solution and it lasted 15 minutes. The flow rate was set to 0.25 mL/min.

The results obtained in both leaching experiments were used to derive the K_d and K_{dOC} values for TFA. The calculations were performed for TFA as a test item, tritiated water as a tracer and atrazine as a reference compound.

For TFA and tritiated water calculations were performed using the following equations (copied from the study report; where calculations were characterised as performed according to Ketelle and Swoboda):

(1) The soil adsorption coefficient K_d is derived from the soil column data using the following formulae:

$$K_d = \left(\frac{V_e}{V_v} - 1 \right) \cdot \frac{V_v}{m_{\text{soil}} (\text{g})}$$

with

K _d	Adsorption constant [mL/g]
V _e	Volume of artificial rain required to leach 50% AR of the test item or reference item through the soil column [mL]
V _v	Void volume of the soil column [mL]
m _{soil} (g)	Dry weight of the soil column [g]

The void volume (V_v) of each soil column was calculated as follows, taken into account the porosity fraction (ϕ) and the volume of soil column ($V_{\text{soil column}}$).

$$\begin{aligned} V_v &= \phi \cdot V_{\text{soil column}} \\ &= \left(1 - \frac{\rho_{\text{bulk}}}{\rho_{\text{particle}}} \right) \cdot V_{\text{soil column}} \\ &= \left(1 - \frac{\frac{m_{\text{soil}}(\text{DM})}{V_{\text{soil column}}}}{\rho_{\text{particle}}} \right) \cdot V_{\text{soil column}} \end{aligned}$$

with:

V_v	Void volume of soil column [mL]
ϕ	Porosity factor of soil column [-]
$V_{\text{soil column}}$	Volume of soil column [cm ³ = mL], calculated by: $V_{\text{soil column}} = \pi \cdot r^2 \cdot h$
ρ_{bulk}	Bulk density of soil [g/cm ³], calculated by: $\rho_{\text{bulk}} = \frac{m_{\text{soil}}(\text{DM})}{V_{\text{soil column}}}$
ρ_{particle}	Particle density of soil [g/cm ³], determined in separate GLP study
$m_{\text{soil}}(\text{DM})$	Dry weight of soil column [g]

The calculations for atrazine were performed using two methods: by Lambert and by Hamker/McCall. The results were subsequently averaged.

The equations used in calculations according to Lambert, as they were presented in the study reports, are shown below:

(1) The soil adsorption coefficient K_d according to Lambert is derived from the soil column data using the following formula:

$$K_d = \frac{V_{\text{total irrigation}} \cdot \alpha + X_0}{\beta \cdot X_0}$$

with:

K_d	Adsorption constant [mL/g]
$V_{\text{total irrigation}}$	Total irrigation volume [mL]
X_0	Distance, measured from top of soil column to segment of max. compound concentration [cm]
α	Column factor [mL/cm + cm ²]
β	Column factor [g/cm]

The input data are described in Table 7 (parameters of soil columns). Based on the experimental results, the distance (X_0) the compound has moved during irrigation is determined using the following formula:

$$X_0 = \frac{h_{\text{soil column}}}{N_{\text{total}}} \cdot N_{\text{max}} - \left(\frac{h_{\text{soil column}}}{2 \cdot N_{\text{total}}} \right)$$

with:

X_0	Distance, measured from top of soil column to segment of max. compound concentration [cm]
$h_{\text{soil column}}$	Height of soil column [cm]
N_{total}	Total number of soil column segments [-]
N_{max}	Number of soil column segment with max. compound concentration (1 = top (start), 5 = bottom (finish) of soil column) [-]

The column factors α and β are calculated as follows:

$$\alpha = \frac{V_v}{h_{\text{soil column}}} \quad \beta = \frac{m_{\text{soil}}(\text{DM})}{h_{\text{soil column}}}$$

with:

V_v	Void volume of soil column [mL = cm ³]
$h_{\text{soil column}}$	Height of soil column [cm]
$m_{\text{soil}}(\text{DM})$	Dry weight of soil column [g]

The equations used in calculations according to Hamaker/McCall, as they were presented in the study reports, are shown below:

(1) The soil adsorption coefficient K_d according to Hamaker / McCall is derived from the soil column data using the following formula:

$$K_d = \left(\frac{\theta^{2/3} - \frac{1}{R}}{\theta^{2/3} - 1} \right) \cdot \frac{1}{\rho_{\text{solid soil constituents}}}$$

with:

K_d	Adsorption constant [mL/g]
θ	Porosity [-]
R	Ratio of distance moved by compound and height of added water column [-]
$\rho_{\text{solid soil constituents}}$	Particle density [g/cm ³ = g/mL]

The input data are described in Table 7 (parameters of soil columns). Based on the experimental results, the porosity (θ) of the soil column, the density of the solid soil constituents (particle density, $\rho_{\text{solid soil constituents}}$), the distance (X_0) the compound has moved during irrigation and the ratio of the distance (R) moved by the compound and the height of added water column are determined using the following formulae:

$$\theta = \frac{V_s + V_r}{V_{\text{soil column}}}$$

with:

θ	Porosity
V_s	Saturation volume of soil column [mL]
V_r	Volume of residual water in air dried soil column [mL]
$V_{\text{soil column}}$	Volume of soil column [mL]

$$\rho_{\text{solid soil constituents}} = \frac{m_{\text{solid}} (\text{gwt})}{\frac{V_{\text{soil column}}}{(1 - \theta)}}$$

with

$\rho_{\text{solid soil constituents}}$ Density of the solid soil constituents (particle density)

$V_{\text{soil column}}$ Volume of soil column

$m_{\text{solid}} (\text{gwt})$ Mass of soil column (dry weight)

θ Porosity

$$K_s = \frac{h_{\text{test column}}}{h_{\text{total}}} \cdot N_{\text{max}} - \left(\frac{h_{\text{test column}}}{2 \cdot h_{\text{total}}} \right)$$

with

h_s Distance, measured from top of soil column to segment of max. compound concentration [cm]

$h_{\text{test column}}$ Height of soil column [cm]

N_{max} Total number of soil column segments [-]

N_{max} Number of soil column segment with max. compound concentration (1 = top (start); 5 = bottom (finish) of soil column) [-]

$$R = \frac{h_s}{V_{\text{total irrigation}}} \cdot A_{\text{column}}$$

with

R Ratio of distance moved by test item and height of added water column [-]

h_s Distance, measured from top of column to segment of max. test item concentration [cm]

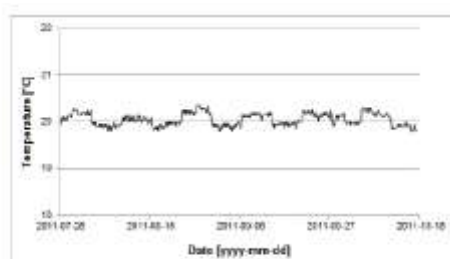

$V_{\text{total irrigation}}$ Total irrigation volume [ml = cm³]

A_{column} Surface of soil column [cm²]

Results and their discussion:

The characteristic of the test soils used in the study has been presented at the beginning of this summary in table B.8.1.3.1._CA-1. It may be stated that the test soils generally meet the acceptability criteria with regard to their textural characteristic, pH range and OC content range.

The leaching experiment was carried out in the dark, in a walk-in climatic chamber at constant temperature. The results of its monitoring during the experiment are presented below on figure B.8.1.3.1._CA-11. On their basis it was stated that the mean $T = 20.1^{\circ}\text{C}$ and its range was $19.8 - 20.4^{\circ}\text{C}$. It was therefore within the pre-defined limits of $T = 20 \pm 2^{\circ}\text{C}$. It may be also stated that the temperature was constant within the study period, therefore that factor had no influence on the obtained results, in particular calculated K_d/K_{dOC} values.

Temperatures were recorded by a data logger (Squirrel 1256, Grant Instr. Ltd.).

Record start date (equilibration of first soil columns)	2011-07-26
Record end date (end of last soil columns)	2011-10-17
Total Readings	3660
Reading interval [min]	30
Minimum [°C]	19.8
Maximum [°C]	20.4
Mean [°C]	20.1
SD [°C]	0.1
RSD [%]	0.7

Figure B.8.1.3.1._CA-11: The graphical results of the monitoring of the temperature during the study (copied from the study report).

The verification of the application rate showed that the amount of the given compound applied per column was on average:

- 38.5 kBq, corresponding to ~11 µg, for the test item – TFA

- 37.5 kBq, corresponding to ~1.4 µg, for the reference item – atrazine;
- 53.0 kBq for the tracer – $^3\text{H}_2\text{O}$.

The verification of the analytical procedure demonstrated its good suitability, reflected by high recoveries of the applied radioactivity – in the experiment labelled **Study design A** the extractable residues were in range 98.6 – 101.8% AR for the test item (TFA) and 90.2 – 94.0% AR for the reference item (atrazine).

The total recovered radioactivity in the experiment labelled **Study design A** was in range 93.5 – 103.2% AR for the test item (TFA) and tracer ($^3\text{H}_2\text{O}$) and 93.2 – 102.6% AR for the reference item (atrazine) and tracer ($^3\text{H}_2\text{O}$). In case of the experiment labelled **Study design B** the total recovered radioactivity for the test item (TFA) and tracer ($^3\text{H}_2\text{O}$) was in range 92.9 – 102.6%.

It was stated that in case of the test compound in the **Study design A**, > 90% of the applied amount was found in leachates from Laacherhof AXXa and Höfchen am Hoheneseh. In Dollendorf II and Laacherhof Wurmweise soil it was more strongly retained by soil, with 62 – 82% of applied recovered in leachates from columns with Dollendorf II soil and 62 – 70% of applied recovered in leachates from columns with Laacherhof Wurmweise soil. Similar observations were made in case of the tracer compound applied alongside. In this experiment atrazine – the reference compound, was demonstrated to be strongly retained by soil – only up to 1% of the applied dose was recovered in leachates. The graphical results of the determination of the mass balance in this experiment are presented below on figure B.8.1.3.1_CA-12. The following abbreviations were used to denominate the test soils used in the experiment:

- LH for soil Laacherhof AXXa,
- DD for soil Dollendorf II,
- HH for soil Höfchen am Hoheneseh,
- WW for soil Laacherhof Wurmweise.

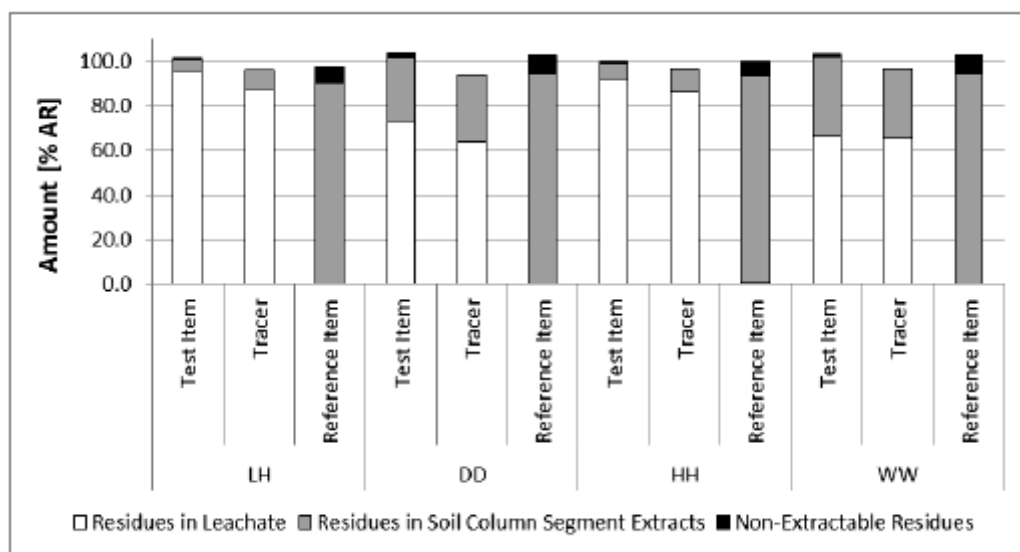

Figure B.8.1.3.1_CA-11: The graphical results of the determination of the mass balance in the experiment labelled **Study design A** (copied from the study report).

The detailed numerical results of the study obtained for the experiment labelled **Study design A** are presented below. To maintain their clarity RMS decided to reproduce them as they were provided by the Applicant in the study report. They are followed by their graphical presentation.

Figure B.8.1.3.1._CA-24: The results of the determination of pH of the leachates (copied from the study report)

The detailed results of the study obtained for the experiment labelled **Study design B** are presented below. First are presented the results of the determination of the pH of collected leachate fraction for each soil column. Next are presented, individually, the numerical results obtained for each type of the soil column, followed by their graphical presentation. To maintain clarity of their reporting RMS decided to reproduce all numerical results as they were provided by the Applicant in the study report.

The results of the determination of the pH of collected leachate fractions are presented below, on figure B.8.1.3.1._CA-25 in form of the table provided by the Applicant in the study report.

Sampling Time [h]	Fraction ID	pH values

Figure B.8.1.3.1_CA-33: The graphical presentation of the results obtained for columns filled with the test soil Laacherhof Wurmwiese (copied from the study report).

The results of the calculations of the K_d and K_{dOC} values for TFA and the tracer in each test soil are presented below in the table B.8.1.3.1._CA-10. RMS analysing these results noticed that for the same soil and the same K_d the calculated K_{dOC} differed, what may be attributed to the applied calculation and rounding procedures.

Table B.8.1.3.1._CA-10: The calculated K_d and K_{dOC} values for TFA and tracer in each test soil used in the experiment.

Conclusions:

The results of the experiment showed that Trifluoroacetic acid may be classified as very mobile in soil.

In the variant with columns eluted for 48 hours with 392 mL of the artificial rain (**Study design A**) the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 95.5% AR for columns filled with Laacherhof AXXa test soil;
 - 73.2% AR for columns filled with Dollendorf II test soil;
 - 92.1% AR for columns filled with Höfchen am Hohenseh test soil;
 - 66.2% AR for columns filled with Laacherhof Wurmwielse test soil.
- the extractable radioactivity retained within soil columns attributed to TFA was (mean values of the two replicates):
 - 5.0% AR for columns filled with Laacherhof AXXa test soil;
 - 28.3% AR for columns filled with Dollendorf II test soil;
 - 6.5% of AR for columns filled with Höfchen am Hohenseh test soil;
 - 35.6% AR for columns filled with Laacherhof Wurmwielse test soil.
- the NER fraction attributed to TFA, expressed as % AR, in the soil columns (mean values of the two replicates) was:
 - 1.2% AR for columns filled with Laacherhof AXXa test soil;
 - 1.8% AR for columns filled with Dollendorf II test soil;
 - 0.8% AR for columns filled with Höfchen am Hohenseh test soil;
 - 1.1% AR for columns filled with Laacherhof Wurmwielse test soil.
- the distribution of residues of TFA in soil was following:
 - for columns filled with Laacherhof AXXa test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Dollendorf II test soil the highest concentration of TFA residues was determined in the top section of the column (segments S1 and S2) with the peak amount in segment S2, and it gradually decreased towards the bottom of the soil column;
 - for columns filled with Höfchen am Hohenseh test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Laacherhof Wurmwielse test soil the residues of TFA were generally found in the lower part of the column, with the peak amount in the middle section S3.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil Laacherhof AXXa $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;

- for the test soil Dollendorf II $K_d = 0.0 \text{ mL/g}$ and $K_{dOC} = 0.0 \text{ mL/g}$;
- for the test soil Höfchen am Hohenseh $K_d = 0.0 \text{ mL/g}$ and $K_{dOC} = 0.0 \text{ mL/g}$;
- for the test soil Laacherhof Wurmweise $K_d = 0.0 \text{ mL/g}$ and $K_{dOC} = 0.0 \text{ mL/g}$;
- mean $K_d = 0.0 \text{ mL/g}$ and $K_{dOC} = 0.0 \text{ mL/g}$.

The results obtained in that experiment for the tracer ($^3\text{H}_2\text{O}$) co-eluted with TFA, also expressed as % AR, were following (mean values of the two replicates):

- amount in the eluates:
 - 87.5% AR for columns filled with Laacherhof AXXa test soil;
 - 63.9% AR for columns filled with Dollendorf II test soil;
 - 85.8% AR for columns filled with Höfchen am Hohenseh test soil;
 - 65.4% AR for columns filled with Laacherhof Wurmweise test soil.
- the extractable radioactivity retained within soil columns attributed to tracer (mean values of the two replicates):
 - 8.4% AR for columns filled with Laacherhof AXXa test soil;
 - 29.7% AR for columns filled with Dollendorf II test soil;
 - 10.4% of AR for columns filled with Höfchen am Hohenseh test soil;
 - 30.8% AR for columns filled with Laacherhof Wurmweise test soil.
- the NER fraction attributed to tracer was not determined in any of the test soils due to the technical reasons:
- the distribution of residues of the tracer in soil was following:
 - for columns filled with Laacherhof AXXa test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Dollendorf II test soil the highest level was determined in segment S2, and it gradually decreased towards the bottom of the soil column;
 - for columns filled with Höfchen am Hohenseh test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Laacherhof Wurmweise test soil the residues of TFA were generally found in the lower part of the column, with the peak amount in the middle sections – S3 and S4.

In the variant with columns eluted for 120 hours with 984 mL of the artificial rain (**Study design B**) the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 101.1% AR for columns filled with Laacherhof AXXa test soil;
 - 96.3% AR for columns filled with Dollendorf II test soil;
 - 98.6% AR for columns filled with Höfchen am Hohenseh test soil;
 - 100.9% AR for columns filled with Laacherhof Wurmweise test soil.
- the amount of radioactivity retained within soil columns attributed to TFA was not analysed because it was wholly recovered in leachates.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil Laacherhof AXXa $K_d = 0.1 \text{ mL/g}$ and $K_{dOC} = 4.5 \text{ mL/g}$;
 - for the test soil Dollendorf II $K_d = 0.0 \text{ mL/g}$ and $K_{dOC} = 0.0 \text{ mL/g}$;
 - for the test soil Höfchen am Hohenseh $K_d = 0.2 \text{ mL/g}$ and $K_{dOC} = 11.3 \text{ mL/g}$;
 - for the test soil Laacherhof Wurmweise $K_d = 0.2 \text{ mL/g}$ and $K_{dOC} = 7.1 \text{ mL/g}$;
 - mean $K_d = 0.2 \text{ mL/g}$ and $K_{dOC} = 9.1 \text{ mL/g}$.

The results obtained in that experiment for the tracer ($^3\text{H}_2\text{O}$) co-eluted with TFA, also expressed as % AR, were following (mean values of the two replicates):

- amount in the eluates:
 - 102.6% AR for columns filled with Laacherhof AXXa test soil;
 - 96.6% AR for columns filled with Dollendorf II test soil;
 - 97.3% AR for columns filled with Höfchen am Hohenseh test soil;
 - 98.2% AR for columns filled with Laacherhof Wurmweise test soil.
- the amount of radioactivity retained within soil columns attributed to the tracer was not analysed because it was wholly recovered in leachates.

The results of this study in format recommended for the List of Endpoints are presented below:

Mobility in soil column leaching transformation products (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.4.1.2 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.2.1)

Column leaching – TFA

RMS performing the repeated literature search for Flufenacet identified two publications addressing the problem of the mobility of Flufenacet through soil columns. They are summarised below.

Study 2:

Report: Gupta S., Gajbhiye V. T., Agnihotri N. P. (2001): “Adsorption-Desorption, Persistence and Leaching Behavior of Flufenacet in Alluvial Soil of India.”; Division of Agricultural Chemicals, Indian Agricultural Research Institute, New Delhi 110 012, India; published study - published in: “Bulletin of Environmental Contamination and Toxicology”, vol 66, 2001, pp 9-16.

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper

RMS comments: The paper presents the results of the examination of soil equilibrium sorption (determination of Freundlich sorption isotherms), mobility in soil profile (column leaching experiment) and persistence in aerobic and anaerobic soil, for Flufenacet. The experiments were performed using one test soil. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with the OECD 307 guideline for soil persistence, OECD 106 Guideline for examining batch sorption and OECD 312 for column leaching. The level of details was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below, in this section of the Assessment Report for its part examining the column leaching of Flufenacet. However, RMS is of the opinion that the results it provides may be regarded only as supplementary study and should not be used as a source of regulatory endpoints.

Summary:

The Editor has not provided the abstract for that publication. However the paper contained the introduction, clearly outlining the aims and scope of the research activity described in it, which may be considered a summary of the study. Due to the copyright restrictions, RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the mobility and persistence of Flufenacet in soil. The test soil used in the experiment was an agricultural soil, of the type of inceptisol, having the following physicochemical properties:

- **particle size distribution:** 64.7% sand, 15.6% silt and 19.7% clay;
- **soil texture class:** Sandy loam;
- **pH:** 7.1;
- **OC:** 0.34%;
- **Moisture content at FC (field capacity):** 20%.

The soil used in the experiment was freshly sampled from the top 15-cm layer of the fields of Indian Agricultural Research Institute in New Delhi, India. It was then air-dried and sieved through 2-mm mesh screen before being used.

The test compound was analytical grade Flufenacet, having a purity of > 99.5%, provided by M/s Bayer India Ltd. It was applied to the test soil in form of aqueous solution in 0.01 N CaCl_2 aq, prepared from the stock solution of Flufenacet in acetone, having a concentration of 0.5 mg/mL.

The aliquot of this solution was transferred into the glass tube and left at $T = 25 \pm 2^\circ\text{C}$ to evaporate acetone. The residue was reconstituted in 0.01N CaCl_2 aq. That solution was used to treat soil used in the experiment.

The examination of leaching of Flufenacet through the soil column was performed using PVC columns, 50-cm long and having the internal diameter of 7 cm. It was performed in duplicate plus the control.

The columns were cut longitudinally into half before the experiment began, then the halves rejoined using the adhesive tape. That was done in order to facilitate the removal of intact soil cores after accomplishing the leaching phase of the experiment. The lower end of each column was capped with polyethylene sheet in which small holes were drilled to allow the leachate flow out. Next the columns were filled up to 35 cm with untreated test soils, and the lower end placed overnight in water to allow soil saturate with water. Then to the top was

introduced 10-g portion of the test soil treated with Flufenacet. The amount of the test compound in soil sample was 0.5 g.

The leaching started with introducing water onto the top of the column. The water was in constant supply to keep its level of 2 cm above the soil surface. The amount of water passed through the column was ~2800 mL and the flow rate was 0.5 mL/min. The leaching lasted for ~3 days at room temperature. During that time leachate was collected in 250-mL fractions, which were processed by filtering, diluting with aqueous solution of NaCl and extracting with three 50-mL portions of CH₂Cl₂. The organic phase was collected, combined, dried by passing through anhydrous Na₂SO₄ and the solvent evaporated to dryness. The residues were reconstituted in n-hexane and analysed by GC-ECD.

The soil column after leaching was cut horizontally into seven 5-cm sections. Each so obtained soil sample was homogenised and its two 100-g aliquots extracted with acetone. The extract was further processed by evaporating the organic solvent, diluting the aqueous residue with saturated NaCl_{aq} solution and partitioning it with three 50-mL portions of CH₂Cl₂. The organic phase was collected and processed as described earlier. The resulting processed sample extracts were analysed by GC-ECD.

All samples were analysed using GC-ECD technique on Hewlett Packard 5890 Gas Chromatograph equipped with ⁶³Ni electron capture detector. The separation was performed on megabore HP-1 capillary GC column, 10-metres long, 0.53-mm of internal diameter and having 2.65 µm-thick film. The GC oven was programmed at initial temperature of T = 160°C lasting for 9 minutes, then increasing at rate 30°C/min to T = 260°C, held at that level for 3 minutes. The carrier gas was N₂ administered at a rate 15 mL/min.

For Flufenacet the R_t = 7.4 min. The LOQ = 0.005 µg/g for both soil and aqueous matrices.

The analysis of the leachate showed that no residues of Flufenacet were detected up to collecting 1250 mL of it. The test compound appeared for the first time in fraction 1250 – 1500 mL, in amount 0.005 µg/mL, that gradually increased to reach the level of 0.049 µg/mL in the last fraction – 2750-2810 mL.

The conversion of the volume of leachate into equivalent rainfall showed that to leach Flufenacet through the soil core of the test soil below 35-cm depth, 32.5 cm of continuous rainfall would be required.

The analysis of the soil profile showed gradual downward movement of Flufenacet through it with the peak concentration of 0.336 µg/g recorded in 20-25 cm layer.

On the basis of the obtained results the authors drew the conclusion that even after the continuous rainfall of 65 cm, what is the equivalent of 2500 mL of leachate, Flufenacet would predominately remain confined within the top 35 cm of the test soil.

RMS comments:

The study protocol indicates that it was in line with the provisions of the OECD 312 Guideline, although some deviations were noticed. These were:

- only one test soil was used;
- water instead of 0.01M CaCl₂ solution was used to saturate the column and for leaching.

These deviations however had, in RMS opinion, no significant impact on the results of the experiment and its validity. On the other hand, the fact that the test soil was a non-EU soil that was not well characterised led to the conclusion that the study cannot be used to derive the EU regulatory endpoints. The results may be therefore considered solely as indicative.

Study 3:

Report: Campagna G. Paci F., Fabbi A., Rapparini G., (2006): “Studio in colonna della percolazione di alcuni diserbanti residuali del mais.” (*title in English*: “Percolation of acetochlor, dimethenamid, flufenacet and s-metolachlor applied in columns.”); Centro di Fitofarmacia – Dipartimento di Protezione e Valorizzazione Agroalimentare – Università degli Studi – Viale Fanin, 46 – 40127 Bologna – Italy; published study - published in: “Giornate Fitopatologiche”, 2006, I, 591 – 598;

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper

RMS comments: The paper presents the results of the examination of mobility of five active substances, used as herbicides in maize, in the soil column. One of the tested compounds was Flufenacet. The experiment was performed using two test soils. In the paper it was not stated that the experiments were performed in line with any relevant guidelines. However the study, in

its part strictly related to the column leaching was in line with the recommendations of OECD 312 Guideline. It shall be noted however that leaching was not continuous and that all test items were administered as formulated products. Finally, the analytical method used to determine the concentrations of the test compounds in soil profiles and leachates was not characterised. Instead in the publication the reference was made to the previous papers presenting it. For these reasons the results presented in that paper may be regarded only as supplementary study and should not be used as a source of regulatory endpoints. Finally, it shall be indicated that the evaluation was based on the translation of the paper into English provided by the Applicant, as the language of the original publication was Italian. RMS however cross-examined both language versions and stated that the translation was well prepared, therefore fully reliable.

Summary:

The publication contained a summary in English. However, because of the copyright restrictions, RMS decided not to present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the mobility of five herbicides commonly used in maize, including Flufenacet, in soil column.

The experiment was performed using two soils, the brief characteristic of which is presented below in the table B.8.1.3.1._CA-11.

Table B.8.1.3.1._CA-11: The characteristic of soils used in the study.

Parameter		Soil	
		<i>Loose</i>	<i>Clayley silt</i>
Soil type (USDA, determined by RMS)		Sandy loam	Clay loam
Particle size distribution	Sand[%]	76	22
	Silt[%]	14	46
	Clay[%]	10	32
Soil pH (measurement medium not specified)		8.3	7.9
Organic matter content (OM) [%]		0.87	2.37
Cation Exchange Capacity – CEC [mEq/100g]		9.4	28.9

The test soils were typical agricultural soils collected on farms in the province of Bologna. They were collected from the top layer of the fields, sieved and air dried before the experiment began.

The test soils were placed in PVC columns, 50-cm high and 10-cm in diameter. In order to obtain uniform packing of the columns the test soils were homogenised using a pestle. After filling columns were saturated with spring water, stabilised and the excess of water removed to obtain the FC soil moisture level.

The test substances – herbicides, were applied to the top of the test columns in treated sand. Flufenacet was applied in form of Cadou 60 % WP formulation, in amount corresponding to 600 g/ha. Under each column dishes were placed to collect the effluent.

The leaching started with simulation of 25 mm of rain to the top of the column over the period of 10 minutes. That was repeated on the same day to obtain the cumulative rainfall of 50 mm and over the next two days to obtain the cumulative rainfall of 100 mm. The effluents were collected while the column were left to achieve the initial FC level of soil moisture.

Then the columns were vertically cut in half and along the soil profiles the sensitive plant species – *Setaria italica* was sown. That plant was declared to be sensitive to the test compounds present in concentrations ≤ 50 ppb. Next, the untreated soil columns were irrigated with collected effluents and processed in the same way as described above, to determine the would-be amounts of the test substances in leachates.

As a final step periodic checking of the test plants for the toxicity symptoms was performed in order to determine the depth of migration of each test compound.

For Flufenacet it was stated that when applied to Sandy loam soil it migrated down to 7.3 cm after 25 mm of rainfall, 9.7 cm when the cumulative rainfall was 50 mm and to 14 cm after application of the 100 mm of the

cumulative rainfall. In Clay loam soil profile it migrated down to 10 cm after 50 mm of the cumulative rainfall and to 11.1 cm after 100 mm of the cumulative rainfall. Although not explicitly stated the compound was most probably not found in leachates.

RMS comments:

The study, because of its methodology, provides results that are indicative, not definitive with regard to the mobility of Flufenacet in soil profile. For that reason it cannot be used to derive the EU regulatory endpoints. The results may be therefore considered solely as indicative. On the other hand its findings demonstrated that Flufenacet may be expected to be confined to the top 25-cm soil layer.

Summary – column leaching studies

The Applicant did not submit any studies covering the issue of the column leaching of Flufenacet. Instead, in the provided justification for the non-submission, stated that it was covered by the results of the examination of sorption in soil at equilibrium (batch sorption studies) and those aimed on the examination of leaching of the aged residues. That justification was found acceptable by the RMS. It shall be indicated however, that the evaluation of the study examining the leaching behaviour of the aged residues of Flufenacet demonstrated that the study was not acceptable. For the details please refer to the next data point – B.8.1.3.2.

Two additional open-literature studies found by the RMS, considered supplementary, indicated that under typical EU conditions Flufenacet should not move in the soil profile below the depth of 25 cm. Such statement seems to be confirmed by the results of the field dissipation studies performed for Flufenacet and summarised in this document under the point B.8.1.1.2.2.

Additionally, a study was submitted examining the column leaching of one of the major soil degradation products of Flufenacet – TFA. That study, performed using four European soils, showed that TFA was very mobile in soil. The key results of that study are presented below.

The leaching behaviour of TFA was examined using soil columns filled with one of the following test soils:

- Loamy sand (*Laacherhof AXXa*) test soil, having OC = 1.8% and pH = 6.2;
- Loam (*Dollendorf II*) test soil, having OC = 5.2% and pH = 7.4;
- Silt loam (*Höfchen am Hohenseh*) test soil, having OC = 1.6 and pH = 6.5;
- Sandy loam (*Laacherhof Wurmwielse*) test soil, having OC = 1.9 and pH = 5.3.

The experiment was performed in two variants, denominated **Study design A** and **Study design B**, that may be characterised as follows:

- in **Study design A** leaching lasted 48 hours and was performed with 393 mL of artificial rain (0.01M CaCl₂ aq), corresponding to 200 mm of rain;
- in **Study design B** leaching lasted 120 hours and was performed with 984 mL of artificial rain (0.01M CaCl₂ aq), corresponding to 502 mm of rain;

In the variant denominated **Study design A** the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 95.5% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 73.2% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 92.1% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 66.2% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the extractable radioactivity retained within soil columns attributed to TFA was (mean values of the two replicates):
 - 5.0% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 28.3% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 6.5% of AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 35.6% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the NER fraction attributed to TFA, expressed as % AR, in the soil columns (mean values of the two replicates) was:
 - 1.2% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 1.8% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 0.8% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 1.1% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.

- the distribution of residues of TFA in soil was following:
 - for columns filled with Loamy sand (*Laacherhof AXXa*) test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Loam (*Dollendorf II*) test soil the highest concentration of TFA residues was determined in the top section of the column (segments S1 and S2) with the peak amount in segment S2, and it gradually decreased towards the bottom of the soil column;
 - for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil the residues of TFA were generally found in the lower part of the column, with the peak amount in the middle section S3.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil Loamy sand (*Laacherhof AXXa*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Loam (*Dollendorf II*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Silt loam (*Höfchen am Hohenseh*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Sandy loam (*Laacherhof Wurmwielse*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - mean $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g.

In the variant denominated **Study design B** the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 101.1% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 96.3% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 98.6% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 100.9% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the amount of radioactivity retained within soil columns attributed to TFA was not analysed because it was wholly recovered in leachates.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil with Loamy sand (*Laacherhof AXXa*) $K_d = 0.1$ mL/g and $K_{dOC} = 4.5$ mL/g;
 - for the test soil Loam (*Dollendorf II*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Silt loam (*Höfchen am Hohenseh*) $K_d = 0.2$ mL/g and $K_{dOC} = 11.3$ mL/g;
 - for the test soil Sandy loam (*Laacherhof Wurmwielse*) $K_d = 0.2$ mL/g and $K_{dOC} = 7.1$ mL/g;
 - mean $K_d = 0.2$ mL/g and $K_{dOC} = 9.1$ mL/g.

B.8.1.3.2. – Aged residues column leaching

One study was submitted to address that data requirement. It is evaluated below.

Study 1:

Report: Kelley I., Wood S., (1993): “Leaching of Aged FOE 5043 Through Soil Columns.”; Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, MO 64120, USA; study No. F3082102 (Miles Inc.); Report No. MR105018; 29 November 1993; study reference number: M-002198-01-1

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Official Testing of Plant Protectants, Part IV, 4-2 (1986): “Leaching Behaviour of Plant Protectants”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.3., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. For the present authorisation in the EU the study was evaluated for its compliance with the following Guidelines:

- OECD Test Guideline No 312, Leaching in Soil Columns, April 2004;
- US. EPA OCSPP Test Guideline No 835.1240, Leaching Studies, October 2008;

The following deviations from the main Guideline – OECD 312 and other procedural problems were stated:

- The leaching part of the experiment was performed using two test soils – sandy loam soil and loamy sand soil. However in the process of ageing only one of them was used – loamy sand soil. In the evoked Guidelines – OECD 312 and US EPA OPPTS 835.1240, it is stated that the soil used to fill the column shall be the same as that used in ageing process. For that reason RMS decided not to take into account the results of the leaching obtained using the sandy loam soil;
- Additionally, in case of sandy loam soil it was stated that its averaged OC content was below the minimal recommended level of 0.5%.
- For leaching deionised water was used instead of the artificial rain (0.01M CaCl₂ aq solution) recommended by both evoked Guidelines;
- OECD 312 Guideline recommends to use in the experiment 28-cm high layer of untreated soil covered with 2-cm thick layer of aged soil. The total height of the soil column should be therefore, preferably, 30 cm. In the study report it was stated that the layer of untreated soil was 28 cm, but the thickness of the aged soil was not specified. Instead the Applicant gave the mass of aged soil used in the experiment per column – 99.0 g or 96.4g;
- The ageing period lasted for either 30 or 90 days. In case of soil subjected to ageing lasting for 30 days, the leaching experiment using the same soil as that aged – loamy sand, was carried out in duplicate. With soil however aged for 90 days only single column filled with untreated loamy sand soil was subjected to leaching. The OECD Guideline recommends to prepare the columns for the given test soil in, at least, duplicate;
- OECD 312 Guideline recommends that the soil treated with the test compound should be analysed at the end of the ageing period for the content and nature of the residues. In the study report are provided the results of, seemingly, such analysis. However the analytical procedure used in that analysis was not characterised. Additionally it was stated that two degradation products – FOE Methylsulfoxide and FOE Methylsulfone were identified “from the leachates of a parallel aged leaching study”. As a result their initial amounts in soil after ageing are uncertain, hence rendering uncertain the determined mass balance in aged soil. Finally, it was stated that the separation of FOE Oxalate from FOE Thioglycolate sulfoxide was incomplete. As a result the initial concentrations of these two compounds in aged soil are uncertain (in the study report it

is even stated that the factual amounts of FOE Oxalate may be lower due to the inadequate separation of the two metabolites listed above).

- The nature of the residues retained within the soil columns was not examined. That deficiency makes difficult the qualitative analysis of the results;
- Analysing the results RMS noticed that the declared application rate was 176 µg Flufenacet/100 g soil using the solution having a test-item related specific activity of 0.69 kBq/µg. That resulted in the would-be amount of radioactivity applied to 400-g portion of the aged soil equal to 485.76 kB. Presenting results of the mass balance in the system after leaching the Applicant declared that the amount of radioactivity applied per column was 142.63 kBq in case of the experiment with soil aged for 30 days. The amount of the aged soil applied per column in that variant was 99.0 g. Therefore the total amount of radioactivity in the aged soil shall be 576.3 kBq. Similar problem was stated in case of soil aged for 90 days, where it was declared that the amount of radioactivity applied per column was 138.2 kBq and the amount of aged soil applied per column was 96.4 g. Therefore the total amount of radioactivity in the aged soil shall be 574.3 kBq. These values are both significantly higher than the amount declared as application dose. It shall be also indicated that the alleged results of the quantitative and qualitative examination of the aged soil showed that the recovery of the radioactivity after ageing period, reported in the study report, was 98.3% in case of treated soil aged for 30 days and 95.6% in case of treated soil aged for 90 days. The reported level of AR recovered after the leaching using columns filled entirely with loamy sand was 98.5 – 103.7% AR in the variant with soil aged for 30 days and 98.9% AR in variant with soil aged for 90 days. All that puts a questionmark over the correctness of the whole application and analysis procedure. In consequence the reliability of the results of the study is questionable.

RMS, on the basis of the weight of evidence, in particular the stated deficiencies and problem with determining the amount of the test substance applied, stated that the study cannot be considered acceptable. For that reason it was decided not to summarise it, nor include its results into the List of EndPoints. The former summary can be found in the Draft Assessment Report prepared by the then-RMS – France, for the previous authorisation of Flufenacet in the EU.

Summary:

The evaluation of the study performed by the RMS showed that it was not acceptable. For that reason, in order not to overburden the Renewal Assessment Report, RMS decided not to summarise it.

B.8.1.3.3. – Lysimeter studies and/or field leaching studies

To address this data point the Applicant submitted six study reports, that may be divided into three sets of data.

First set contains three reports presenting the results obtained for two lysimeters on which maize (corn) was grown over the period of two years. Two reports are the interim reports presenting the results obtained during the 1st and the 2nd year of the experiment. The third report is the final report of the study, presenting the results obtained for the whole experimental period and it contains the same data as the two interim reports. All three were submitted and evaluated for the previous authorisation of Flufenacet in the EU. The summaries of the interim reports were presented in the Draft Assessment Report for Flufenacet under the point B.7.2.4.1, while the final report was summarised in one of the Addenda – “Addendum to the monograph of Flufenacet (FOE 5043) (Environmental fate).” under the same data point – B.7.2.4.1. For the purpose of the present evaluation RMS decided to rely on the final report, summarised below as **Study 1**. The interim reports were verified for their compliance with the final report. As the differences, if stated, were minimal, RMS decided not to provide their summaries in the RAR. Instead they are cited as **Study 1a** and **Study 1b**.

Second set contains two study reports that present the results of the 2-year lasting lysimeter study carried out in parallel to the experiment briefly characterised above, but in which the crop rotation was maize (corn)/winter wheat. One of those reports is an interim report, presenting the results obtained during the 1st year of the experiment, while the second is the final report of the whole experiment. Both were submitted and evaluated for the previous authorisation of Flufenacet in the EU. Their joint summary was presented in the Draft Assessment Report for Flufenacet under the point B.7.2.4.2. For the purpose of the present evaluation RMS decided to rely on the final report, summarised below as **Study 2**. The interim report was verified for its compliance with the final report. As the differences, if stated, were minimal, RMS decided not to provide its summary in the RAR. Instead it is cited as **Study 2a**.

Last component was a single study presenting the results of the comparative analysis of the results of the lysimeter studies with those obtained as PEC_{GW} values using the simulation model PESTLA. Its is evaluated below as **Study 3**.

Study 1:

Report: Hellpointner E., (1997): “Lysimeter study on the translocation of *FOE 5043* into the subsoil after 2-year use as pre-emergence herbicide in corn.”; Bayer AG, Agrochemical Division, Development, Institute for Metabolism Research and Residue analysis; D-51368 Leverkusen, Germany; report No. PF-4188 (MR-074/97); 19 September 1997; study reference number: M-002187-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Testing of Plant Protection Products in Registration Procedure, Part IV, 43- (February 1990) – “Lysimeter tests for the translocation of plant protection products into the subsoil.”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found in the “Addendum to the monograph of Flufenacet (FOE 5043) (Environmental fate).” under the point B.7.2.4.1., prepared by the RMS – France, for Flufenacet. RMS re-evaluated the study and found it acceptable. It is summarised below.

Summary:

The aim of the study was to examine for three consecutive years the leaching behaviour of Flufenacet and its degradation products through the undisturbed soil profiles under the climatic and agronomic conditions relevant for Germany.

The experiment was carried out using two undisturbed soil monoliths having a surface area of 1.0 m² and depth 135 cm. They were taken from the field plot located at the Bayer’s Experimental Farm Laacherhof by pressing a stainless steel cylinder, 100-cm long, 100-cm wide and 134-cm high, into the ground until ~4 cm of the frame remained above the soil surface. The soil monolith was separated from the ground below by pulling the cutting plate under the steel frame. Next the soil core was placed into 10-cm high steel tray, slightly sloping towards its centre, where the outlet was located, half filled with gravel (having particle size 8 – 12 mm). Then the cutting plate was removed and the soil core, now standing on the gravel bed, straightened. The total height of so prepared lysimeter was 135 cm, of which top 130 cm was soil monolith and bottom 5 cm gravel layer.

The design of the lysimeter is presented below on figure B.8.1.3.3._CA-1.

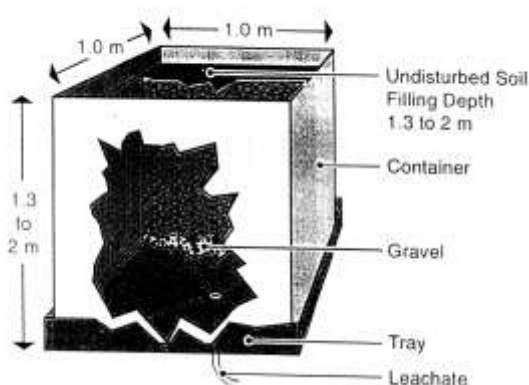

Figure B.8.1.3.3._CA-1: The scheme of the lysimeter used in the study (copied from the study report).

The soil forming soil monolith of the lysimeter was described as brown soil from sand with a low degree of profile differentiation, that originated and then developed from sandy to sandy-loamy sediment overlying the deposits of the lower terrace of the river Rhine. According to German classification it was “Braunerde” from sand and according to FAO Eutric Cambisol. The detailed characteristic of the soil monolith filling the lysimeter is provided in the table B.8.1.3.3._CA-1. The data are presented only for layers down to the depth of 135, as the soil core was sampled down to approximately that depth.

Table B.8.1.3.3._CA-1: The characteristic of soil forming the lysimeter's soil monolith

Parameter		Soil layer (symbol, depth)				
		A_{hs} 0 – 30 cm	B_{vs} 30 – 60 cm	B_{vs} 60 – 100 cm	B_{vs} 100 – 115 cm	IIB_{vs} 115 – 135 cm
Soil texture (USDA)		Sandy loam	Sandy loam	Loamy sand	Loamy sand	Sand
Particle size distribution	Sand (50 – 2000 μm)	71.8	72.2	79.4	82.7	95.5
	Silt (2 – 50 μm)	16.5	16.6	11.0	9.1	2.4
	Clay (<2 μm)	11.8	11.2	9.7	8.2	2.1
Physico-chemical properties	pH in H_2O	7.04	7.24	7.18	7.46	7.41
	pH in CaCl_2	6.05	6.42	6.32	6.61	6.63
	OC [%]	1.41	0.34	0.19	0.17	0.09
	CEC [meq/100g]	9.61	7.43	7.57	8.52	4.73
	Microbial biomass [mg/kg]	235	34	11	13	not determined
	Pore volume [vol. %]	44.94	37.97	42.47	42.90	45.49
Physical parameters	air capacity AC [vol. % H_2O]	12.49	17.36	24.31	21.64	35.74
	field capacity FC [vol. % H_2O]	32.45	20.61	18.16	21.15	9.75
	available water capacity AWC [vol. % H_2O]	23.83	13.10	10.46	11.82	7.34
	permanent wilting point PWC [vol. % H_2O]	8.83	7.51	7.70	9.43	2.41
	saturated hydraulic conductivity K [$\text{cm} \cdot \text{s}^{-1}$]	5.4 E-3	9.8 E-3	7.5 E-3	5.5 E-3	2.9 E-3
	intrinsic permeability k [cm^2]	5.4 E-8	9.8 E-8	7.5 E-8	5.5 E-8	2.9 E-8

The lysimeters were transferred to the open-air lysimeter station located in Bayer AG' Landwirtschaftszentrum, Monheim, Germany (latitude $51^{\circ}4'$ N, longitude $6^{\circ}55'$ E, ~40 m above the sea level), shown on figure B.8.1.3.3._CA-2, and installed in positions #15 and #16. The schematic presentation of the cross-section of the lysimeter station, showing the way the lysimeters were maintained, is presented on figure B.8.1.3.3._CA-3.

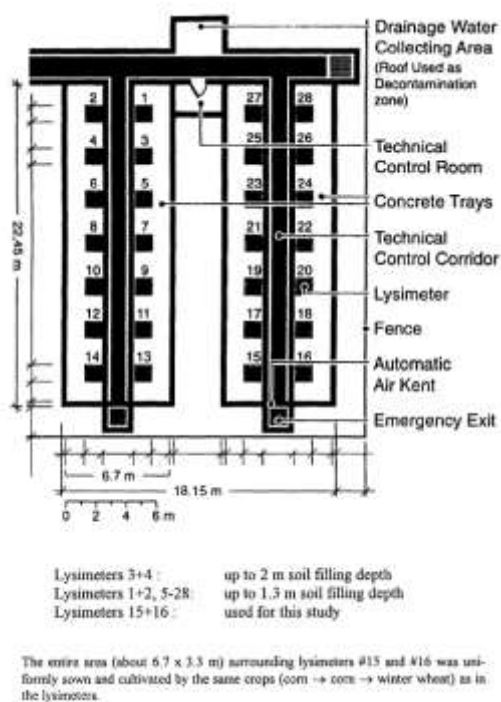

Figure B.8.1.3.3._CA-2: The general view of the lysimeter station of Bayer AG. (copied from the study report).

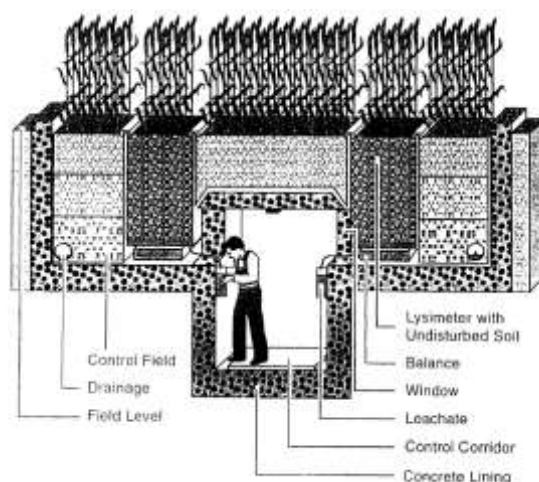

Figure B.8.1.3.3._CA-3: The cross-section general view of the lysimeter station of Bayer AG.
(copied from the study report).

The lysimeters were installed in March 1992, then in April 1992 the grass “Welsches Weidelgras” was sown as a first vegetation after their acquisition. It was broken up and incorporated into top 15 cm. of the soil core in January 1993, then the lysimeters were left until the preparation of the seed bed for the 1st crop – corn (maize), variety Mutin, occurred shortly before its sowing on 10th May 1993.

The experiment started on the 10th of May 1993 by sowing the 1st target crop – maize and ended in May 1996, when the soil was analysed for the residues of Flufenacet.

During that experimental period the following crops were grown on the lysimeters:

- corn (grain maize) var. Mutin as the 1st, target crop; it was sown on the 10th of May 1993 and harvested on the 12th November 1993, 26 weeks after sowing and 1st application of the test compound;
- corn (grain maize) var. Mutin D as the 2nd, target crop, it was sown on the 5th May 1994 and harvested on 10th October 1994, 23 weeks after sowing and 2nd application of the test compound;
- sugar beet var. Sonja as the 3rd, succeeding crop; it was sown on the 13th April 1995 and harvested on 7th November 1995, 30 weeks after sowing;

Corn grown as 1st and 2nd crop was sown in two rows 60-cm apart, at seed density 18 grains/m². Shortly after germination, on 25th May 1993 for the 1st crop and on 2nd June 1994 for the 2nd crop, the number of plants growing was manually reduced to 10 plants/m². The 3rd crop – sugar beet, was sown in three rows, 33-cm apart and 17-cm distant from the walls of lysimeter, at seed density 9 seeds/m² (3 seeds per row).

After harvest of the 1st and 2nd crop – corn, the plant residues – corn stubble and straw, left on the lysimeter were incorporated into the top soil layer (15 cm) as organic fertiliser.

All major crop maintenance measures used during the experiment are presented below in the table B.8.1.3.3._CA-2. In the table, in the columns for crop protection, are also presented the applications of the test compound, marked red. Additionally, when necessary, artificial irrigation was performed as maintenance measure. That was done in order to supply the crops growing on the surface of lysimeters with water in periods of relative drought (in summer, when the level of soil water available to plants is low). The details on that maintenance measure will be provided further down the summary, together with the characteristic of precipitation recorded on site.

Table B.8.1.3.3._CA-2: Major crop maintenance measures used during the experiment.

Fertilisation			Crop Protection			Other measures	
Date	Fertiliser used	Dose rate	Date	Crop protection measure	Dose rate	Date	Measure
April 1992	Thomas phosphate potash	1500 kg/ha	----	----	----	April 1992	Sowing of grass “Welsches Weidelgras”
	Lime ammonium salpêtre	500 kg/ha					
19 March 1993	Thomas phosphate potash	1500 kg/ha	10 May 1993	Corn seeds treated with TMTD	not specified	January 1993	Digging up and incorporation of residues of grass into the top soil layers (~15 cm)
	Lime ammonium salpêtre	500 kg/ha					
03 June 1993	Basfoliar	8 L/ha	12 May 1993	1 st application of the test compound – [¹⁴ C] Flufenacet	48.14 mg/ha (480 g/ha)	10 May 1993	Digging up the top soil layer, tilling, crumbling and seed bed preparation for corn; sowing of the 1 st crop
08 June 1993	Nitrophoska permanent	400 kg/ha					
18 June 1993	Basfoliar	8 L/ha	02 June 1993	E605 forte	0.1%	25 May 1993	Manual reduction of the number of growing corn plants
24 June 1993	Basfoliar	10 L/ha				12 November 1993	Harvest of the 1 st crop
07 December 1993	Organic fertilisation (corn straw)	----				07 December 1993	Incorporation of the corn stubble and straw into the top soil layer
03 May 1994	Thomas phosphate potash	1500 kg/ha				February 1994	Digging up top soil layer (“ploughing”)
	Lime ammonium salpêtre	360 kg/ha	05 May 1994	Corn seeds treated with TMTD	not specified		
13 June 1994	Basfoliar	8 L/ha	05 May 1994	2 nd application of the test compound – [¹⁴ C] Flufenacet	48.05 mg/ha (480 g/ha)	05 May 1994	Tilling, crumbling and seed bed preparation for corn; sowing of the 2 nd crop
20 June 1994	Basfoliar	8 L/ha	24 May 1994	Metasystox R special	0.125%	02 June 1994	Manual reduction of the number of growing corn plants
	Lime ammonium salpêtre	180 kg/ha					
21 November 1994	Organic fertilisation (corn straw)	----	13 June 1994	E605 forte	0.05%	10 October 1994	Harvest of the 2 nd crop
						21 November 1994	Incorporation of the corn stubble and straw into the top soil layer
23 March 1995	Thomas phosphate potash	1500 kg/ha	13 April 1995	Sugar beet seeds treated with TMTD, Hymexazole and Imidachloprid 90 FS 600	----	23 March 1995	Digging up the top soil layer, tilling, crumbling and seed bed preparation for sugar beet
	Lime ammonium salpêtre	660 kg/ha				13 April 1995	Sowing of sugar beet – 3 rd crop
23 June 1995	Lime ammonium salpêtre	280 kg/ha	25 August 1995	Bardos	1.0 L/ha	07 November 1995	Harvest of the 3 rd crop – sugar beet
			22 September 1995	Bardos	1.0 L/ha		

The test substance used in the study was [Phenyl-UL-¹⁴C] Flufenacet, having a specific activity of 2.0 MBq/mg (54 µCi/mg) and radiochemical and chemical purity of >99%. Its structural formula is presented below on figure B.8.1.3.3._CA-4. It was used to prepare the application solution.

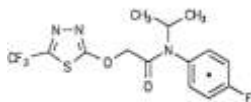

Figure B.8.1.3.3_CA-4: The structural formula of the test compound – the [^{14}C]-Flufenacet. Asterisk (*) denotes the radiolabelling position (copied from the study report).

It was stated that the test compound should be applied as 60 WG (Water Dispersible Granule) formulation. However, because it was not possible at of the experiment to prepare in microscale a representative and homogenous WG formulation containing the radiolabelled active substance, the pure solution of [^{14}C]-Flufenacet was used instead.

The first application of the test substance took place on the 12th of May 1993, 2 days after the 1st crop – corn, was sown. The assumed application rate was 480 g Flufenacet/ha and the actual was 48.14 mg/m² (+0.3% of the intended amount). For that purpose the whole delivered sample of Flufenacet was dissolved in 4 mL of C₂H₅OH. Next for the given lysimeter 0.976 mL of that solution was mixed with 100 g of the lysimeter top soil (mixing lasted 1 hour). Then the volume of soil was increased to obtain a final amount of ~4000g of fortified soil. That amount was uniformly distributed onto the lysimeter's surface. The application was terminated by irrigation with 5 mm/m² of water to minimise losses due to wind erosion. The amount of radioactivity introduced that way onto each lysimeter #15 and #16 was 96273 kBq. The overall loss of radioactivity during application was 27.5 kBq/Lysimeter. That value was taken into account inn further calculations.

The second application of the test compound occurred on the 5th May 1994, just after sowing the 2nd crop – corn. The assumed application rate was 480 g Flufenacet/ha and the actual was 48.05 mg/m² (+0.1% of the intended amount). For that purpose the whole delivered sample of Flufenacet was dissolved in 5 mL of C₂H₅OH. Next for the given lysimeter 2.36 mL of that solution was mixed with 100 g of the lysimeter top soil (mixing lasted 1 hour). Then the volume of soil was increased to obtain a final amount of ~4000g of fortified soil. That amount was uniformly distributed onto the lysimeter's surface. The application was terminated by irrigation with 5 mm/m² of water to minimise losses due to wind erosion. The amount of radioactivity introduced that way was 96090 kBq for Lysimeter No. #15 and 96097 kBq for Lysimeter No. #16. The overall loss of radioactivity during application was 11.6 kBq for Lysimeter #15 and 4.4 kBq for Lysimeter #16.

The experiment lasted for three consecutive years, from May 1993, when the 1st crop was sown and first application of the test compound occurred, until June 1996, when soil monolith filling the lysimeter was analysed for the amount and nature of the residues of Flufenacet (active substance and its degradation products) retained within it.

During that whole period the weather conditions on the experimental site, such as air temperature, soil temterature at various depths, duration of sunshine, wind velocity, rainfall air humidity, were constantly monitored and daily recorded by wheather station of the experimental facility, located within 1 km from the test site. At the test site the soil temperature at the depth of 20 cm was measured continuously in one of the lysimeters. The collected data were processed to obtain monthly and yearly averages, presented in section **Results and their discussion** of this summary. The weights of each lysimeter were continuously recorded. They will be presented, in graphical form, also in section **Results and their discussion** of this summary.

The leachates from each lysimeter were collected in two replacable 20-L steel containers attached in sequence to the lysimeter's outlet. The collected leachates were taken for analysis in 2-week intervals, or shorter if necessary. To do that the containers were emptied, the volume of the collected leachates determined gravimetrically and their pH measured.

The gross radioactivity in the fresh leachate was determined by LSC using 10-mL aliquots. For that purpose three 10-mL aliquots were mixed with 0.1 mL of 1M NaOH. Next to each of them 10 mL of Quickszint 401 LS cocktail was added and the samples were analysed by LSC. The results represented the content of radioactive residues adjusted to alkaline pH.

Another three aliquots were mixed with 0.1 mL of 18% HCl_{aq}, ultrasonicated in open vessels for ~30 minutes in order to release of ¹⁴CO₂ possibly forming in sample and analysed by LSC after addition of 10 mL of Quickszint 401 LS cocktail. The results represented the content of radioactive residues adjusted to acidic pH.

10% of leachates collected at each sampling were stored combined in the container for annual leachate sample. That container was stored in the deep-freeze storage room. Another 10% of each leachate was stored as a separate sample in the deep-freeze storage room.

The deep-frozen leachates were stored for up to 13 months between collection and analysis. The selected leachates obtained from each lysimeter – 1st-year early leachate, 1st-year leachate with the highest radioactivity

content, 1st-year late leachate, annual 1st-year leachate and annual 2nd-year leachate were analysed qualitatively and quantitatively by TLC. The profiling of radioactivity in leachates – identification and quantitation of Flufenacet and its degradation products, was performed in processed leachates. In case of 1st-year leachates the processing started by concentrating 500 mL of leachate under vacuum to the volume of 50 mL. Its 10-mL aliquot was passed through SPE cartridge. The eluate was discarded and the residue eluted from the SPE column using 5 mL of CH₃CN + 0.4% CH₃COOH (9:1) solution. That eluate was collected and analysed by TLC.

The processing of the 2nd-year annual leachate began with concentrating its 100 mL aliquot to 10 mL. Then the procedure was the same as described above for the 1st-year leachates.

Annual leachates were also analysed for pH, TOC, and content of Cl⁻, SO₄²⁻, NO₂⁻, NO₃⁻ and NH₄⁺.

The plant material collected at harvest for 1st and 2nd target crop – corn, were kernels, cobs and hulls, while straw was left at spot, in line with agricultural practice, and then incorporated into lysimeter's topsoil as organic fertilizer. The harvested fresh plant material was homogenised under liquid nitrogen, dried at T = 50°C and its aliquots were analysed, after combustion, for radioactivity content.

The plant material collected at harvest for the 3rd (succeeding) crop – sugar beets, were tubers and leaves. They were processed in the same way as described above for corn.

After harvest of the 3rd crop the surface of the lysimeters was left bare. It was covered with a protective plastic plate and left to dry.

The two top layers – 0-10 cm and 10-20 cm, were completely removed from each lysimeter on 16th of July 1996.

From each layer 5 portions of soil were taken for further processing. Their fresh weight was recorded, then they were combined and thoroughly mixed. The mixed soil was divided into 5 subsamples, and each was weighed to determine its dry weight. Finally five aliquots of each subsample were taken for the determination of the content of radioactivity by LSC after combustion.

For the deeper layers – from 20 to 110 (120) cm depth five soil cores, each having the diameter of 8 cm², were taken using an electric soil corer. The cores were sampled on the 18th July 1996. The distribution of the sampling points is presented below on figure B.8.1.3.3._CA-5.

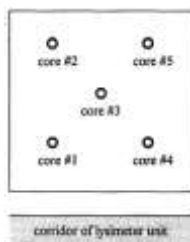

Figure B.8.1.3.3._CA-5: The sampling scheme for the soil cores taken from the lysimeters (copied from the study report).

The obtained 20-cm segments were cut into two 10-cm sections. These 10-cm sections from each core were combined and their total fresh weight recorded. Next, the soil was let to dry for 6 days, homogenised and 5 aliquots of so prepared soil samples analysed for radioactivity content using LSC.

The deepest layers were not reached by the corer. Therefore the individual soil sample representing them was taken after the lysimeter was removed from the frame. It was analysed for the radioactivity content using LSC.

Also the gravel filling the bottom of the lysimeter was sampled to determine the amount of radioactivity it retained. For that purpose two 500-g aliquots of gravel were extracted for two hours with 200 mL CH₃CN/0.1M HCl 1:1 (v/v) solution. The extract was analysed for radioactivity content.

The profiling of radioactivity in soil – identification and quantitation of Flufenacet and its degradation products, was performed down to the depth of 40 cm. For that purpose two 30-g aliquots of each layer (0-10 cm, 10-20 cm, 20-30 cm and 30-40 cm) from each lysimeter were extracted with two 100-mL portions of CH₃CN/0.1M HCl 1:1 (v/v) solution. Each extraction step lasted 1 hour and was followed by 20-minutes centrifugation. The extracts were filtered through paper filter, combined, and their volume recorded. Next, they were analysed for radioactivity content by LSC.

40 mL of crude extract was concentrated to ~5 mL and brought to the volume of 10 mL using 0.005M HCl_{aq}. Then it was analysed by TLC.

The LSC analysis of the liquid samples was carried out using one of the following LS counters: PW 4700, Wallac 1410, Rackbeta 1219, Beckman LS 6000 LL or Beckman LS 6500.

In case of non-processed leachates their 10-mL aliquots were used, mixed with 10 mL of Quickszint 401 LS cocktail. The minimum sensitivity of LSC analysis for those samples was 3.1 E-7 ppm. It corresponded to 58 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 29 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 29 cpm ($LAGC = 2 \cdot BCGK$ and $LANC = LAGC - BCGK$). The greatest probable error GPE = 5.61%.

In case of the organic extracts their 0.1 – 2 mL aliquots were used, mixed with 7 mL of Instant Scint Gel or 2 mL of Quicksafe A LS cocktails. The minimum sensitivity of LSC analysis for those samples was 1.5 E-6 ppm. It corresponded to 58 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 29 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 29 cpm ($LAGC = 2 \cdot BCGK$ and $LANC = LAGC - BCGK$). The greatest probable error GPE = 5.61%.

The radioactivity in the solid samples was determined after their combustion in an oxidiser (Oxidiser 306 Tri-Carb or OX 300). The generated $^{14}\text{CO}_2$ was absorbed in the LS cocktail (the mixture of 8 mL Carbosorb and 10 mL Permafluor, or 15 mL Oxsolv C 400) and analysed by LSC. The analysis was performed for soil samples weighing 1.0 g and plant material samples weighing 0.055 g. The minimum sensitivity of LSC analysis was 2.7 E-6 ppm for soil and 5.0 E-5 ppm for plant samples. It corresponded to 48 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 24 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 24 cpm ($LAGC = 2 \cdot BCGK$ and $LANC = LAGC - BCGK$). The greatest probable error GPE = 4.46%.

The TLC analysis was carried out in one of the three following variants:

- 1) on 20 • 20 cm, 0.25 mm thick, silica gel 60 F₂₅₄ TLC plates developed at room temperature in closed glass chamber using following solvent system $\text{CHCl}_3/\text{CH}_3\text{COOC}_2\text{H}_5$ 3:1 (v/v), it was used for identification and quantitation of Flufenacet and FOE Alcohol;
- 2) on 20 • 20 cm, 0.25 mm thick, silica gel 60 F₂₅₄ TLC plates developed at room temperature in closed glass chamber using following solvent system: $\text{CH}_3\text{CN}/(\text{CH}_3)_2\text{CHOH}/\text{CH}_3\text{COOC}_2\text{H}_5/\text{H}_2\text{O}$ 60:9:6:3 (v/v/v/v); it was used for identification and quantitation of Flufenacet, FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide (it shall be pointed out that in the study report that variant was indicated to be not suitable for the analysis of Flufenacet);
- 3) on 20 • 20 cm, 0.25 mm thick, RP-18 F₂₅₄ TLC plates developed at room temperature in closed glass chamber using following solvent system: $\text{CH}_3\text{CN}/(\text{CH}_3\text{OH}/0.5\% \text{ NaCl}_{\text{aq}})$ 2:2:1 (v/v/v); that method was not further used because of the stated poor separation of polar compounds;

The detectors used in the analysis were:

- TLC Scanner CS-930 or UV light chamber for “cold” reference standards;
- Radio-TLC-Scanner RITA 6800 used only in the purity check of the applied parent compound
- Bio-Imaging Analyser BAS 2000 for radiolabelled standard solutions and samples;

The identification was performed by means of the comparison of the R_f values of the constituents of the analysed samples with those of the known reference compounds.

The quantitative analysis was performed by means of LSC analysis of the separated bands (spots) on the TLC plate.

Additionally, for the analysis of standard solutions, purity checks of application solutions and for isolation and verification of degradation products in leachates, the HPLC analysis was performed. It was carried out using HP 1090 work station equipped with DAD (UV) and Ramona 4 (LSC) detectors. The chromatographic separation was performed on LiChrosorb RP 18, 250 • 4 mm, 5 μm , chromatographic column. In the study report it was stated that more detailed information on the HPLC analysis was provided in the raw data.

Results and their discussion:

The long-term weather characteristic of the test site is presented below on figure B.8.1.3.3._CA-6 (the frame-table copied from the study report). The values marked with an asterisk (*) are the mean of those recorded by the Experimental Farm's wether station in years 1966 – 1995, while those marked with (#) are the mean of the measurables recorded in years 1968 – 1995. The weather conditions – air temperature, soil temperature, wind speed, radiant heat, precipitation and irrigation, recorded at the test site during the experiment are presented in the table B.8.1.3.3._CA-3. The table provides monthly mean values. The air temperature, soil temperature at different depths, with exception of that at the depth of 20 cm, radiant heat, wind speed and precipitation are the weather data recorded by the weather station located 1 km apart from the lysimeter site. The soil temperature at 20-cm depth was measured at spot, in Lysimeter #15. Additionally the sum curve of precipitation and irrigation during study is presented on figure B.8.1.3.3._CA-7, immediately below the table B.8.1.3.3._CA-3.

Table 2: Long-term weather characteristics of test location

Annual rainfall (*):	745 mm
Max. / min. monthly rainfall (*):	June (78.1 mm) / February (42.7 mm)
Annual relative humidity of the air (*):	73%
Annual air temperature at 2 m above ground level (*):	10.0°C
Max. / min. monthly air temperature at 2 m above ground level (*):	July (18.4 °C) / January (2.6 °C)
Annual soil temperature (-10 cm) (#):	9.5°C
Annual soil temperature (-30 cm) (#):	10.3°C
Annual soil temperature (-50 cm) (#):	10.7°C
Annual soil temperature (-100 cm) (#):	10.6°C
Annual wind velocity (*):	2.5 m/sec
Annual radiant heat (#):	29.1 kJ/cm ²
Max. / min. monthly radiant heat (#):	July (53.1 kJ/cm ²) / Dec. (5.8 kJ/cm ²)

Figure B.8.1.3.3._CA-6: The table presenting long-term weather characteristic at the lysimeter test site (copied from the study report).

Table B.8.1.3.3._CA-3: The monthly weather data recorded at the test site during the experiment.

Time period		Mean air temperature 2 metres above the ground [°C]	Mean soil temperature [°C] at the depth						Mean monthly radiant heat [kJ/cm ²]	Wind speed [m/s.]	Precipitation (P) and Irrigation (I) [mm]

Figure B.8.1.3.3_CA-7: The sum curve of precipitation and irrigation [mm] recorded during the study (copied from the study report).

The total 1st-year precipitation was 897.1 mm and irrigation was 46.0 mm. Therefore the amount of water received by each lysimeter during that experimental year as precipitation and irrigation was 943.1 mm, 143.1 mm more than the BBA Guideline requirement – 800 mm.

The total 2nd-year precipitation was 814.2 mm and irrigation was 100.0 mm. Therefore the amount of water received by each lysimeter that experimental year as precipitation and irrigation was 914.2 mm, 114.2 mm more than the BBA Guideline requirement – 800 mm.

The total 3rd-year precipitation was 496.1 mm and irrigation was 104.0 mm. Therefore the amount of water received by each lysimeter that experimental year as precipitation and irrigation was 600.1 mm, 199.9 mm less than the BBA Guideline requirement – 800 mm.

The total precipitation and irrigation during the study was 2457 mm, what gave average annual precipitation at the level of 819 mm – 19 mm higher than the regulatory requirement.

The weight of the lysimeters during the study is presented below, in graphical form, on figure B.8.1.3.3_CA-8.

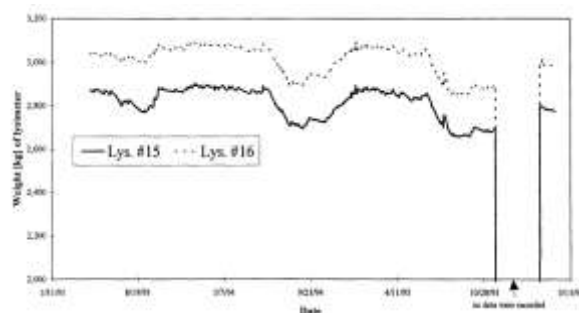

Figure B.8.1.3.3_CA-8: The weight of the lysimeters recorded during the study (copied from the study report).

The leachate from Lysimeter #15 was collected during the 1st experimental year 22 times – on weeks of experiment: 0, 11, 21, 22, 23, 24, 27, 30, 31, 32, 33 (twice), 35, 36, 37, 38, 41, 43, 45, 46, 47 and 50. The total volume of leachate collected during that period was ~350 L. During the 2nd year of experiment the leachates from that lysimeter were collected 17 times – on weeks of experiment 55, 58, 79, 85, 87, 88, 89 (twice), 90, 91, 92, 93, 94, 96, 96, 100 and 103. The total volume of leachate collected during that period was ~318 L. On the 3rd experimental year the leachate from that lysimeter was collected only once – on week 115 of the experiment. Its volume was 13.0 L. Therefore the total, exact, volume of leachate collected from that lysimeter during the experimental period of 3 years was 680.4 L, of which 667.4 L were collected during the first two years. The total number of sampling points during the experiment for that lysimeter was 40. The leachate collected on week 0 is the leachate collected before the application of the test compound.

The leachate from Lysimeter #16 was collected during the 1st experimental year 23 times – on weeks of experiment: 0, 1, 11, 21, 22, 23, 24, 27, 30, 31, 32, 33 (twice), 35, 36, 37, 38, 41, 43, 45, 46, 47 and 50. The total

volume of leachate collected during that period was ~402 L. During the 2nd year of experiment the leachates from that lysimeter were collected 16 times – on weeks of experiment 55, 58, 79, 85, 87, 88, 89, 90, 91, 92, 93, 94, 96, 96, 100 and 103. The total volume of leachate collected during that period was ~300 L. On the 3rd experimental year the leachate from that lysimeter was collected only once – on week 115 of the experiment. Its volume was 17.0 L. Therefore the total, exact, volume of leachate collected from that lysimeter during the experimental period of 3 years was 719.3 L, of which 702.3 L were collected during the first two years. The total number of sampling points during the experiment for that lysimeter was 40. The leachate collected on week 0 is the leachate collected before the application of the test compound.

The detailed information on the collection dates and volumes of individual leachates are presented below in table B.8.1.3.3._CA-4.

Table B.8.1.3.3._CA-4: The sampling time and volume of the individual leachate samples collected during the experiment.

The results of the determination of radioactivity in leachates – the amounts of radioactivity recovered, are presented below in two tables – B.8.1.3.3._CA-5 for the Lysimeter #15 and B.8.1.3.3._CA-6 for the Lysimeter #16. Additionally the same results are presented in graphical form on figure B.8.1.3.3._CA-9.

In the study report it was stated that “During and shortly after the application an accidental run-off event down to the leachate containers (soil and run-off water from the top soil layer) was recognised in case of lysimeter #16. This artificial contamination occurred through two holes in the stainless steel container located

quite in the area of the treated soil. The holes resulting from the installation procedure were observed on 25 May 1993 and were closed, immediately. Meanwhile, some radioactivity had been translocated by means of irrigation and/or rainwater outside the soil monolith down to the gravel layer and into the leachate containers. Therefore the leachates of the early period after application could be evaluated from lysimeter #15 only. The leachates of week 0, 1 and 11 were excluded from preparation of AL (93/94) of lysimeter #16 and from residue calculations.”. That event is also marked on the figure B.8.1.3.3._CA-9. As a result RMS decided to mark the results of concern in the table B.8.1.3.3._CA-6 with italics.

TableB.8.1.3.3._CA-5: The total radioactivity recovered in the leachates from Lysimeter #15.

For the further, TLC analysis, aimed on the identification and quantitation of the individual constituents of leachates, the following leachates were taken:

- 24th week leachate, collected on 29 October 1993, representing the 1st-year's early leachate;
- 37th week leachate, collected on 28 January 1994, representing the 1st-year's leachate with maximum TRR;

- 47th week leachate, collected on 11 April 1994, representing the 1st-year's late leachate;
- 1st-year annual leachate;
- 2nd-year annual leachate.

TableB.8.1.3.3_CA-6: The total radioactivity recovered in the leachates from Lysimeter #16.

Footnotes to the table:

- 1) Value resulting from the contamination, not further considered in calculations;
 2) The corresponding value obtained in Lysimeter #15 used instead;

For the further, TLC analysis, aimed on the identification and quantitation of the individual constituents of leachates, the following leachates were taken:

- 24th week leachate, collected on 29 October 1993, representing the 1st-year's early leachate;
- 35th week leachate, collected on 28 January 1994, representing the 1st-year's leachate with maximum TRR;
- 47th week leachate, collected on 11 April 1994, representing the 1st-year's late leachate;
- 1st-year annual leachate;
- 2nd-year annual leachate.

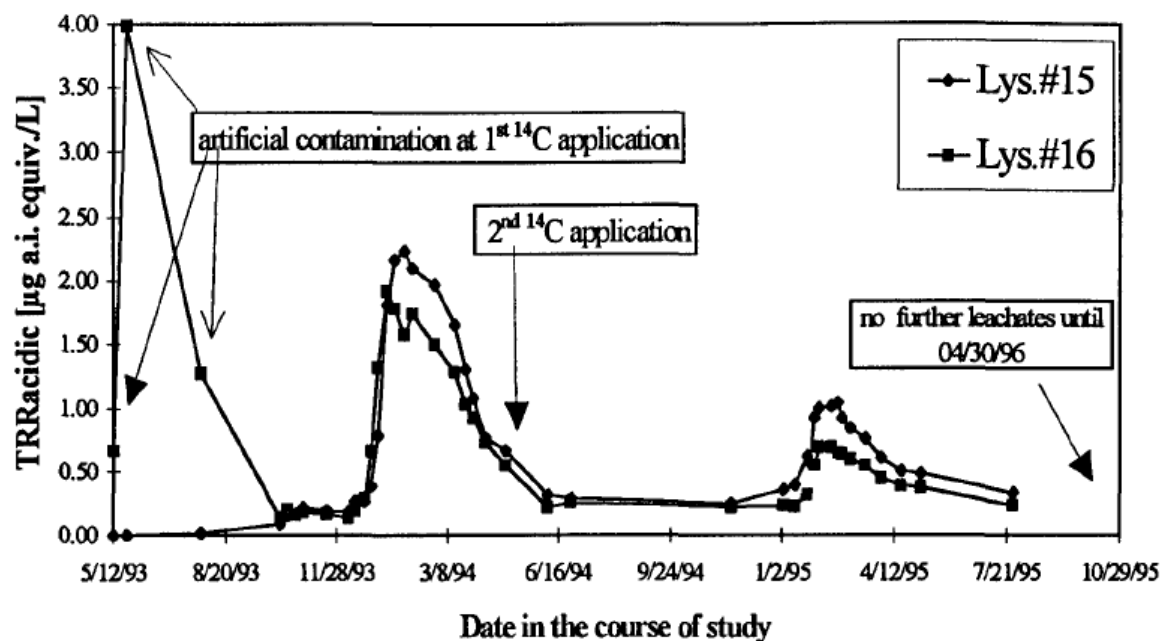

Figure B.8.1.3.3_CA-9: The graphical results of the determination of the total radioactivity recovered (TRR) in leachates from the two lysimeters (copied from the study report).

The detailed results of the characterisation of leachates – measured pH, the concentration of the total (alkaline) TRR and acidic TRR, as well as the content of ¹⁴CO₂ (expressed as % of TRR) are presented below, individually for each lysimeter, in two tables – Table B.8.1.3.3_CA-7 for Lysimeter #15 and Table B.8.1.3.3_CA-8 for Lysimeter #16. For the completeness of the results also was provided the volume of each leachate collected.

Table B.8.1.3.3_CA-7: The detailed results of the examination of the leachates from Lysimeter #15.

Experimental period	Sampling time		Volume of leachate [L]	pH of leachate	Radioactivity recovered (TRR)

Footnotes to the table:

1) Value resulting from the contamination, not further considered in calculations.

The results of the profiling of single leachates collected during the 1st year of the study and the pooled 1st-year and 2nd-year leachates showed that they contained, apart from detectable amounts of Flufenacet, also FOE Alcohol, FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide. Additionally a fraction further called unknown “Unknown 1” was found using both TLC methods in all analysed leachates. In case of the 3rd-year leachates the TRR (total radioactivity recovered) was attributed totally to FOE Sulfonic acid. The detailed results of the profiling of the leachates collected from Lysimeter #15 are presented in the table B.8.1.3.3._CA-9. In the next table – B.8.1.3.3._CA-10 are presented the results of the profiling of the leachates collected from the Lysimeter # 16. Finally, in the table B.8.1.3.3._CA-11 are presented the results of the quantitation of the selected

constituents of the annual leachates collected from the Lysimeter #15 and the Lysimeter #16. The results of the profiling of individual and annual leachates showed that the leaching to groundwater recharge in amounts $> 0.1 \mu\text{g/L}$ occurred only for FOE Sulfonic acid. It shall be also indicated that in leachates was also detected, and in quantifiable amounts, FOE Thioglycolate sulfoxide (FOE TGS) – the soil degradation product of Flufenacet identified in the experiments examining route and rate of degradation of Flufenacet in soil only as a minor compound and hence not covered by the modelling exposure assessment for the groundwater compartment. These results may indicate that under unfavourable conditions FOE Thioglycolate sulfoxide might become a compound of concern, although the identity of that compound was not fully confirmed in the study.

Table B.8.1.3.3._CA-9: Results of the profiling of the leachates collected from the Lysimeter # 15.

Type of leachate	Sampling time		Content [$\mu\text{g/L}$] of:					
	Date	Week of experiment	Flufenacet	FOE Alcohol	FOE Oxalate	FOE Sulfonic acid	FOE TGS ¹⁾	Unknown 1 [$\mu\text{g a. i. equiv./L}$]

Ratio TOC/TRR _{acidic}	3192	8357	< 2457	8989

The results of the determination of the radioactivity in soil monoliths from each lysimeter are presented below in numerical form in the table B.8.1.3.3._CA-12 (together with the results of the determination of fresh weight – FW, and dry weight – DW, of each soil layer) and in graphical form on figure B.8.1.3.3._CA-10 (in [% AR] – left hand-side graph, and in [mg a. i. equivalent/kg soil, fresh weight] – right-hand-side graph). These results show that radioactivity in the soil monoliths was located predominantly in the top 20 cm and below 40-cm depth it accounted for less that 1.0% AR in each of the analysed soil layers.

Table B.8.1.3.3._CA-12: The numerical results of the determination radioactivity in soil monoliths from each lysimeter.

Lysimeter #15					Lysimeter #16				
Soil layer [cm]	Weight of soil layer [g]		Amount of radioactivity determined as:		Soil layer [cm]	Weight of soil layer [g]		Amount of radioactivity determined as:	
	Fresh weight (FW)	Dry weight (DW)	[% AR]	[mg a. i. equiv./kg FW]		Fresh weight (FW)	Dry weight (DW)	[% AR]	[mg a. i. equiv./kg FW]

Footnotes to the table:

1) Assumed value.

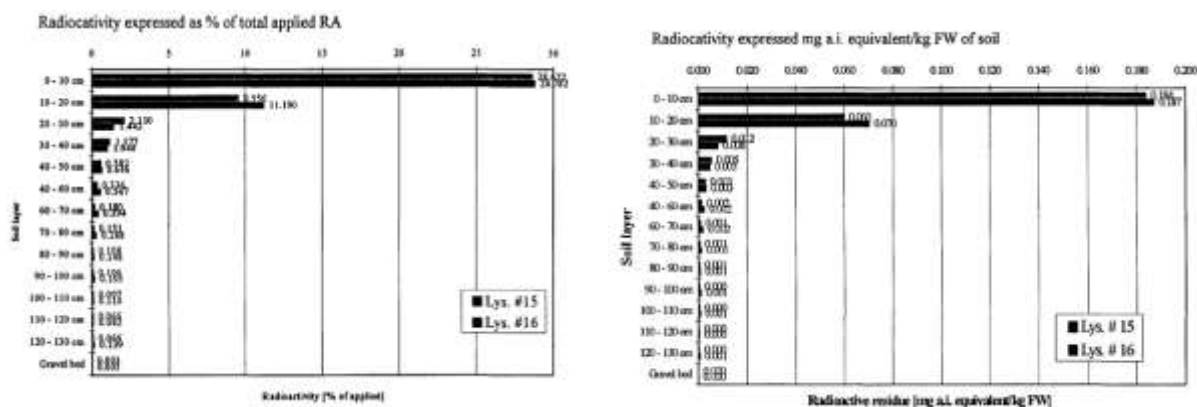

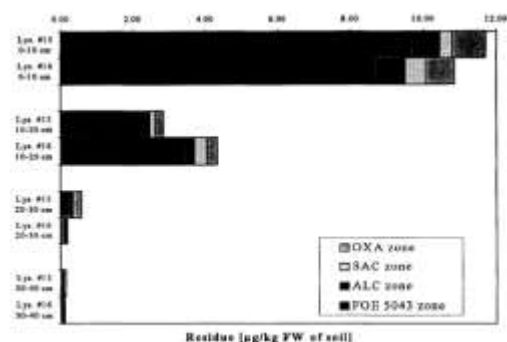

Figure B.8.1.3.3._CA-10: The graphical results of the determination radioactivity in soil monoliths from each lysimeter (copied from the study report).

The 10-cm soil layers sampled down to the depth of 40 cm were further analysed, using TLC for the individual compounds. That analysis enabled the identification and quantitation of the following compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid. Its detailed results are presented in numerical form below in the table B.8.1.3.3._CA-13 and in graphical form on figure B.8.1.3.3._CA-11. It shall be indicated that in that experiment quite substantial amounts of FOE Alcohol were detected in soil, what stands in some contrast with the results of the examination of route and rate of degradation of Flufenacet in aerobic soil, where FOE Alcohol was demonstrated to be minor degradation product.

Table B.8.1.3.3._CA-13: The numerical results of the profiling of the 10-cm layers of the soil monoliths of the lysimeters sampled down to 40-cm depth.

**Figure B.8.1.3.3._CA-11:** The graphical results of the profiling of the 10-cm layers of the soil monoliths of the lysimeters sampled down to 40-cm depth (copied from the study report).

The results of the analysis of the crops grown on each lysimeter are presented below in the table B.8.1.3.3._CA-14. These results show that the translocation and accumulation of the residues of Flufenacet in crops was minimal – well below 0.1% AR.

Table B.8.1.3.3._CA-14: The results of the analysis of the crops grown on Lysimeters

Lysimeter	Crop	Plant material collected	Yield [dt/ha]	Weight of collected plant material		Radioactivity recovered, expressed as:	
				Fresh weight (FW) [kg]	Dry weight (DW) [g]	[µg a. i. equiv./kg FW]	% applied

		Cobs and huls	56	0.562	455.2	10.89	0.006
	Succeeding crop – sugar beet	Tubers	966	9.66	----	2.25	0.0225
		Leaves	446	4.46	----	8.15	0.0375

Finally, on the basis of the obtained results was determined the mass balance for the applied radioactivity. The results of these calculations are presented below on figure B.8.1.3.3._CA-12, showing the mass balance table provided in the study report. On the basis of these results it can be stated that it was possible to recover from the system 44 – 46% AR of the radioactivity applied, predominantly from soil (43 – 45% AR). The radioactivity recovered from soil profile was located predominantly in the top 30-cm layer. 0.58 – 0.64% AR was found in leachates and only 0.08% AR was uptaken by crops grown on the lysimeters' surface. 54 – 56% AR was lost, and that was attributed to the total mineralization of the test compound – [^{14}C] Flufenacet and the release of the generated [$^{14}\text{CO}_2$] into the air.

Figure B.8.1.3.3._CA-12: The results of the determination of mass balance, as presented in the study (table copied from the study report)

Conclusions:

The results of the examination of the leaching behaviour of Flufenacet through two undisturbed soil profiles (two lysimeters filled with soil monoliths consisting of Sandy loam-Loamy sand-Sand soil, having pH in range 6.05 – 6.63 and OC content in the top 30-cm layer of 1.41%) during three consecutive years showed that 44 – 46% of radioactivity applied as [^{14}C]-Flufenacet was recovered. The lost 54-56% AR was attributed to the $^{14}\text{CO}_2$ formed in soil and escaped from there, hence it was stated that such would be the level of the total mineralisation of the test compound.

Of the radioactivity recovered from the test system 0.08% AR (Both Lysimeters) was recovered in collected plant material. 0.58% AR (Lysimeter #16) – 0.64% AR (Lysimeter #15) was recovered in leachates, of which 0.772% AR (Lysimeter #15) – 0.815% AR (Lysimeter #16) in the 1st year annual leachate, 0.161% AR (Lysimeter #15) – 0.250% AR (Lysimeter #16) in the 2nd year annual leachate and only 0.006% AR (both Lysimeters) in the 3rd year annual leachate. That corresponded to:

- for Lysimeter #15:
 - in the 1st year annual leachate to 1.062 [$\mu\text{g a. i. equivalent/L}$] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 6.47% was $^{14}\text{CO}_2$ -associated radioactivity, and to 0.990 [$\mu\text{g a. i. equivalent/L}$] acidic TRR subsequently profiled using TLC;
 - in the 2nd year annual leachate to 0.758 [$\mu\text{g a. i. equivalent/L}$] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 11.10% was $^{14}\text{CO}_2$ -associated radioactivity, and to 0.670 [$\mu\text{g a. i. equivalent/L}$] acidic TRR subsequently profiled using TLC;
 - in the 3rd year annual leachate to 0.432 [$\mu\text{g a. i. equivalent/L}$] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 22.80% was $^{14}\text{CO}_2$ -associated radioactivity, and to 0.334 [$\mu\text{g a. i. equivalent/L}$] acidic TRR not profiled;

- on average in annual leachate to 0.906 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 8.42% was ¹⁴CO₂-associated radioactivity, and to 0.830 [µg a. i. equivalent/L] acidic TRR.
- for Lysimeter #16:
 - in the 1st year annual leachate to 0.931 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 6.82% was ¹⁴CO₂-associated radioactivity, and to 0.870 [µg a. i. equivalent/L] acidic TRR subsequently profiled using TLC;
 - in the 2nd year annual leachate to 0.516 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 11.19% was ¹⁴CO₂-associated radioactivity, and to 0.460 [µg a. i. equivalent/L] acidic TRR subsequently profiled using TLC;
 - in the 3rd year annual leachate to 0.353 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 35.56% was ¹⁴CO₂-associated radioactivity, and to 0.230 [µg a. i. equivalent/L] acidic TRR not profiled;
 - on average in annual leachate to 0.742 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 8.39% was ¹⁴CO₂-associated radioactivity, and to 0.680 [µg a. i. equivalent/L] acidic TRR.

The TLC profiling of the leachates (acidic TRR) lead to the identification of its following constituents: Flufenacet, FOE Alcohol, FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide (FOE TGS). The quantitative analysis gave the following results:

- for Lysimeter #15:
 - the 1st year annual leachate contained 0.020 [µg/L] of Flufenacet, <0.002 [µg/L] of FOE Alcohol, 0.015 [µg/L] of FOE Oxalate, 0.589 [µg/L] of FOE Sulfonic acid, 0.016 [µg/L] of FOE TGS and 0.030 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - the 2nd year annual leachate contained 0.003 [µg/L] of Flufenacet, 0.003 [µg/L] of FOE Alcohol, <0.018 [µg/L] of FOE Oxalate, 0.235 [µg/L] of FOE Sulfonic acid, 0.020 [µg/L] of FOE TGS and 0.039 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - in the 3rd year leachate <0.025 [µg/L] was attributed to FOE Sulfonic acid, no other compounds were taken into consideration.
- for Lysimeter #16:
 - the 1st year annual leachate contained 0.033 [µg/L] of Flufenacet, 0.000 [µg/L] of FOE Alcohol, 0.004 [µg/L] of FOE Oxalate, 0.489 [µg/L] of FOE Sulfonic acid, 0.014 [µg/L] of FOE TGS and 0.033 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - the 2nd year annual leachate contained 0.003 [µg/L] of Flufenacet, 0.005 [µg/L] of FOE Alcohol, <0.014 [µg/L] of FOE Oxalate, 0.149 [µg/L] of FOE Sulfonic acid, 0.015 [µg/L] of FOE TGS and 0.041 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - in the 3rd year leachate <0.017 [µg/L] was attributed to FOE Sulfonic acid, no other compounds were taken into consideration.

The radioactivity determined in the soil monoliths was on the level:

- for Lysimeter #15: 43.16%AR, of which 40.29% AR in the top 30 cm, 2.095% AR in the next 30-60cm layer and the remaining 0.777% AR below that depth, the content of radioactivity decreased with depth being highest - ~28% AR in the top 10-cm section, and below 40 cm not surpassing 1% AR in any of the 10-cm sections;
- for Lysimeter #16: 45.03%AR, of which 41.41% AR in the top 30 cm, 3.128% AR in the next 30-60cm layer and the remaining 0.485% AR below that depth, the content of radioactivity decreased with depth being highest - ~28% AR in the top 10-cm section, and below 40 cm not surpassing 1% AR in any of the 10-cm sections.

The profiling of radioactivity in soil extracts from samples taken from 0-30 cm layer resulted in identification of four compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid. The RMS calculated their concentrations in that layer using the sumarily weight of soil (Fresh Weight, further denominated FW) within that layer, being 475.768 kg for Lysimeter #15 and 470.466 kg for Lysimeter #16.

The determined amounts and corresponding concentrations of the identified compound were following:

- for Lysimeter #15: content of Flufenacet was 1860.96 µg and its concentration 3.91 [µg/kg soil FW], content of FOE Alcohol was 143.49 µg and its concentration 0.30 [µg/kg soil FW], content of FOE Oxalate was 212.84 µg and its concentration 0.45 [µg/kg soil FW], content of FOE Sulfonic acid was 71.44 µg and its concentration 0.15 [µg/kg soil FW];

- for Lysimeter #16: content of Flufenacet was 1839.68 µg and its concentration 3.91 [µg/kg soil FW], content of FOE Alcohol was 159.02 µg and its concentration 0.34 [µg/kg soil FW], content of FOE Oxalate was 167.72 µg and its concentration 0.36 [µg/kg soil FW], content of FOE Sulfonic acid was 138.39 µg and its concentration 0.29 [µg/kg soil FW].

As a result it may be stated that of all the compounds possible to be identified as originating from Flufenacet radiolabelled in fluorophenyl ring (including Flufenacet itself) only FOE Sulfonic acid was demonstrated to be found in leachates in amounts > 0.1 µg/L, what confirmed the risk to GW associated to that degradation product demonstrated in GW model exposure assessment (for details please refer to the results of calculations presented under the point B.8.5 in the Vol. 3-CP, B.8 of this Renewal Assessment Report).

Neither Flufenacet nor the second major soil degradation product relevant for that radiolabelling position – FOE Oxalate, were detected in leachates in amounts > 0.1 µg/L, what may indicate that they would not pose a threat to the GW compartment.

In soil and leachates FOE Alcohol was detected – the compound determined in the studies examining the route of degradation of Flufenacet in aerobic soil to be minor/transient and therefore not taken into account in the GW model exposure assessment. It shall be indicated however that the would-be risk it may pose to the GW compartment was covered by the calculations carried out for FOE Oxalate – its immediate degradate.

Also detected in leachates was FOE Thioglycolate sulfoxide (FOE TGS), the compound not taken in the model GW exposure assessment into consideration, being identified as minor soil degradation product. It shall be indicated however, that in the study it was determined in leachates in amounts <0.1 µg/L, what may indicate that it would not pose a serious threat to the GW compartment.

It shall be indicated that, due to the fact that in the study was used Flufenacet radiolabelled only in the fluorophenyl ring, the study gave no information of the leaching potential of the degradation products formed from the second moiety present within the molecule of Flufenacet – thiadiazole.

Finally, it shall be indicated that the study, although provides vital information regarding the mobility and leaching behaviour of Flufenacet and some of its soil degradation products within the undisturbed soil profile, and hence the risk posed to the groundwater recharge, is not fully suitable for assessing such risk in case of the present evaluation. The reason is that the test compound, although in higher rate, was applied at spring and not in autumn. Therefore the climatic conditions observed on the test site during the period of the peak concentrations of Flufenacet and its degradation products may not fully reflect those usually occurring in autumn (temperature profile, precipitation), what in turn may influence the degradation in soil (mainly kinetics) and the leaching potential of each detected/quantified compound originating from Flufenacet (including the test compound).

It may be therefore stated that, on the basis of the comparative analysis of the application pattern (crops, application timing and application rates) used in the study and the EU-representative application pattern proposed for the current authorisation of Flufenacet in the EU, the study may be considered as providing supplementary information with regard to the risk posed by Flufenacet and its soil degradation products to the GW compartment, but for the purpose of the decision making it should be considered with care.

Study 1a:

Report: Hellpointner E., (1995): “Lysimeter study on the translocation of *FOE 5043* into the subsoil after 2-year use as pre-emergence herbicide in corn. 1st year of study.”; Bayer AG, Agrochemical Division, Development, Institute for Metabolism Research and Residue analysis; D-51368 Leverkusen, Germany; report No. PF-4024; 09 January 1995; study reference number M-002195-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Testing of Plant Protection Products in Registration Procedure, Part IV, 43- (February 1990) – “Lysimeter tests for the translocation of plant protection products into the subsoil.”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.4.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. RMS re-evaluated the study and found it acceptable. It was noticed however, that this is an interim report presenting a part of the results presented in summarised above, as **Study 1**, final report of the same study. RMS compared both reports and stated that they contained the same results, in case of this report limited however to one, 1st, year. Therefore it was not necessary to summarise this study and such summary was not provided in order not to overburden the Renewal Assessment Report. However the RMS

used some of its parts, in particular some figures, in cases they were more clear/better looking than the corresponding figures in the full report.

Summary:

The study report was not summarised because it contained the same data as summarised above, as **Study 1**, full-study report.

Study 1b:

Report: Hellpointner E., (1995): “Lysimeter study on the translocation of *FOE 5043* into the subsoil after 2-year use as pre-emergence herbicide in corn. 2nd year of study.”; Bayer AG, Agrochemical Division, Development, Institute for Metabolism Research and Residue analysis; D-51368 Leverkusen, Germany; report No. PF-4081 (107728); 04 August 1995; study reference number M-002192-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Testing of Plant Protection Products in Registration Procedure, Part IV, 43- (February 1990) – “Lysimeter tests for the translocation of plant protection products into the subsoil.”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.4.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. RMS re-evaluated the study and found it acceptable. It was noticed however, that this is an interim report presenting a part of the results presented in summarised above, as **Study 1**, final report of the same study. RMS compared both reports and stated that they contained the same results, in case of this report limited however to one, 2nd, year. Therefore it was not necessary to summarise this study and such summary was not provided in order not to overburden the Renewal Assessment Report. However the RMS used some of its parts, in particular some figures, in cases they were more clear/better looking than the corresponding figures in the full report. It shall also be noted that the same study was probably used for the evaluation of Flufenacet in the USA. It was then submitted by *Bayer Corporation, Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120-0013*, bearing the identification number (for Bayer Report) 107728. However, for the evaluation in the EU the report bore the ID number PF-4081.

Summary:

The study report was not summarised because it contained the same data as summarised above, as **Study 1**, full-study report.

Study 2:

Report: Hellpointner E., (1996): “Lysimeter study on the translocation of *FOE 5043* into the subsoil after use as pre-emergence herbicide in a maize/winter wheat crop rotation.”; Bayer AG, Agrochemical Division, Development, Institute for Metabolism Research and Residue analysis; D-51368 Leverkusen, Germany; report No. PF-4184 (107688); 18 November 1996; study reference number: M-002190-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Testing of Plant Protection Products in Registration Procedure, Part IV, 43- (February 1990) – “Lysimeter tests for the translocation of plant protection products into the subsoil.”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.4.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. RMS re-evaluated the study and found it acceptable. It is summarised below. It shall be noted that the same study was probably used for the evaluation of Flufenacet in the USA. It was then submitted by *Bayer Corporation, Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120-0013*, bearing the identification number (for Bayer Report) 107688. However, for the evaluation in the EU the report bore the ID number PF-4184 and under that number it will be presented in the list of references.

Summary:

The aim of the study was to examine, for 2.5 consecutive years, the leaching behaviour of Flufenacet and its degradation products through the undisturbed soil profiles under the climatic and agronomic conditions relevant for Germany. The study was carried out in a way very similar to that described above for *Study 1*. The major differences consisted in:

- the 1st crop was fodder (silage) maize;
- the 2nd crop was Winter cereals sown in autumn of the same year as the 1st crop;
- the test substance – [¹⁴C]-Flufenacet was applied not at the beginning of the Year 1 and Year 2 of the experiment, but both application occurred during the Year 1 of the study – at spring, after maize was sown, and in autumn, shortly after sowing Winter wheat as the 2nd crop;
- the application rates of [¹⁴C]-Flufenacet for the 1st and 2nd applications were different – the 2nd application rate was less than half of that used during the 1st application of the test compound;
- finally the soil monoliths were shallower – they were sampled only down to ~115 cm instead of ~130 cm, as it was in *Study 1*.

The experiment was carried out using two undisturbed soil monoliths having a surface area of 1.0 m² and depth 115 cm. They were taken from the field plot located at the Bayer’s Experimental Farm Laacherhof by pressing a stainless steel cylinder, 100-cm long, 100-cm wide and 115-cm high, into the ground until ~10 cm of the frame remained above the soil surface. The soil monolith was separated from the ground below by pulling the cutting plate under the steel frame. Next, the soil core was placed into 10-cm high steel tray, slightly sloping towards its centre where the outlet was located, half filled with gravel (having particle size 8 – 12 mm). Then the cutting plate was removed and the soil core, now standing on the gravel bed, straightened. The total height of so prepared lysimeter was 120 cm, of which top 115 cm was soil monolith and bottom 5 cm gravel layer.

The design of the lysimeter is presented below on figure B.8.1.3.3._CA-13.

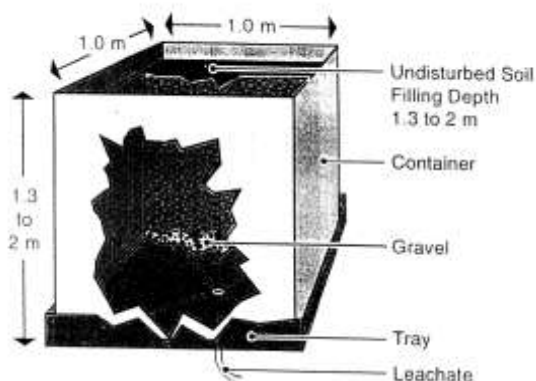

Figure B.8.1.3.3._CA-13: The scheme of the lysimeter used in the study (copied from the study report).

The soil forming soil monolith of the lysimeter was described as brown soil from sand with a low degree of profile differentiation, that originated and then developed from sandy to sandy-loamy sediment overlying the deposits of the lower terrace of the river Rhine. According to German classification it was “Braunerde” from sand and according to FAO – Eutric Cambisol. The detailed characteristic of the soil monolith filling the lysimeter is provided in the table B.8.1.3.3._CA-15. The data are presented only for layers down to the depth of 115, as that was declared target depth for soil core sampling.

Table B.8.1.3.3._CA-15: The characteristic of soil forming the lysimeter’s soil monolith.

Parameter		Soil layer (symbol, depth)			
		A_b , 0 – 30 cm	B_v , 30 – 60 cm	B_v , 60 – 100 cm	B_v , 100 – 115 cm
Soil texture (USDA)		Sandy loam	Sandy loam	Loamy sand	Loamy sand
Particle size distribution	Sand (50 – 2000 μm)	71.8	72.2	79.4	82.7
	Silt (2 – 50 μm)	16.5	16.6	11.0	9.1
	Clay (<2 μm)	11.8	11.2	9.7	8.2
Physico-chemical properties	pH in H_2O	7.04	7.24	7.18	7.46
	pH in CaCl_2	6.05	6.42	6.32	6.61
	OC [%]	1.41	0.34	0.19	0.17
	CEC [meq/100g]	9.61	7.43	7.57	8.52
	Microbial biomass [mg/kg]	235	34	11	13
Physical parameters	Pore volume [vol. %]	44.94	37.97	42.47	42.90
	air capacity AC [vol. % H_2O]	12.49	17.36	24.31	21.64
	field capacity FC [vol. % H_2O]	32.45	20.61	18.16	21.15
	available water capacity AWC [vol. % H_2O]	23.83	13.10	10.46	11.82
	permanent wilting point PWC [vol. % H_2O]	8.83	7.51	7.70	9.43
	saturated hydraulic conductivity K [$\text{cm} \cdot \text{s}^{-1}$]	5.4 E-3	9.8 E-3	7.5 E-3	5.5 E-3
	intrinsic permeability k [cm^2]	5.4 E-8	9.8 E-8	7.5 E-8	5.5 E-8

The lysimeters were transferred to the open-air lysimeter station located in Bayer AG’ Landwirtschaftszentrum, Monheim, Germany (latitude 51°4’ N, longitude 6°55’ E, ~40 m above the sea level), shown on figure B.8.1.3.3._CA-14, and installed in positions #75 and #18. The schematic presentation of the cross-section of the lysimeter station, showing the way the lysimeters were maintained, is presented on figure B.8.1.3.3._CA-15.

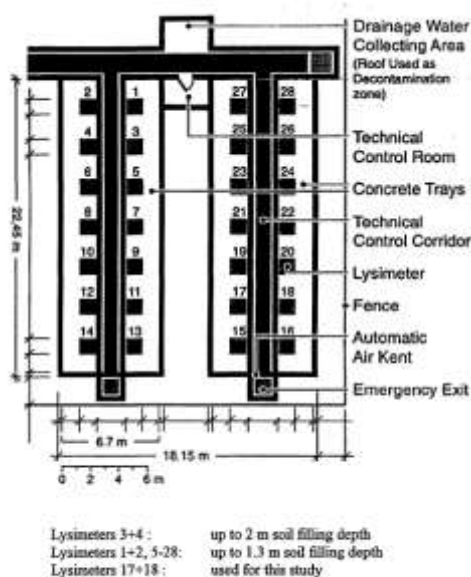

Figure B.8.1.3.3_CA-14: The general view of the lysimeter station of Bayer AG. (copied from the study report).

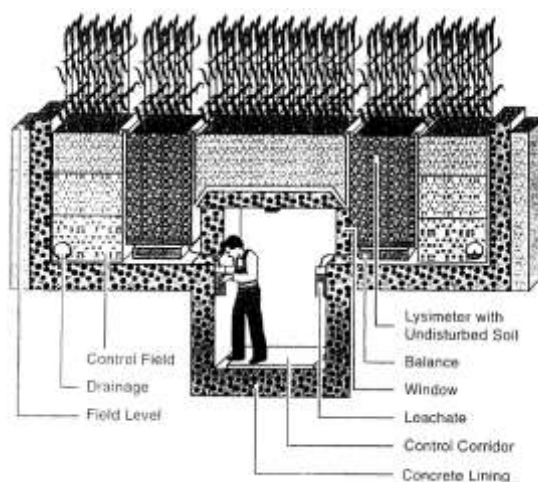

Figure B.8.1.3.3_CA-15: The cross-section general view of the lysimeter station of Bayer AG. (copied from the study report).

The lysimeters were installed in March 1992, then in April 1992 the Inkarnat Clover was sown as a first vegetation after their acquisition. It was broken up and incorporated into top 15 cm. of the soil core in October 1992, then on the 26th November 1992 the Winter wheat var. Orestes was sown. That crop was also incorporated on the lysimeters' top soil on 3rd March 1999 and then the lysimeters were left bare until the preparation of the seed bed for the 1st crop – fodder (silage) maize, variety Mutin, occurred shortly before its sowing on 10th May 1993. The experiment started on the 10th of May 1993 by sowing the 1st target crop – maize and ended in November 1995, when the soil was analysed for the residues of Flufenacet.

During that experimental period the following crops were grown on the lysimeters:

- Maize (fodder) var. Mutin as the 1st, target crop; it was sown on the 10th of May 1993 and harvested on the 28th September 1993, 20 weeks after sowing and 1st application of the test compound;

- Winter wheat, var. Orestis as the 2nd, target crop, it was sown on the 2nd November 1993 and harvested on 3rd August 1994, 64 weeks after 1st application of the test compound and 39 weeks after sowing and 2nd application of the test compound;
- Sugar beet var. Sonja as the 3rd, succeeding crop; it was sown on the 13th April 1995 and harvested on 7th November 1995, 30 weeks after sowing, 130 weeks after the 1st application and 105 weeks after the 2nd application of the test compound;

Maize grown as the 1st crop was sown in two rows 60-cm apart, at seed density 20 grains/m². Shortly after germination, on 25th May 1993 the number of plants was manually reduced to 12 plants/m². Winter wheat, grown as the 2nd crop was sown at seed density 420 grains/m². The 3rd crop – sugar beet, was sown in three rows, 33-cm apart and 17-cm distant from the walls of lysimeter, at seed density 9 seeds/m² (3 seeds per row).

After harvest of the 1st and 2nd crop the plant residues – maize stubble as well as wheat stubble plus 90% of wheat straw, left on the lysimeter were incorporated into the top soil layer (15 cm) as organic fertiliser.

All major crop maintenance measures used during the experiment are presented below in the table B.8.1.3.3._CA-16. In the table, in the columns for crop protection, are also presented the applications of the test compound, marked red. Additionally, when necessary, artificial irrigation was performed as maintenance measure. That was done in order to supply the crops growing on the surface of lysimeters with water in periods of relative drought (in summer, when the level of soil water available to plants is low). The details on that maintenance measure will be provided further down the summary, together with the characteristic of precipitation recorded on site.

The test substance used in the study was [Phenyl-UL-¹⁴C] Flufenacet, having a specific activity of 2.0 MBq/mg (54 µCi/mg) and radiochemical and chemical purity of >99%. Its structural formula is presented below on figure B.8.1.3.3._CA-16. It was used to prepare the application solution.

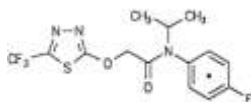

Figure B.8.1.3.3._CA-16: The structural formula of the test compound – the [¹⁴C]-Flufenacet. Asterisk (*) denotes the radiolabelling position (copied from the study report).

It was stated that the test compound should be applied as 60 WG (Water Dispersible Granule) formulation. However, because it was not possible at the time of the experiment to prepare in microscale a representative and homogenous WG formulation containing the radiolabelled active substance, the pure solution of [¹⁴C]-Flufenacet was used instead.

The first application of the test substance took place on the 13th of May 1993, 3 days after the 1st crop – corn, was sown. The assumed application rate was 480 g Flufenacet/ha and the actual was 48.14 mg/m² (+0.29% of the intended amount). For that purpose the whole delivered sample of Flufenacet was dissolved in 4 mL of C₂H₅OH. Next, for the given lysimeter 0.976 mL of that solution was mixed with 100 g of the lysimeter top soil (mixing lasted 1 hour). Then the volume of soil was increased to obtain a final amount of ~4000g of fortified soil. That amount was uniformly distributed onto the lysimeter's surface. The application was terminated by irrigation with 5 mm/m² of water to minimise losses due to wind erosion. The amount of radioactivity introduced that way onto each lysimeter – #17 and #18 was 96273 kBq. The overall loss of radioactivity during application was 27.5 kBq/Lysimeter. That value was taken into account in further calculations.

The second application of the test compound occurred on the 3rd November 1993, 1 day after sowing the 2nd crop – winter wheat. The assumed application rate was 180 g Flufenacet/ha and the actual was 18.02 mg/m² (+0.11% of the intended amount). For that purpose the whole delivered sample of Flufenacet was dissolved in 5 mL of C₂H₅OH. Next, for the given lysimeter 2.21 mL of that solution was mixed with 100 g of the lysimeter top soil (mixing lasted 1 hour). Then the volume of soil was increased to obtain a final amount of ~4000g of fortified soil. That amount was uniformly distributed onto the lysimeter's surface. The application was terminated by irrigation with 5 mm/m² of water to minimise losses due to wind erosion. The amount of radioactivity introduced that way onto each lysimeter – #17 and #18 was 34044 kBq. The overall loss of radioactivity during application was 106.4 kBq/Lysimeter. That value was taken into account in further calculations.

Table B.8.1.3.3._CA-16: Major crop maintenance measures used during the experiment.

Fertilisation			Crop Protection			Other measures	
Date	Fertiliser used	Dose rate	Date	Crop protection measure	Dose rate	Date	Measure
April 1992	Thomas phosphate potash	1500 kg/ha	1992	----	----	April 1992	Sowing of Inkarnat Clover
						October 1992	Digging up and incorporation of residues of clover into the top soil layers (~15 cm)
						26 November 1992	Sowing of Winter wheat var. Orestis
19 March 1993	Thomas phosphate potash	1500 kg/ha	10 May 1993	Maize seeds treated with TMTD	not specified	03 March 1993	Digging up and incorporation of residues of Winter wheat into the top soil layers (~15 cm)
	Lime ammonium salpetre	540 kg/ha					
03 June 1993	Basfoliar	8 L/ha	13 May 1993	1 st application of the test compound – [¹⁴ C] Flufenacet	48.14 mg/ha (480 g/ha)	10 May 1993	Digging up the top soil layer, tilling, crumbling and seed bed preparation for maize; sowing of the 1 st crop
08 June 1993	Nitrophoska permanent	400 kg/ha					
18 June 1993	Basfoliar	8 L/ha				25 May 1993	Manual reduction of the number of growing corn plants
24 June 1993	Basfoliar	10 L/ha					
30 September 1993	Organic fertilisation (corn stubble)	----	02 June 1993	E605 combi	0.1%	28 September 1993	Harvest of the 1 st crop
						30 September 1993	Incorporation of the maize stubble into the top soil layer
			02 November 1993	Winter wheat treated with Baytan univ.	not specified	02 November 1993	Digging up the top soil layer, tilling, crumbling and seed bed preparation Winter wheat; sowing of the 2nd crop
			03 November 1993	2 nd application of the test compound – [¹⁴ C] Flufenacet	18.02 mg/ha (180 g/ha)		
18 February 1994	Lime ammonium salpetre	254 kg/ha	15 April 1994	Tolkan Fox	3.5 L/ha	03 August 1994	Harvest of the 2nd crop
18 May 1994	Lime ammonium salpetre	220 kg/ha	10 May 1994	Sportak Alpha	1.5 L/ha		
23 August 1994	Lime	500 kg/ha		Colt	1.0 L/ha		
11 August 1994	Organic fertilisation (wheat stubble and straw)	----	30 May 1994	Metasystox R	0.125%	11 August 1994	Cutting up and incorporation of residues of Winter wheat (stubbles and 90% straw) into the top soil layers (~15 cm)
				E605 forte	0.05%		
			13 June 1994	E605 forte	0.05%		
				Matador	1.0 L/ha		
				Dyrene	2.0 L/ha		
13 March 1995	Lime ammonium salpetre	660 kg/ha	13 april 1995	Sugar beet seeds treated with TMTD, Hymexazole and Imidachloprid 90 FS 600	----	13 April 1995	Digging up the top soil layer, tilling, crumbling and seed bed preparation for sugar beet; sowing of sugar beet – 3 rd crop
	Thomas phosphate potash	1500 kg/ha					
23 June 1995	Lime ammonium salpetre	280 kg/ha	25 August 1995	Bardos	1.0 L/ha	07 November 1995	Harvest of the 3 rd crop – sugar beet
			22 September 1995	Bardos	1.0 L/ha		

The experiment lasted for two and a half consecutive years, from May 1993, when the 1st crop was sown and first application of the test compound occurred, until November 1995, when soil monolith filling the lysimeter was analysed for the amount and nature of the residues of Flufenacet (active substance and its degradation products) retained within it.

During that whole period the weather conditions on the experimental site, such as air temperature, soil temperature at various depths, duration of sunshine, wind velocity, rainfall air humidity, were constantly monitored and daily recorded by weather station of the experimental facility, located within 1 km from the test site. At the test site the soil temperature at the depth of 20 cm was measured continuously in one of the lysimeters. The collected data were processed to obtain monthly and yearly averages, presented in section **Results and their discussion** of this summary. The weights of each lysimeter were continuously recorded. They will be presented, in graphical form, also in section **Results and their discussion** of this summary.

The leachates from each lysimeter were collected in two replacable 20-L steel containers attached in sequence to the lysimeter's outlet. The collected leachates were taken for analysis in 2-week intervals, or shorter if necessary. To do that the containers were emptied, the volume of the collected leachates determined gravimetrically and their pH measured.

The gross radioactivity in the fresh leachate was determined by LSC using 10-mL aliquots. For that purpose three 10-mL aliquots were mixed with 0.1 mL of 1M NaOH. Next to each of them 10 mL of Quickszint 401 LS cocktail was added and the samples were analysed by LSC. The results represented the content of radioactive residues adjusted to alkaline pH.

Another three aliquots were mixed with 0.1 mL of 18% HCl_{aq}, ultrasonicated in open vessels for ~30 minutes in order to release of ¹⁴CO₂ possibly forming in sample and analysed by LSC after addition of 10 mL of Quickszint 401 LS cocktail. The results represented the content of radioactive residues adjusted to acidic pH.

10% of leachates collected at each sampling were stored combined in the container for annual leachate sample. That container was stored in the deep-freeze storage room. Another 10% of each leachate was stored as a separate sample in the deep-freeze storage room.

The deep-frozen leachates were stored for up to 13 months between collection and analysis. The selected leachates obtained from each lysimeter – 1st-year early leachate, 1st-year leachate with the highest radioactivity content, 1st-year late leachate, annual 1st-year leachate and annual 2nd-year leachate were analysed qualitatively and quantitatively TLC. The profiling of radioactivity in leachates soil – identification and quantitation of Flufenacet and its degradation products, was performed in processed leachates. In case of 1st-year leachates the processing started by concentrating 500 mL of leachate under vacuum to the volume of 50 mL. Its 10-mL aliquot was passed through SPE cartridge. The eluate was discarded and the residue eluted from the SPE column using 5 mL of CH₃CN + 0.4% CH₃COOH (9:1) solution. That eluate was collected and analysed by TLC.

The processing of the 2nd-year annual leachate began with concentrating its 100 mL aliquot to 10 mL. Then the procedure was the same as described above for the 1st-year leachates.

Annual leachates were also analysed for pH, TOC, and content of Cl⁻, SO₄²⁻, NO₂⁻, NO₃⁻ and NH₄⁺.

The plant material collected at harvest for 1st target crop – maize, were above-ground parts – “silage material”, while stubbs were left at spot, in line with agricultural practice, and then incorporated into lysimeter's topsoil as organic fertilizer. In case of the 2nd target crop – Winter wheat the collected plant material were also above-ground parts - kernels, hulls and straw. The stubs were left at spot to be subsequently, together with 90% of the collected straw, incorporated into lysimeter's topsoil as organic fertilizer, in line with agricultural practice

The plant material collected at harvest for the 3rd (succeeding) crop – sugar beets, were tubers and leaves. The harvested fresh plant material was homogenised under liquid nitrogen, dried at T = 50°C and its aliquots were analysed, after combustion, for radioactivity content.

After harvest of the 3rd crop the surface of the lysimeters was left bare, covered by a protective plastic plate until being processed.

On the 14th November 1995 three top 10-cm layers were removed from the Lysimeter #17, followed by the next 10-cm layer sampled two days later – on the 16th November 1995. Each collected layer was weighed to determine its fresh weight.

Next the soil from each layer was air-dried in greenhouse, mixed thoroughly and divided into 9 subsamples the weight of which was determined. Three aliquots of each subsample were taken for the determination of the content of radioactivity by LSC after combustion.

For the deeper layers – from 40 to 100 (120) cm depth five soil cores were taken using an electric soil corer, each having the diameter of 8 cm². The cores were sampled on the 13th December 1995. The distribution of the sampling points is presented below on figure B.8.1.3.3._CA-17.

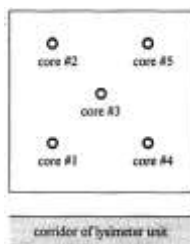

Figure B.8.1.3.3_CA-17: The sampling scheme for the soil cores taken from the lysimeters (copied from the study report).

The obtained 20-cm segments were cut into two 10-cm sections. These 10-cm sections from each core were combined and their total fresh weight recorded. Next the soil was let to dry for 12 days, homogenised and 3 aliquots of so prepared soil samples analysed for radioactivity content using LSC.

The deepest layers were not reached by the corer. Therefore the individual soil sample representing them was taken after the lysimeter was removed from the frame. It was analysed for the radioactivity content using LSC.

Also the gravel filling the bottom of the lysimeter was sampled to determine the amount of radioactivity it retained. For that purpose two 500-g aliquots of gravel were extracted for two hours with 200 mL $\text{CH}_3\text{CN}/0.1\text{M}$ HCl 1:1 (v/v) solution. The extract was analysed for radioactivity content.

In case of the Lysimeter #18 the top layers were not removed, but from the whole soil monolith 5 soil cores were taken on the 13th December 1995 and processed using the same procedure as described above for sampling soil cores from Lysimeter #17.

The profiling of radioactivity in soil – identification and quantitation of Flufenacet and its degradation products, was performed down to the depth of 40 cm. For that purpose two 30-g aliquots of each layer (0-10 cm, 10-20 cm, 20-30 cm and 30-40 cm) from each lysimeter were extracted with two 100-mL portions of $\text{CH}_3\text{CN}/0.1\text{M}$ HCl 1:1 (v/v) solution. Each extraction step lasted 1 hour and was followed by 20-minutes centrifugation. The extracts were filtered through paper filter, combined and their volume recorded. Next they were analysed for radioactivity content by LSC.

The LSC analysys of the liquid samples was carried out using one of the following LS counters: PW 4700, Wallac 1410, Rackbeta 1219, Beckman LS 6000 LL or Beckman LS 6500.

In case of non-processed leachates their 10-mL aliquots were used mixed with 10 mL of Quickszint 401 LS cocktail. The minimum sensitivity of LSC analysis for those samples was $3.1 \text{ E-}7$ ppm. It corresponded to 58 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 29 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 29 cpm ($\text{LAGC} = 2 \times \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 5.61\%$.

In case of the organic extracts their 0.1 – 2 mL aliquots were used mixed with 7 mL of Instant Scint Gel or 2 mL of Quicksafe A LS cocktails. The minimum sensitivity of LSC analysis for those samples was $1.5 \text{ E-}6$ ppm. It corresponded to 58 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 29 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 29 cpm ($\text{LAGC} = 2 \times \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 5.61\%$.

The radioactivity in the solid samples was determined after their combustion in an oxidiser (Oxidiser 306 Tri-Carb or OX 300). The generated $^{14}\text{CO}_2$ was absorbed in the LS cocktail (the mixture of 8 mL Carbosorb and 10 mL Permafluor, or 15 mL Oxysolv C 400) and analysed by LSC. The analysis was performed for soil and plant material, using samples weighing 0.055 g.

The TLC analysis was carried out in one of the three following variants:

- 1) on 20 • 20 cm, 0.25 mm thick, silica gel 60 F_{254} TLC plates developed at room temperature in closed glass chamber using following solvent system $\text{CHCl}_3/\text{CH}_3\text{COOC}_2\text{H}_5$ 3:1 (v/v), it was used for identification and quantitation of Flufenacet and FOE Alcohol;
- 2) on 20 • 20 cm, 0.25 mm thick, silica gel 60 F_{254} TLC plates developed at room temperature in closed glass chamber using following solvent system: $\text{CH}_3\text{CN}/(\text{CH}_3)_2\text{CHOH}/\text{CH}_3\text{COOC}_2\text{H}_5/\text{H}_2\text{O}$ 60:9:6:3 (v/v/v/v); it was used for identification and quantitation of Flufenacet, FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide;
- 3) on 20 • 20 cm, 0.25 mm thick, RP-18 F_{254} TLC plates developed at room temperature in closed glass chamber using following solvent system: $\text{CH}_3\text{CN}/(\text{CH}_3\text{OH}/0.5\% \text{ NaCl}_{\text{aq}})$ 2:2:1 (v/v/v);

The detectors used in the analysis were:

- TLC Scanner CS-930 or UV light chamber for “cold” reference standards;
- Radio-TLC-Scanner RITA 6800 used only in the purity check of the applied parent compound
- Bio-Imaging Analyser BAS 2000 for radiolabelled standard solutions and samples;

The identification was performed by means of the comparison of the R_f values of the constituents of the analysed samples with those of the known reference compounds.

The quantitative analysis was performed by means of LSC analysis of the separated bands (spots) on the TLC plate.

Additionally, for the analysis of standard solutions, purity checks of application solutions and for isolation and verification of degradation products in leachates, the HPLC analysis was performed. It was carried out using HP 1090 work station equipped with DAD (UV) and Ramona 4 (LSC) detectors. The chromatographic separation was performed on LiChrosorb RP 18, 250 • 4 mm, 5 μ m, chromatographic column. In the study report it was stated that more detailed information on the HPLC analysis was provided in the raw data.

Results and their discussion:

The long-term weather characteristic of the test site is presented below on figure B.8.1.3.3._CA-18 (the frame-table copied from the study report). The values marked with an asterisk (*) are the mean of those recorded by the Experimental Farm’s wether station in years 1966 – 1995, while those marked with (#) are the mean of the the measurables recorded in years 1968 – 1995. The weather conditions – air temperature, soil temperature, wind speed, radiant heat, precipitation and irrigation, recorded at the test site during the experiment are presented in the table B.8.1.3.3._CA-17. The table provides monthly mean values. The air temperature, soil temperature at different depths, with exception of that at the depth of 20 cm, radiant heat, wind speed and precipitation are the weather data recorded by the weather station located 1 km apart from the lysimeter site. The soil temperature at 20-cm depth was measured at spot, in Lysimeter #17. Additionally the sum curve of precipitation and irrigation during study is presented on figure B.8.1.3.3._CA-19, immediately below the table B.8.1.3.3._CA-17.

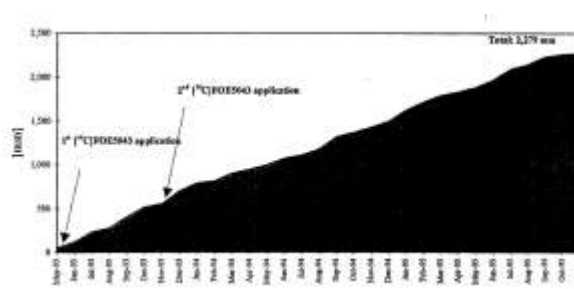

Table 2: Long-term weather characteristics of test location

Annual rainfall (*):	745 mm
Max. / min. monthly rainfall (*):	June (78.1 mm) / February (42.7 mm)
Annual relative humidity of the air (*):	73%
Annual air temperature at 2 m above ground level (*):	10.0°C
Max. / min. monthly air temperature at 2 m above ground level (*):	July (18.4 °C) / January (2.6 °C)
Annual soil temperature (-10 cm) (#):	9.5°C
Annual soil temperature (-30 cm) (#):	10.3°C
Annual soil temperature (-50 cm) (#):	10.7°C
Annual soil temperature (-100 cm) (#):	10.6°C
Annual wind velocity (*):	2.5 m/sec
Annual radiant heat (#):	29.1 kJ/cm ²
Max. / min. monthly radiant heat (#):	July (53.1 kJ/cm ²) / Dec. (5.8 kJ/cm ²)

Figure B.8.1.3.3._CA-18: The table presenting long-term weather characteristic at the lysimeter test site (copied from the study report).

Table B.8.1.3.3._CA-17: The monthly weather data recorded at the test site during the experiment.

Time period		Mean air temperature 2 metres above the ground [°C]	Mean soil temperature [°C] at the depth						Mean monthly radiant heat [kJ/cm ²]	Wind speed [m/s.]	Precipitation (P) and Irrigation (I) [mm]

**Figure B.8.1.3.3._CA-19:** The sum curve of precipitation and irrigation [mm] recorded during the study (copied from the study report).

The total 1st-year precipitation was 897.1 mm and irrigation was 51.0 mm. Therefore the amount of water received by each lysimeter that experimental year as precipitation and irrigation was 948.1 mm, 148.1 mm more than the BBA Guideline requirement – 800 mm.

The total 2nd-year precipitation was 813.9 mm and irrigation was 75.0 mm. Therefore the amount of water received by each lysimeter that experimental year as precipitation and irrigation was 888.9 mm, 88.9 mm more than the BBA Guideline requirement – 800 mm.

The total 3rd-year precipitation was 338 mm and irrigation was 104.0 mm. Therefore the amount of water received by each lysimeter that experimental year as precipitation and irrigation was 442.0 mm, 358 mm less than the BBA Guideline requirement – 800 mm.

The total precipitation and irrigation during the study was 2279 mm, what gave the average annual precipitation at the level of 912 mm – 112 mm higher than the regulatory requirement.

The weight of the lysimeters during the study is presented below, in graphical form, on figure B.8.1.3.3._CA-20.

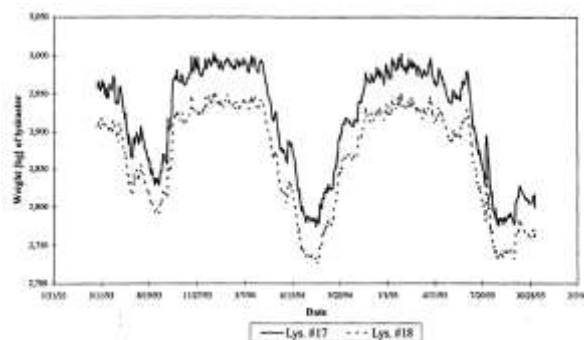

Figure B.8.1.3.3._CA-20: The weight of the lysimeters recorded during the study (copied from the study report).

The leachate from Lysimeter #17 was collected during the 1st experimental year 22 times – on weeks of experiment: 0, 2, 11, 22, 23, 24, 27, 30, 31, 32, 33 (twice), 35, 36, 37, 38, 41, 43, 45, 46, 47 and 50. The total volume of leachate collected during that period was 399.1 L. During the 2nd year of experiment the leachates from that lysimeter were collected 19 times – on weeks of experiment 55, 79, 82, 83, 84, 85, 87, 88, 89 (twice), 90, 91, 92, 93, 94, 96, 96, 100 and 103. The total volume of leachate collected during that period was 365.4 L. On the 3rd experimental year the leachate from that lysimeter was collected only once – on week 115 of the experiment. Its volume was 17.5 L. Therefore the total, exact, volume of leachate collected from that lysimeter during the experimental period of 2.5 years was 781.0 L, of which 764.5 L were collected during the first two years. The total number of sampling points during the experiment for that lysimeter was 41. The leachate collected on week 0 is the leachate collected before the application of the test compound.

The leachate from Lysimeter #16 was collected during the 1st experimental year 22 times – on weeks of experiment: 0, 2, 11, 22, 23, 24, 27, 30, 31, 32, 33 (twice), 35, 36, 37, 38, 41, 43, 45, 46, 47 and 50. The total volume of leachate collected during that period was 383.1 L. During the 2nd year of experiment the leachates from that lysimeter were collected 19 times – on weeks of experiment 55, 79, 82, 83, 84, 85, 87, 88, 89 (twice), 90, 91, 92, 93, 94, 96, 96, 100 and 103. The total volume of leachate collected during that period was 368.9 L. On the 3rd experimental year the leachate from that lysimeter was collected only one – on week 115 of the experiment. Its volume was 19.1 L. Therefore the total, exact, volume of leachate collected from that lysimeter during the experimental period of 2.5 years was 771.1 L, of which 752.0 L were collected during the first two years. The total number of sampling points during the experiment for that lysimeter was 41. The leachate collected on week 0 is the leachate collected before the application of the test compound.

The detailed information on the collection dates and volumes of individual leachates are presented below in table B.8.1.3.3._CA-18.

Table B.8.1.3.3._CA-18: The sampling time and volume of the individual leachate samples collected during the experiment.

The results of the determination of radioactivity in leachates – the amounts of radioactivity recovered, are presented below in two tables – B.8.1.3.3._CA-19 for the Lysimeter #17 and B.8.1.3.3._CA-20 for the Lysimeter #18. Additionally the same results are presented in graphical form on figure B.8.1.3.3._CA-21.

TableB.8.1.3.3._CA-19: The total radioactivity recovered in the leachates from Lysimeter #17.

For the further, TLC analysis, aimed on the identification and quantitation of the individual constituents of leachates, the following leachates were taken:

- 24th week leachate, collected on 29 October 1993, representing the 1st-year's early leachate;
- 38th week leachate, collected on 04 February 1994, representing the 1st-year's leachate with maximum TRR;
- 47th week leachate, collected on 11 April 1994, representing the 1st-year's late leachate;
- 1st-year annual leachate;
- 2nd-year annual leachate.

For the further, TLC analysis, aimed on the identification and quantitation of the individual constituents of leachates, the following leachates were taken:

- 24th week leachate, collected on 29 October 1993, representing the 1st-year's early leachate;
- 38th week leachate, collected on 04 February 1994, representing the 1st-year's leachate with maximum TRR;
- 47th week leachate, collected on 11 April 1994, representing the 1st-year's late leachate;
- 1st-year annual leachate;
- 2nd-year annual leachate.

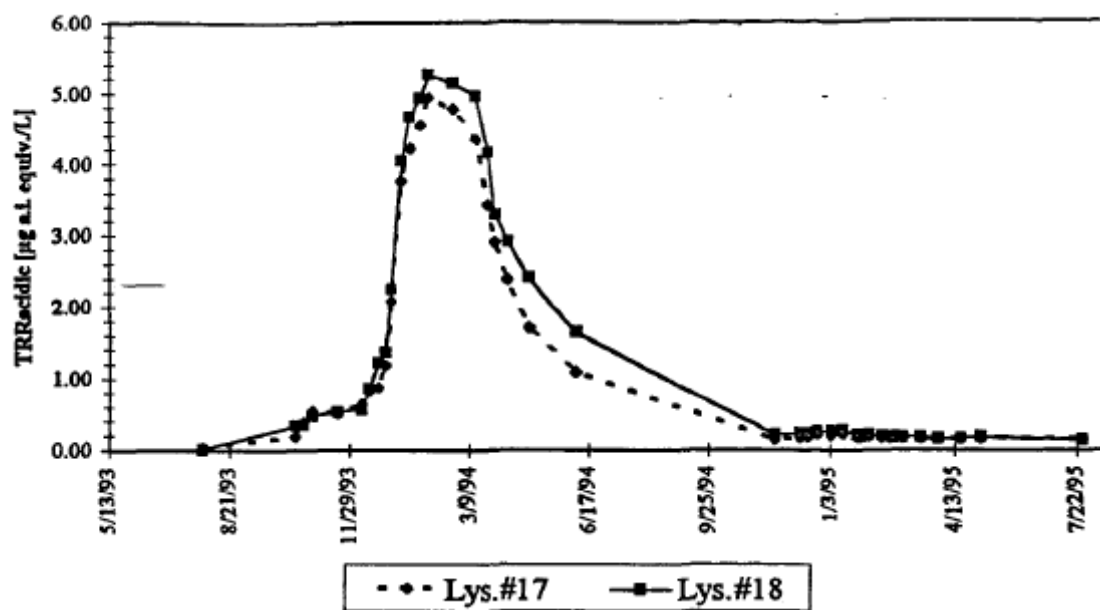

Figure B.8.1.3.3._CA-21: The graphical results of the determination of the total radioactivity recovered (TRR) in leachates from the two lysimeters (copied from the study report).

The detailed results of the characterisation of leachates – measured pH, the concentration of the total (alkaline) TRR and acidic TRR, as well as the content of $^{14}\text{CO}_2$ (expressed as % of TRR) are presented below, individually for each lysimeter, in two tables – Table B.8.1.3.3._CA-21 for Lysimeter #17 and Table B.8.1.3.3._CA-22 for Lysimeter #18. For the completeness of the results also was provided the volume of each leachate collected.

Table B.8.1.3.3._CA-21: The detailed results of the examination of the leachates from Lysimeter #17.

The results of the profiling of single leachates collected during the 1st year of the study and the pooled 1st-year and 2nd-year leachates showed that they contained, apart from detectable amounts of Flufenacet, also FOE Alcohol, FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide. Additionally a fraction further called unknown “Unknown 1” was found using both TLC methods in all analysed leachates. In case of the 3rd-year leachates the TRR (total radioactivity recovered) was not further analysed, because it was stated that it was approaching the qualitative background level. The detailed results of the profiling of the leachates collected from Lysimeter #17 are presented in the table B.8.1.3.3._CA-23. In the next table – B.8.1.3.3._CA-24 are presented the results of the profiling of the leachates collected from the Lysimeter # 18. Finally, in the table B.8.1.3.3._CA-25 are presented the results of the quantitation of the selected constituents of the annual leachates

collected from the Lysimeter #17 and the Lysimeter #18. The results of the profiling of individual and annual leachates showed that the leaching to groundwater recharge in amounts > 0.1 µg/L occurred only for FOE Sulfonic acid. It shall be also indicated that in leachates was also detected, and in quantifiable amounts, FOE Thioglycolate sulfoxide – the soil degradation product of Flufenacet identified in the experiments examining route and rate of degradation of Flufenacet in soil only as a minor compound and hence not covered by the modeling exposure assessment for the groundwater compartment. These results may indicate that under unfavourable conditions FOE Thioglycolate sulfoxide might become a compound of concern, although the identity of that compound was not fully confirmed in the study.

Table B.8.1.3.3._CA-23: Results of the profiling of the leachates collected from the Lysimeter # 17.

Type of leachate	Sampling time		Content [µg/L] of:					
	Date	Week of experiment	Flufenacet	FOE Alcohol	FOE Oxalate	FOE Sulfonic acid	FOE TGS ¹⁾	Unknown 1 [µg a. i. equiv./L]

The results of the determination of the radioactivity in soil monoliths from each lysimeter, expressed as the % of applied radioactivity – [%AR], are presented below in graphical form on figure B.8.1.3.3._CA-22 (for the Lysimeter #17 on the left hand-side graph, and for the Lysimeter #18 on the right-hand-side graph). These results show that radioactivity in the soil monoliths was located predominantly in the top 20 cm and below 40-cm depth it accounted for less that 1.0% AR in each of the analysed soil layers.

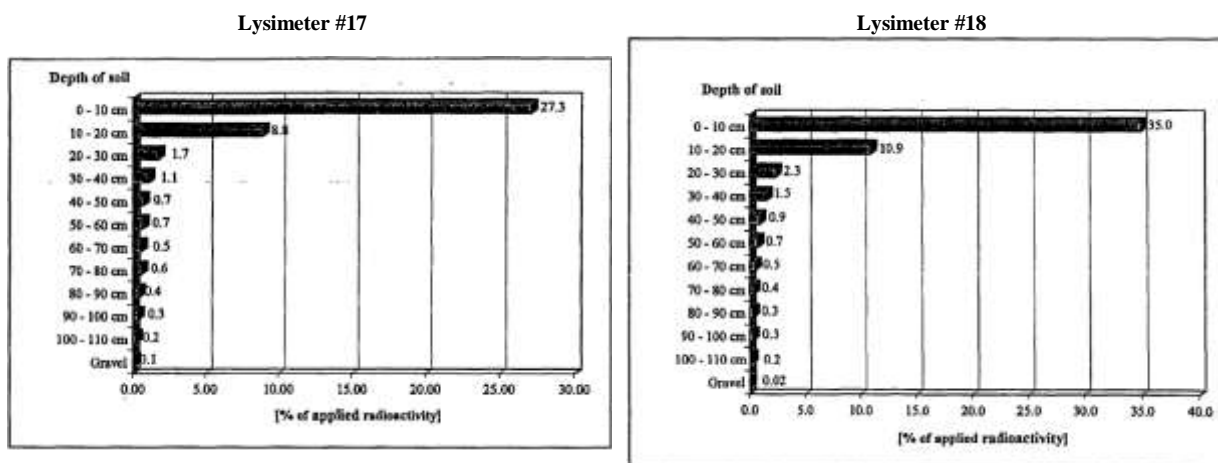

Figure B.8.1.3.3._CA-22: The graphical results of the determination radioactivity in soil monoliths from each lysimeter (copied from the study report).

The 10-cm soil layers sampled down to the depth of 40 cm were further analysed, using TLC for the individual compounds. That analysis enabled the identification and quantitation of the following compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid. Its detailed results are presented in numerical form below in the table B.8.1.3.3._CA-26 and in graphical form on figure B.8.1.3.3._CA-23. It shall be indicated that in that experiment quite substantial amounts of FOE Alcohol were detected in soil, what stands in some contrast with the results of the examination of route and rate of degradation of Flufenacet in aerobic soil, where FOE Alcohol was demonstrated to be minor degradation product.

Table B.8.1.3.3._CA-26: The numerical results of the profiling of the 10-cm layers of the soil monoliths of the lysimeters sampled down to 40-cm depth.

Results obtained for the Lysimeter #17

		Leaves	537	5.370	----	5.83	0.048

Finally, on the basis of the obtained results was determined the mass balance for the applied radioactivity. The results of these calculations are presented below, on figure B.8.1.3.3_CA-24 showing the mass balance table provided in the study report. On the basis of these results it can be stated that in the experiment on Lysimeter #17 it was possible to recover 44.38% of the applied radioactivity, most of it – 42.33% AR in the soil monolith, 1.56% AR in leachates and the remaining amount – 0.48% AR, in plant material collected from the lysimeter. The lost radioactivity – 55.62% AR was attributed to the ¹⁴CO₂ and, possibly other volatile compounds formed in soil and then escaped to the air compartment, what indicates substantial level of mineralisation of the test compound.

In case of Lysimeter #18 it was possible to recover 55.18% of the applied radioactivity, most of it – 52.96% AR in the soil monolith, 1.72% AR in leachates and the remaining amount – 0.50% AR, in plant material collected from the lysimeter. The lost radioactivity – 44.82% AR was attributed to the ¹⁴CO₂ and, possibly other volatile compounds formed in soil and then escaped to the air compartment, what also indicates substantial level of mineralisation of the test compound.

It was not however explained why the proportions of the radioactivity recovered from the system and that lost were reversed in the Lysimeter #18 in comparison to Lysimeter #17, bearing in mind that the experimental conditions were the same for both lysimeters and other obtained results were quite similar.

Figure B.8.1.3.3._CA-24 The results of the determination of mass balance, as presented in the study (table copied from the study report)

Conclusions:

The results of the examination of the leaching behaviour of Flufenacet through two undisturbed soil profiles (two lysimeters filled with soil monoliths consisting of Sandy loam-Loamy sand soil, having pH in range 6.05 – 6.63 and OC content in the top 30-cm layer of 1.41%) during three consecutive years showed that:

- in case of Lysimeter #17 44.38% of radioactivity applied as [¹⁴C]-Flufenacet was recovered, of which 42.33% AR in soil monolith, 1.56% AR in leachates and 0.48% in collected plant material; the lost 55.62% AR was attributed to the ¹⁴CO₂ formed in soil and escaped from there, hence it was stated that such would be the level of the total mineralisation of the test compound;
- in case of Lysimeter #18 55.18% of radioactivity applied as [¹⁴C]-Flufenacet was recovered, of which 52.96% AR in soil monolith, 1.72% AR in leachates and 0.50% in collected plant material; the lost 44.82% AR was attributed to the ¹⁴CO₂ formed in soil and escaped from there, hence it was stated that such would be the level of the total mineralisation of the test compound.

In case of the Lysimeter #18

Of the radioactivity recovered within Lysimeter #17 in leachates – 1.56% AR in total, 1.436% AR was recovered in the 1st year annual leachate, 0.122% AR in the 2nd year annual leachate and only 0.006% AR in 3rd year annual leachate. That corresponded to:

- in the 1st year annual leachate to 2.380 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 5.31% was ¹⁴CO₂-associated radioactivity, and to 2.26 [µg a. i. equivalent/L] acidic TRR subsequently profiled using TLC;
- in the 2nd year annual leachate to 0.221 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 17.06% was ¹⁴CO₂-associated radioactivity, and to 0.19 [µg a. i. equivalent/L] acidic TRR subsequently profiled using TLC;
- in the 3rd year annual leachate to 0.239 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 35.22% was ¹⁴CO₂-associated radioactivity, and to 0.15 [µg a. i. equivalent/L] acidic TRR not profiled;
- on average in annual leachate to 1.310 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 6.28% was ¹⁴CO₂-associated radioactivity, and to 1.25 [µg a. i. equivalent/L] acidic TRR.

Of the radioactivity recovered within Lysimeter #18 in leachates – 1.72% AR in total, 1.563% AR was recovered in the 1st year annual leachate, 0.150% AR in the 2nd year annual leachate and only 0.007% AR in 3rd year annual leachate. That corresponded to:

- in the 1st year annual leachate to 2.699 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 5.35% was ¹⁴CO₂-associated radioactivity, and to 2.56 [µg a. i. equivalent/L] acidic TRR subsequently profiled using TLC;
- in the 2nd year annual leachate to 0.269 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 23.02% was ¹⁴CO₂-associated radioactivity, and to 0.22 [µg a. i. equivalent/L] acidic TRR subsequently profiled using TLC;
- in the 3rd year annual leachate to 0.238 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 40.88% was ¹⁴CO₂-associated radioactivity, and to 0.14 [µg a. i. equivalent/L] acidic TRR not profiled;
- on average in annual leachate to 1.492 [µg a. i. equivalent/L] total (alkaline) TRR (TRR = Total Radioactivity Recovered), of which 6.85% was ¹⁴CO₂-associated radioactivity, and to 1.38 [µg a. i. equivalent/L] acidic TRR.

The TLC profiling of the leachates (acidic TRR) led to the identification of its following constituents: Flufenacet, FOE Alcohol, FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide (FOE TGS). The quantitative analysis gave the following results:

- for Lysimeter #17:
 - the 1st year annual leachate contained 0.004 [µg/L] of Flufenacet, 0.034 [µg/L] of FOE Alcohol, 0.017 [µg/L] of FOE Oxalate, 1.355 [µg/L] of FOE Sulfonic acid, 0.030 [µg/L] of FOE TGS and 0.035 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - the 2nd year annual leachate contained 0.002 [µg/L] of Flufenacet, 0.001 [µg/L] of FOE Alcohol, 0.009 [µg/L] of FOE Oxalate, 0.013 [µg/L] of FOE Sulfonic acid, 0.022 [µg/L] of FOE TGS and 0.007 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - the 3rd year leachate was not profiled.
- for Lysimeter #18
 - the 1st year annual leachate contained 0.005 [µg/L] of Flufenacet, 0.016 [µg/L] of FOE Alcohol, 0.006 [µg/L] of FOE Oxalate, 1.616 [µg/L] of FOE Sulfonic acid, 0.027 [µg/L] of FOE TGS and 0.045 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - the 2nd year annual leachate contained 0.005 [µg/L] of Flufenacet, 0.004 [µg/L] of FOE Alcohol, 0.006 [µg/L] of FOE Oxalate, 0.016 [µg/L] of FOE Sulfonic acid, 0.019 [µg/L] of FOE TGS and 0.008 [µg a. i. equivalent/L] of the “Unknown” fraction;
 - the 3rd year leachate was not profiled.

The radioactivity determined in the soil monoliths was on the level:

- for Lysimeter #17: 42.33% AR, of which 37.80% AR in the top 30 cm, 2.46% AR in the next 30-60cm layer and the remaining ~2.00% AR below that depth, the content of radioactivity decreased with depth being highest – 27.26% AR in the top 10-cm section, and below 40 cm not surpassing 1% AR in any of the 10-cm sections;
- for Lysimeter #18: 52.96% AR, of which ~48.2% AR in the top 30 cm, ~3.1% AR in the next 30-60cm layer and the remaining ~1.7% AR below that depth, the content of radioactivity decreased with depth being highest - ~35% AR in the top 10-cm section, and below 40 cm not surpassing 1% AR in any of the 10-cm sections.

The profiling of radioactivity in soil extracts from samples taken from 0-30 cm layer resulted in identification of four compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid. The RMS calculated their concentrations in that layer using the sumarily weight of soil (Fresh Weight, further denominated FW) within that layer, being 418.40 kg for Lysimeter #17 and 498.71 kg for Lysimeter #18.

The determined amounts and corresponding concentrations of the identified compound were following:

- for Lysimeter #17: content of Flufenacet was 450.75 µg and its concentration 1.07 [µg/kg soil FW], content of FOE Alcohol was 60.09 µg and its concentration 0.14 [µg/kg soil FW], content of FOE Oxalate was 28.23 µg and its concentration 0.07 [µg/kg soil FW], content of FOE Sulfonic acid was 45.74 µg and its concentration 0.11 [µg/kg soil FW];
- for Lysimeter #18: content of Flufenacet was 528.48 µg and its concentration 1.06 [µg/kg soil FW], content of FOE Alcohol was 87.67 µg and its concentration 0.18 [µg/kg soil FW], content of FOE Oxalate was 63.74 µg and its concentration 0.13 [µg/kg soil FW], content of FOE Sulfonic acid was 43.42 µg and its concentration 0.09 [µg/kg soil FW].

It may be stated that of all the compounds possible to be identified as originating from Flufenacet radiolabelled in fluorophenyl ring (including Flufenacet itself) only FOE Sulfonic acid was demonstrated to be found in leachates in amounts > 0.1 µg/L, although only in the 1st-year leachates (individual and annual) and not in the 2nd-year one, what confirmed the risk to GW associated to that degradation product demonstrated in GW model exposure assessment (for details please refer to the results of calculations presented under the point B.8.5 in the Vol. 3-CP, B.8 of this Renewal Assessment Report).

Neither Flufenacet nor the second major soil degradation product relevant for that radiolabelling position – FOE Oxalate, were detected in leachates in amounts > 0.1 µg/L, what may indicate that they would not pose a threat to the GW compartment.

In soil and leachates FOE Alcohol was detected – the compound determined in the studies examining the route of degradation of Flufenacet in aerobic soil to be minor/transient and therefore not taken into account in the GW model exposure assessment. It shall be indicated however that the would-be risk it may pose to the GW compartment was covered by the calculations carried out for FOE Oxalate – its immediate degradate.

Also detected in leachates was FOE Thioglycolate sulfoxide (FOE TGS), the compound not taken in the model GW exposure assessment into consideration, being identified as minor soil degradation product. It shall be indicated however, that in the study it was determined in leachates in amounts <0.1 µg/L, what may indicate that it would not pose a serious threat to the GW compartment.

Finally, it shall be indicated that, due to the fact that in the study was used Flufenacet radiolabelled only in the fluorophenyl ring, the study gave no information of the laching potential of the degradation products formed from the second moiety present within the molecule of Flufenacet – thiadiazole.

The comparative analysis of the application pattern (crops, application timing and application rates) used in the study and the EU-representative application pattern proposed for the current authorisation of Flufenacet in the EU showed that the study may be considered as providing supplementary information with regard to the risk posed by Flufenacet and its soil degradation products to the GW compartment, but for the purpose of the decision making should be considered with care.

Study 2a:

Report: Report: Hellpointner E., (1995): “Lysimeter study on the translocation of *FOE 5043* into the subsoil after use as pre-emergence herbicide in a maize/winter wheat crop rotation. 1st year of study.”; Bayer AG, Agrochemical Division, Development, Institute for Metabolism Research and Residue analysis; D-51368 Leverkusen, Germany; report No. PF-4025 (107688); 09 January 1995; study reference number M-002194-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Testing of Plant Protection Products in Registration Procedure, Part IV, 43- (February 1990) – “Lysimeter tests for the translocation of plant protection products into the subsoil.”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.2.4.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. RMS re-evaluated the study and found it acceptable. It was noticed however, that this is an interim report presenting a part of the results presented in summarised above, as **Study 2**, final report of the same study. RMS compared both reports and stated that they contained the same results, in case of this report limited however to one, 1st, year. Therefore it was not necessary to summarise this study and such summary was not provided in order not to overburden the Renewal Assessment Report. However the RMS used some of its parts, in particular some figures, in cases they were more clear/better looking than the analogical figures in the full report.

Summary:

The study report was not summarised because it contained the same data as summarised above, as **Study 2**, full-study report.

Study 3:

Report: Schäfer H., (2000): “Comparison of Results of Lysimeter Studies with PEC_{GW} Values Obtained with Simulation Model PESTLA.”; Bayer AG, Crop Protection Business Group, Institute for Metabolism Research and Residue Analysis, 51368 Leverkusen, Germany; report No. MR-378/00; 2000. 08. 14.; study reference number M-060287-01-1;

Guidelines: The study was not declared to be performed in line with any Guidelines. It was however declared to follow the procedures used the Dutch registration process.

GLP: No (modelling study);

RMS comments: This is a newly submitted study, not previously submitted for the evaluation of Flufenacet at the EU level. However, it was probably used to support the registration of the plant protection products containing Flufenacet in The Netherlands, because it contains several references to the Dutch registration process. RMS evaluated the study and stated that its utility in the EU-evaluation procedure is limited for the following reasons:

- the tool used in calculation was PESTLA ver 3.3, the tool not recommended by FOCUS;
- the pedo-climatic scenario used in calculations was the “Dutch standard scenario”, probably then representative for the local Dutch conditions, so of limited relevance for the EU as a whole;
- the application pattern used in calculations was not defined at all;
- of the substance-specific parameters used in calculations only the average DT_{50} and K_{OM} values were reported, and these changed as a result of the currently performed evaluation;

Therefore RMS stated that although some MS states may still find the report relevant for the purpose of their national registration, it cannot be considered such for the purpose of the renewal of authorisation in the EU. For that reason RMS decided not to summarise it in order not to overburden the Assessment Report. The report was also not included in the list of references relied upon nor its findings used in the List of Endpoints.

Summary:

Study was not summarised for the reasons listed above.

Lysimeter studies – a summary:

The leaching behaviour of Flufenacet and its degradation products through the undisturbed soil profiles under the agronomic and climatic conditions relevant for Germany was examined on four outdoor lysimeters. The results of that examination were presented in two study reports submitted by the Applicant for the purpose of the current evaluation. Additionally the Applicant submitted the interim reports of the same experiments, not summarised in the Renewal Assessment Report for Flufenacet, but analysed for their compliance with the adequate final reports. The third study submitted for evaluation was aimed on the validation of the lysimeter studies by comparing their results with those of the modelling exposure assessment carried out for the GW compartment. RMS however decided not to use it, as the modelling tools and scenarios were not those recommended by FOCUS.

The key data and results obtained in the two studies are summarily presented below in tables B.8.1.3.3._CA-28 – B.8.1.3.3._CA-28c. Additionally RMS decided to present the key results in the format recommended for reporting the data in the EU List of EndPoints.

Table B.8.1.3.3._CA-28: The key data and results obtained in the outdoor lysimeter studies.

Footnotes to the table:

1) Abbreviations used: FOE SA – FOE Sulfonic acid.

It may be stated that of all the compounds possible to be identified as originating from Flufenacet radiolabelled in fluorophenyl ring (including Flufenacet itself) only FOE Sulfonic acid was demonstrated to be found in leachates in amounts > 0.1 µg/L, what conformed the risk to GW associated to that degradation product demonstrated in GW model exposure assessment (for details please refer to the results of calculations presented under the point B.8.5 in the Vol. 3-CP, B.8 of this Renewal Assessment Report).

Neither Flufenacet nor the second major soil degradation product relevant for that radiolabelling position – FOE Oxalate, were detected in leachates in amounts > 0.1 µg/L, what may indicate that they would not pose a threat to the GW compartment.

In soil and leachates FOE Alcohol was detected – the compound determined in the studies examining the route of degradation of Flufenacet in aerobic soil to be minor/transient and therefore not taken into account in the GW model exposure assessment. It shall be indicated however that the would-be risk it may pose to the GW compartment was covered by the calculations carried out for FOE Oxalate – its immediate degradate.

Also detected in leachates was FOE Thioglycolate sulfoxide (FOE TGS), the compound not taken in the model GW exposure assessment into consideration, being identified as minor soil degradation product. It shall be indicated however, that in the study it was determined in leachates in amounts <0.1 µg/L, what may indicate that it would not pose a serious threat to the GW compartment.

Finally, it shall be indicated that, due to the fact that in the experiments was used Flufenacet radiolabelled only in the fluorophenyl ring, they gave no information of the laching potential of the degradation products formed from the second moiety present within the molecule of Flufenacet – thiadiazole.

The comparative analysis of the application pattern (crops, application timing and application rates) used in the experiments and the EU-representative application pattern proposed for the current authorisation of Flufenacet in the EU showed that they may be considered as providing supplementary information with regard to the risk posed by Flufenacet and its soil degradation products to the GW compartment, but for the purpose of the decision making should be considered with care.

Lysimeter / field leaching studies (Regulation (EU) N° 283/2013, Annex Part A, points 7.1.4.2 / 7.1.4.3 and Regulation (EU) N° 284/2013, Annex Part A, points 9.1.2.2 / 9.1.2.3)

Lysimeter/ field leaching studies *Lysimeter #15*

Location: *Experimental lysimeter farm of BAYER AG, Monheim NRW, Germany; 51° 4' N, 6°55' E;*

Study type (e.g. lysimeter, field): *outdoor lysimeter*

Soil properties: *topsoil layer 0 – 30 cm texture: Sandy loam, pH = 7.04, OC= 1.41%, WHC = 32.45 [vol % H₂O] – Field Capacity*

Dates of application : *10/05/1993 – 1st application; 05/05/1994 – 2nd application;*

Crop : */Interception estimated: Grain maize (corn) – 1st, target crop, CI = 0%; Grain maize (corn) – 2nd, target crop, CI = 0%; Sugar beet, 3rd, succeeding, crop, CI not required;*

Number of applications: **2 years (+ one without application), 1 application per year**

Duration. *3 years*

Application rate: **480 g/ha – 1st and 2nd application**

Average annual rainfall (mm): **745 mm** (*long-term value covering period 1966–1995*); *1st experimental year precipitation (rainfall + irrigation): 943.1 mm, 2nd experimental year precipitation (rainfall + irrigation): 914.2 mm, 3rd experimental year precipitation (rainfall + irrigation): 600.1 mm; total: 2457 mm*

Average annual leachate volume (mm): *Volume of leachate collected (total): 1st experimental year: 349.8 L, 2nd experimental year: 317.6 L, 3rd experimental year: 13.0 L, total volume collected: 680.4 L*

% radioactivity in leachate (maximum/year): *1st experimental year: 0.772% AR, 2nd experimental year: 0.250% AR, 3rd experimental year: 0.006% AR, total: 0.64% AR*

Individual annual maximum concentrations (e.g. 1st, 2nd, 3rd yr): *1st experimental year (leachate collected on week 37): total TRR 2.350 [µg a. i. equivalents/L], acidic TRR 2.228 [µg a. i. equivalents/L], ¹⁴CO₂-associated radioactivity 5.19 [% total TRR], Flufenacet ≤0.007 [µg/L], FOE Alcohol 0.001 [µg/L], FOE Oxalate 0.007 [µg/L], FOE Sulfonic acid 1.293 [µg/L], FOE Thioglycolate sulfoxide 0.079 [µg/L] Unidentified radioactivity, no of components: 1, 0.052 µg/L parent equivalents.*

Individual annual average concentrations (e.g. 1st, 2nd, 3rd yr): *1st experimental year annual leachate: total TRR 1.062 [µg a. i. equivalents/L], acidic TRR 0.99 [µg a. i. equivalents/L], ¹⁴CO₂-associated radioactivity 6.47 [% total TRR], Flufenacet 0.020 [µg/L], FOE Alcohol <0.002 [µg/L], FOE Oxalate 0.015 [µg/L], FOE Sulfonic acid 0.589 [µg/L], FOE Thioglycolate sulfoxide 0.016 [µg/L] Unidentified radioactivity, no of components: 1, 0.030 µg/L parent equivalents.*

2nd experimental year annual leachate: total TRR 0.758 [µg a. i. equivalents/L], acidic TRR 0.670 [µg a. i. equivalents/L], ¹⁴CO₂-associated radioactivity 11.10 [% total TRR], Flufenacet 0.003 [µg/L], FOE Alcohol 0.003 [µg/L], FOE Oxalate <0.018 [µg/L], FOE Sulfonic acid 0.235 [µg/L], FOE Thioglycolate sulfoxide 0.020 [µg/L] Unidentified radioactivity, no of components: 1, 0.037 µg/L parent equivalents.

3rd experimental year annual leachate: total TRR 0.432 [µg a. i. equivalents/L], acidic TRR 0.334 [µg a. i. equivalents/L], ¹⁴CO₂-associated radioactivity 22.80 [% total TRR], FOE Sulfonic acid ≤0.25 [µg/L], Unidentified radioactivity: no data.

average annual leachate: total TRR 0.906 [µg a. i. equivalents/L], acidic TRR 0.83 [µg a. i. equivalents/L], ¹⁴CO₂-associated radioactivity 8.42 [% total TRR],

Amount of radioactivity in the soils at the end of the study = *total 43.16 % AR, in top 0-30cm layer 40.289% AR, in 30-60 cm layer 2.095% AR, below 60 cm 0.777% AR, identified in the top 30-cm layer: Flufenacet 1860.96 [µg] (concentration 3.91 [µg/kg]), FOE Alcohol 143.49 [µg] (concentration 0.30 [µg/kg]), FOE Oxalate 212.84 [µg] (concentration 0.45 [µg/kg]), FOE*

B.8.1.3.4. – Other studies

The Applicant has submitted four study reports presenting the results of the determination of the Plant Uptake Factor – PUF. Two of them are GLP studies, one is a non-GLP study and one is a position paper prepared in support of the findings of one of the studies.

As these reports present the results related to the mobility in soil RMS decided to present them in the Renewal Assessment Report under that data point as “Other studies”. That was done in line with how they were listed in the Document L submitted by the Applicant.

Study 1:

Report: Schmeling S., Bongartz R., (2012): “Determination of the Plant Uptake Factor of FOE Methylsulfone, FOE Sulfonic acid and Trifluoroethanesulfonic acid in Wheat.”; Bayer Crop Science AG, Development-Environmental Safety-Metabolism/ADME and Environmental Fate, 40789 Monheim am Rhein, Germany; Study ID: M9992073-9, Report No. EnSa-12-260; 2012. 06. 28, updated with Amendment No. 1 on 2013. 02. 19; study reference number: M-434257-02-1;

Guidelines: The study was not declared to be performed in line with any specific Guidelines.

GLP: Yes;

RMS comments: This is a newly submitted study, submitted to provide the values required as input parameters in GW and SW modelling exposure assessment. It does not follow any specific Guideline due to the lack of such. RMS evaluated it for the purpose of the current assessment and found acceptable. It is summarised below.

Summary:

The aim of the study was to determine the plant uptake factors – PUF, for three major soil degradation products of Flufenacet – FOE Sulfonic acid, FOE Methylsulfone and FOE 5043-Trifluoroethanesulfonic acid, in wheat.

The test compounds were:

- FOE Sulfonic acid in form of Na⁺ salt, having a chemical purity 87.6%, delivered as a white powder;
- FOE Methylsulfone, having a chemical purity of 97.2%, delivered as a light yellow powder;
- FOE 5043-Trifluoroethanesulfonic acid in form of Na⁺ salt, having a chemical purity of 99.4%, delivered as a white solid.

They were used to prepare stock solutions having a concentration:

- 120 mg/L for FOE Sulfonic acid,
- 24.5 mg/L for FOE Methylsulfone,
- 52.5 mg/L for FOE 5043-Trifluoroethanesulfonic acid.

The test plant used in the experiment was Wheat, variety Thasos, pre-grown on artificial substrate – vermiculite and the nutrient solution, prepared from a commercial fertiliser solution WUXAL TOP K, characterised below in the table B.8.1.3.4._CA-1, with water to obtain a solution having concentration 0.2%. That was done by adding 7 mL of the fertiliser to 3493 mL of water. The same nutrient solution was used in determination of PUF, to prepare the test solution for each test compound. That was done by adding 1 mL of the respective stock solution to 3500 mL of the nutrient solution to obtain the following concentrations:

- 30 µg/L for FOE Sulfonic acid,
- 7 µg/L for FOE Methylsulfone,
- 15 µg/L for FOE 5043-trifluoroethanesulfonic acid.

The test solutions were prepared individually for each test compound. The concentrations of the given test compound in the relevant test solution were determined by HPLC-MS/MS.

Table B.8.1.3.4._CA-1: The composition of the fertiliser solution “WUXAL TOP K” used to prepare the nutrient solution.

Constituent ¹⁾		Constituent's concentration	
Common name	Formula	[g/L]	[%]
Urea	CH ₄ NO	50.0	4.0
Sodium nitrate	NaNO ₃	12.5	1.0
Phosphoric anhydride	P ₂ O ₅	100.0	8.0
Potassium oxide	K ₂ O	150.0	12.0
Boric acid	B (OH) ₃	0.124	0.01
Copper (EDTA chelate)	Cu	0.049	0.04
Iron (EDTA Chelate)	Fe	0.248	0.02
Manganese (EDTA Chelate)	Mn	0.148	0.012
Molybdenum	Mo	0.012	0.001
Zinc (EDTA Chelate)	Zn	0.049	0.004

Footnotes to the table:

1) Common name and formula of each constituent as presented in the study report, probably taken from the product's label;

The plants were pre-grown in the greenhouse in the conditions similar to the natural conditions of Central Europe: daily temperature $T = 18 - 21^{\circ}\text{C}$, relative humidity of 60% and light conditions – artificial light having intensity of at least 35 kLux from 6 am to 8 pm, until reaching the growth phase BBCH 15. At reaching that stage wheat plants were washed and transferred to brown 1-L glass bottles containing 800 mL of the test solution spiked with the given test compound. The number of the individual plants per bottle was ten. Plants were fixed in the bottle with elastomer foam. Then the bottles were wrapped in aluminium foil to prevent lossess of liquid due to evaporation.

For each test solution four bottles were prepared – three test sample bottles containing the equal number of plants (ten), and one without plants, serving as a control.

The bottles were placed in the greenhouse and kept there for eight days in the same conditions as described above for pre-growing of the test plants.

At pre-defined sampling points – DAT 0 (0 h after the experiment started), DAT 0.15 (4 hours after the experiment started), DAT 1, DAT 4 and DAT 8, single 1-mL samples of liquid were taken from each bottle (test samples and control) for determination of the content of test compound.

At the beginning of the experiment – on DAT 0, and on its end DAT 8, the volume of the test solution in each bottle was determined.

The analysis of the concentration of each test compound in the solution sampled from the given test bottle was performed by HPLC-MS/MS.

The chromatographic analysis was performed using Agilent HP 1200 chromatographic station coupled with Finnigan TQS Vantage MS/MS detector. The chromatographic separation was performed on Nucleodur C8 Gravity 50 • 2 mm, 5 µm chromatographic column working in a gradient mode, placed in chromatographic oven set to the constant temperature $T = 40^{\circ}\text{C}$.

The parameters of chromatographic analysis were following:

- **elution mode:** gradient;
- **composition of the mobile phase:**
 - **Solvent A:** 0.1% HCOOH in water
 - **Solvent B:** 0.1% HCOOH in CH₃CN
- **gradient mode:** individual for each analysed compound, presented in the tabler B.8.1.3.4._CA-2;
- **injection volume:** 5 µL for samples containing FOE Sulfonic acid or FOE Methylsulfone, 20 µL for samples containing FOE 5043-Trifluoroethanesulfonic acid;
- **flow rate:** 0.3 mL/min;
- **elution time:** 6 min.

Table B.8.1.3.4._CA-2: Gradient mode used in the study for each analysed compound.

Gradient mode for:								
FOE Sulfonic acid			FOE Methylsulfone			FOE 5043-Trifluoroethanesulfonic acid		
Time	Composition of mobile phase		Time	Composition of mobile phase		Time	Composition of mobile phase	
	% Solvent A	% Solvent B		% Solvent A	% Solvent B		% Solvent A	% Solvent B
0	95	5	0	80	20	0	100	0
1	95	5	1	80	20	3	100	0
2	50	50	2	60	40	5	80	80
5	40	60	5	40	60	6	5	95
6	5	95	6	5	95			

The key parameters of MS/MS analysis for each test compound are presented below in the table B.8.1.3.4._CA-3.

Table B.8.1.3.4._CA-3: The parameters of MS/MS analysis used in the study.

MS/MS parameters	Compound		
	FOE Sulfonic acid	FOE Methylsulfone	FOE 5043-Trifluoroethanesulfonic acid
Q1 Mass [amu]	276.1	274.1	163.0
Q3 Mass [amu]	234.1	232.1	143.0
Ionisation mode	ESI positive	ESI positive	ESI negative
Ion spray voltage [V]	3000	3000	3000
Collision energy [eV]	15	14	15
Collision gas pressure [mTorr]	1.5	1.5	1.5
Vapouriser temp [°C]	60	60	60
Capillary temp. [°C]	280	280	280

The identification of the test compounds in chromatograms was performed by means of the retention time, which were following:

- for FOE Sulfonic acid $R_t \approx 3.4$ min.;
- for FOE Methylsulfone $R_t \approx 3.5$ min.;
- for FOE 5043-Trifluoroethanesulfonic acid $R_t \approx 1.3$ min.

It was confirmed by the results of MS/MS analysis. The quantitative analysis was carried out using the calibration curves constructed for each of the test compound.

The calculations of PUF were carried out using the equation presented below on figure B.8.1.3.4._CA-1.

$$PUF = \frac{\ln(m_{day0} / m_{day8})}{\ln(V_{day0} / V_{day8})}$$

Legend:

m_{day0} = initial mass of test compound / 800 mL test solution [µg]

m_{day8} = mass of test compound in the test solution after 8 days [µg]

V_{day0} = initial volume of test solution (default 800 mL) [L]

V_{day8} = volume of test solution after 8 days [L]

Figure B.8.1.3.4._CA-1: The equation used to calculate PUF (copied from the study report).

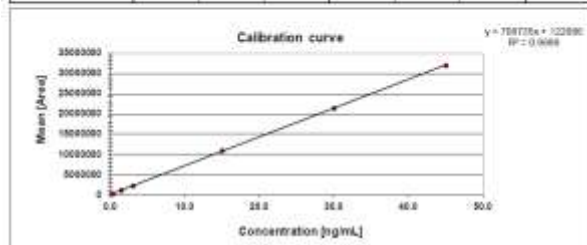

Results and their discussion:

The calibration curves used in the experiment for the quantitative analysis of each of the test compounds are presented below on figure B.8.1.3.4._CA-2.

Figure B.8.1.3.4_CA-2: The calibration curves used in the study (copied from the study report).

The initial concentrations of the test compounds in the test solutions were following:

- for FOE Sulfonic acid: 34.44 µg/L;
- for FOE Methylsulfone: 7.86 µg/L;
- for FOE 5043-trifluoroethanesulfonic acid: 15.89 µg/L.

The results of the determination of the volume of the solution at the beginning and the end of experiment for the test with each test compound are presented below in the table B.8.1.3.4_CA-4. In case of the control samples, containing no plants, the changes of the volume were attributed to the losses that resulted from sampling during incubation.

Table B.8.1.3.4._CA-4: The results of the determination of the volume of solution during incubation and its changes.

Sample characteristics			Determined volume [L]		
Test compound	Type of sample	Replicate	Day 0 – V_{day0}	Day 8 – V_{day0}	Amount uptaken by plants – V_{uptake}
FOE Sulfonic acid	Test sample	1	0.80	0.66	0.14
	Test sample	2	0.80	0.67	0.13

Study 2:

Report: Bongartz R., (2013): “Determination of the Plant Uptake Factor of Trifluoroacetic acid (TFA) in Wheat.”; Bayer Crop Science AG, BCS-D-EnSA-Testing, Monheim, Germany; Study ID: M9992182-0, Report No. EnSa-13-0357; 2013. 06. 05, updated with Amendment No. 1 on 2013. 06. 24 and with Amendment No. 2 on 2013. 07. 25; study reference number: M-456754-03-1.

Guidelines: The study was not performed in line with any specific Guidelines.

GLP: Yes;

RMS comments: This is a newly submitted study, submitted to provide the values required as input parameters in GW and SW modelling exposure assessment. It does not follow any specific Guideline due to the lack of such. RMS evaluated it for the purpose of the current assessment and found acceptable. It is summarised below.

Summary:

The aim of the study was to determine the plant uptake factor – PUF, for a major soil degradation product of Flufenacet – Trifluoroacetic acid (TFA).

The test compounds was Trifluoroacetic acid (TFA), in form of its Na⁺ salt, radiolabelled in C1 position, as shown below on figure B.8.1.3.4._CA-3. It had radiochemical purity of ≥ 98% and specific activity of 4.08 MBq/mg. To the test facility it was delivered as a solid dried under vacuum.

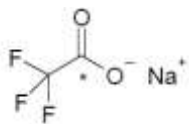

Figure B.8.1.3.4._CA-3: The structural formula of the radiolabelled test compound used in the experiment. The radiolabelling position is indicated by an asterisk – (*)
(copied from the study report).

It was used to prepare the stock solution having a concentration 13.32 µg/mL and specific radioactivity 54.34 kBq/mL, by dissolving its appropriate amount in 100 mL of ultrapure (Milli-Q) water. The stock solution was subsequently used to fortify the test solution to obtain the intended concentration of 70 µg TFA/L. The test solution was a buffer solution consisting of 0.01M 2-morpholino-ethanesulfonic acid (MES) and 0.01M CaCl₂ adjusted to pH = 6.5 with appropriate amount of NaOH_{aq}. 24 mL of the characterised above stock solution of TFA was added to 4.5 L of that buffer solution to obtain the intended concentration of TFA of 70 µg/L.

The test plant used in the experiment was Wheat, variety Thasos, pre-grown in soil until reaching the growth phase BBCH = 15 (five unfolded leaves). The plants were pre-grown in the greenhouse in the conditions similar to the natural conditions of Central Europe: daily temperature T = ~20°C, relative humidity of 60 – 75% and light conditions – artificial light having intensity of at least 35 kLux from 6 am to 8 pm. At reaching the pre-designated growth stage – BBCH 15, wheat plants were removed from growing pots, soil from their root systems was removed by washing with water, and they were transferred to brown 1-L glass bottles containing 800 mL of the test solution spiked with the test compound. The number of the individual plants per bottle was ten. Plants were fixed in the bottle with elastomer foam. Then the bottles were wrapped in aluminium foil to prevent loss of liquid due to evaporation.

Five bottles containing the test solution and equal number of plants (ten) were prepared. Additionally, in the same way, were prepared two bottles containing test plants and buffer solution without test compound. These were used as a control to examine the water uptake by the test plants.

The bottles were placed in the greenhouse and kept there for eight days in the same conditions as described above for pre-growing of the test plants.

At pre-defined sampling points – DAT 0 (0 h after the experiment started), DAT 2, DAT 5 and DAT 8, three 1-mL samples of liquid were taken from each bottle (test samples and control) for determination of the radioactivity content in solution using LSC.

At the beginning of the experiment – on DAT 0, and on its end DAT 8, the volume of the test solution in each bottle was determined.

At the end of the experiment the plant roots from each jar were washed with 200 mL of CH₃CN/H₂O (1:1) solution. The volume of that solution was determined, after what the radioactivity content in it measured using LSC.

Finally, the plants from each jar were weighed, homogenized and combusted to determine the amount of uptaken TFA. That was done by measuring by LSC the amount of ¹⁴CO₂ generated during combustion.

The LSC analysis of liquid samples was carried out using either LKB/Wallac 1219 Spectral scintillation counter or Beckman LS 6500 scintillation counter. The mean measurement efficiency was 89.5%. The counting lasted from few seconds up to 20 minutes. To analyse stock solution of the test compound its 0.020 mL aliquots were mixed with 2 mL of Quicksafe A + 5% water scintillation cocktail. To analyse test solutions their 1-mL samples were mixed with 7 mL of Quicksafe A + 5% water scintillation cocktail.

In case of solid samples the generated ¹⁴CO₂ was absorbed in Oxysolve C400 scintillation cocktail and analysed using LKB/Wallac 1219 Spectral scintillation counter.

Two other analytical methods used in the experiment were radio- HPLC and HPLC-MS. The radio-HPLC was used for checking purity and stability of the test compound – TFA, in stock solution as well as in the DAT-8 test. In the study report it was not specified which samples were analysed using HPLC–MS method.

The radio-HPLC analysis was performed using Agilent HP 1110 chromatographic station equipped with autosampler, gradient pump, chromatographic column oven set to T = 40°C and UV-DAD detector set to λ = 254 nm, coupled with a flow-through Ramona Star radioactivity detector. The chromatographic separation was performed on LiChroCART 250 • 4.6 mm, 5 µm chromatographic column.

The parameters of chromatographic analysis were following:

- **elution mode:** gradient;
- **composition of the mobile phase:**
 - **Solvent A:** HCOOH in water 1:99 (v/v)
 - **Solvent B:** HCOOH in CH₃CN 1:99 (v/v)
- **gradient mode:** presented in the table B.8.1.3.4._CA-7;
- **flow rate:** 1.0 mL/min;
- **elution time:** 70min.

Table B.8.1.3.4._CA-7: Gradient mode used in the study.

Elution time [min]		0	5	55	60	61	70
Composition of mobile phase	% A	100	100	0	0	100	100
	% B	0	0	100	100	0	0

The calculations of PUF were carried out using the equation presented below on figure B.8.1.3.4._CA-4.

$$PUF = \frac{\ln((m_{final} + m_{wash}) / m_{day0})}{\ln(V_{final} / V_{day0})}$$

Legend:
 m_{day0} = initial mass of test compound / 800 mL test solution [µg]
 m_{final} = mass of test compound in the test solution after 8 days [µg]
 m_{wash} = mass of test compound in the wash solution [µg]
 V_{day0} = initial volume of test solution (default 800 mL) [L]
 V_{final} = volume of test solution after 8 days [L]

Figure B.8.1.3.4._CA-4: The equation used to calculate PUF (copied from the study report).

Results and their discussion:

The mean initial concentration of the test compound in the test solution was 75.6 µg/L. Its purity in the stock solution was demonstrated to be 100%. It was demonstrated to be stable within the whole experimental period lasting 8 days.

The results of the determination of the volume of the solution at the beginning and the end of the experiment are presented below in the table B.8.1.3.4._CA-8. The control samples, used to examine the volume of the solution taken by test plants, were blank (not containing the test compound).

Table B.8.1.3.4._CA-8: The results of the determination of the volume of solution during incubation and its changes.

Sample characteristics			Determined volume [L]		
Test compound	Type of sample	Replicate	Day 0 – V_{day0}	Day 8 – V_{day0}	Amount uptaken by plants – V_{uptake}
Trifluoroacetic acid	Test sample	1	0.800	0.260	0.540
	Test sample	2	0.800	0.270	0.530
	Test sample	3	0.800	0.420	0.380
	Test sample	4	0.800	0.280	0.520
	Test sample	5	0.800	0.370	0.430
	Control	1	0.800	0.440	0.360
	Control	2	0.800	0.450	0.350

The results of the determination of concentration of TFA in the solution are presented below in the table B.8.1.3.4._CA-9.

Table B.8.1.3.4._CA-9: The results of the determination of the concentration of TFA in solution during the experiment.

Sampling time	Type of sample		Volume of sample [mL]	Concentration of TFA in solution [$\mu\text{g/L}$]	Mass of TFA in solution [μg]

Study 3:

Report: Bongartz R., (2013): “Determination of the Plant Uptake Factor of Trifluoroacetic acid (TFA) in Wheat, Corn and Tomatoes.”; Bayer Crop Science AG, BCS-D-EnSA-Testing, Monheim, Germany; Study ID: M9992182-0, Report No. EnSa-12-0581; 2012. 10. 18; study reference number M-440106-01-1.

Guidelines: The study was not performed in line with any specific Guidelines.

GLP: No;

RMS comments: This is a newly submitted study, submitted to provide the values required as input parameters in GW and SW modelling exposure assessment. It does not follow any specific Guideline due to the lack of such. RMS evaluated it for the purpose of the current assessment and found acceptable, although, being a non-GLP study it can be considered only as a supplementary study. It is summarised below.

Summary:

The aim of the study was to determine the plant uptake factor – PUF, for a major soil degradation product of Flufenacet – Trifluoroacetic acid (TFA).

The test compounds was Trifluoroacetic acid (TFA), in form of Na^+ salt, radiolabelled in C1 position, as shown below on figure B.8.1.3.4._CA-5. It had radiochemical purity of $\geq 98\%$ and specific activity of 3.48 MBq/mg. To the test facility it was delivered as a solid dried under vacuum.

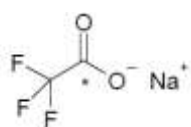

Figure B.8.1.3.4._CA-5: The structural formula of the radiolabelled test compound used in the experiment. The radiolabelling position is indicated by an asterisk – (*)
(copied from the study report).

It was used to prepare two stock solutions. One of them, labelled VG0105D1, had a concentration 1.060 mg TFA/mL (in the study report it was incorrectly reported in g/mL) and specific radioactivity 3.69 MBq/mL. The second one, labelled VG0105D5, had a concentration 1.138 mg TFA/mL (once again in the study report the units were incorrectly reported as [g/mL]) and specific activity of 3.96 MBq/mL. These stock solutions were subsequently used to fortify the 800-mL portions of the nutrient solution to obtain the test solution having the intended concentration of 800 μg TFA/L. The nutrient solution contained 10 mL Hoagland's solution no. 2 and 75 mL 1M KH_2PO_4 aq. The pH of the test solution was 6.

The amount of the stock solution VG0105D1 added to 800 mL of nutrient solution was 0.604 mL and that of the stock solution VG0105D5 – 0.562 mL.

The test plants used in the experiment were:

- Wheat, variety Thasos,

- Corn,
- Tomato.

The test plants were pre-grown in Vermiculite in the greenhouse in the conditions similar to the natural conditions of Central Europe: daily temperature $T = \sim 20^{\circ}\text{C}$, mean relative humidity of $\sim 75\%$ and light conditions – artificial light having intensity of at least 35 kLux from 6 am to 8 pm.

1 day before the beginning of the experiment test plants were removed from growing pots, and Vermiculite removed from their root systems by washing with water.

They were then transferred to brown 1-L glass bottles containing 800 mL of the test solution spiked with the test compound. The number of the individual plants per bottle was:

- ten for the experiment with wheat,
- one for the experiment with corn,
- one for the experiment with tomato.

Plants were fixed in the bottle with elastomer foam. Then the bottles were covered with aluminium foil to prevent loss of liquid due to evaporation.

The experiment with wheat plants was carried out for a single bottle, that for corn using three replicates (bottles) and that with tomato plants using two replicates (bottles). The control samples (bottles) were not prepared.

The bottles were placed in the greenhouse and kept there for eight days in case of experiment with wheat and tomato plants, or for eleven days – in case of the experiment with corn plants, in the same conditions as described above for pre-growing of the test plants.

At pre-defined sampling points three 1-mL samples of liquid were taken from each bottle for determination of the radioactivity content in solution using LSC.

The sampling points were:

- for experiment with wheat: DAT 0 (0 hours after treatment), DAT 0.146 (3.5 hours after treatment), DAT 1 (1 day after treatment), DAT 4 (4 days after treatment) and DAT 8 (8 days after treatment);
- for experiment with corn: DAT 0 (0 hours after treatment), DAT 0.166 (4 hours after treatment), DAT 1 (1 day after treatment), DAT 4 (4 days after treatment), DAT 8 (8 days after treatment) and DAT 11 (11 days after treatment);
- for experiment with tomato: DAT 0 (0 hours after treatment), DAT 0.104 (2.5 hours after treatment), DAT 1 (1 day after treatment), DAT 4 (4 days after treatment) and DAT 8 (8 days after treatment)

The volume of the solution in each bottle was determined at each sampling point specified above.

At the end of the experiment the plant roots from each jar were washed with ~ 50 of H_2O . The volume of that solution was determined, after what the radioactivity content in it measured using LSC.

The LSC analysis of liquid samples was carried out using either LKB/Wallac 1219 Spectral scintillation counter Beckman LS 6600 LL scintillation counter or Beckman LS 6500 scintillation counter. The mean measurement efficiency was 84.3%. The counting lasted from few seconds up to 20 minutes. To analyse stock solutions of the test compound their 0.025 mL aliquots were mixed with 2 mL of Quicksafe A + 5% water scintillation cocktail. To analyse test solutions their 0.1-mL aliquots were mixed with 2 mL of Quicksafe A + 5% water scintillation cocktail.

The calculations of PUF were carried out using the equation presented below on figure B.8.1.3.4._CA-6.

$$PUF = \frac{\ln((m_{\text{final}} + m_{\text{wash}}) / m_{\text{day0}})}{\ln(V_{\text{final}} / V_{\text{day0}})}$$

Legend:
 m_{day0} = initial mass of test compound / 800 mL test solution [μg]
 m_{final} = mass of test compound in the test solution after 8 or 11 days [μg]
 m_{wash} = mass of test compound in the wash solution [μg]
 V_{day0} = initial volume of test solution (default 800 mL) [L]
 V_{final} = volume of test solution after 8 or 11 days [L]

Figure B.8.1.3.4._CA-6: The equation used to calculate PUF (copied from the study report).

Results and their discussion:

The mean initial concentration of the test compound in the test solution was 767.8 $\mu\text{g/L}$ in the experiment with wheat, 769.1 $\mu\text{g/L}$ in the experiment with corn and 711.8 $\mu\text{g/L}$ in the experiment with tomato plants.

The results of the determination of the initial and final volume of the solution for the test with each test compound are presented below in the table B.8.1.3.4._CA-11. The control samples, used to examine the volume of the solution taken by test plants, were blank (not containing the test compound).

Table B.8.1.3.4._CA-11: The results of the determination of the volume of solution during incubation and its changes.

Sample characteristics			Determined volume [L]		
Test plant	Type of sample	Replicate	Day 0 – V_{day0}	Final – V_{final}	Amount uptaken by plants – V_{uptake}
Wheat	Test solution	---	0.800	0.550	0.250
Corn	Test solution	1	0.800	0.640	0.160
	Test solution	2	0.800	0.672	0.128
	Test solution	3	0.800	0.670	0.130
tomato	Test solution	1	0.800	0.535	0.265
	Test solution	2	0.800	0.585	0.215

The results of the determination of concentration of TFA in the solution are presented below, individually for each test plant, in tables: B.8.1.3.4._CA-12 for wheat, B.8.1.3.4._CA-13 for corn and B.8.1.3.4._CA-14 for tomato.

Table B.8.1.3.4._CA-12: The results of the determination of the concentration of TFA in solution during the experiment with wheat.

The values used in the calculation of PUF and the results of these calculations are presented below in the table B.8.1.3.4._CA-15. RMS verified them and found them correct. The calculated mean values reported in that table are the final results of the study. RMS however is of the opinion that due to the deficiencies of the study its results – the determined PUF values, should be considered only as indicative and not used as input parameters in modelling.

Table B.8.1.3.4._CA-15: The results of the determination of PUF (as presented in the study report).

Test crop: wheat								
Type of sample	Day-0 results			Final – Day-8 results				PUF
	V_{day0} [L]	C_{day0} [$\mu\text{g/L}$]	m_{day0} [μg]	V_{day8} [L]	C_{day8} [$\mu\text{g/L}$]	m_{day8} [μg]	m_{wash} [μg]	
Test sample replicate 1	0.800	767.8	614.3	0.550	854.1	469.8	9.1	0.66

Study 4:

Report: Roepke B., (2013): “Determination of a suitable Plant Uptake Factor (PUF) of Trifluoroacetic acid (TFA) for use in Environmental Fate Models in the Target Crop Wheat.”; Bayer Crop Science AG, Environmental Safety, Alfred Nobel Str. 50, D-40789 Monheim am Rhein, Germany; Report No. EnSa-13-0545; 24. 10. 2013; study reference number M-468684-01-1.

Guidelines: The study is a position paper examining existing experimental data, therefore it was not performed in line with any specific Guidelines.

GLP: No, not applicable – position paper;

RMS comments: This is a newly submitted study, analysing the available data in order to determine the most appropriate PUF value for Trifluoroacetic acid to be used in regulatory GW model exposure assessment. It did not follow any specific Guidelines, as no such Guidelines exist, but it bears references to several EU documents that may be considered as such, e.g. Report of FOCUS Groundwater Scenarios Workgroup ([FOCUS, 2000]) and Report of FOCUS Ground Water Work Group ([FOCUS, 2009]), Scientific Opinion of EFSA PPR Panel on the report of FOCUS groundwater working group ([EFSA Journal, 2013]). RMS evaluated it for the purpose of the current assessment and found acceptable. It shall be indicated however, that it can be considered only as a supplementary study. It is briefly summarised below.

Summary:

The aim of the study was to examine the available experimental data in order to determine the most appropriate value of plant uptake factor – PUF, for Trifluoroacetic acid (TFA), a major soil degradation product of Flufenacet, to be used in the regulatory GW model exposure assessment.

Four studies were selected as a source of data:

- Bongartz [2012], study reference number: M-440106-01-1;
- Bongartz [2013], study reference number: M-456754-03-1;
- Bongartz and Klankers [2012], study reference number: M-443538-01-1;
- Roohi and Buntain [2004], study reference number: M-222225-01-1;

Studies by [Bongartz, 2012] and [Bongartz, 2013] are both laboratory studies that were aimed on the determination of the PUF value for TFA in Wheat (both studies), Corn and Tomato plants. They are summarised in this Renewal Assessment Report, under this point, as **Study 2** and **Study 3**.

The other two studies referred to in the report are crop rotational studies.

First of them – by [Bongartz and Klankers; 2012], was performed in order to examine the metabolism of Flufenacet, precursor of TFA, in confined rotational crops. The test crops used in that experiment were Wheat, Turnip and Swiss chard.

On the basis of the results presented below on figure B.8.1.3.4._CA-7 (table copied from the study report) it was stated that the increase in the concentration of TFA in plants was correlated with its decrease in soil, as well as may be correlated with its formation pattern in soil from Flufenacet. It shall be indicated that in the table are presented the values obtained for Total Radioactive Residues (TRR) measured in rotational crops and expressed as [mg Flufenacet equivalents/kg]. However, their further qualitative analysis showed that >92.5% TRR could be attributed to TFA. To support that statement another table from that study report was presented, showing the results of the qualitative and quantitative analysis of TRR in Wheat of the 1st rotation. These results are presented on figure B.8.1.3.4._CA-8. On their basis it was stated that it may be postulated that the decline of the concentration of TFA in soil may be explained by its uptake by plants and not by its further transformation.

Table 4: Plant Residues in Confined Rotational Crop Matrices (Bongartz & Klankers, 2012)

Total Radioactive Residues (TRRs) in Confined Rotational Crops (mg flufenacet equivalents / kg)			
Matrix	1 st rotation	2 nd rotation	3 rd rotation
wheat forage	1.543	2.318	1.441
wheat hay	3.755	8.225	3.740
wheat straw	4.376	9.335	4.035
wheat grain	3.024	7.673	1.371
turnip leaves	6.792	3.536	0.993
turnip roots	0.601	0.197	0.087
Swiss chard (intermediate)	6.117	1.951	4.784
Swiss chard (at maturity)	3.386	2.950	1.973

Figure B.8.1.3.4._CA-7: The results of the study by [Bongartz and Klankers; 2012] – the TRR in the rotational crops (copied from the study report).**Table 5: Recovery of TFA in matrices of the target crop wheat (Bongartz & Klankers, 2012)**

Distribution of Metabolites in Wheat of the 1 st Rotation

Figure B.8.1.3.4._CA-8: The results of the study by [Bongartz and Klankers; 2012] – the results of the profiling of TRR in the rotational crops (copied from the study report).

The second study – by [Roohi and Buntain; 2004] was aimed on the determination of the residues flurtamone, a compound also identified as a precursor of TFA, in rotational crop. Due to the fact that in the study was used the active compound other than the compound of interest of the present evaluation – Flurtamone and not Flufenacet, the study is of the limited utility for the current evaluation. However, in the summarised study report it was stated that the results of the study by [Roohi and Buntain; 2004] confirmed the statement that TFA will dissipate from soil throughout its uptake by plants.

On the basis of the performed evaluation it was proposed to consider the PUF = 0.59, determined in the **Study 2** (by [Bongartz; 2013]) as appropriate input value to be used in higher-tier leaching model calculations, in line with recommendations of the EFSA PPR-Panel [EFSA Journal; 2013].

RMS considers that conclusion correctly drawn and therefore valid.

**Summary – the determination of PUF values suitable as input parameter
for GW/SW model exposure assessment**

The PUF – plant uptake factor was determined in three separate experiments – *Study 1*, *Study 2* and *Study 3*, for the following major soil degradation products of Flufenacet: FOE Sulfonic acid, FOE Methylsulfone, FOE 5043-Trifluoroethanesulfonic acid – FOE TFESA (all in *Study 1*), and Trifluoroacetic acid – TFA (in *Study 2* and *Study 3*). The PUF values for FOE Sulfonic acid, FOE Methylsulfone and FOE TFESA were determined for Wheat as the experimental crop, while for TFA the test crops for which the PUF values were determined were Wheat, Corn (Maize) and Tomato.

Additionally was submitted a study, being in fact a position paper, supporting the value of PUF proposed for TFA.

For all four test compounds the experimental PUF values were determined for Wheat, the crop that may be considered representative for all cereals.

The determined values are:

- for FOE Sulfonic acid the PUF in cereals is **0.46**;
- for FOE Methylsulfone the PUF in cereals is **1.31**;
- for FOE 5043-Trifluoroethanesulfonic acid the PUF in cereals is **1.36**;
- for TFA (Trifluoroacetic acid) the PUF in cereals is **0.59**.

The Applicant proposed to use two of these experimentally derived values – PUF for FOE Sulfonic acid and PUF for TFA, as input values for GW model exposure assessment (please also refer to the point B.8.3. in the document Vol. 3_CP – B.8. of this Renewal Assessment Report).

RMS decided to verify the correctness of that selection in light of the recommendations of the current Guidelines. That was done using the *Generic Guidance for Tier 1 FOCUS Ground Water Assessments, Version 2.2, May 2014*, the document, which in paragraph 2.4.4 – *Crop related substance parameters* provides the recommendations with regard to the appropriate selection of the Plant Uptake Factor value. It is stated that the recommended default value for all compounds is 0. However, when a reliable measured K_{OW} value determined for neutral pH is available, the Briggs equation proposed for calculation of TSCF (Transpiration Stream Concentration Factor) may be used. So determined TSCF value may be used as input parameter for PUF in GW model exposure assessment. The Briggs equation for calculating TSCF presented in the cited above Guidance document looks as follows:

$$TSCF = 0.784 \exp \{(-[\text{Log}(K_{OW}) - 1.78]^2 / 2.44)\}$$

RMS decided to use it in order to calculate the TSCF values for Flufenacet and all its major soil degradation products, for which the GW model exposure assessment shall be performed and for which were available the reliable $\text{Log } P_{OW}$ (= $\text{Log } K_{OW}$) presented in section B.2 (Physicochemical properties) of this Renewal Assessment Report. The results of the calculations, together with the input parameters used in them, are presented below in the table B.8.1.3.4._CA-16. As a next step, the calculated values were compared with the proposed in the same Guideline maximum recommended TSCF value – 0.8, and, where available, with the experimental value. That was done in order to determine the suitable value representing TSCF/PUF to be used as input parameter in GW model exposure assessment. These values are also presented in the table B.8.1.3.4._CA-16. The TSCF/PUF values recommended as input for GW/SW modelling are given in **bold**.

Table B.8.1.3.4._CA-16: The results of the determination of TSCF/PUF value suitable for GW/SW model exposure assessment

Compound	Ionisable substance	Experimental values		TSCF		Measured PUF	TSCF/PUF value selected for modelling
		$\text{Log } P_{OW}$	measured at pH	calculated	Regulatory upper limit		
Flufenacet	No	3.5	7.0	0.744	0.8	n. a. ³⁾	0.744
FOE Oxalate	No	2.2	7.0	0.983	0.8	n. a. ³⁾	0.8
FOE Sulfonic acid	Yes	-2.72	7.0	0.133	0.8	0.46	0.46
FOE Methylsulfone	No	1.7	7.0	0.999	0.8	1.31	0.8
FOE Thiadone	No	0.62	7.0	0.874	0.8	n. a. ³⁾	0.8
FOE TFESA ¹⁾	Yes	-2.95	7.0	0.107	0.8	1.36	0.8
TFA ²⁾	Yes	-2.6	7.0	0.148	0.8	0.59	0.59

Footnotes to the table:

1) FOE TFESA = FOE 5043-Trifluoroethanesulfonic acid;

2) TFA = Trifluoroacetic acid;

3) n. a. = value not available (not determined experimentally).

B.8.1.3.5. – Summary of the soil mobility

The examination of the mobility of Flufenacet and its major transformation products in soil covered following issues:

- column leaching,
- aged residue column leaching,
- lysimeter studies,
- determination of the Plant Uptake Factor – PUF, as “Other studies”

The Applicant did not submit any studies covering the issue of the column leaching of Flufenacet. Instead, in the provided justification for the non-submission, stated that it was covered by the results of the examination of sorption in soil at equilibrium (batch sorption studies) and those aimed on the examination of leaching of the aged residues. That justification was found acceptable by the RMS. It shall be indicated however, that the evaluation of the study examining the leaching behaviour of the aged residues of Flufenacet demonstrated that the study was not acceptable.

Two additional open-literature studies found by the RMS, considered supplementary, indicated that under typical EU conditions Flufenacet should not move in the soil profile below the depth of 25 cm. Such statement seems to be confirmed by the results of the field dissipation studies performed for Flufenacet.

Additionally, a study was submitted examining the column leaching of one of the major soil degradation products of Flufenacet – TFA. That study, performed using four European soils, showed that TFA was very mobile in soil. The key results of that study are presented below.

The leaching behaviour of TFA was examined using soil columns filled with one of the following test soils:

- Loamy sand (*Laacherhof AXXa*) test soil, having OC = 1.8% and pH = 6.2;
- Loam (*Dollendorf II*) test soil, having OC = 5.2% and pH = 7.4;
- Silt loam (*Höfchen am Hohenseh*) test soil, having OC = 1.6 and pH = 6.5;
- Sandy loam (*Laacherhof Wurmwielse*) test soil, having OC = 1.9 and pH = 5.3.

The experiment was performed in two variants, denominated **Study design A** and **Study design B**, that may be characterised as follows:

- in **Study design A** leaching lasted 48 hours and was performed with 393 mL of artificial rain (0.01M $\text{CaCl}_{2\text{aq}}$), corresponding to 200 mm of rain;
- in **Study design B** leaching lasted 120 hours and was performed with 984 mL of artificial rain (0.01M $\text{CaCl}_{2\text{aq}}$), corresponding to 502 mm of rain;

In the variant denominated **Study design A** the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 95.5% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 73.2% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 92.1% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 66.2% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the extractable radioactivity retained within soil columns attributed to TFA was (mean values of the two replicates):
 - 5.0% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 28.3% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 6.5% of AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 35.6% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the NER fraction attributed to TFA, expressed as % AR, in the soil columns (mean values of the two replicates) was:
 - 1.2% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 1.8% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 0.8% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 1.1% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the distribution of residues of TFA in soil was following:
 - for columns filled with Loamy sand (*Laacherhof AXXa*) test soil they were found predominantly in the lowest segment – S5;

- for columns filled with Loam (*Dollendorf II*) test soil the highest concentration of TFA residues was determined in the top section of the column (segments S1 and S2) with the peak amount in segment S2, and it gradually decreased towards the bottom of the soil column;
- for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil they were found predominantly in the lowest segment – S5;
- for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil the residues of TFA were generally found in the lower part of the column, with the peak amount in the middle section S3.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil Loamy sand (*Laacherhof AXXa*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Loam (*Dollendorf II*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Silt loam (*Höfchen am Hohenseh*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Sandy loam (*Laacherhof Wurmwielse*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - mean $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g.

In the variant denominated **Study design B** the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 101.1% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 96.3% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 98.6% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 100.9% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the amount of radioactivity retained within soil columns attributed to TFA was not analysed because it was wholly recovered in leachates.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil with Loamy sand (*Laacherhof AXXa*) $K_d = 0.1$ mL/g and $K_{dOC} = 4.5$ mL/g;
 - for the test soil Loam (*Dollendorf II*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Silt loam (*Höfchen am Hohenseh*) $K_d = 0.2$ mL/g and $K_{dOC} = 11.3$ mL/g;
 - for the test soil Sandy loam (*Laacherhof Wurmwielse*) $K_d = 0.2$ mL/g and $K_{dOC} = 7.1$ mL/g;
 - mean $K_d = 0.2$ mL/g and $K_{dOC} = 9.1$ mL/g.

The aged residues leaching was examined in one study, submitted also for the previous authorisation of Flufenacet in the EU. RMS evaluated that study for its compliance with the current guidelines, in particular the OECD Guideline for testing chemicals No. 312. Several minor deficiencies were stated that had no impact on the validity of the study. However, the thorough examination of the study report showed that there was a significant discrepancy between the application rate declared to be used to treat soil subjected to the ageing procedure and that used in the leaching experiment with aged soil.

Second problem identified in the study report was the fact that the analytical procedure used to characterise quantitatively and qualitatively the residues in soil after ageing was not presented.

As a result, mainly due to the discrepancies in the amount of the radioactivity introduced into soil at the beginning of the ageing period and that used in leaching experiment, introduced with aged soils, RMS decided to consider the study not acceptable because of the significant uncertainty related to the reliability of the obtained results.

The leaching behaviour of Flufenacet and its degradation products through the undisturbed soil profiles under the agronomic and climatic conditions relevant for Germany was examined on four outdoor lysimeters. The results of that examination were presented in two study reports submitted by the Applicant for the purpose of the current evaluation. Additionally the Applicant submitted the interim reports of the same experiments, not summarised in the Renewal Assessment Report for Flufenacet, but analysed for their compliance with the adequate final reports. The third study submitted for evaluation was aimed on the validation of the lysimeter studies by comparing their results with those of the modelling exposure assessment carried out for the GW compartment. RMS however decided not to use it, as the modelling tools and scenarios were not those recommended by FOCUS.

The key data and results obtained in the two studies are summarily presented below in tables B.8.1.3.5._CA-1 – B.8.1.3.5._CA-1c.

Footnotes to the table:

1) Abbreviations used: FOE SA – FOE Sulfonic acid.

It may be stated that of all the compounds possible to be identified as originating from Flufenacet radiolabelled in fluorophenyl ring (including Flufenacet itself) only FOE Sulfonic acid was demonstrated to be found in leachates in amounts > 0.1 µg/L, what conformed the risk to GW associated to that degradation product demonstrated in GW model exposure assessment (for details please refer to the results of calculations presented under the point B.8.5 in the Vol. 3-CP, B.8 of this Renewal Assessment Report).

Neither Flufenacet nor the second major soil degradation product relevant for that radiolabelling position – FOE Oxalate, were detected in leachates in amounts > 0.1 µg/L, what may indicate that they would not pose a threat to the GW compartment.

In soil and leachates FOE Alcohol was detected – the compound determined in the studies examining the route of degradation of Flufenacet in aerobic soil to be minor/transient and therefore not taken into account in the GW model exposure assessment. It shall be indicated however that the would-be risk it may pose to the GW compartment was covered by the calculations carried out for FOE Oxalate – its immediate degradate.

Also detected in leachates was FOE Thioglycolate sulfoxide (FOE TGS), the compound not taken in the model GW exposure assessment into consideration, being identified as minor soil degradation product. It shall be indicated however, that in the study it was determined in leachates in amounts <0.1 µg/L, what may indicate that it would not pose a serious threat to the GW compartment.

Finally, it shall be indicated that, due to the fact that in the experiments was used Flufenacet radiolabelled only in the fluorophenyl ring, they gave no information of the laching potential of the degradation products formed from the second moiety present within the molecule of Flufenacet – thiadiazole.

The comparative analysis of the application pattern (crops, application timing and application rates) used in the experiments and the EU-representative application pattern proposed for the current authorisation of Flufenacet in the EU showed that they may be considered as providing supplementary information with regard to the risk posed by Flufenacet and its soil degradation products to the GW compartment, but for the purpose of the decision making should be considered with care.

The PUF – plant uptake factor was determined in three separate experiments for the following major soil degradation products of Flufenacet: FOE Sulfonic acid, FOE Methylsulfone, FOE 5043-Trifluoroethanesulfonic acid – FOE TFESA (for all three in one experiment), and Trifluoroacetic acid – TFA (in two separate experiments). The PUF values for FOE Sulfonic acid, FOE Methylsulfone and FOE TFESA were determined for Wheat as the experimental crop, while for TFA the test crops for which the PUF values were determined were Wheat, Corn (Maize) and Tomato.

Additionally was submitted a study, being in fact a position paper, supporting the value of PUF proposed for TFA.

For all four test compounds the experimental PUF values were determined for Wheat, the crop that may be considered representative for all cereals.

The determined values are:

- for FOE Sulfonic acid the PUF in cereals is **0.46**;
- for FOE Methylsulfone the PUF in cereals is **1.31**;
- for FOE 5043-Trifluoroethanesulfonic acid the PUF in cereals is **1.36**;
- for TFA (Trifluoroacetic acid) the PUF in cereals is **0.59**.

The Applicant proposed to use two of these experimentally derived values – PUF for FOE Sulfonic acid and PUF for TFA, as input values for GW model exposure assessment (please also refer to the point B.8.3. in the document Vol. 3_CP – B.8. of this Renewal Assessment Report).

RMS decided to verify the correctness of that selection in light of the recommendations of the current Guidelines. That was done using the *Generic Guidance for Tier 1 FOCUS Ground Water Assessments, Version 2.2, May 2014*, document, which in paragraph 2.4.4 – *Crop related substance parameters* provides the recommendations with regard to the appropriate selection of the Plant Uptake Factor value. It is stated that the recommended default value for all compounds is 0. However, when a reliable measured K_{OW} value determined for neutral pH is available, the Briggs equation proposed for calculation of TSCF (Transpiration Stream Concentration Factor) may be used and so determined TSCF value used as input parameter for PUF in GW model exposure assessment. The Briggs equation for calculating TSCF presented in the cited above Guidance document looks as follows:

$$TSCF = 0.784 \exp \{(-[\text{Log}(K_{OW}) - 1.78]^2 / 2.44)\}$$

RMS decided to use it in order to calculate the TSCF values for Flufenacet and all its major soil degradation products, for which the GW model exposure assessment shall be performed and for which were available the reliable $\text{Log } P_{OW}$ (= $\text{Log } K_{OW}$) presented in section B.2 (Physicochemical properties) of this Renewal Assessment Report. The results of the calculations, together with the input parameters used in them, are presented below in the table B.8.1.3.5._CA-2. As a next step the calculated values were compared with the proposed in the same Guideline maximum recommended TSCF value – 0.8, and, where available, with the experimental value. That was done in order to determine the suitable value representing TSCF/PUF to be used as input parameter in GW model exposure assessment. These value are also presented in the table B.8.1.3.5._CA-2. The TSCF/PUF values recommended as input for GW/SW modelling are given in **bold**.

Table B.8.1.3.5._CA-2: The results of the determination of TSCF/PUF value suitable for GW/SW model exposure assessment

Compound	Ionisable substance	Experimental values		TSCF		Measured PUF	TSCF/PUF value selected for modelling
		$\text{Log } P_{OW}$	measured at pH	calculated	Regulatory upper limit		
Flufenacet	No	3.5	7.0	0.744	0.8	n. a. ³⁾	0.744
FOE Oxalate	No	2.2	7.0	0.983	0.8	n. a. ³⁾	0.8
FOE Sulfonic acid	Yes	-2.72	7.0	0.133	0.8	0.46	0.46
FOE Methylsulfone	No	1.7	7.0	0.999	0.8	1.31	0.8
FOE Thiadone	No	0.62	7.0	0.874	0.8	n. a. ³⁾	0.8
FOE TFESA ¹⁾	Yes	-2.95	7.0	0.107	0.8	1.36	0.8
TFA ²⁾	Yes	-2.6	7.0	0.148	0.8	0.59	0.59

Footnotes to the table:

1) FOE TFESA = FOE 5043-Trifluoroethanesulfonic acid;

2) TFA = Trifluoroacetic acid;

3) n. a. = value not available (not determined experimentally).

B.8.1.4. – Summary of adsorption, desorption and mobility in soil

The sorption of Flufenacet onto soil at equilibrium was extensively examined in four studies using fourteen test soils. The results of that examination were used to obtain Freundlich sorption isotherms for adsorption and desorption processes and derive Freundlich sorption isotherm parameters. In case of adsorption reliable parameters of Freundlich isotherm were obtained for ten test soils, while for desorption the reliable Freundlich parameters were derived using nine test soils. They are presented below in two tables: B.8.1.4._CA-1 for adsorption and B.8.1.4._CA-2 for desorption. The results obtained for adsorption indicate that Flufenacet is moderately to strongly sorbed onto soil and that the process is not preferential. It was also determined that it was not pH-dependent.

Table B.8.1.4._CA-1: The results of the determination of the adsorption of Flufenacet onto soil at equilibrium – the reliable parameters of the Freundlich adsorption isotherm.

Soil name	Soil properties			Adsorption distribution coefficients		Freundlich adsorption isotherm parameters			
	Soil type (USDA)	pH	OC [%]	K_d [mL/g]	$K_{d oc}$ [mL/g]	K_f [mL/g]	$K_{f oc}$ [mL/g]	1/n	R^2

The additional information on the soil sorption of Flufenacet at equilibrium were provided by three open-literature scientific papers. The key results obtained in them are presented below in the table B.8.1.4._CA-3. The values reported below may be considered as indicative and should not be used to derive the regulatory endpoints characterising soil sorption of Flufenacet.

Table B.8.1.4._CA-3: The results of the determination of the adsorption of Flufenacet onto soil at equilibrium obtained in the open-source literature scientific papers.

Study	Soil name	Soil properties			Freundlich adsorption isotherm parameters			
		Soil type	pH	OC [%]	K_f [mL/g]	K_{fOC} [mL/g]	1/n	r

Footnotes to the table:

1) OM content reported, no values for OC content.

In the studies by [Gupta, Gajbhiye and Agnihotri; 2001] and [Gajbhiye and Gupta; 2001] for adsorption of Flufenacet onto test soil the value of the free Gibbs energy of adsorption – ΔG , was determined. It was in range $\Delta G = (-3.27) - (-5.08)$ [Kcal/mol], indicating that adsorption of Flufenacet onto soil was a spontaneous process and mechanistically it was predominantly physisorption. It was also demonstrated, in the study by [Gupta, Gajbhiye and Agnihotri; 2001], that the soil sorption of Flufenacet was strongly positively correlated with soil OC/OM content. As the results obtained in these two studies are in line with those from reliable regulatory studies, that conclusion may be considered to be a general conclusion with regard to the adsorption of Flufenacet onto soil.

Also examined was sorption onto soil at equilibrium of major soil degradation products of Flufenacet: FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid (TFESA) and Trifluoroacetic acid (TFA). The key results – Freundlich sorption parameters, are presented below, individually for each test compound.

For FOE Oxalate the reliable Freundlich isotherm parameters for adsorption were determined in three test soils. The desorption was not examined because of the low level of adsorption onto soil. The results are presented below in the table B.8.1.4._CA-4.

Table B.8.1.4._CA-4: The Freundlich adsorption and desorption parameters determined for FOE Oxalate.

pH dependence			No					

Footnotes to the table:

1) Measured in water;

The results showed that FOE Methylsulfone and FOE Thiadone were moderately sorbed onto soil. FOE Oxalate and FOE Sulfonic acid were only weakly sorbed onto soil, while FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid were practically not sorbed onto soil. No pH-dependence of the adsorption was stated for any of the degradation products, but in case of FOE Thiadone, FOE Sulfonic acid and FOE Oxalate that may be due to the limited number of soils used in the experiment as well as their narrow pH range.

Additionally for FOE Methylsulfide – major aquatic degradation product of Flufenacet, the K_{OC} value was estimated using KOCWIN – a part of EPISuite 4.1 modelling tool. The estimated value is **K_{OC} = 598 L/kg** and is recommended to be used as an input value in SW/SED model exposure assessment.

For FOE Sulfonic acid the additional examination of the soil sorption in function of time – time-dependent sorption, was performed. The key results of that examination – adsorption parameters in function of time, are provided below in the table B.8.1.4._CA-10.

Table B.8.1.4._CA-10: The key results of the examination of the time-dependent sorption of FOE Sulfonic acid onto soil.

Results obtained for <i>Laacherhof AXXa</i> test soil					Results obtained for <i>Laacherhof AIII</i> test soil

The calculated adsorption coefficient increase factor was **2** for Laacherhof AXXa test soil and **1.5** for Laacherhof AIII test soil, indicating that the compound became more strongly sorbed onto soil with elapsing time. However that increase did not strongly influenced the mobility of FOE Sulfonic acid in soil, which remained very mobile, as indicated K_d and K_{d OC} values.

The examination of the mobility of Flufenacet and its major transformation products in soil covered following issues:

- column leaching,
- aged residue column leaching,
- lysimeter studies,
- determination of the Plant Uptake Factor – PUF, as “Other studies”

The Applicant did not submit any studies covering the issue of the column leaching of Flufenacet. Instead, in the provided justification for the non-submission, stated that it was covered by the results of the examination of sorption in soil at equilibrium (batch sorption studies) and those aimed on the examination of leaching of the aged residues. That justification was found acceptable by the RMS. It shall be indicated however, that the evaluation of the study examining the leaching behaviour of the aged residues of Flufenacet demonstrated that the study was not acceptable.

Two additional open-literature studies found by the RMS, considered supplementary, indicated that under typical EU conditions Flufenacet should not move in the soil profile below the depth of 25 cm. Such statement seems to be confirmed by the results of the field dissipation studies performed for Flufenacet.

Additionally, a study was submitted examining the column leaching of one of the major soil degradation products of Flufenacet – TFA. That study, performed using four European soils, showed that TFA was very mobile in soil. The key results of that study are presented below.

The leaching behaviour of TFA was examined using soil columns filled with one of the following test soils:

- Loamy sand (*Laacherhof AXXa*) test soil, having OC = 1.8% and pH = 6.2;
- Loam (*Dollendorf II*) test soil, having OC = 5.2% and pH = 7.4;
- Silt loam (*Höfchen am Hohenseh*) test soil, having OC = 1.6 and pH = 6.5;
- Sandy loam (*Laacherhof Wurmwiese*) test soil, having OC = 1.9 and pH = 5.3.

The experiment was performed in two variants, denominated **Study design A** and **Study design B**, that may be characterised as follows:

- in **Study design A** leaching lasted 48 hours and was performed with 393 mL of artificial rain (0.01M $\text{CaCl}_{2\text{aq}}$), corresponding to 200 mm of rain;
- in **Study design B** leaching lasted 120 hours and was performed with 984 mL of artificial rain (0.01M $\text{CaCl}_{2\text{aq}}$), corresponding to 502 mm of rain;

In the variant denominated **Study design A** the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 95.5% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 73.2% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 92.1% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 66.2% AR for columns filled with Sandy loam (*Laacherhof Wurmwiese*) test soil.
- the extractable radioactivity retained within soil columns attributed to TFA was (mean values of the two replicates):
 - 5.0% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 28.3% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 6.5% of AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 35.6% AR for columns filled with Sandy loam (*Laacherhof Wurmwiese*) test soil.
- the NER fraction attributed to TFA, expressed as % AR, in the soil columns (mean values of the two replicates) was:
 - 1.2% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 1.8% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 0.8% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 1.1% AR for columns filled with Sandy loam (*Laacherhof Wurmwiese*) test soil.
- the distribution of residues of TFA in soil was following:
 - for columns filled with Loamy sand (*Laacherhof AXXa*) test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Loam (*Dollendorf II*) test soil the highest concentration of TFA residues was determined in the top section of the column (segments S1 and S2) with the peak amount in segment S2, and it gradually decreased towards the bottom of the soil column;
 - for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil they were found predominantly in the lowest segment – S5;
 - for columns filled with Sandy loam (*Laacherhof Wurmwiese*) test soil the residues of TFA were generally found in the lower part of the column, with the peak amount in the middle section S3.

- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil Loamy sand (*Laacherhof AXXa*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Loam (*Dollendorf II*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Silt loam (*Höfchen am Hohenseh*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Sandy loam (*Laacherhof Wurmwielse*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - mean $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g.

In the variant denominated **Study design B** the following results were obtained for TFA:

- amount of TFA in the eluates (mean values of the two replicates), expressed as % AR, was:
 - 101.1% AR for columns filled with Loamy sand (*Laacherhof AXXa*) test soil;
 - 96.3% AR for columns filled with Loam (*Dollendorf II*) test soil;
 - 98.6% AR for columns filled with Silt loam (*Höfchen am Hohenseh*) test soil;
 - 100.9% AR for columns filled with Sandy loam (*Laacherhof Wurmwielse*) test soil.
- the amount of radioactivity retained within soil columns attributed to TFA was not analysed because it was wholly recovered in leachates.
- The K_d and K_{dOC} values determined for TFA in this experiment were following:
 - for the test soil with Loamy sand (*Laacherhof AXXa*) $K_d = 0.1$ mL/g and $K_{dOC} = 4.5$ mL/g;
 - for the test soil Loam (*Dollendorf II*) $K_d = 0.0$ mL/g and $K_{dOC} = 0.0$ mL/g;
 - for the test soil Silt loam (*Höfchen am Hohenseh*) $K_d = 0.2$ mL/g and $K_{dOC} = 11.3$ mL/g;
 - for the test soil Sandy loam (*Laacherhof Wurmwielse*) $K_d = 0.2$ mL/g and $K_{dOC} = 7.1$ mL/g;
 - mean $K_d = 0.2$ mL/g and $K_{dOC} = 9.1$ mL/g.

The aged residues leaching was examined in one study, submitted also for the previous authorisation of Flufenacet in the EU. RMS evaluated that study for its compliance with the current guidelines, in particular the OECD Guideline for testing chemicals No. 312. Several minor deficiencies were stated that had no impact on the validity of the study. However, the thorough examination of the study report showed that there was a significant discrepancy between the application rate declared to be used to treat soil subjected to the ageing procedure and that used in the leaching experiment with aged soil.

Second problem identified in the study report was the fact that the analytical procedure used to characterise quantitatively and qualitatively the residues in soil after ageing was not presented.

As a result, mainly due to the discrepancies in the amount of the radioactivity introduced into soil at the beginning of the ageing period and that used in leaching experiment, introduced with aged soils, RMS decided to consider the study not acceptable because of the significant uncertainty related to the reliability of the obtained results.

The leaching behaviour of Flufenacet and its degradation products through the undisturbed soil profiles under the agronomic and climatic conditions relevant for Germany was examined on four outdoor lysimeters. The results of that examination were presented in two study reports submitted by the Applicant for the purpose of the current evaluation. Additionally the Applicant submitted the interim reports of the same experiments, not summarised in the Renewal Assessment Report for Flufenacet, but analysed for their compliance with the adequate final reports. The third study submitted for evaluation was aimed on the validation of the lysimeter studies by comparing their results with those of the modelling exposure assessment carried out for the GW compartment. RMS however decided not to use it, as the modelling tools and scenarios were not those recommended by FOCUS.

The key data and results obtained in the two studies are summarily presented below in tables B.8.1.4._CA-10 – B.8.1.4._CA-10c.

Table B.8.1.4._CA-10: The key data and results obtained in the outdoor lysimeter studies.

Footnotes to the table:

1) Abbreviations used: FOE SA – FOE Sulfonic acid.

It may be stated that of all the compounds possible to be identified as originating from Flufenacet radiolabelled in fluorophenyl ring (including Flufenacet itself) only FOE Sulfonic acid was demonstrated to be found in leachates in amounts > 0.1 µg/L, what conformed the risk to GW associated to that degradation product demonstrated in GW model exposure assessment (for details please refer to the results of calculations presented under the point B.8.5 in the Vol. 3-CP, B.8 of this Renewal Assessment Report).

Neither Flufenacet nor the second major soil degradation product relevant for that radiolabelling position – FOE Oxalate, were detected in leachates in amounts > 0.1 µg/L, what may indicate that they would not pose a threat to the GW compartment.

In soil and leachates FOE Alcohol was detected – the compound determined in the studies examining the route of degradation of Flufenacet in aerobic soil to be minor/transient and therefore not taken into account in the GW model exposure assessment. It shall be indicated however that the would-be risk it may pose to the GW compartment was covered by the calculations carried out for FOE Oxalate – its immediate degradate.

Also detected in leachates was FOE Thioglycolate sulfoxide (FOE TGS), the compound not taken in the model GW exposure assessment into consideration, being identified as minor soil degradation product. It shall be indicated however, that in the study it was determined in leachates in amounts < 0.1 µg/L, what may indicate that it would not pose a serious threat to the GW compartment.

Finally, it shall be indicated that, due to the fact that in the experiments was used Flufenacet radiolabelled only in the fluorophenyl ring, they gave no information of the laching potential of the degradation products formed from the second moiety present within the molecule of Flufenacet – thiadiazole.

The comparative analysis of the application pattern (crops, application timing and application rates) used in the experiments and the EU-representative application pattern proposed for the current authorisation of Flufenacet in the EU showed that they may be considered as providing supplementary information with regard to the risk posed by Flufenacet and its soil degradation products to the GW compartment, but for the purpose of the decision making should be considered with care.

The PUF – plant uptake factor was determined in three separate experiments for the following major soil degradation products of Flufenacet: FOE Sulfonic acid, FOE Methylsulfone, FOE 5043-Trifluoroethanesulfonic acid – FOE TFESA (for all three in one experiment), and Trifluoroacetic acid – TFA (in two separate experiments). The PUF values for FOE Sulfonic acid, FOE Methylsulfone and FOE TFESA were determined for Wheat as the experimental crop, while for TFA the test crops for which the PUF values were determined were Wheat, Corn (Maize) and Tomato.

Additionally was submitted a study, being in fact a position paper, supporting the value of PUF proposed for TFA.

For all four test compounds the experimental PUF values were determined for Wheat, the crop that may be considered representative for all cereals.

The determined values are:

- for FOE Sulfonic acid the PUF in cereals is **0.46**;
- for FOE Methylsulfone the PUF in cereals is **1.31**;
- for FOE 5043-Trifluoroethanesulfonic acid the PUF in cereals is **1.36**;
- for TFA (Trifluoroacetic acid) the PUF in cereals is **0.59**.

The Applicant proposed to use two of these experimentally derived values – PUF for FOE Sulfonic acid and PUF for TFA, as input values for GW model exposure assessment (please also refer to the point B.8.3. in the document Vol. 3_CP – B.8. of this Renewal Assessment Report).

RMS decided to verify the correctness of that selection in light of the recommendations of the current Guidelines. That was done using the *Generic Guidance for Tier 1 FOCUS Ground Water Assessments, Version 2.2, May 2014*, document, which in paragraph 2.4.4 – *Crop related substance parameters* provides the recommendations with regard to the appropriate selection of the Plant Uptake Factor value. It is stated that the recommended default value for all compounds is 0. However, when a reliable measured K_{OW} value determined for neutral pH is available, the Briggs equation proposed for calculation of TSCF (Transpiration Stream Concentration Factor) may be used and so determined TSCF value used as input parameter for PUF in GW model exposure assessment. The Briggs equation for calculating TSCF presented in the cited above Guidance document looks as follows:

$$TSCF = 0.784 \exp \{(-[\text{Log}(K_{OW}) - 1.78]^2 / 2.44)\}$$

RMS decided to use it in order to calculate the TSCF values for Flufenacet and all its major soil degradation products, for which the GW model exposure assessment shall be performed and for which were available the reliable $\text{Log } P_{OW}$ (= $\text{Log } K_{OW}$) presented in section B.2 (Physicochemical properties) of this Renewal Assessment Report. The results of the calculations, together with the input parameters used in them, are presented below in the table B.8.4._CA-11. As a next step the calculated values were compared with the proposed in the same Guideline maximum recommended TSCF value – 0.8, and, where available, with the experimental value. That was done in order to determine the suitable value representing TSCF/PUF to be used as input parameter in GW model exposure assessment. These value are also presented in the table B.8.1.4._CA-11. The TSCF/PUF values recommended as input for GW/SW modelling are given **in bold**.

Table B.8.1.4._CA-11: The results of the determination of TSCF/PUF value suitable for GW/SW model exposure assessment

Compound	Ionisable substance	Experimental values		TSCF		Measured PUF	TSCF/PUF value selected for modelling
		$\text{Log } P_{OW}$	measured at pH	calculated	Regulatory upper limit		
Flufenacet	No	3.5	7.0	0.744	0.8	n. a. ³⁾	0.744
FOE Oxalate	No	2.2	7.0	0.983	0.8	n. a. ³⁾	0.8
FOE Sulfonic acid	Yes	-2.72	7.0	0.133	0.8	0.46	0.46
FOE Methylsulfone	No	1.7	7.0	0.999	0.8	1.31	0.8
FOE Thiadone	No	0.62	7.0	0.874	0.8	n. a. ³⁾	0.8
FOE TFESA ¹⁾	Yes	-2.95	7.0	0.107	0.8	1.36	0.8
TFA ²⁾	Yes	-2.6	7.0	0.148	0.8	0.59	0.59

Footnotes to the table:

1) FOE TFESA = FOE 5043-Trifluoroethanesulfonic acid;

2) TFA = Trifluoroacetic acid;

3) n. a. = value not available (not determined experimentally).

B.8.2 - Fate and behaviour in water and sediment

In order to adequately evaluate the studies examining the fate and behaviour of Flufenacet in aquatic systems it has become necessary to determine the application rate expressed in volumetric units (mg/L) that may be subsequently used as a reference value. The analysis of the proposed EU-representative application pattern for Flufenacet (please refer to the table B.8.0._CA-1) enabled the identification of the critical use with regard to the soil exposure – 240 g Flufenacet/ha. The calculation of the would be application rate were performed assuming the direct overspray of the theoretical water body having the following dimensions: 1-metre length, 1-metre width and 0.3-metre depth. The resulting application rate expressed in volumetric units (mg/L) is **A = 0.08 mg/L, or 80 µg/L**. This value will be used as a reference in determining the validity of the studies examining fate and behaviour of flufenacet in water.

B.8.2.1. – Route and rate of degradation in aquatic systems (chemical and photochemical degradation)

B.8.2.1.1 – Hydrolytic degradation

For the purpose of the current evaluation the Applicant submitted three study reports presenting the results of the examination of aqueous hydrolysis of Flufenacet. One of them had been evaluated for the previous authorisation of Flufenacet in the EU, while the remaining two are newly submitted studies. Additionally, the literature search resulted in the identification of the study examining the rate of degradation of Flufenacet in aqueous environment in function of pH.

Study 1:

Report: Zeng Z., Wood S., (1992): “Stability of FOE 5043 in Sterile Aqueous Buffer Solution.”; Miles Inc., Agriculture Division, Research and Development Department, P. O. box 4913, Kansas City, MO 64120, USA; study No. F3072401 (Miles Inc.); Report No. 102623 (Miles Inc.); 12 March 1992; study reference number: M-002203-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, 161-1, Hydrolysis Studies.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.4.1.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. The study was evaluated for its compliance with OECD Guideline 111 – Hydrolysis as a Function of pH. RMS stated that the study complied with the provisions of the reference Guideline, therefore it can be considered acceptable for the present assessment. It is summarised below.

Summary:

The aim of the study was to investigate the hydrolysis of Flufenacet in aqueous solution in the environmentally relevant pH range of 5-9 and temperature $T = 25^{\circ}\text{C}$.

The test compound used in the experiment was radiolabelled Flufenacet, labelled evenly in phenyl ring, as shown below on figure B.8.2.1.1._CA-1. It had radiochemical purity of 97.48% (determined by HPLC) and specific activity of 60.6 mCi/mmol.

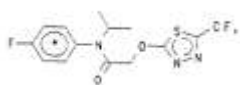

Figure B.8.2.1.1._CA-1: The structural formula of the test compound; radiolabelling position is indicated by an asterisk - (*); (copied from the study report).

The test compound was used to prepare a **Stock solution** having a concentration 7.77 mg/mL.

The test vessels were sterilised 6-mL borosilicate glass vials sealed with Teflon-coated silicone discs and aluminium closure seals. The sealed vials were sterilised prior to the experiment by autoclaving them for 55 min at $T = 120^{\circ}\text{C}$ and pressure 96.53 kPa (14 lbs/in²). Each vial was then weighed and the weight recorded. The amount of so prepared vials was such to prepare for each buffer solution three replicate samples for each time point.

The experiment was performed using three buffer solutions:

- pH 5 buffer (acetate buffer),
- pH 7 buffer (phosphate buffer),
- pH 9 buffer (borate buffer),

each having a concentration of 0.01 M. The detailed information on the composition of each buffer and method of its preparation is given below in the table B.8.2.1.1._CA-1.

Table B.8.2.1.1._CA-1: The composition and properties of the buffer solutions used in the experiment.

Type of buffer solution	Nominal pH	Composition	Method of preparation	Final concentration
<i>Acetate buffer</i>	5	0.01M CH ₃ COOH + 0.01M CH ₃ COONa	a) 0.142 mL of 99.7% CH ₃ COOH was diluted with distilled water to obtain 250 mL 0.01M solution; b) 0.2g of CH ₃ COONa was dissolved in distilled water to obtain 250 mL of 0.01M solution; c) both solutions were mixed, while pH was monitored, until pH = 5 was reached.	0.01M
<i>Phosphate buffer</i>	7	0.01M KH ₂ PO ₄ + 0.01M K ₂ HPO ₄	a) 0.34 g KH ₂ PO ₄ was dissolved in distilled water to obtain 250 mL of 0.01M solution; b) 0.43 g K ₂ HPO ₄ was dissolved in distilled water to obtain 250 mL of 0.01M solution; c) both solutions were mixed, while pH was monitored, until pH = 5 was reached.	0.01M
<i>Borate buffer</i>	9	H ₃ BO ₃ _{aq} + 3M NaOH _{aq}	a) 0.16g H ₃ BO ₃ was dissolved in 100 mL of distilled water; b) pH of the solution was adjusted to 9 with 3M NaOH aqueous solution.	0.01M

The characterised above aqueous buffer solutions were used to prepare the buffer solutions of the test compound used in the experiment. The **test buffer solutions** had the concentration of the test item (Flufenacet) $C = \sim 10$ ppm.

That was done in the following way: three 0.15-mL aliquots of the **Stock solution** were placed in three separate test tubes and the organic solvent removed under the gentle stream of N₂. Next, the residue containing ¹⁴C-Flufenacet was gradually redissolved in 100 mL of the one of characterised above three buffers, to prepare the **test buffer solution** having pH = 5 (**Acetate test buffer solution**), pH = 7 (**Phosphate test buffer solution**) or pH = 9 (**Borate test buffer solution**). The concentration of the dissolved test item in each **test buffer solution** was determined experimentally by LSC.

5-mL aliquots of so prepared **test buffer solutions** were sterilised by filtering them through sterile 0.45-μm nylon filters and injected into the sterilised test vials with sterile needles.

The test vials after introduction of the **test buffer solutions** were weighed in order to determine the exact volume of the solution in each vial (assuming that the density of the **test buffer solutions** was 1.0 g/cm³).

The so prepared samples were then placed in the incubation chamber and incubated in the darkness at the constant temperature $T = 25 \pm 1^{\circ}\text{C}$ for up to 30 days.

At pre-designated time points – 0, 7, 14, 21, 28 and 30 days after the experiment began, triplicate samples of each buffer solution were taken for the analysis.

Some of the test vials were periodically weighed during incubation to determine if there were any loss of solution.

The solution from each sampled vial was analysed for the total radioactivity content. That was done by LSC using three 0.10-mL aliquots. Each sample was also analysed directly by HPLC in order to quantify the levels of the parent compound and the products of hydrolysis. Also the pH of each sample was measured at sampling.

LSC analysis was performed in 15 mL of UltimaGold liquid scintillation cocktail using Packard Tri-Carb LS counter equipped with automatic external standardisation. The minimum sensitivity of LSC analysis was 1.0 E-3

ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 70 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 35 cpm, assuming average background (BCGK) of 35 cpm ($LAGC = 2 \times BCGK$ and $LANC = LAGC - BCGK$). The greatest probable error GPE = 8.83%. The average sample counting size was 0.1 mL, sample counting time was 5 min., background counting time 5 min. and the average counting efficiency – 95%.

The quantitative HPLC analysis was performed using Shimadzu-6A HPLC system equipped with UV detector and radioactivity detector. The chromatographic separation was performed in a gradient mode on Econosil C18 chromatographic column. The elution lasted for 35 minutes. The gradient mode used in the analysis is presented below in the table B.8.2.1.1._CA-2.

Table B.8.2.1.1._CA-2: The gradient mode used in the HPLC analysis of samples collected during the study.

Time [minutes]	Solvent system	
	% Solvent A – water + 0.025% CH ₃ COOH	% Solvent B – CH ₃ CN + 0.025% CH ₃ COOH
0	90	10
25	0	100
30	0	100
35	90	10

Additional chromatographic method used in the experiment was TLC. It was carried out on Silica gel 60 F-254, 0.25-mm thick plates developed in 100% CH₃COOC₂H₅. The detection was carried out using TLC-radioactivity scanner and UV detector.

Finally, the GC-MS method was used. The GC system consisted of Hewlett Packard 5890 device, equipped with DB-5ms capillary GC column (15-m long, 0.25-mm i. d, 0.25-μm film thickness). The chromatographic analysis was carried out using the following programme: the initial T = 80°C held for 1 min, then increased to T = 250°C at rate 20°C/min and was hold at T = 250°C for another 20 min. The temperature of injector was T = 250°C. The GC instrument was coupled with Finnigan Incos 50 mass spectrometer, scanning in range 50 – 350 amu at rate 0.4 sec./scan. The source temperature was T = 180°C and the carrier gas was HE administered at rate 25 cm/sec.

Results and their discussion:

The results of the verification of the pH of each **test buffer solution** are presented below in the table B.8.2.1.1._CA-3. On their basis it can be stated that the pH of the buffer solutions was stable throughout the experiment.

Table B.8.2.1.1._CA-3: The results of the verification of the pH of each **test buffer solution** in function of time.

Sampling time point [day]	Measured pH of the buffer solution:		
	pH 5 (Acetate)	pH 7 (Phosphate)	pH 9 (Borate)
0	5.20	7.11	9.01
7	4.92	6.97	8.82
14	5.00	7.06	8.84
21	5.05	7.10	8.81
28	5.01	7.06	8.77
30	5.20	7.14	8.92
Average pH (SD)	5.06 (0.10)	7.07 (0.05)	8.86 (0.08)

The results of the experiment – amount of the radioactivity in the solution at each time point, determined by LSC, and its identity, determined using HPLC, are presented below, separately for each **test buffer solution**, in tables B.8.2.1.1._CA-4 – B.8.2.1.1._CA-6.

These results show that no hydrolytic degradation of Flufenacet was observed at any tested pH and T = 25°C.

It shall be indicated that in case of all three **test buffer solutions** some results of the determination of the total radioactivity in solution were rejected, as being lower and not passing the quotient test. The Applicant attributed those lower amounts of recovered radioactivity to the fact that it could have been bound to the nylon filter during sterilization. RMS decided, in order to distinguish these values, to give them in italics.

The results were kinetically examined using linear regression method. As they do not comply with the current standards RMS decided to repeat that examination using non-linear regression method. The modelling tool used in the kinetic fitting was CAKE ver 3.1. The values used in the analysis are those reported in tables B.8.2.1.1._CA-4 – B.8.2.1.1._CA-6 as *Radioactivity recovered identified as Flufenacet*. The graphical results are presented below on figure B.8.2.1.1._CA-2. The key numerical results of that examination are presented in the table B.8.2.1.1._CA-7

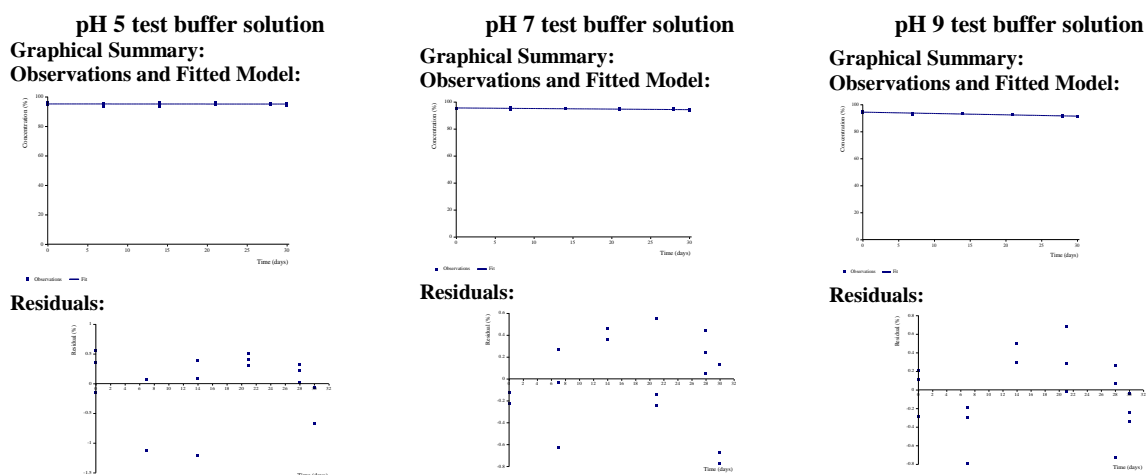

Figure B.8.2.1.1_CA-2: The graphical results of the examination of the rate of abiotic aquatic hydrolysis of Flufenacet.

Table B.8.2.1.1.1_CA-7: The numerical results of the examination of the rate of abiotic aquatic hydrolysis of Flufenacet.

Conclusions: The results of the study demonstrated that at $T = 25^{\circ}\text{C}$ Flufenacet was hydrolytically stable in the whole examined pH range pH 5 – pH 9. No products of hydrolytical degradation of that compound were detected.

Study 2:

Report: Shah J. F., Bloomberg A. M., (1999): "Hydrolysis study of Thiadone (A Metabolite of FOE 5043)."; Ricerca LLC, Department of Environmental and Metabolic Fate, 7528 Auburn Road, Painesville, Ohio 44077, USA (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, MO 64120, USA; Ricerca document No. 7410-0058-EF-001, study No. F3082402 (Bayer); Bayer Report No. 108719; 22 February 1999; study reference number: M-009620-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-1.

GLP: Yes;

RMS comments: This is a newly submitted study, examining the aqueous hydrolysis of FOE Thiadone – a major degradation product of Flufenacet in both soil and aquatic environment (water/sediment systems). For the purpose of the current assessment the study was evaluated for its compliance with OECD Guideline 111 – Hydrolysis as a Function of pH. RMS stated that the study complied with the provisions of the reference Guideline, therefore it can be considered acceptable for the present assessment. It is summarised below.

Summary:

The aim of the study was to investigate the hydrolysis of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet, in aqueous solution in the environmentally relevant pH range of 5-9 and temperature $T = 25^{\circ}\text{C}$.

The test compound used in the experiment was radiolabelled FOE Thiadone, labelled in C2 position, as shown below on figure B.8.2.1.1._CA-3. It had radiochemical purity of 97.7% and specific activity of 50.5 mCi/mmol, corresponding to 0.294 mCi/mg or 652680 dpm/ μg .

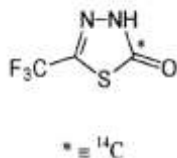

Figure B.8.2.1.1._CA-3: The structural formula of the test compound; radiolabelling position is indicated by an asterisk - (*); (copied from the study report).

Also the non-radiolabelled test compound, having a chemical purity of 99.3%, was used in the experiment. From it a stock solution was prepared by dissolving ~10 mg of the test compound in 10 mL of CH_3CN .

The test vessels were sterile autosampler vials, which were placed in the dark in environmental chambers and kept at $T = 25 \pm 1^{\circ}\text{C}$.

All glassware used in the experiment was sterilised with steam at $\sim 123^{\circ}\text{C}$ for about 20 minutes, after being wrapped in foil. After sterilisation they were kept covered with foil until being used.

The experiment was performed using three buffer solutions:

- pH 5 buffer (acetate buffer),
- pH 7 buffer (phosphate buffer),
- pH 9 buffer (borate buffer),

each having a concentration of 0.05 M. The detailed information on the composition of each buffer and method of its preparation is given below in the table B.8.2.1.1._CA-8.

Table B.8.2.1.1._CA-8: The composition and properties of the buffer solutions used in the experiment.

Type of buffer solution	Nominal pH	Composition	Method of preparation	Final concentration
<i>Acetate buffer</i>	5	0.2 M CH ₃ COOH + 0.2 M CH ₃ COONa	a) 72.5 mL of 0.2M CH ₃ COOH (glacial) were combined with 177,5 mL of 0.2M diluted with CH ₃ COONa; b) The solution was brought to the volume of 1000 mL with HPLC-grade water.	0.05M
<i>Phosphate buffer</i>	7	0.2M KH ₂ PO ₄ + 1.0 M NaOH _{aq}	a) 250 mL of 0.2M KH ₂ PO ₄ were combined with 29 mL of 1.0M NaOH _{aq} ; b) The solution was brought to the volume of 1000 mL with HPLC-grade water.	0.05M
<i>Borate buffer</i>	9	0.2M KCl/H ₃ BO ₃ _{aq} + 1.0 M NaOH _{aq}	a) 250 mL of 0.2M KCl/H ₃ BO ₃ _{aq} solution were combined with 21 mL of 1.0M NaOH _{aq} ; b) The solution was brought to the volume of 1000 mL with HPLC-grade water.	0.05M

The so prepared buffer solutions were sterilised by passing them through a 0.22-µm cellulose acetate membrane filters.

Next the **fortification solution** of FOE Thiadone was prepared by placing 0.75 µL of the stock solution of radiolabelled test compound, having a specific activity of ~2396.7 µg/mL, in 5-mL volumetric flask. The solvent – acetone, was allowed to evaporate and the residue was reconstituted in 3 mL of CH₃CN. The so prepared solution had a specific activity, determined by LSC, of ~59.92 µg/mL. Its purity was conformed by radio-HPLC.

So prepared **fortification solution** was used to treat the samples of each test buffer solution. That was performed in the following way: 0.68 mL of the **fortification solution** was added to the 80 mL of each sterilised buffer using 1-mL gas-tight syringe. The amount of the organic co-solvent – CH₃CN, in so prepared buffer solutions did not exceed 1%. The levels of fortification of so prepared solutions were: ~0.52 ppm for pH 5 buffer, ~0.53 ppm for pH 7 buffer and ~0.53 ppm for pH 9 buffer solutions.

Next, to each sterilised sample vial ~4.7 mL of the given treated buffer solution were introduced using the sterilised pipette. The vials were then capped, adequately labelled and placed in the darkness at T = 25 ± 1 °C to be incubated for up to 30 days.

At pre-designated time points – 0, 3, 7, 14, 21, and 30 days after the experiment began, samples of each buffer solution were taken for the analysis.

The solution from each sampled vial was analysed for the total radioactivity content. That was done by LSC using three 0.10-mL aliquots. Each sample was also analysed directly by HPLC in order to quantify the levels of the parent compound and the products of hydrolysis. Also the pH of each sample was measured at sampling.

LSC analysis was performed in 5 or 10 mL of UltimaGold liquid scintillation cocktail using Beckman LS 6500 LC liquid scintillation counter. Samples were counted for two minutes. The device operated in the constant background subtraction mode.

The quantitative HPLC analysis was performed using Waters HPLC system equipped with Waters 484 Tunable Absorbance detector set to λ = 254 nm, and Radiomatic Flo-One/β A-250 radio-chromatography detector.

The chromatographic separation was performed in a gradient mode on Phenomenex Luna C18 (150 x 4.6 mm, 5 µm) chromatographic column preceded by Zorbax Rx-C18 (12.5 X 4.6 mm) guard column. The elution lasted for 70 minutes. The gradient mode used in the analysis is presented below in the table B.8.2.1.1._CA-9. The flow rate of the mobile phase was 1.0 mL/min.

Table B.8.2.1.1._CA-9: The gradient mode used in the HPLC analysis of samples collected during the study.

Time [minutes]	Solvent system	
	% Solvent A – water + 0.05% CH ₃ COOH	% Solvent B – CH ₃ OH
0	100	0
40	30	70
60	30	70
61	100	0
70	100	0

Additional chromatographic method used in the experiment was LC-MS. The chromatographic analysis was carried out in a gradient mode using Phenomenex Columbus C8 (150 x 2.0 mm, 5 µm) chromatographic column. The mobile phase consisted as 0.05% HCOOH in water as **Solvent A** and CH₃OH as **Solvent B**. The gradient was following: for the first 2 minutes 1:1 then until minute 8th of elution to 3:7 (ratio **Solvent A: Solvent B**). The flow rate of the mobile phase was 0.2 mL/min.

The LC instrument was coupled with Finnigan mass spectrometer, scanning in range 95 – 300 amu at rate 1.5 sec./scan. The source temperature was T = 220°C. The detector worked in (-)ESI ionisation mode.

Results and their discussion:

The results of the verification of the pH of each **test buffer solution** are presented below in the table B.8.2.1.1._CA-10. On their basis it can be stated that the pH of the buffer solutions was stable throughout the experiment.

Table B.8.2.1.1._CA-10: The results of the verification of the pH of each **test buffer solution** in function of time.

Sampling time point [day]	Measured pH of the buffer solution:					
	pH 5 (Acetate)		pH 7 (Phosphate)		pH 9 (Borate)	
	Replicate 1	Replicate 2	Replicate 1	Replicate 2	Replicate 1	Replicate 2
0	5.03	5.03	7.02	7.00	9.07	9.01
3	5.07	5.05	7.03	7.03	9.06	9.04
7	5.05	5.05	7.07	7.05	9.07	9.07
14	5.06	5.05	7.04	7.03	9.05	9.05
21	5.03	5.05	7.05	7.06	9.09	9.09
30	5.06	5.05	7.04	7.06	9.07	9.06

The results of the experiment – amount of the radioactivity in the solution at each time point, determined by LSC, and its identity, determined using HPLC, are presented below, separately for each **test buffer solution**, in tables B.8.2.1.1._CA-11 – B.8.2.1.1._CA-13. These results show that no hydrolytic degradation of FOE Thiadone was observed at any tested pH and T = 25°C. The “Other constituents” fraction is a multi-component fraction, attributed to the presence of impurities in fortification solution. None of its constituents was in amounts enabling its further identification.

The data were not kinetically examined as it was stated that the concentration of FOE Thiadone remained generally the same in all buffer samples throughout the study duration. As a result, it was stated that FOE Thiadone was hydrolytically stable in the environmentally relevant pH range – pH = 5 – 9 and at environmentally relevant temperature T = 25°C.

RMS having examined the results stated that the conclusion drawn by the Applicant was correct and decided not to perform own kinetic analysis of the data as that would not change the final conclusions, but would unnecessary overburden the summary.

Conclusions: The results of the study demonstrated that at T = 25°C FOE Thiadone was hydrolytically stable in the whole examined pH range pH 5 – pH 9. No identifiable products of hydrolytic degradation of that compound were detected and quantified.

Study 3:

Report: Babczinski P., Jantzen T., (2009): “[Thiadiazole-2-¹⁴C]FOE5043-Thiadone (BCS-AA41715): Hydrolytic degradation.”; Bayer Crop Science AG, Alfred-Nobel-Str. 50, D-40789 Monheim am Rhein, Germany; study No. M1111833-8, Report No. MEF-009/308; 2009. 10. 26; study reference number M-358419-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline No. 111, Hydrolysis as a Function of pH, 2004;
- Commission Directive 94/37/EC (1994) and 95/36/EC (1995) amending Council Directive 91/414/EEC (Fate and Behaviour in the Environment).

GLP: Yes;

RMS comments: This is a newly submitted study, examining the aqueous hydrolysis of FOE Thiadone – a major degradation product of Flufenacet in both soil and aquatic environment (water/sediment systems). It was evaluated for its compliance with the evoked guideline – OECD Guideline 111, Hydrolysis as a Function of pH. RMS stated that the study complied with the provisions of the reference Guideline, therefore it can be considered acceptable for the present assessment. It is summarised below.

Summary:

The aim of the study was to investigate the hydrolysis of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet, in aqueous solution in the pH range of 4 – 9 and temperature T = 50°C.

The test compound used in the experiment was radiolabelled Flufenacet, labelled evenly in phenyl ring, as shown below on figure B.8.2.1.1._CA-4. It had radiochemical purity of > 99% (determined by radio-HPLC and radio-TLC) and chemical purity of > 99% (determined by HPLC). The compound's specific activity was 4.28 MBq/mg. It was delivered to the test facility as a vacuum-dried solid.

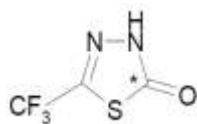

Figure B.8.2.1.1._CA-4: The structural formula of the test compound; radiolabelling position is indicated by an asterisk - (*); (copied from the study report).

The test compound was used to prepare a **Stock solution**, by dissolving the whole delivered sample in 3 mL of CH₃CN. That **stock solution** was used directly as application solution.

The test vessels were sterilised 10-mL glass crimp-top vials, closed with crimp caps with Teflon-faced septa. The vessels and other equipment used in the experiment were sterilised by steam pressure sterilisation.

The experiment was performed using three buffer solutions:

- pH 4 buffer (acetate buffer),
- pH 7 buffer (TRIS buffer),
- pH 9 buffer (borate buffer),

each having a concentration of 0.01 M. The detailed information on the composition of each buffer and method of its preparation is given below in the table B.8.2.1.1._CA-14.

Table B.8.2.1.1._CA-14: The composition and properties of the buffer solutions used in the experiment.

Type of buffer solution	Nominal pH	Composition	Method of preparation	Final concentration
<i>Acetate buffer</i>	4	CH ₃ COOH + CH ₃ COONa	a) 1.36 g of CH ₃ COONa x 3 H ₂ O was dissolved in 900 mL of demineralised ultrapure water; b) the pH of so prepared solution was measured and adjusted to pH = 4.0 using CH ₃ COOH; c) the whole solution was brought to the volume of 1 L with demineralised ultrapure water; d) oxygen was removed from the solution by passing through it N ₂ for 5 minutes; e) the so prepared buffer solution was sterilised by autoclaving it.	0.01M
<i>TRIS buffer</i>	7	(HOCH ₂) ₃ CNH ₂ + 0.1M HCl _{aq}	a) 1.21 g of TRIS – (HOCH ₂) ₃ CNH ₂ , was mixed with 46.6 mL of 0.1M HCl _{aq} and diluted to 800 mL with demineralised ultrapure water; b) the pH of so prepared solution was measured, adjusted to pH = 7.0 using 0.1M HCl _{aq} and its final volume brought to 1L using demineralised ultrapure water; c) oxygen was removed from the solution by passing through it N ₂ for 5 minutes; d) the so prepared buffer solution was sterilised by autoclaving it.	0.01M
<i>Borate buffer</i>	9	H ₃ BO ₃ aq + KCl + 0.5M NaOH _{aq}	a) 0.62g of H ₃ BO ₃ and 0.75 g of KCl were dissolved in ~800 mL of demineralised ultrapure water; b) the pH of so prepared solution was measured, adjusted to pH = 9.0 using 0.5M NaOH _{aq} and its final volume brought to 1L using demineralised ultrapure water; c) oxygen was removed from the solution by passing through it N ₂ for 5 minutes; d) the so prepared buffer solution was sterilised by autoclaving it.	0.01M

The characterised above aqueous buffer solutions were used to prepare the buffer solutions of the test compound used in the experiment. The **test buffer solutions** had the concentration of the test item (FOE Thiadone) $C = 1 \text{ mg/L}$.

That was done in the following way: 0.123-mL aliquots of the **stock solution** were pipetted into sterile Erlenmeyer flasks containing 100 mL of the given sterile and oxygen-free buffer. The solutions were homogenised and their 5-mL samples were pipetted, under sterile conditions, into 10-mL sterilised test vials. The number of prepared test vials was such to obtain, for each **test buffer solution** duplicate samples for each time point, 16 in total for each pH. The test vials were then closed with sterilised Teflon-faced septa, placed in a temperature-controlled water bath and incubated in the darkness at the constant temperature $T = 50 \pm 0.1^\circ\text{C}$ for up to 7 days. The sampling points were set to: 0, 0.1, 0.25, 1, 2, 5 and 7 days after introduction of the **test buffer solution**. The day-0 samples after taking aliquots for analysis were stored in a freezer.

The incubation chamber used in the study is shown below on figure B.8.2.1.1._CA-5.

The samples after removal from the incubation chamber were analysed in line with the general procedure presented on figure B.8.2.1.1._CA-6. The samples were not processed prior to the analysis.

The application rate and homogeneity of the **test buffer solutions** was verified by LSC before and after filling the test vials. All calculations were carried out using as a reference value the specific activity of the sample of the test item delivered to the laboratory performing the experiment – 4.28 MBq/mg.

Figure B.8.2.1.1._CA-5: The incubation chamber used in the experiment (copied from the study report).

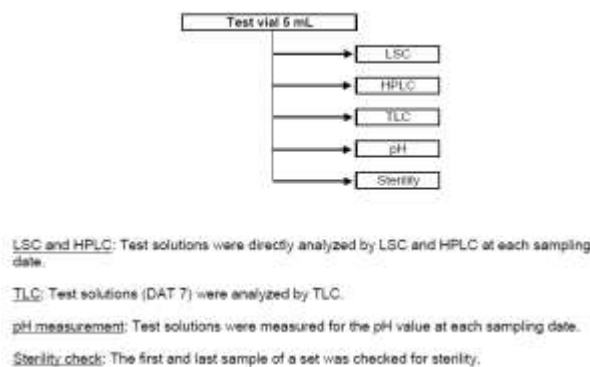

Figure B.8.2.1.1._CA-6: The general procedure for sample analysis used in the study (copied from the study report).

The sterility check in day-0 and day-7 samples was performed in the following way: 100- μL aliquot of the given sample was applied onto a mixed culture medium and incubated for 18 days in the darkness at the constant temperature $T = 30^\circ\text{C}$. After that period the microbial contamination was evaluated visually.

The LSC analysis of the samples was performed for their 0.1-mL aliquots in 2 mL of Quicksafe A + 5% water LS cocktail. The measurements were carried out using LS6000LL/LS6500 (Beckman) counter. The average counting efficiency was 91-92% and background 13-14 cpm.

The HPLC analysis was performed using 1.0-mL aliquots of each sample. It was carried out using Agilent 1100 HPLC system coupled to Ramona Star radioactivity detector and Agilent UV detector set to the wavelength $\lambda = 254 \text{ nm}$. The chromatographic separation was performed in a gradient mode on Purospher STAR RP-18

(250 x 4.6 mm, 5 µm) chromatographic column preceded by an unspecified guard column. The elution lasted for 35 minutes at the flow rate of the mobile phase of 1 mL/min. The gradient mode used in the analysis is presented below in the table B.8.2.1.1._CA-15.

Table B.8.2.1.1._CA-15: The gradient mode used in the HPLC analysis of samples collected during the study.

Time [minutes]	Solvent system	
	% Solvent A – Water + 1% HCOOH	% Solvent B – CH ₃ CN + 1% HCOOH
0	100.0	0.0
2	100.0	0.0
6	80.0	20.0
24	20.0	80.0
25	5.0	95.0
28	5.0	95.0
29	100.0	0.0

The identification of the test item was done by comparison of the retention times. The quantification was performed using the calibration curve, also used to determine the values of LOD and LOQ.

The HPLC-MS(/MS) analysis, used for the verification of the test item, was performed using Agilent HP110 HPLC system coupled with UV detector and Finnigan TSQ 7000 Mass Spectrometer.

The chromatographic separation was performed in a gradient mode on Nucleodur C18 Gravity(250 x 2.0 mm, 5 µm) chromatographic column. The elution lasted for 35 minutes at the flow rate of the mobile phase was set to 0.2 mL/min. The gradient mode used in the analysis is presented below in the table B.8.2.1.1._CA-16.

Table B.8.2.1.1._CA-16: The gradient mode used in the HPLC-MS (/MS) analysis of samples collected during the study.

Time [minutes]	Solvent system	
	% Solvent A – Water + 0.1% HCOOH	% Solvent B – CH ₃ CN + 0.1% HCOOH
0	95	5
1	95	5
25	5	95
35	5	95

Additional chromatographic method used in the experiment was TLC. It was carried out on silica gel plates Merck Si60, F-254, 0.25-mm thick, developed in CH₂Cl₂/CH₃COOC₂H₅/HCOOH 80:20:1 solvent system. The detection was carried out using TLC-radioactivity scanner and UV detector.

Results and their discussion:

The results of the verification of the application rate for each **test buffer solution** are presented below in the table B.8.2.1.1._CA-17.

Table B.8.2.1.1._CA-17: The results of the application rate of each **test buffer solution**.

Test buffer solution	Radioactivity in test buffer solution [Bq/5 mL]	Amount of FOE Thiadone in solution [µg/5 mL]	Concentration of FOE Thiadone in solution [µg/L]
<i>pH 4 (acetate buffer)</i>	21522	5.036	1.007
<i>pH 7 (TRIS buffer)</i>	21193	4.952	0.990
<i>pH 9 (borate buffer)</i>	22258	5.200	1.040

The continuous monitoring of the temperature in the incubation chamber showed that it was constant throughout the study – the temperature of the water bath was T = 50°C and that recorded in the chamber was T = 50.1°C.

The results of the determination of the pH in each buffer solution throughout the experiment were following:

- for pH = 4 (acetate) buffer the mean pH = 4.1 and did not vary;
- for pH = 7 (TRIS) buffer the mean pH = 7.0 with range 6.9 – 7.0;
- for pH = 9 (borate) buffer the mean pH = 9.0 and did not vary.

The results of the sterility check of each test solution showed no contamination with microorganisms, indicating that the sterility was maintained throughout the experiment.

For the HPLC method the determined LOD < 1% AR, corresponding to ~< 10 µg/L.

The results of the experiment – amount of the radioactivity in the solution at each time point, determined by LSC, and its identity, determined using HPLC, are presented below, separately for each **test buffer solution**, in tables B.8.2.1.1._CA-18 – B.8.2.1.1._CA-20.

These results show that no hydrolytic degradation of FOE Thiadone was observed at any tested pH and T = 50°C – the amount of recovered radioactivity identified as a test compound was in all samples > 90% AR and the amount of not identified radioactivity never surpassed 2%AR, most commonly being below 1% AR. For that reason it was decided not to perform the kinetic analysis of the data nor to examine the hydrolysis at lower temperature – T = 25°C or T = 20°C.

Table B.8.2.1.1._CA-18: The results of the experiment in **pH = 4 (Acetate) test buffer solution**.

The data were not kinetically examined as it was stated that the concentration of FOE Thiadone remained the generally same in all buffer samples throughout the study duration. As a result, it was stated that FOE Thiadone was hydrolytically stable in the pH range 4 – 9 and at temperature – T = 50°C.

RMS having examined the results stated that the conclusion drawn by the Applicant was correct and decided not to perform own kinetic analysis of the data as that would not change the final conclusions, but would unnecessary overburden the summary.

Conclusions: The results of the study demonstrated that at T = 50°C FOE Thiadone was hydrolytically stable in the whole examined range of pH = 4 – 9. No identifiable products of hydrolytical degradation of that compound were detected and quantified.

Additionally RMS, performing the repeated literature search, identified one paper relevant for the evaluation of Flufenacet in the area of its hydrolytical degradation in aqueous environment. The study is summarised below as **Study 4**.

Study 4:

Report: Sunita Rani, Beena Kumari, TS Kathpal, (2006): “Effect of pH on the Dissipation Behaviour of Flufenacet (FOE-5043) in Water.”; Department of Entomology, CCS Haryana Agricultural University, Hisar (India); published study - published in: “Pesticide Research Journal”, 2006, 18 (2), 201 – 204;

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper

RMS comments: The paper presents the results of the examination of the effect of pH on the rate of dissipation of Flufenacet from water column. The experiment was performed for two different concentrations of Flufenacet – 0.5 µg/mL (0.5 mg/L) and 1.0 µg/mL (1.0 mg/L) at three different pH values – pH = 5.2, pH = 7.2 and pH = 8.2. The tested pH range corresponded to that observed in the environment. In the study report it was not specified what kind of water was used – natural, tap, distilled or specially prepared water, nor whether the test water was sterilised or not. The paper however bears several references to the microbial activity of water, therefore it may be assumed that the test medium – water used in the experiment, was not sterilised.

It shall be indicated that the study does not seem to follow the analytical protocol outlined in the OECD 111 Guideline. However, it provides a good insight into the problem of whether the pH of water may have any influence on the dissipation/degradation of Flufenacet from water column and what may be the extent of that effect. For that reason RMS decided to include it into the assessment. However, due to the noted drawbacks:

- water used in the study was not characterised,
- the exact sampling dates, in days after treatment, were not provided,
- the concentrations of Flufenacet are provided only for water column and there is no information on the amount of the test compound remaining in the test system (adhering to the test vessels, precipitated at the bottom of the test vessels, forming an emulsion film on its surface), so there is no proper mass balance performed,
- the temperature during incubation period, lasting for 28 weeks, was not constant, but, being room temperature, it varied in a substantial range of (as reported in the summarised paper) T = 1.0 – 39.5°C,

RMS is of the opinion that the results it provides are only indicative. Therefore they may be regarded only as supplementary and should not be used as a source of regulatory endpoints.

Summary:

The publication contained a summary in English. However, because of the copyright restrictions, RMS decided not to present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to investigate the dissipation of Flufenacet in water at different pH levels. The test compound was non-radiolabelled analytical grade (99% purity) Flufenacet obtained from M/s Bayer India Ltd. It

was used to prepare the stock solution, having the concentration of 0.1 mg/mL, in hexane. The application solutions were prepared by diluting it.

The dissipation was examined in water samples having three different pH levels – 5.2, 7.2 or 8.2. The water samples having pH = 5.2 were obtained using the phosphate buffer ($\text{KH}_2\text{PO}_4 + 10\% \text{H}_3\text{PO}_4$ in water) and those having pH = 8.2 using the ammonium buffer ($\text{NH}_4\text{Cl} + \text{NH}_4\text{OH}$ in water). It was not specified how the water samples having pH = 7.2 were obtained, but it may be assumed that that was probably the original pH of water used in the experiment and as such it was probably not adjusted.

The water samples having a different pH, were prepared in triplicate for each fortification level, which was either 0.5 mg Flufenacet/L or 1.0 mg Flufenacet/L. The volume of each replicate sample was 6 litres.

The treated water samples were stored in Winchester bottles from July 2001 to February 2002 at room temperature ($T = 1.0 - 39.5^\circ\text{C}$). The untreated control samples were set along the treated ones. At pre-designated time points – 0 (1 hour), 1, 2, 5, 8, 11, 14, 16 and 28 weeks after treatment samples were drawn from each replicate and analysed for the content of Flufenacet.

The water samples taken at each sampling point were processed as follows: representative 200-mL samples were placed into 1-L funnel to which 5-10 g NaCl was added, and extracted three times with n-hexane, using 50 mL-, 30 mL- and 30 mL-portions of the organic solvent. The organic extracts were combined, passed through the anhydrous Na_2SO_4 and concentrated to dryness under vacuum. The residues were reconstituted in 1 mL of n-hexane and analysed by GC-ECD.

The chromatographic analysis was carried out using SPB-5 capillary column, 30-metres long, 0.32 mm i.d. 0.25 μm film thickness. The GC oven temperature was set to $T = 210^\circ\text{C}$. The identification was performed by means of the retention time – $R_t = 3.76$ min.

The LOD determined for the analytical procedure was 0.005 $\mu\text{g/mL}$ and the procedural recoveries of the test item were 88.98% at pH = 7.0 and 88.97% at pH = 8.2 (for the fortification levels of 0.25 $\mu\text{g/mL}$ and 0.50 $\mu\text{g/mL}$).

The numerical results of the experiments – the concentration of Flufenacet in water in function of time, at different pH and fortification levels, are presented below in the table B.8.2.1.1._CA-7. On their basis the authors performed the kinetic analysis of the process of dissipation of Flufenacet from water using the linear regression method. The key results of that analysis are presented in the next table – B.8.2.1.1._CA-8.

Table B.8.2.1.1._CA-7: The concentrations of Flufenacet in water at different pH and fortification levels in function of time.

Time point [weeks]	Amount of Flufenacet in water having pH = 5.2 and the fortification level:				Amount of Flufenacet in water having pH = 7.2 and the fortification level:				Amount of Flufenacet in water having pH = 8.2 and the fortification level:

			Rate constant	DT ₅₀ [days]	
5.2	0.5	$y = 2.76 - 0.0651 x$	0.0214	32.4	0.94
	1.0	$y = 3.03 - 0.0568 x$	0.0187	37.0	0.95
7.2	0.5	$y = 2.77 - 0.0627 x$	0.0206	33.6	0.94
	1.0	$y = 3.03 - 0.0559 x$	0.0184	37.7	0.94
8.0	0.5	$y = 2.71 - 0.0694 x$	0.0228	30.4	0.92
	1.0	$y = 3.00 - 0.0600 x$	0.0197	35.1	0.93

Characterising the performed kinetic analysis the authors of the publication stated that the decline curves were three-phase 1st order curves, with slow initial and terminal phases and fast middle phase. On the figures presenting the graphical results of the kinetic analysis of the data they had sigmoidal shape, similar to that taken by the titration curves.

It was also stated that the shape of the decline curves and the concentrations at each time point for the given fortification level were similar for all three tested pH values. Therefore it was stated that the process of dissipation of Flufenacet from water phase was independent of its pH.

RMS comments:

The study, because of its design, provides results that can be considered solely as indicative and supplementary with regard to the examination of hydrolytic degradation of Flufenacet in aquatic systems. For that reason it cannot be used to derive the EU regulatory endpoints. They confirm however the statement that abiotic hydrolysis will not play any significant role in transformation of Flufenacet in water.

Summary – Hydrolysis of Flufenacet

The abiotic hydrolysis of Flufenacet was examined at three different pH – pH = 5, pH = 7 and pH = 9 (environmentally relevant pH range) and T = 25°C. The results of that examination, presented in one study report, demonstrated that Flufenacet was hydrolytically stable within the whole examined pH range. The determined in that experiment half-lives at T = 25°C were: DT₅₀ > 1000 days for pH 5-7 and DT₅₀ = 655 days for pH = 9.

Additionally the results presented in the open source paper identified as a relevant for the evaluation of Flufenacet showed that the pH of the aqueous solution, and hence the hydrolysis, had only minimal influence on the rate of dissipation/degradation of Flufenacet from water (biologically viable). The results of that study were considered however only as indicative and were not used to derive the regulatory endpoints.

Also stable to abiotic hydrolysis in the aquatic environment, for the same environmentally relevant conditions, was demonstrated to be the major soil and aquatic major degradation product of Flufenacet – FOE Thiadone. The determined half-lives were DT₅₀ > 1000 days for the whole tested range pH = 5-9 and T = 25°C.

The results of the examination of the hydrolytic degradation of Flufenacet in water, in form recommended for reporting the regulatory endpoints in the EU, are presented below.

Hydrolytic degradation (Regulation (EU) N° 283/2013, Annex Part A, point 7.2.1.1

Hydrolytic degradation of the active substance and metabolites > 10 % *results for Flufenacet – active substance*

pH 5: *stable (DT₅₀ > 10000 days) at 25 °C (1st order - SFO, $\chi^2=0.234$)*
no degradation products detected

pH 7: *stable (DT₅₀ = 1570 days) at 25 °C (1st order - SFO, $\chi^2=0.238$)*
no degradation products detected

pH 9: *stable (DT₅₀ = 655 days) at 25 °C (1st order - SFO, $\chi^2=0.255$)*
no degradation products detected

Hydrolytic degradation of the active substance and metabolites > 10 % *results for FOE Thiadone – major soil and aquatic degradation product of Flufenacet*

pH 5: *stable at 25 °C*
no degradation products detected

pH 7: *stable at 25 °C*
no degradation products detected

pH 9: *stable at 25 °C*
no degradation products detected

B.8.2.1.2 – Photochemical degradation

To address the issue of photochemical degradation of Flufenacet and its major degradation products in aquatic environment the Applicant submitted four study reports. Two of them, both for Flufenacet, were also submitted for the previous authorisation of Flufenacet in the EU. One of them is summarised under the data point for direct aqueous photolysis and under that for indirect aqueous photolysis, as it covers both aspects of phototransformation in the aquatic environment. The second study is related only to the direct photochemical transformation in water.

The Applicant also submitted two new studies, not previously evaluated in the EU. Their aim was to examine the direct and indirect photodegradation of FOE Thiadone – the major aquatic degradation product of Flufenacet identified in water/sediment studies. Each of them will be summarised under the relevant data point of this Renewal Assessment Report.

It shall be indicated that in the previous Assessment Report it was stated that “As no relevant metabolites were formed in the photolysis study on the active ingredient, no further studies are necessary”.

However, FOE Thiadone, although not a photodegrade of Flufenacet, was shown to be formed from the parent compound in the aquatic environment, in other processes, in substantial amounts (> 80%). Due to its physicochemical properties – aqueous solubility $S \geq 95.5$ g/L at $T = 20^{\circ}\text{C}$ and whole environmentally relevant pH range – pH = 5-9, as well as its moderate adsorption potential – in soil the Freundlich adsorption constant was in range $K_f = 0.115 - 0.703$ mL/g, that compound is expected to be present mainly in water phase (the results of water/sediment study seem to confirm that). Therefore the examination of its potential direct aqueous photodegradation, and possibly also indirect, is required.

B.8.2.1.2.1. – Direct Photochemical degradation

The following two studies present the results of the examination of the direct photolysis of Flufenacet in water.

Study 1:

Report: Kasper A. M., Shadrick B. A., (1995): “Aqueous Photolysis of [Phenyl- ^{14}C] FOE 5043.”; Bayer Corporation (formerly Miles Inc.), Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3082401 (Bayer); unpublished Miles Report No. MR 106246; 30 May 1995; study reference number: M-002206-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Studies.

GLP: Yes, for the part off the study aimed on the examination of direct aqueous photolysis

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its summary can be found under the point B.7.4.2.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. It presents the results of the examination of both direct photolysis of Flufenacet in water (a GLP study) and the indirect aqueous photolysis of that compound (a non-GLP study). For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- OECD Guideline 316: Phototransformation of Chemicals in Water – Direct Photolysis, Adopted 3 October 2008;
- US EPA Guideline OPPTS 835.2210 – Direct Photolysis Rate in Water by Sunlight; January 1998;
- US EPA Guideline OPPTS 835.2240 – Photodegradation in Water; October 2008;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Studies (indicated as reference Guideline in the study report);
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals in Water – Direct and Indirect Photolysis, Draft Document August 2000 (additional reference document);

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable. It is summarised, in its part related to the examination of direct aqueous photolysis, below. The summary for the part of the experiment aimed on the examination of indirect aqueous photolysis of Flufenacet will be provided under the data point B.8.2.1.2.2.

Summary:

The aim of the study was to examine the direct photodegradation of Flufenacet in aqueous solution through:

- determining the half-life of that compound when exposed to artificial sunlight in sterile aqueous buffer;
- identifying the transformation pattern and in particular the degradation products formed in amounts greater than 10% AR.

The experiment was performed in sterilised buffer solution having pH = 5, as at that pH Flufenacet was demonstrated to display the highest hydrolytic stability. The glassware used in it was sterilised by autoclaving for 20 minutes at T = 121°C and p = 14 psi.

The buffer used in the experiment was 0.01 M acetate buffer, prepared by mixing 0.01M CH₃COONa_{aq} with 0.01M CH₃COOH_{aq} solutions until reaching pH = 5. It was used to prepare the test solution.

The test compound was [Phenyl-U-¹⁴C] Flufenacet, having a specific radioactivity of 66.5 mCi/mmol. Its structural formula is presented below on figure B.8.2.1.2.1._CA-1. It was delivered in form of benzene solution, having a concentration 4.55 mg Flufenacet/mL.

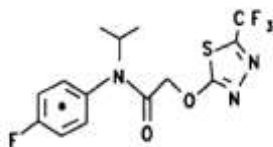

Figure B.8.2.1.2.1._CA-1: The structural formula of the test compound; radiolabelling position indicated with an asterisk (copied from the study report).

To prepare the test solution 0.44 mL of the benzene solution of [Phenyl-U-¹⁴C] Flufenacet was transferred to 45-mL graduated centrifuge tube and evaporated to dryness. The residue was dissolved in 20 mL of CH₃CN and quantitatively transferred to a sterilised 2-L volumetric flask, where it was brought to the volume with the appropriate amount of acetate buffer. So prepared test solution had the concentration 1 mg Flufenacet/L and the content of organic co-solvent of 1%. Its radiochemical purity, determined by HPLC, was 99.2%, and when determined by TLC – 99.9%.

At the beginning of the experiment 60-mL portions of the test solution characterised above were filtered through a Millex GV 0.22 µm sterile filters into the sterilised, foil-wrapped quartz vessels used as test vessels.

The sterility of filtered test solution was checked using Petrifilm Aerobic Count Plates. To do that 1 mL of filtered test solution was plated on the film and placed in incubator set at T = 21°C. The plates were checked for colony growth after 24 and 48 hours.

The vessels filled with test solution were sealed with the volatile trapping columns to form the incubation vessels shown below on figure B.8.2.1.2.1._CA-2. The joints were wrapped with parafilm to grant the air-tightness.

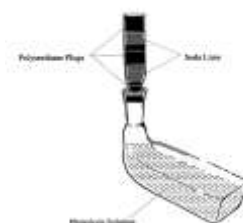

Figure B.8.2.1.2.1._CA-2: Test vessel used in the experiment (copied from the study's report).

The so prepared test vessels designated to be irradiated were placed, after removal of the foil wrapping them, in the irradiation chamber to be irradiated for up to 246 hours (10.25 days). The irradiation chamber was Suntest CPS unit, equipped with Heraeus xenon-arc lamp as light source. It is presented below on figure

B.8.2.1.2.1._CA-3. The lamp was equipped with a UV-filter to cut-off all radiation below $\lambda = 290$ nm. The Suntest CPS unit was a part of the photolysis system shown on the figure B.8.2.1.2.1._CA-4.

The dark-control samples were prepared alongside the irradiated samples. The test vessels were prepared in the same way as described above for irradiation samples, but without removing the foil wrapping them after they were sealed with the volatile trapping columns, and they were placed in the water bath and incubated for the same time and at the same temperature as irradiated samples. The number of prepared test vessels was such to grant duplicate irradiated samples and a single dark control sample per each sampling points. The number of sampling points was 7. The sampling protocol (sampling dates and number of samples collected at each time point) is provided below in the table B.8.2.1.2.1._CA-1.

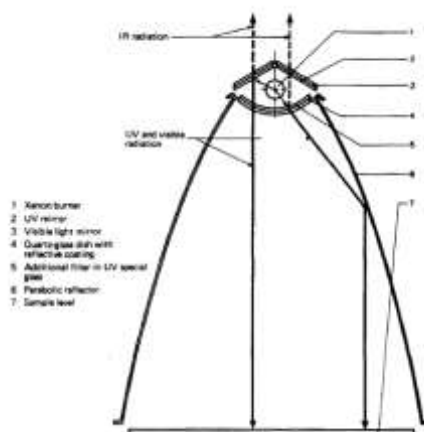

Figure B.8.2.1.2.1._CA-3: The Suntest CPS unit used in the experiment (copied from the study report).

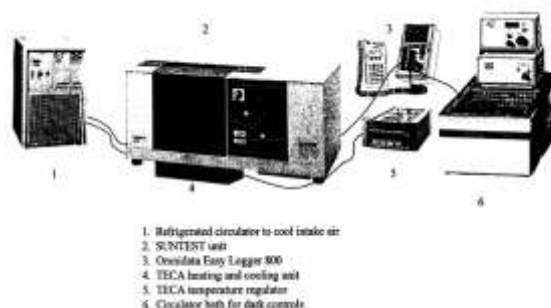

Figure B.8.2.1.2.1._CA-4: The photolysis system used in the experiment (copied from the study report).

The vessels were kept in the irradiation/incubation chambers for up to 246 h, or 10.25 Suntest days (24-hours periods), the irradiated samples under constant exposure to the light emitted by xenon-arc lamp. That exposure period was determined to match a 30-days exposure to sunlight at worst case conditions in Phoenix, Arizona. That estimate was based on the following assumptions:

- total irradiance <800 nm measured in a weather station in Phoenix, AZ (site: New River), on 23rd June 1988 was **681.7 W/m²** (68%),
- total radiant exposure measured at the same site on the same day was **29.5 MJ/m²**.

The calculated from these values daily “global irradiation” at noon on the 23rd June 1988 in Phoenix, AZ, was **20 MJ/m²**.

Using that value it was determined that simulating such irradiation conditions with Suntest unit operating at 680 W/m² would result in **8.2-h** exposure corresponding to one solar day under the worst case conditions assumed above. Using that value the time of irradiation corresponding to the required in Guidelines 30-days exposure to natural sunlight was determined.

The experiment was performed under the constant temperature of 25⁰C by placing all test vessels – irradiated and dark controls (wrapped with foil to cut the light off), in the water bath set to the constant temperature $T = 25 \pm 1^0\text{C}$.

Table B.8.2.1.2.1._CA-1: The sampling protocol used in the study.

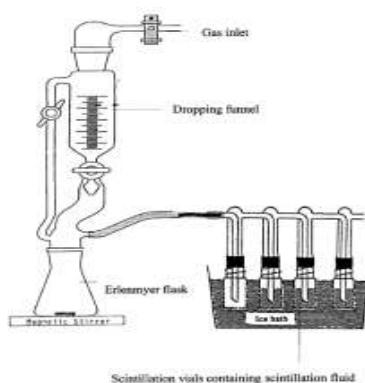

Sampling interval	Sampling time for:			Samples collected – type and number
	Suntest unit (real sampling dates)		Natural sunlight (calculated) [days]	
	[hours]	[days]		
1	0	0	0	Irradiated samples – 2 vessels; dark control – 1 vessel;
2	41	1.71	5	Irradiated samples – 2 vessels; dark control – 1 vessel;
3	86	3.58	10.5	Irradiated samples – 2 vessels; dark control – 1 vessel;
4	123	5.13	15	Irradiated samples – 2 vessels; dark control – 1 vessel;
5	164	6.83	20	Irradiated samples – 2 vessels; dark control – 1 vessel;
6	206	8.58	25.1	Irradiated samples – 2 vessels; dark control – 1 vessel;
7	246	10.25	30	Irradiated samples – 2 vessels; dark control – 1 vessel;

After sample removal, at specified sampling intervals, from the incubation/irradiation chamber, irradiated samples were wrapped with aluminium foil, tower traps for volatile compounds removed and processed for the content of radioactivity.

From each collected test vessel three 0.2-mL aliquots of the test solution were sampled to be analysed for radioactivity content by LSC. Then the pH of the solution was determined and the sterility of the solution in irradiated samples checked using the solution taken from one of the replicates. The sterility was checked using a Pertifilm Aerobic Count Plate method, the same as used to check the sterility of filtered test solution introduced to the test vessels. Next, 1-mL aliquots of each sample were analysed by HPLC. That was done immediately after collecting the test vessels at the given sampling point. Finally 14-mL aliquots of each sample were concentrated to 1 mL on rotary evaporator and analysed by TLC.

The collected traps for volatile compounds were analysed in a following way:

- Polyurethane plugs were removed, rinsed with CH₃CN and both rinse and the plug were analysed for the content of radioactivity using LSC;
- ¹⁴CO₂ captured in soda lime was liberated using the apparatus presented on figure B.8.2.1.2.1._CA-5. This was done by placing the whole 4-g portion of soda lime from each trapping column in 250-mL Erlenmeyer flask containing 10 mL of H₂O, to which 15 mL of concentrated HCl was added. The system was vented with N₂ and released ¹⁴CO₂ captured in a set of three scintillation vials, each containing 15 mL of scintillation cocktail – Carbo-Sorb E and Permafluor E⁺ 2:5 (v/v). The content of vials was analysed quantitatively by LSC.

**Figure B.8.2.1.2.1._CA-5:** The apparatus used to liberate ¹⁴CO₂ from soda lime traps (copied from the study report).

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a Packard Tri-Carb Model 4640 counter, equipped with automatic external standardisation.

Liquid samples were analysed in triplicate, with 15 of Ultima Gold solution added to 0.1-mL aliquots of the analysed sample. The minimum sensitivity of LSC analysis for those samples was 3.9 E-4 ppm. It corresponded to 60 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 30 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 30 cpm ($LAGC = 2 \cdot BCGK$ and $LANC = LAGC - BCGK$). The greatest probable error $GPE = 9.54\%$.

All samples were also analysed using the following techniques:

- HPLC – identification and quantitation method for parent compound and its degradation products;
- TLC – identification and quantitation method for parent compound and its degradation products;

The HPLC analysis was performed using a Shimadzu SCL-6A HPLC chromatograph coupled to Ramona 5-LS radioactivity monitor and Shimadzu SPD-6A UV detector set to $\lambda = 280$ nm. The system was equipped with PRP-1, 5 μ m, 305 \cdot 7 mm chromatographic column (Hamilton Co., Reno) and PRP-1 cartridge as a guard column. The chromatographic separation was performed in a gradient mode, using the mobile phase consisting of:

- water + 0.4% CH_3COOH as **Solvent A**, and
- CH_3CN + 0.4% CH_3COOH as **Solvent B**.

Gradient elution lasted 90 minutes. Its parameters are shown below in the table B.8.2.1.2.1._CA-2. The flow rate was set to 2 mL/min.

Table B.8.2.1.2.1._CA-2: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH_3COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH_3COOH</i>
0	100	0
15	70	30
65	40	60
70	0	100
80	0	100
90	100	0

The LOD for chromatographic method, in reference to the performance of the used radioactivity detector, was determined to be 3000 dpm, what corresponded to 0.7% AR. The value was determined experimentally on the basis of the comparison of radioactivity injected and integrated area under the chromatographic peak. The linearity of the analysis, expressed as r^2 , was: $r^2 = 1.00$. Sample recoveries from the column were on average 93.2% with range 88.6 – 97.2% AR.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards. The retention times of the known reference standards are presented below in the table B.8.2.1.2.1._CA-3.

Table B.8.2.1.2.1._CA-3: HPLC identification of Flufenacet and its degradation products in the study.

Compound	HPLC identification – retention time (R_t) [min]:
<i>Flufenacet (FOE 5043)</i>	70.4
<i>FOE Alcohol</i>	33.7
<i>FOE Oxalate</i>	19.4
<i>FOE Sulfonic acid</i>	19.8
<i>FOE Methylsulfoxide</i>	25.3
<i>FOE Methylsulfone</i>	38.5
<i>FOE 5043 N-isomer</i>	74.4

The TLC analysis of the extracts was performed as RP-TLC (reversed phase TLC). It was carried out on Whatman $KC_{18}F$ TLC plates, having a dimensions 20x20 cm and 200- μ m thick, with a fluorescent indicator. The solvent system used to develop the TLC plates was $CH_3CN:CH_3OH:0.5N NaCl_{aq}$ 2:2:1 (v/v) solution. The identification of each individual constituent of the analysed extract was performed by means of the comparison of R_f values with those of the known standards. In case of Flufenacet the average $R_f = 0.47$.

The quantitative analysis was performed using RITA 68000 Radio-TLC analyser. The LOD of the method was experimentally determined to be 300 dpm, what enabled to detect the radioactivity residues at the level of at least 1 % AR. The linearity of the analysis, expressed as r^2 was: $r^2 = 0.9998$.

The UV-Vis absorption spectra of Flufenacet were determined at different pH – pH = 5, pH = 7 and pH = 9, using Shimadzu UV 260 spectrometer with a slit of 0.8 nm. The absorption spectrum was scanned within the wavelength range of $\lambda = 190 - 400$ nm.

Results and their discussion:

The absorption spectrum of Flufenacet, recorded at various pH for the wavelength range of $\lambda = 190 - 400$ nm, is presented below on figure B.8.2.1.2.1._CA-6. It shows that the maximum absorption for the test compound occurred at $\lambda \approx 220$ nm and the effective absorption range may be estimated to occur within the range of $\lambda = 200 - 250$ nm. Within the environmentally relevant range of $\lambda = 290 - 400$ nm the absorption of radiation was residual, what may indicate that the direct photolysis of Flufenacet in aqueous solutions would be negligible.

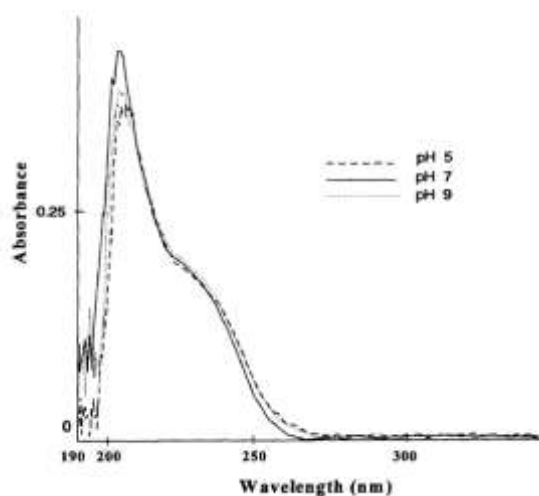

Figure B.8.2.1.2.1._CA-6: The UV-Vis absorption spectrum of Flufenacet recorded for $\lambda = 190 - 400$ nm (copied from the study report).

The examination of the sterility of irradiated samples showed that they were sterile throughout the duration of the experiment.

The irradiated samples in the Suntest unit and dark control samples in the water bath were kept in the constant temperature $T = 25 \pm 1^\circ\text{C}$. In case of the dark control samples that parameter was kept in a range $25.0 - 25.1^\circ\text{C}$, while for irradiated samples the range of incubation temperature was slightly broader: $23.3 - 25.6^\circ\text{C}$, but generally the temperature was $\geq 25.0^\circ\text{C}$.

The pH of the buffer solution in irradiated and dark control samples was on the generally constant level of 5.00. The detailed results of its determination are presented below in the table B.8.2.1.2.1._CA-4.

Table B.8.2.1.2.1._CA-4: The results of the determination of pH in irradiated and dark control samples.

Sampling point	Sampling time – hours of irradiation/incubation	pH measured in		
		Irradiated samples		Dark control samples
		Replicate 1	Replicate 2	
1	0	----	----	5.02 (Rep 1)/5.02 (Rep 2)
2	41	5.03	5.01	5.02
3	86	5.03	5.01	4.99
4	123	5.07	5.04	5.04
5	164	5.01	5.05	5.06
6	206	5.10	5.11	5.20
7	246	5.26	5.23	5.50

The characteristics of the light source – xenon lamp, is presented below in graphical form on figures B.8.2.1.2.1._CA-7 – spectral irradiance graph, and B.8.2.1.2.1._CA-8 – comparison of spectral distribution of xenon lamp used in the experiment and that of the natural sunlight.

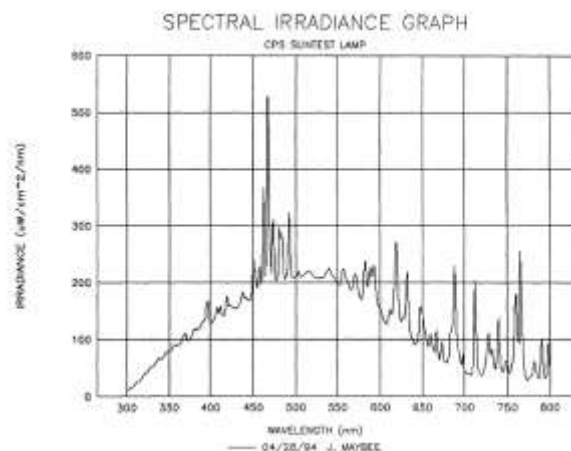

Figure B.8.2.1.2.1._CA-7: Spectral characteristic of the light source – xenon lamp, used in the study (copied from the study report).

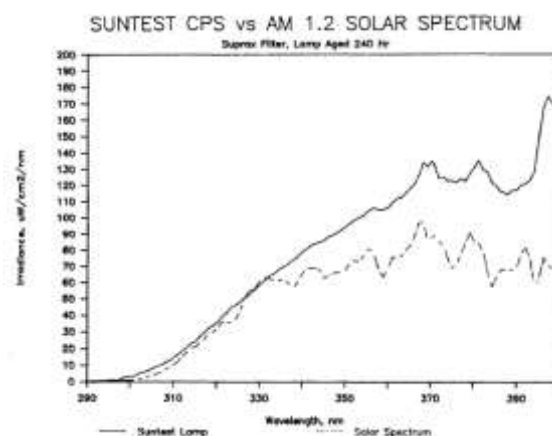

Figure B.8.2.1.2.1._CA-8: The comparison of the spectra of xenon lamp used in the study and of the natural sunlight (copied from the study report).

The quantitative analysis of solutions and traps for volatile compounds, showed that the recovery of applied radioactivity throughout the study was within the recommended range:

- for irradiated samples it ranged from 98.7% AR to 101.2% AR;
- for dark control samples it was in range of 95.0 – 101.1% AR.

The recovered radioactivity was generally found in the solution, with <0.1% AR detected in traps for volatile compounds at any sampling points.

The HPLC analysis showed that the recovered radioactivity consisted mainly of the test compound – Flufenacet, in amounts > 98%. Additionally two degradation products were identified: FOE Methylsulfone and FOE Alcohol. None of them was detected in amounts > 1.0% AR.

The TLC analysis of the content of the test vessels showed that the solutions contained only Flufenacet in amounts > 98%.

Practically no decrease of the concentration of Flufenacet was observed in either irradiated samples or in the dark control samples.

The detailed results are presented below in the table B.8.2.1.2.1._CA-5. The results of the HPLC and TLC analysis – the content of Flufenacet and other identified and quantified components of the sample are given as they were presented in the study report. The Applicant stated that since virtually all radioactivity was recovered in the solution, it was decided to report the concentrations as they were determined in integrated HPLC or TLC

chromatograms, not correcting them for the %AR determined in LSC analysis. In RMS's opinion that approach is acceptable.

Table B.8.2.1.2.1._CA-5: The detailed results of the experiment.

Results obtained for irradiated samples:								
Parameter		Value determined for the sampling point:

The results presented above indicate that there was practically no degradation of Flufenacet during the experimental period in either irradiated samples or in the dark control. Also the results obtained in irradiated control samples and in the dark control samples were almost identical indicating that the negligible transaformation of the test compound observed in irradiated samples could not be attributed to the influence of light.

The data obtained for Flufenacet were further kinetically examined. The analysis was performed using first order kinetics and linear-regression model. As it does not comply with the current standards set by FOCUS Kinetics Guidance [FOCUS, 2006], it was repeated by the RMS. It was performed using CAKE 3.1 kinetic tool developed by Tessella. The input data used in the repeated kinetic analysis are presented below in the table B.8.2.1.2.1._CA-6. The analysis was performed using solely the SFO model. RMS decided, to maintain the consistency of the results, to use the Suntest days as time points for both irradiated samples and the dark control samples, as in case of dark control samples the use of recalculated time points – Natural sunlight days would bias the results. Additional fitting was performed for the irradiated samples using the Natural Sunlight days. The concentrations of Flufenacet used in the kinetic examination were those determined in HPLC analysis.

Table B.8.2.1.2.1._CA-6: The data for Flufenacet used in the kinetic examination performed by RMS.

Irradiated sample			Dark control sample	
Time point [days]		Concentration of Flufenacet [%]	Time point [days]	Concentration of Flufenacet [% AR]

The results of the repeated kinetic analysis of the data obtained for Flufenacet are presented below in the graphical form on figure B.8.2.1.2.1._CA-9 and in numerical form in table B.8.2.1.2.1._CA-7.

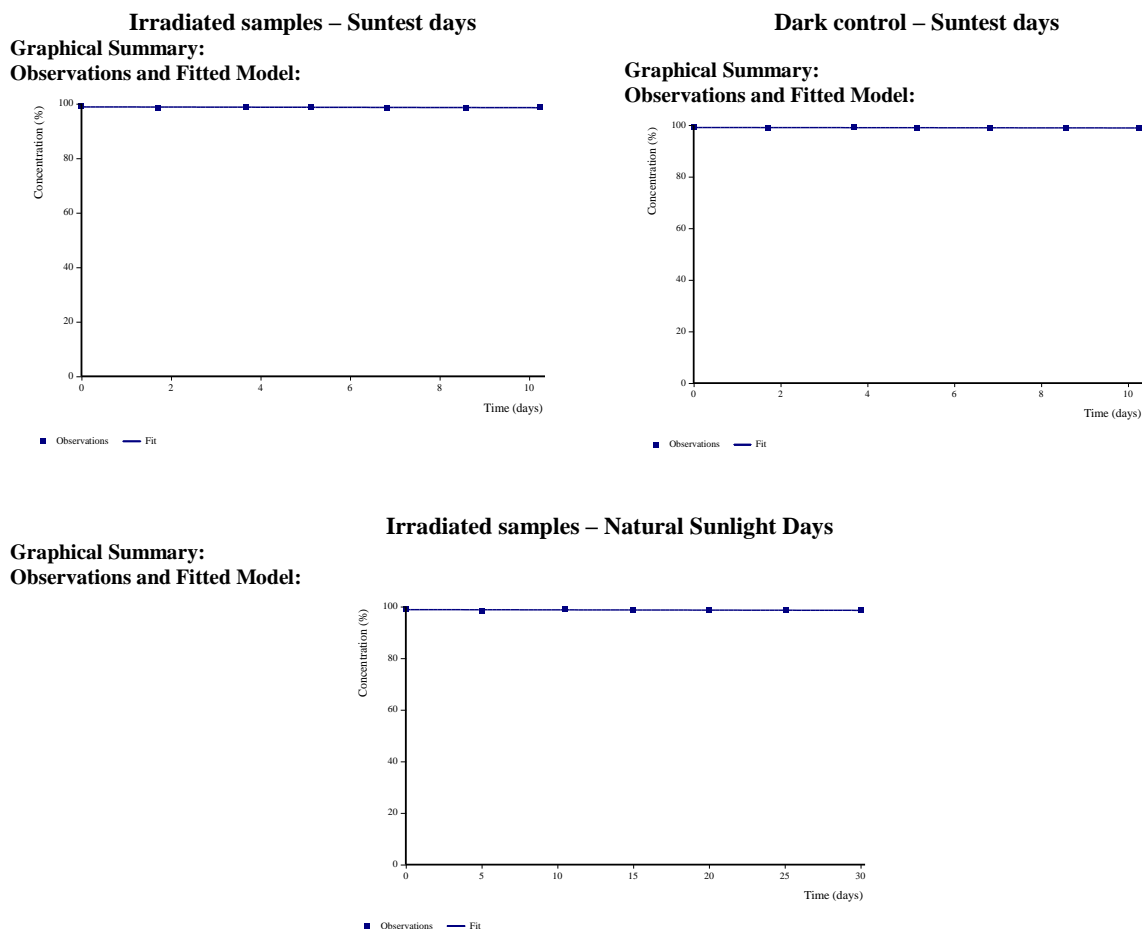

Figure B.8.2.1.2.1._CA-9: The graphical results of the examination of the direct aqueous photolysis of Flufenacet.

Table B.8.2.1.2.1._CA-7: The numerical results of the examination of the direct aqueous photolysis of Flufenacet.

Type of samples	Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	r
					Lower	Upper			
Irradiated-Suntest days	SFO	M_0	98.84	0.162	98.42	99.26	----	0.162	0.172
		k	0.000272	0.000267	-4.14 E-4	0.0001	0.177		
Dark control-Suntest days	SFO	M_0	99.07	0.066	98.9	99.24	----	0.065	0.322
		k	0.000167	0.000108	-1.11 E-4	0.00	0.092		
Irradiated-Natural Sunlight days	SFO	M_0	98.84	0.162	98.42	99.26	----	0.161	0.174
		k	0.0000934	0.0000909	-1.40 E-4	0.00	0.176		

The obtained fits, because virtually no degradation was observed, are of limited reliability. However, the tool returned the DT_{50} values, that may be considered indicative. They are following:

- for irradiated sample using Suntest days $DT_{50} = 2550$ days;
- for irradiated sample using Natural Sunlight days $DT_{50} = 7430$ days;
- for the dark control sample $DT_{50} = 4160$ days

These results clearly indicate that Flufenacet in water is photolytically stable and that direct photolysis as a mechanism of degradation of Flufenacet in surface water bodies will be of the negligible relevance.

Conclusions:

On the basis of the obtained results it may be stated that Flufenacet is not prone to direct photolysis in water. The relevance of that process for the overall degradation of Flufenacet in aquatic environment is therefore negligible.

Study 2:

Report: Hellpointner E., (1993): “Determination of the Quantum Yield and Assessment of the Environmental Half-life of the Direct Photodegradation of FOE 5043 in Water.”; Bayer AG, Crop Protection, Development, Institute for Metabolism Research, 51368 Leverkusen, Germany Study No. M 112 0566-1, Report No. PF-3919 (HPO-103); 27 September 1993; study reference number M-002206-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Phototransformation of Chemicals in Water, Part A: Direct Phototransformation, UBA, Berlin, FRG, 1990;
- ECETOC (polychromatic light); (RMS’s comment: the full reference to that document is: *ECETOC, Technical Report No. 12. The Phototransformation of Chemicals in Water: Results of a Ring-Test. Brussels June 1984*;

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its summary can be found under the point B.7.4.2.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. It presents the results of the determination of quantum yield of direct photolysis of Flufenacet in water. For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- OECD Guideline 316: Phototransformation of Chemicals in Water – Direct Photolysis, Adopted 3 October 2008;
- US EPA Guideline OPPTS 835.2210 – Direct Photolysis Rate in Water by Sunlight; January 1998;
- US EPA Guideline OPPTS 835.2240 – Photodegradation in Water; October 2008;
- *ECETOC, Technical Report No. 12. The Phototransformation of Chemicals in Water: Results of a Ring-Test. Brussels June 1984* (indicated as technical reference Guideline in the study report);
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals in Water – Direct and Indirect Photolysis, Draft Document August 2000 (additional reference document);

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable and as such it is summarised below. At the same time it can be stated that the study may be considered as facultative, because, in light of the recommendations provided by the Commission Regulation (EC) 283/2013, the determination of the quantum yield shall be carried out in case the direct photolysis of the given compound is demonstrated to be significant. The results of the study summarised above as **Study 1** show that Flufenacet is photolytically stable in the aquatic environment.

Summary:

The aim of the study was to determine the quantum yield of the direct photodegradation of Flufenacet in water and to estimate “environmental half-lives” of Flufenacet for that transformation process. The experiment was performed in line with the methodology presented in the document: *ECETOC, Technical Report No. 12. The Phototransformation of Chemicals in Water: Results of a Ring-Test. Brussels June 1984*

The test compound used in the experiment was non-radiolabelled Flufenacet, having a chemical purity of 99.5%. Its structural formula is presented below on figure B.8.2.1.2.1._CA-10.

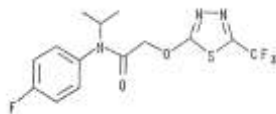

Figure B.8.2.1.2.1._CA-10: The structural formula of the test compound – Flufenacet (copied from the study report).

It was used to prepare the **Stock solution** by dissolving 50.9 mg of it in 10 mL of C₂H₅OH in 10-mL volumetric flask. The concentration of so prepared **Stock solution** was 5.09 mg/mL. That solution was subsequently used to prepare the test solutions used in the study.

The study consisted of the experimental part and the numerical analysis of the results using two numerical models.

The experimental part consisted of two steps:

- recording of UV-absorption spectrum of Flufenacet,
- the degradation experiment,

The test vessels used in the experiment were quartz cuvettes with teflon plugs, having optical path length $d = 1\text{ cm}$ and height $h = 4.4\text{ cm}$.

The recording of UV-absorption spectrum was carried out using UV-Vis spectrometer DMS 90 working in wavelength range $\lambda = 190 - 400\text{ nm}$. The absorption spectrum was collected using test solutions prepared in a following way: 0.2-mL, 0.5-mL and 1.0-mL aliquots of the **Stock solution** were diluted to 100 mL with the appropriate amount of CH₃CN/H₂O 1:9 solution. The obtained solutions had concentrations 10.18 mg/L, 25.45 mg/L and 50.9 mg/L. For calculations of quantum yield was used the UV spectrum determined for the solution having the concentration of 25.45 mg Flufenacet/L.

The degradation experiment was performed using a merry-go-round irradiation apparatus equipped with Hg lamp TO 150 and Duran 50 filter tube to cut-off the UV-radiation having wavelengths $\lambda < 295\text{ nm}$. It is presented below on figure B.8.2.1.2.1._CA-11.

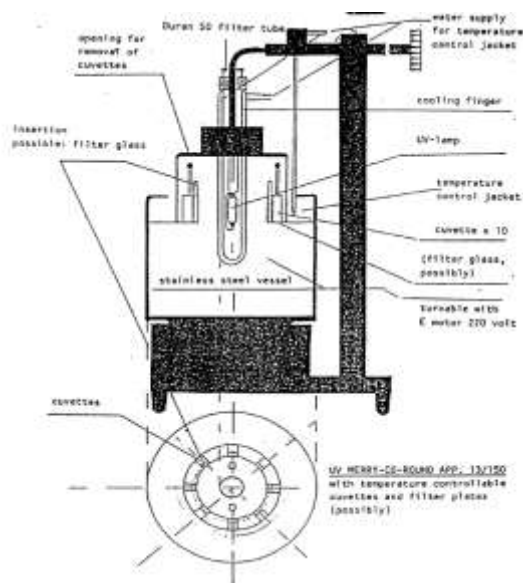

Figure B.8.2.1.2.1._CA-11: The merry-go-round irradiation apparatus used in the study (copied from the study report).

The experiment was carried out using the test solutions prepared from the **Stock solution** of Flufenacet by diluting its 0.1-mL aliquots to 100 mL with the appropriate amount of CH₃CN/H₂O 1:9 solution. The nominal concentration of so prepared test solutions was 5 mg Flufenacet/L and the measured concentrations were: 5.68 mg Flufenacet/L for the test solution used in the **Experiment 1** and 5.56 for the test solution used in the **Experiment 2**.

Other solutions used in the experiment were:

- **Actinometer solution (A)** prepared by dissolving 1.255g of uranyl nitrate (UO₂(NO₃)₂ · 6 H₂O) and 1.576g of oxalic acid ((COOH)₂ · 2 H₂O) in 250 mL water to obtain a solution containing 0.01 M UO₂²⁺ and 0.05M (COOH)₂;
- **Catalyzer solution for the titration (K)** prepared by dissolving 8.5 g manganese sulfate (MnSO₄ · H₂O) in 250 mL 1M sulphuric acid (1M H₂SO_{4 aq});
- **Titration solution (T)** – 0.05 N KMnO_{4 aq};

The irradiation apparatus was started approx. 30 minutes before the beginning of the exposure of the samples. That was done to guarantee the constant intensity of radiation emitted by the light source. The whole experiment was performed at constant temperature T = 25°C.

After that period two test vessels containing each 3 mL of the **Actinometer solution (A)** were placed in the apparatus and irradiated for 10 minutes. Then ten test vessels, each containing 3 mL of the test solution, were placed in the apparatus on a merry-go-round and irradiated for up to 7.5 hours. At pre-defined time points single samples were removed from the irradiation chamber to be analysed.

These sampling points, expressed in [hours of irradiation] were following:

- for **Experiment 1**: 0.00 hours, 0.65 hours, 1.46 hours, 2.26 hours, 3.08 hours, 4.71 hours, 5.40 hours, 6.15 hours, 6.78 hours, 7.31 hours;
- for **Experiment 2**: 0.00 hours, 0.75 hours, 1.48 hours, 2.25 hours, 3.00 hours, 3.75 hours, 4.50 hours, 5.25 hours, 6.00 hours, 6.76 hours, 7.46 hours;

At the end of the irradiation period another two vessels with 3 mL of the **Actinometer solution (A)** were placed on vacated positions in the irradiation apparatus and exposed to irradiation for 10 minutes.

The actinometers were used to determine the intensity of light acting on the testing solution. For that purpose the content of each actinometer (**Actinometer solution**) after irradiation was transferred to Erlenmeyer flask and brought to 50 mL with water. Next, 5 mL of the **Catalyzer solution for the titration (K)** was added to each flask and titrated with **Titration solution (T)** until the solution became permanently pink after addition of one droplet of the solution **T**. In the same way was titrated the unexposed **Actinometer solution**. The results were used to calculate the intensity of radiation absorbed by actinometers in range $\lambda = 295 - 490$ nm. That was done using QUANT programme calculating the light intensity and quantum yield.

The irradiated test solutions were analysed for the content of Flufenacet using RP-HPLC method. The HPLC analysis was carried out on HP1090 work station coupled with DAD detector set to $\lambda = 200$ nm, equipped with Select B RP 18 chromatographic column, 250mm · 4 mm, 5 μ m. The column was kept at constant temperature T = 40°C. The chromatographic elution lasted for 12 minutes and was carried out in isocratic mode using the mixture of two solvents: **A** and **B** in ratio 45:55. **Solvent A** was water/acetonitrile/phosphoric acid in ratio 95:5:0.2 (v:v:v) and **Solvent B** – 100% acetonitrile. The identification of the test compound was performed by means of the comparison of retention time with that of the standard. The quantitative analysis was also carried out using the external standard.

The calculation of quantum yield was carried out using the following sets of equations presented below on figure B.8.2.1.2.1._CA-12.

$$c_2 = \frac{E_1 + 1000}{V_1 \cdot F_1} ; c_3 = \frac{c_1}{M \cdot 1000} ; \epsilon_{10\%} = \frac{c_2 \cdot M \cdot V_3 \cdot 0.1}{1000}$$

Input of the user

E_1 : Amount weighed for degradation experiment
 V_1 : Volume in which the weighed amount is dissolved
 F_1 : Dilution factor concerning experiment 1
 M : Molecular weight of the test substance
 V_3 : Irradiated volume [ml]
Constants: $M_L = 5,022 \cdot 10^{23}$; $\tau = 0,05$;

Calculated values

c_1 : Concentration of the test substance [mg/l]
 c_2 : Concentration of the test substance [mole/l]
 $\epsilon_{10\%}$: 10% of applied molar extinction of the test substance

$$V_4 = V_3 - V_5 ; I_{ak} = \frac{V_4 \cdot E + E_0}{1000 \cdot 0,55 + 60 \cdot \tau} ; I_0 = \frac{E_0 \cdot I_1}{E_2}$$

Input of the user

τ : Time of exposure [min]
 V_4 : Consumption for the zero sample [ml]
 V_5 : Consumption for the irradiated solution [ml]

Calculated values

I_{ak} : Intensity of the radiation being absorbed by the actinometer [photons/e/exposed volume]
 I_0 : Intensity of the radiation entering in the degradation experiment
 V_4 : Volume difference in the case of the titration of the actinometer solution

Established values given by the data file (Quant.Quant.SAT):
 I_1 : Intensity of the radiation emitted by the lamp
 I_2 : Intensity of the radiation absorbed by the actinometer

$$c_3 = \frac{E_2 + 1000}{V_2 \cdot F_2} ; \epsilon_4 = \frac{c_3}{M \cdot 1000}$$

Input of the user

E_2 : Amount weighed for the UV-spectrum
 V_2 : Volume, in which the weighed amount was dissolved
 F_2 : Dilution factor (UV-spectrum)

Calculated values

c_3 : Concentration of the test substance [mg/l]
 c_4 : Concentration of the test substance [mole/l]

$$\epsilon = \frac{E}{c_4 \cdot d}$$

Input of the user

E : Extinction values for the individual wavelength
Constants: $d = 1$
 d : optical path length of the measuring cuvette

The molar extinction coefficients ϵ are then averaged over various ranges. These ranges are also included as established values in the data file of configurations Quant.Quant.SAT.

The averaging is done as follows:

Wavelength range [nm]	Number of values
295 - 300 nm	5 values
301 - 400 nm	10 values each
401 - 490 nm	10 values each

These averaged molar extinction coefficients are used for the following calculations:

$$OO = \epsilon \cdot c_2 ; \alpha = 1 - \frac{1}{10^{\frac{OO}{10}}} ; I_a = I_0 \cdot \alpha ; \epsilon = \frac{c_2 \cdot 10\%}{t_{10\%} \cdot 60 \cdot 0,95 \cdot 22}$$

Input of the user

$t_{10\%}$: Time for the degradation of 10% of the test substance [min]

Calculated values

OO: Optical density
 α : Degree of absorption
 I_a : Radiation being absorbed by the test substance in the degradation experiment
 ϵ : Quantum yield

Figure B.8.2.1.2.1._CA-12: The equations used in calculation of quantum yield (copied from the study report).

The calculated quantum yield was used to calculate the environmental half-lives for Flufenacet using GC-SOLAR and Frank-and Klöpffer computer models.

Results and their discussion:

The absorption spectrum of Flufenacet, recorded at various pH for the wavelength range of $\lambda = 190 - 400$ nm, is presented below on figure B.8.2.1.2.1._CA-13. It shows that the effective absorption range may be estimated to occur within the range of $\lambda = 190 - 250$ nm. Within the environmentally relevant range of $\lambda = 290 - 400$ nm the absorption of radiation was residual, what may indicate that the direct photolysis of Flufenacet in aqueous solutions would be negligible. The results – values of absorbance (in the study report called *Extinction* – E) and molar absorption coefficient ϵ (in the study report named *molar extinction coefficient*) for wavelength range $\lambda = 290 - 336$ nm, are presented in the table B.8.2.1.2.1._CA-8.

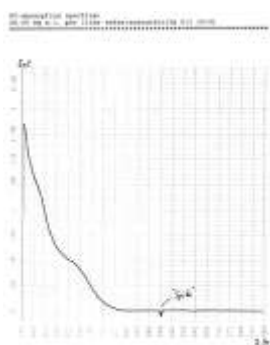

Figure B.8.2.1.2.1._CA-13: The absorption spectrum recorded for the solution of Flufenacet having concentration 25.45 mg/L (copied from the study report).

Table B.8.2.1.2.1._CA-8: The results of the determination of absorbance and molar absorption coefficient of Flufenacet in solution having concentration $C = 25.45 \text{ mg/L}$.

The results of the determination of the concentration of Flufenacet in irradiated solution in function of time are presented below in the table B.8.2.1.2.1._CA-9. These values were logarithmically transformed to determine the parameters of the degradation kinetics of Flufenacet in the process of direct aqueous photolysis. The graphical results of that determination are presented on figure B.8.2.1.2.1._CA-14 and the numerical results in the table B.8.2.1.2.1._CA-10. The rate constant determined that way was used to calculate the DT_{10} – value necessary to calculate the quantum yield ϕ .

Table B.8.2.1.2.1._CA-8: The results of the determination of concentration of Flufenacet in irradiated test solutions in function of time.

Experiment 1		Experiment 2	
Irradiation time [hours]	Concentration of Flufenacet [mg/L]	Irradiation time [hours]	Concentration of Flufenacet [mg/L]

Figure B.8.2.1.2.1_CA-16: The results of the degermination of the environmental half-lives for the process of the direct photolysis of Flufenacet in aquatic environment (copied from the study report).

Conclusions:

The results of the study show that Flufenacet displayed very low level of absorption of UV-Vis radiation in the environmentally relevant wavelength range - $\lambda = 290 - 400$ nm.

The calculated quantum yield for the direct aqueous photolysis of Flufenacet was very low - $\phi = 0.00096$, what resulted in very low environmental half-lives – the $DT_{50} = 130$ days - > 365 days..

On the basis of those results it was stated that the direct aqueous photolysis will not be a relevant degradation process for Flufenacet in natural water bodies.

These results are in line with the results of the previously summarised *Study 1*.

Study 3:

Report: Lentz N. R., Bloomberg A. M., (1999): “Aqueous Photolysis of Thiadone (A Metabolite of FOE 5043).”; Ricerca Inc., Department of Environmental and Metabolic Fate, 7528 Auburn Road, Painesville, Ohio 44077, USA (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, MO 64120, USA; Ricerca document No. 7410-98-0056-EF-001, study No. F3082402 (Bayer); Bayer Report No. 108720; 19 August 1999; study reference number: M-017985-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Study.

GLP: Yes;

RMS comments: This is a newly submitted study, the aim of which was to further examine the photolytic degradation of Flufenacet in soil through the determination of the would-be photodegradation of one of its major degradation products – FOE Thiadone. For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- OECD Guideline 316: Phototransformation of Chemicals in Water – Direct Photolysis, Adopted 3 October 2008;
- US EPA Guideline OPPTS 835.2210 – Direct Photolysis Rate in Water by Sunlight; January 1998;
- US EPA Guideline OPPTS 835.2240 – Photodegradation in Water; October 2008;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Studies (indicated as reference Guideline in the study report);
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals in Water – Direct and Indirect Photolysis, Draft Document August 2000 (additional reference document);

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable and is summarised below.

Summary:

The aim of the study was to examine direct aqueous photodegradation of FOE Thiadone – the metabolite of Flufenacet, through:

- determining the half-life of that compound when exposed to artificial sunlight in sterile aqueous buffer;
- identifying the transformation pattern, and in particular the degradation products formed in amounts greater than 10% AR.

The experiment was performed in sterile pH = 7 aqueous buffer – 0.05M phosphate buffer, prepared by mixing 250 mL of 0.2M KH_2PO_4 aq with 29 mL of 1M NaOH aq and bringing the solution to the volume of 1L with HPLC-grade water. So prepared buffer solution was sterilised by steam autoclaving at $T = 123^\circ\text{C}$.

The experiment was performed in 59-mL (2 oz.) flint glass sample jars with either quartz glass lids (irradiated samples) or opaque screw caps (dark control samples).

The test vessels, like all remaining glassware used in the study, were sterilised by steam autoclaving at $T = 123^\circ\text{C}$.

The test compound was $[2\text{-}^{14}\text{C}]$ -Thiadone, having a specific activity of 50 mCi/mmol, corresponding to 652680 dpm/ μg . It was provided in form of a solution in acetone (**Stock solution**), having a volume of 9 mL and containing 6 mCi (0.12 mmol) of the test compound. **Stock solution** was shipped and stored frozen until being used. The structural formula of the test compound, with radiolabelling position indicated by an asterisk, is presented below on figure B.8.2.1.2.1._CA-17.

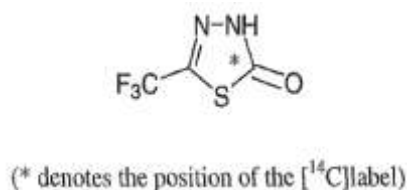

Figure B.8.2.1.2.1._CA-17: The structural formula of $[2\text{-}^{14}\text{C}]$ -Thiadone used in the experiment (copied from the study report).

Stock solution was used to prepare the **Application solution** used in the experiment. To do that ~210 μL of the **Stock solution**, containing 0.486 mg of FOE Thiadone, were transferred to 5-mL volumetric flask, evaporated to dryness under the stream of N_2 , and the residue redissolved in small portion of CH_3CN . The solution was once again evaporated to dryness and then brought to volume with CH_3CN . Prior to application the so prepared solution was analysed by LSC (quantitation of $[^{14}\text{C}]$ -FOE Thiadone), as well as by HPLC with LSC detection, to determine its radiopurity. The measured concentration of the **Application solution** was 4.86 $\mu\text{g}/50 \mu\text{L}$ (3,171,787 dpm/50 μL) and radiochemical purity 95.3%.

The experiment was carried out using 18 dark-control sample jars (sterilised), including two for additional analysis and four for sterility check, and 18 irradiated sample jars (sterilised), including eight extra jars for additional analyses. The test vessels are characterised above, in the third paragraph of the summary. The dark-control sample jars and irradiated sample jars were assigned sequential numbers.

Next, to each of the test vessels used as the dark-control and irradiated samples, 10 mL of sterilised buffer were added. Then 50 μL of the characterised above **Application solution** were added to each vessel. That volume was selected to obtain the fortification level of 0.49 mg FOE Thiadone/L, declared to be the half of the application rate of Flufenacet used to examine its aqueous photolysis. It was determined assuming that 100% of Flufenacet is converted into FOE Thiadone and using the molar weights for Flufenacet $M = 363 \text{ g/mol}$ and for FOE Thiadone $M' = 170 \text{ g/mol}$.

Duplicate dark-control samples were taken immediately after fortification for sterility check and determination of the concentration of the test compound.

The remaining test vessels were sealed with opaque screw caps fitted with Teflon liners, wrapped with foil and stored in the darkness at $T = 25 \pm 2^\circ\text{C}$ until being analysed.

All samples designated to be irradiated were sealed immediately after treatment with quartz lids and placed in the water bath set to $T = 25 \pm 2^\circ\text{C}$ in irradiation chamber.

The irradiation was performed in 12 hours light/12 hours darkness regime using light having a range $\lambda = 250 - 750 \text{ nm}$ and intensity comparable to that of natural sunlight measured at Painesville, Ohio, USA, in June. The light source used in the experiment was a 5000-W Xenon lamp, emitting light in range of $\lambda > 290 \text{ nm}$ – a range of natural sunlight reaching the soil surface. Lower wavelengths were eliminated using appropriate filters. The design of the irradiation device used in the experiment is shown below on figure B.8.2.1.2.1._CA-18.

The samples were irradiated or incubated in the darkness (the dark-control samples) for up to 30 days, corresponding for the irradiated samples to 30 Natural Sunlight Days.

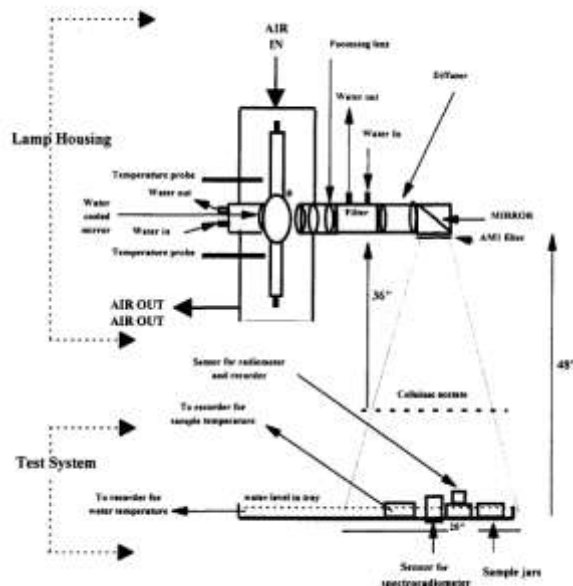

Figure B.8.2.1.2.1._CA-18: The schematic presentation of the photolysis system used in the experiment (copied from the study report).

At the following sampling dates: DAT 0, DAT 3, DAT 7, DAT 14, DAT 21 and DAT 30 (DAT stands for Days After Treatment), duplicate dark-control and irradiated samples were taken for the analysis. In case DAT 0 samples only the dark-control samples were analysed, as they were considered to be representative for both dark-control and irradiated parts of the experiment.

All samples were analysed, immediately after sampling, for their pH, and for the content of FOE Thiadone and other compounds using LSC and HPLC. For that reason it was not necessary to examine the sample stability.

Samples were processed in the following way:

- **for the dark-control samples** the contents of the vessels sampled on the given time point were transferred to the graduated cylinders and the volumes recorded; next two 0.25-mL aliquots were taken for LSC analysis; finally the 0.25-mL aliquots were diluted with 0.25 mL of 0.5% CH_3COOH in HPLC-grade H_2O , mixed with 0.01 mL of the standard solution and analysed by HPLC; the entire HPLC-effluents were collected and their 2-mL aliquots analysed by LSC;
- **for the dark-control samples** the whole procedure was slightly modified and looked as follows: the contents of the vessels sampled on the given time point were transferred to the graduated cylinders, then the vessels rinsed with small amounts of MeOH, rinses combined with the samples and the total volumes recorded; next two 0.25-mL aliquots were taken for LSC analysis; finally the 0.25-mL aliquots were diluted with 0.25 mL of 0.5% CH_3COOH in HPLC-grade H_2O , mixed with 0.01 mL of the standard solution and analysed by HPLC; the entire HPLC-effluents were collected and their 2-mL aliquots analysed by LSC;

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using either Tractor Mark V Model 5303 LS counter or Beckman LS 6500 counter.

Liquid samples were analysed in duplicate with 5 mL of Ultima Gold liquid scintillation cocktail. The counting of each analysed sample lasted for 2 minutes. The detection limit was calculated to be 87 dpm with 95% confidence level. The average background level was set to 38 dpm.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- LC-MS – conformatory identification method for parent compound and its degradation products.

The HPLC analysis was performed using a Waters™ HPLC system equipped with autosampler, Tunable Absorbance Detector and fraction collector, coupled to one of the following LSC detectors:

- Radiomatic A-500 Radio-chromatography Detector;
- IN/US β-RAM Radio-HPLC Detector.

The system was equipped with Phenomenex Luna™, 5 µm C18, 150 · 4.6 mm chromatographic column and Zorbax® Rx-C18 10 · 4.6 mm guard column. The chromatographic separation was performed in a gradient mode, using the mobile phase consisting of:

- water + 0.5% CH₃COOH as **Solvent A**, and
- CH₃OH as **Solvent B**.

Gradient elution lasted 70 minutes. Its parameters are shown below in the table B.8.2.1.2.1._CA-10. The flow rate was set to 1.0 mL/min.

Table B.8.2.1.2.1._CA-10: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.5% CH₃COOH</i>	<i>Solvent B – Methanol</i>
0	100	0
40	30	70
60	30	70
61	100	0
70	100	0

The minimum detection limit for HPLC method was 1000 dpm and its linearity, expressed as r^2 , was: $r^2 = 0.9$. That corresponded to 1.25% AR when the injected volume of analysed sample was 0.25 mL. The average recovery of the chromatographed samples was 100.8% AR (with range 96.5 – 105.6% AR).

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards.

The LC-MS analysis was performed using Finnigan SSQ710 LC/MS device equipped with a Phenomenex Columbus 5µm C8 100 · 2 mm LC column. The chromatographic analysis was carried out in a gradient mode. Its parameters were following:

- **Mobile phase A:** 0.05% HCOOH in Water,
- **Mobile phase B:** CH₃OH,
- **Gradient mode:** A/B1:1 hold 2 min. to A/B 3:7 at 8 min.

The flow rate was set to 0.2 mL/min.

The reported parameters of MS detector were following:

- Ionization mode: (-)ESI;
- Mass range: 95 – 300 amu;
- Scan rate: 1.5 sec/scan;
- Source temperature: 220°C;
- ESI spray voltage: 4.5 kV.

The UV-Vis absorption spectrum of FOE Thiadone was determined using GBC 918 UV-Vis spectrometer with a slit of 2 nm. The absorption spectrum was scanned within the wavelength range of $\lambda = 200 – 800$ nm at a scanning rate 720 nm/min.

Results and their discussion:

The experiment was performed in sterile phosphate buffer having pH = 7. The results of the determination of the pH of test solutions collected at each time point showed that that parameter was stable throughout the study duration. It shall be indicated that the pH in irradiated samples for DAT 0 time point was not recorded, as they

were not collected. Instead, it was assumed that the results recorded at that sampling point for the dark-control samples should be representative also for them.

The sterility checks showed that the samples maintained their sterility throughout the whole irradiation/incubation period. The monitoring of the temperature during the experiment showed that both irradiated and dark-control samples were kept at constant temperature $T = 25 \pm 2^{\circ}\text{C}$.

The characteristic of the light source – xenon lamp, is presented in a graphical form on figure B.8.2.1.2.1._CA-19 (comparison of spectral distribution of xenon lamp used in the experiment and natural sunlight).

Table B.8.2.1.2.1._CA-11: The results of the determination of pH of the test slutions.

Sampling time point (corresponding for irradiated samples to [Natural Sunlight Days])	pH measured in:			
	Irradiated samples		Dark-control samples	
	Replicate 1	Replicate 2	Replicate 1	Replicate 2
<i>DAT 0</i>	----	----	7.04	7.05
<i>DAT 3</i>	7.06	7.03	7.06	7.06
<i>DAT 7</i>	6.98	7.00	7.07	7.11
<i>DAT14</i>	7.03	7.02	7.09	7.00
<i>DAT 21</i>	7.05	7.04	7.03	7.07
<i>DAT 30</i>	7.07	7.02	7.07	7.07

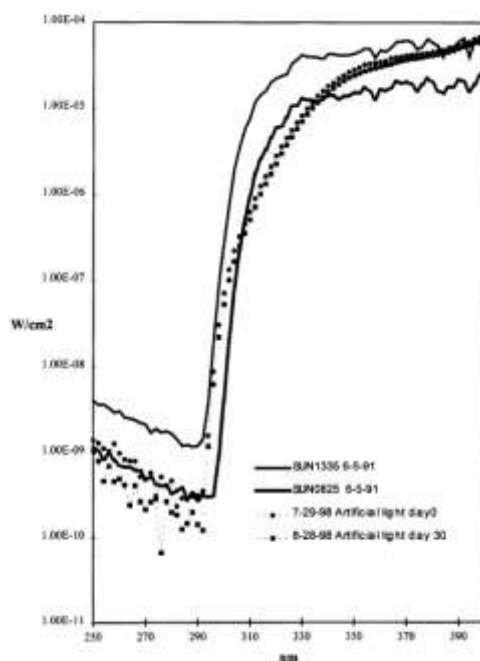

Figure B.8.2.1.2.1._CA-19: The comparison of the spectra of xenon lamp used in the study and of natural sunlight (copied from the study report).

The absorption spectrum of FOE Thiadone recorded for the wavelength range of $\lambda = 200 - 800$ nm is presented below on figure B.8.2.1.2.1._CA-20. It shows that the effective absorption occurred within the wavelength range of $\lambda = 200 - 270$ nm. Within the environmentally relevant range of $\lambda = 290 - 800$ nm it was residual.

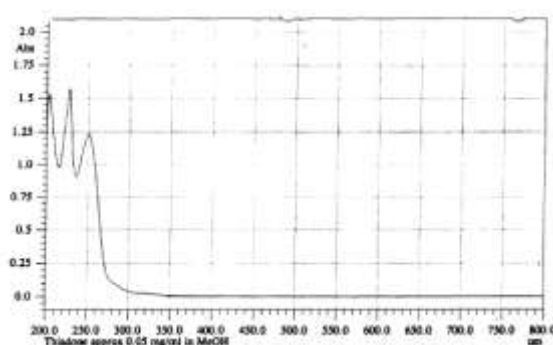

Figure B.8.2.1.2.1._CA-20: The UV-Vis absorption spectrum of FOE Thiadone recorded for $\lambda = 200 - 800$ nm (copied from the study report).

The preliminary study showed no loss of radioactivity from samples, therefore no trapping system for volatile compounds was used in the definitive part of the study. The recovery of radioactivity, determined by LSC, was in range 95.0% AR – 104.7% AR, with the average value of 100.2% AR. The detailed results are presented below in the table B.8.2.1.2.1._CA-12. The values given for irradiated and the dark-control samples at each sampling point are the averages of the two replicates.

Table B.8.2.1.2.1._CA-12: The results of the determination of the recovery of radioactivity in the test samples, as determined by LSC.

Sampling time point (corresponding for irradiated samples to [Natural Sunlight Days])	Radioactivity recovered in the samples, expressed as [% AR]:	
	Irradiated samples	Dark-control samples
<i>DAT 0</i>	----	104.7
<i>DAT 3</i>	104.3	101.5
<i>DAT 7</i>	101.3	98.2
<i>DAT14</i>	100.5	101.9
<i>DAT 21</i>	96.4	100.7
<i>DAT 30</i>	95.0	97.2

The HPLC profiling of recovered radioactivity showed that it consisted almost totally of FOE Thiadone, with small amounts, individually not surpassing 2%, of three other fractions, of which two are fortification impurities. The detailed results are presented in the table B.8.2.1.2.1._CA-13.

Table B.8.2.1.2.1._CA-13: The detailed results of the HPLC-profiling of radioactivity recovered in the test samples at each sampling point.

Sampling time point (corresponding in irradiated samples to [Natural Sunlight Days])	Amounts [% in chromatogram] detected in irradiated samples of				Amounts [% in chromatogram] detected in the dark-control sample of			
	Fortification impurity 1	FOE Thiadone	Fortification impurity 2	Other	Fortification impurity 1	FOE Thiadone	Fortification impurity 2	Other
<i>DAT 0</i>	----	----	----	----	1.2	97.1	1.8	0.0
<i>DAT 3</i>	0.9	98.6	0.3	0.3	1.1	98.9	not detected	0.0
<i>DAT 7</i>	0.4	99.3	not detected	0.3	1.0	99.1	not detected	0.0
<i>DAT14</i>	not detected	99.8	not detected	0.2	1.1	99.0	not detected	0.0
<i>DAT 21</i>	not detected	100.0	not detected	0.0	1.1	98.9	not detected	0.0
<i>DAT 30</i>	not detected	100.0	not detected	0.0	not detected	100.0	not detected	0.0

The results demonstrated virtually no degradation of FOE Thiadone in either irradiated samples or in the dark control ones. On that basis it was stated that FOE Thiadone was not prone to the direct photolysis. The kinetic analysis of the obtained results was therefore not carried out.

Conclusions:

On the basis of the obtained result it may be stated that FOE Thiadone is not prone to direct photolysis in the aquatic environment.

Summary – Direct aqueous photolysis of Flufenacet

The direct aqueous photolysis of Flufenacet was examined in a sterile buffer solution having pH = 5 and T = 21°C. The samples were exposed to UV-Vis radiation generated by the artificial light source. The irradiation conditions were similar to those recorded during 30-days exposure to natural summer sunlight in Phoenix, Arizona, USA. The results demonstrated that Flufenacet was not prone to the direct aqueous photolysis – practically no photodegradation of Flufenacet, in comparison to what was observed in the dark control samples, was stated. The determined half-lives were: for irradiated sample DT₅₀ = 7430 days when expressed in Natural Sunlight days, and for the dark control samples DT₅₀ = 4160 days.

In a separate experiment the quantum yield of the process of direct photodegradation of Flufenacet in water was determined. The quantum yield value determined in that experiment was $\phi = 0.00096$ [mol/Einstein]. The calculated using that value environmental photolytical half-lives for Flufenacet, determined using GC-Solar method in water were:

- for the latitude 30°N in range DT₅₀ = 126 – 308 days;
- for the latitude 40°N in range DT₅₀ = 131 – >365 days;
- for the latitude 50°N in range DT₅₀ = 142 – >365 days;
- for the latitude 60°N in range DT₅₀ = 160 – >365 days;

Additionally, in a separate study, was examined the direct aqueous photolysis of the major soil and aquatic degradation product of Flufenacet – FOE Thiadone. The experiment was performed in a sterile buffer solution having pH = 7 and T = 25°C. The samples were exposed to UV-Vis radiation generated by the artificial light source. The irradiation conditions were similar to those recorded during 30-days exposure to natural summer sunlight in Phoenix, Arizona, USA. The results demonstrated that FOE Thiadone was not prone to the direct aqueous photolysis – practically no photodegradation of that compound was observed in either irradiated samples or in dark control ones, and it was not possible to determine the reliable DT₅₀ values.

The results of the examination of the direct aqueous photolysis of Flufenacet and FOE Thiadone in water, in form recommended for reporting the regulatory endpoints in the EU, are presented below.

Aqueous photochemical degradation (Regulation (EU) N° 283/2013, Annex Part A, points 7.2.1.2 / 7.2.1.3)

Photolytic degradation of active substance and metabolites above 10 % - [results for Flufenacet, direct photolysis](#)

B.8.2.1.2.2. – Indirect Photochemical degradation

To address this data requirement the Applicant submitted two study reports, one for Flufenacet as a test substance and another for FOE Thiadone as a test substance.

The examination of the indirect photodegradation of Flufenacet in the aquatic environment was a part of a broader study examining the photodegradation of Flufenacet in water. It is summarised below as **Study 1**.

The indirect aqueous photolysis of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet, was examined in a separate study presented below as **Study 2**.

Study 1:

Report: Kasper A. M., Shadrick B. A., (1995): “Aqueous Photolysis of [Phenyl-U-¹⁴C] FOE 5043.”; Bayer Corporation (formerly Miles Inc.), Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3082401 (Bayer); unpublished Miles Report No. MR 106246; 30 May 1995; study reference number: M-002206-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Studies.

GLP: Yes, for the part off the study aimed on the examination of direct aqueous photolysis; for the examination of indirect aqueous photolysis of Flufenacet it was declared to be a non-GLP study

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its summary can be found under the point B.7.4.2.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. It presents the results of the examination of both direct photolysis of Flufenacet in water (a GLP study) and the indirect aqueous photolysis of that compound (a non-GLP study). For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- OECD Guideline 316: Phototransformation of Chemicals in Water – Direct Photolysis, Adopted 3 October 2008;
- US EPA Guideline OPPTS 835.2210 – Direct Photolysis Rate in Water by Sunlight; January 1998;
- US EPA Guideline OPPTS 835.2240 – Photodegradation in Water; October 2008;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Studies (indicated as reference Guideline in the study report);
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals in Water – Direct and Indirect Photolysis, Draft Document August 2000 (additional reference document);

RMS stated that in general the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable. However, in its part related to the examination of the indirect aqueous photolysis, because at the time of examination that part was considered to be only supplementary, it was only briefly summarised in Appendix 12 to the study report. Additionally the part of the experiment that examined indirect aqueous photolysis was declared to be a non-GLP study. RMS examined the provided summary. The characteristic is provided only in the areas where the study protocol differed from the GLP-part of the study – the experiment on the direct photolysis, characterisation of reaction medium and irradiation-and sampling protocol, as well as the presentation of obtained results, however it bears several indications enabling to make a conclusion that it was carried out in the same way as the experiment on the direct aqueous photolysis of Flufenacet. For that reason RMS decided to consider the study valid also in its part related to the indirect aqueous photodegradation of Flufenacet, although it may be considered to have a merit only as supplementary/indicative study. For that reason RMS decided not to include its results into the List of EndPoints. It is summarised, in its part strictly related to indirect photolysis, below.

Summary:

The aim of the experiment was to examine the indirect aqueous photolysis of Flufenacet. The examination was carried out in:

- natural pond water sampled at two different locations (**Experiment 1** and **Experiment 2**),
- aqueous solution containing humic material 15 ppm (**Experiment 3**),
- aqueous solution containing 50 ppm of KNO₃ (**Experiment 4**)

That part of the study focused only on the determination of the rate of the process, as the examination of the direct aqueous photolysis of Flufenacet showed, that the compound did not degrade under the influence of light.

The test compound used in ther experiment was [Phenyl-U-¹⁴C] Flufenacet, having a specific radioactivity of 66.5 mCi/mmol. Its structural formula is presented below on figure B.8.2.1.2.2._CA-1. It was delivered in form of benzene solution, having a concentration 4.55 mg Flufenacet/mL.

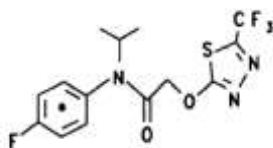

Figure B.8.2.1.2.2._CA-1: The structural formula of the test compound; radiolabelling position indicated with an asterisk (copied from the study report).

It was used to prepare three different test solutions:

- **Test Solution 1**, used in the experiments with natural pond water; to prepare it 0.243 mL of the benzene solution of [Phenyl-U-¹⁴C] Flufenacet was transferred to 45-mL graduated centrifuge tube and evaporated to dryness; the residue was redissolved in 10.8 mL of CH₃CN (1% of co-solvent);
- **Test solution 2**, used in the experiment with aqueous solution of humic material; to prepare it 0.173 mL of the benzene solution of [Phenyl-U-¹⁴C] Flufenacet was transferred to 45-mL graduated centrifuge tube and evaporated to dryness; the residue was redissolved in 8.0 mL of CH₃CN (1% of co-solvent);
- **Test solution 3**, used in the experiment with aqueous solution of KNO₃; to prepare it 0.206 mL of the benzene solution of [Phenyl-U-¹⁴C] Flufenacet was transferred to 45-mL graduated centrifuge tube and evaporated to dryness; the residue was redissolved in 9.5 mL of CH₃CN (1% of co-solvent);

Experiment 1 was performed using natural pond water sampled from the pond located in Howe, Indiana, USA. It had the following characteristic:

- pH = 6.5;
- Alkalinity: 65 [mg/CaCO₃/L];
- Total Suspended Solids: 160 mg/L;
- Hardness: 66 [mg CaCO₃/L];
- Conductivity: 220 [μmho/cm];
- NO₃⁻: not determined;
- NO₂⁻: 0.015 [mg/L];
- NH₄⁺: not determined;
- Total Organic Carbon: 20.7 [mg/L].

To the foil-wrapped (with aluminium foil) test vessels, presented in the summary of the same study (as **Study I**) under the point B.8.2.1.2.1. on figure B.8.2.1.2.1._CA-2, were introduced 60-mL portions of the pond water characterised above, filtered through Curity® cheese cloth. Next, to each test vessel 0.6-mL portions of the **Test solution 1** were introduced. The number of so prepared test vessels was such to be sufficient for six single irradiation samples and six single dark-control samples including DAT-0 sample. The DAT 0 sample was analysed immediately after treatment by LSC and HPLC for the content of [¹⁴C]-Flufenacet and radiochemical purity. The determined concentration of the test compound was 0.95 ppm with radiochemical purity of 99.5%.

The remaining test vessels, irradiated samples and the dark-control samples, were placed in the Suntest irradiation unit and kept there for up to 10.83 days (corresponding to 31.7 Natural Sunlight Days; for the

definition please refer to the summary of the *Study 1* presented under the point B.8.2.1.2.1.). In case of irradiated samples the foil wrapping vessels was removed, while the dark-control samples were kept wrapped with it.

At pre-designated time points irradiated samples and the dark-control samples were taken for the analysis.

The sampling points for the **dark-control samples** were set at the following time points, expressed as Natural Sunlight Days: 0, 0.5, 1.1, 2.4, 11.3 and 31.7. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0, 0.17 (4.1 hours), 0.38 (9.02 hours), 0.82 (19.68 hours), 3.86 (92.66 hours) and 10.83 (259.94 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit. The DAT 0 sample in the dark control can be also considered the DAT-0 irradiated sample.

The sampling points for the **irradiated samples** were set at the following time points, expressed as Natural Sunlight Days: 0.5, 1.1, 2.4, 11.3, 20.1 and 31.7. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0.17 (4.1 hours), 0.38 (9.02 hours), 0.82 (19.68 hours), 3.86 (92.66 hours), 6.87 (164.82 hours) and 10.83 (259.94 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit.

At sampling intervals listed above single irradiated and dark control samples were removed from the Suntest unit. Vessels containing irradiated samples were immediately wrapped with aluminium foil to cut-off the light.

0.2-mL aliquots were analysed by LSC to quantify the [^{14}C] residues. Next 1-mL aliquots were analysed by HPLC to identify the compounds present in sample and quantify them. The example chromatograms for the irradiated and dark-control samples collected on DAT 10.83 (Suntest days) are presented below on figure B.8.2.1.2.2._CA-2.

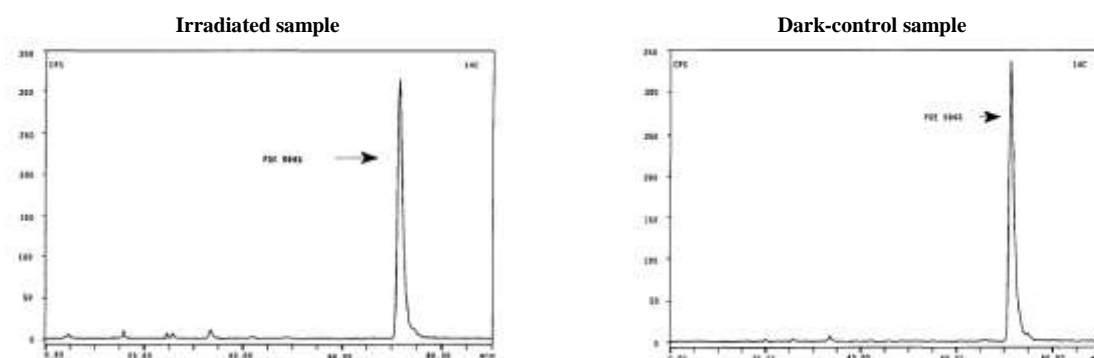

Figure B.8.2.1.2.2._CA-2: The DAT 10.83 (Suntest days; corresponding to 31.7 Natural Sunlight Days timepoint) HPLC chromatograms for irradiated and Dark-control samples (copied from the study report).

In all analysed samples Flufenacet was demonstrated to be the dominant compound. The numerical results of the analysis – the amounts of Flufenacet in each sample determined by HPLC are presented below in the table B.8.2.1.2.2._CA-1. The time-points expressed in Suntest days and Suntest hours were recalculated by the RMS on the basis of the time-points expressed in Natural Sunlight Days provided in the study report.

Table B.8.2.1.2.2._CA-1: The concentration of Flufenacet in the irradiated and dark-control samples in function of time.

Time point			Content of Flufenacet [%] in:	
Natural Sunlight Days	Sunttest Days	Sunttest hours	Irradiated sampels	Dark-control samples
0	0	0	99.5	99.5
0.5	0.17	4.1	98.5	98.8
1.1	0.38	9.02	98.5	99.4
2.4	0.82	19.68	98.2	98.8
11.3	3.86	92.66	97.0	98.7
20.1	6.87	164.82	92.2	not determined
31.7	10.83	259.94	92.9	96.5

The Applicant performed the kinetic analysis of the data presented in the table above. The kinetic fitting was carried out using linear regression for logarithmically-transformed concentrations of Flufenacet. RMS decided to repeat the analysis using the non-linear regression method, as recommended by FOCUS.

The analysis was performed for irradiated samples using time points expressed as Suntest Days and as Natural Sunlight Days. In case of the dark-control samples the kinetic fitting was carried out using solely Suntest Days, as these are the real sampling points and the dark-control samples do not require any conversion of the sampling points to make them representative for natural irradiation conditions.

The fitting was carried out using CAKE 3.1 modelling tool with IRLS as optimisation method. Only SFO kinetic model was tested, as very low level of degradation was observed.

The results are presented below, in graphical form on figure B.8.2.1.2.2._CA-3 and in the numerical form in the table B.8.2.1.2.2._CA-2.

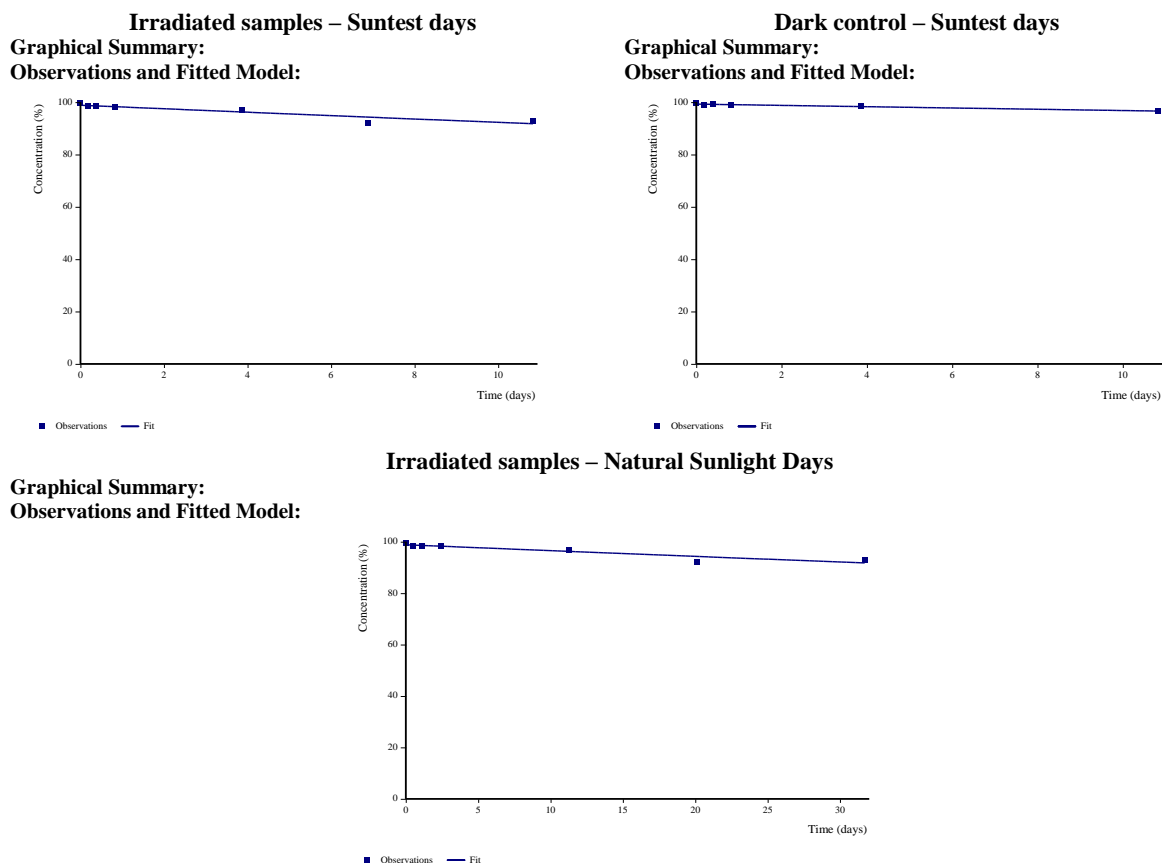

Figure B.8.2.1.2.2._CA-3: The graphical results of the examination of the indirect aqueous photolysis of Flufenacet in Howe pond water.

Table B.8.2.1.2.2._CA-2: The numerical results of the examination of the indirect aqueous photolysis of Flufenacet in Howe pond water.

Type of samples	Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	r
					Lower	Upper			
Irradiated-Suntest days	SFO	M_0	98.84	0.577	97.36	100.3	----	0.805	0.869
		k	0.006836	0.001198	0.003756	0.001	0.001156		
Dark control-Suntest days	SFO	M_0	99.28	0.179	98.78	99.77	----	0.237	0.913
		k	0.002506	3.90 E-4	0.0014234	0.004	0.001507		
Irradiated-Natural Sunlight days	SFO	M_0	98.84	0.577	97.36	100.3	----	0.806	0.869
		k	0.002335	4.1 E-4	0.0012824	0.003	0.001159		

The obtained fits are reliable. They also returned the DT_{50} values, which are following:

- for irradiated sample using Suntest days $DT_{50} = 101$ days;
- for irradiated sample using Natural Sunlight days $DT_{50} = 297$ days;
- for the dark control sample using Suntest days $DT_{50} = 277$ days

Comparison of the results obtained for irradiated samples and the dark-control samples using the Suntest days showed that Flufenacet degraded much faster in irradiated samples. That in turn indicates that indirect photolysis played an important role in degradation of that compound. For that reason the net degradation rate constant for photolysis was calculated using the following equation: $k_{\text{photol}} = k_{\text{irrad}} - k_{\text{dark}}$. The resulting $k_{\text{photol}} = 0.00433 \text{ [days}^{-1}\text{]}$. That value was subsequently used to calculate the DT_{50} for the net indirect aqueous photolysis of Flufenacet in Howe pond water. The calculated $DT_{50} = 160.08$ days for Suntest days. RMS additionally recalculated that value to Natural Sunlight Days, using assumption that 1 Natural Sunlight Day is equal to 8.2 Suntest hours. The resulting $DT_{50} = 468.53$ days when expressed in Natral Sunlight Days.

Experiment 2 was performed using natural pond water sampled from the pond located in Stilwell, Kansas, USA. It had the following characteristic:

- pH = 7.8;
- Alkalinity: 159 [mg/CaCO₃/L];

To the foil-wrapped (with aluminium foil) test vessels, presented in the summary of the same study (as *Study I*) under the point B.8.2.1.2.1. on figure B.8.2.1.2.1._CA-2, were introduced 60-mL portions of the pond water characterised above, filtered through Curity® cheese cloth. Next to each test vessel 0.6-mL portions of the **Test solution 1** were introduced. The number of so prepared test vessels was such to be sufficient for four single irradiation samples and five single dark-control samples including DAT-0 sample. The DAT 0 sample was analysed immediately after treatment by LSC and HPLC for the content of [¹⁴C]-Flufenacet and radiochemical purity. The determined concentration of the test compound was 0.95 ppm with radiochemical purity of 98.9%.

The remaining test vessels, irradiated samples and the dark-control samples, were placed in the Suntest irradiation unit and kept there for up to 10.25 days (corresponding to 30.0 Natural Sunlight Days; for the definition please refer to the summary of the *Study I* presented under the point B.8.2.1.2.1.). In case of irradiated samples the foil wrapping vessels was removed, while the dark-control samples were kept wrapped with it.

At pre-designated time points irradiated samples and the dark-control samples were taken for the analysis.

The sampling points for the **dark-control samples** were set at the following time points, expressed as Natural Sunlight Days: 0, 8.0, 13.9, 19.8 and 30.0. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0, 2.73 (65.6 hours), 4.75 (113.98 hours), 6.77 (162.36 hours) and 10.25 (246 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit. The DAT 0 sample in the dark control can be also considered the DAT-0 irradiated sample.

The sampling points for the **irradiated samples** were set at the following time points, expressed as Natural Sunlight Days: 8.0, 13.9, 19.8 and 30.0. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 2.73 (65.6 hours), 4.75 (113.98 hours), 6.77 (162.36 hours) and 10.25 (246 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit.

At sampling intervals listed above single irradiated and dark control samples were removed from the Suntest unit. Vessels containing irradiated samples were immediately wrapped with aluminium foil to cut-off the light.

0.2-mL aliquots were analysed by LSC to quantify the [¹⁴C] residues. Next 1-mL aliquots were analysed by HPLC to identify the compounds present in sample and quantify them. The example chromatograms for the irradiated and dark-control samples collected on DAT 10.25 (Sunttest days) are presented below on figure B.8.2.1.2.2._CA-4.

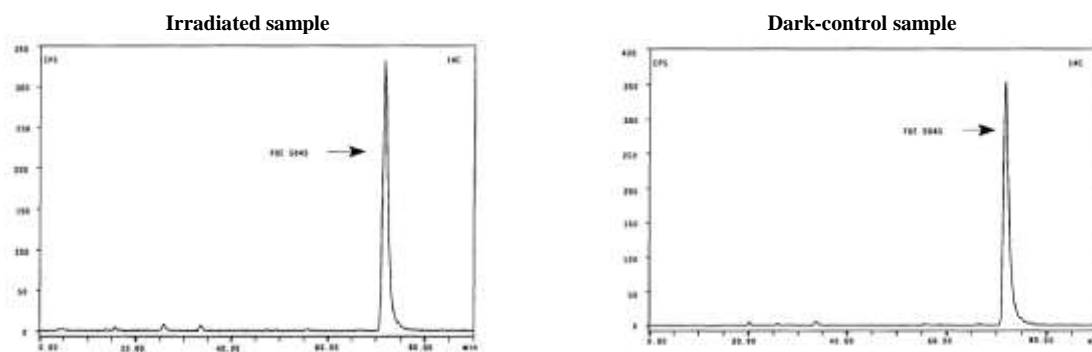

Figure B.8.2.1.2.2._CA-4: The DAT 10.25 (Suntest days; corresponding to 31.7 Natural Sunlight Days timepoint) HPLC chromatograms for irradiated and Dark-control samples (copied from the study report).

In all analysed samples Flufenacet was demonstrated to be the dominant compound. The numerical results of the analysis – the amounts of Flufenacet in each sample determined by HPLC are presented below in the table B.8.2.1.2.2._CA-3. The time-points expressed in Suntest days and Suntest hours were recalculated by the RMS on the basis of the time-points expressed in Natural Sunlight Days provided in the study report.

Table B.8.2.1.2.2._CA-3: The concentration of Flufenacet in the irradiated and dark-control samples in function of time.

Time point			Content of Flufenacet [%] in:	
<i>Natural Sunlight Days</i>	<i>Suntest Days</i>	<i>Suntest hours</i>	<i>Irradiated samples</i>	<i>Dark-control samples</i>
0	0	0	98.9	98.9
8.0	2.73	65.6	97.7	98.2
13.9	4.75	113.98	97.8	95.7
19.8	6.77	162.36	96.2	96.2
30.0	10.25	246	96.6	98.5

The Applicant performed the kinetic analysis of the data presented in the table above. The kinetic fitting was carried out using linear regression for logarithmically-transformed concentrations of Flufenacet. RMS decided to repeat the analysis using the non-linear regression method, as recommended by FOCUS.

The analysis was performed for irradiated samples using time points expressed as Suntest Days and as Natural Sunlight Days. In case of the dark-control samples the kinetic fitting was carried out using solely Suntest Days, as these are the real sampling points and the dark-control samples do not require any conversion of the sampling points to make them representative for natural irradiation conditions.

The fitting was carried out using CAKE 3.1 modelling tool with IRLS as optimisation method. Only SFO kinetic model was tested, as very low level of degradation was observed.

The results are presented below, in graphical form on figure B.8.2.1.2.2._CA-5 and in the numerical form in the table B.8.2.1.2.2._CA-4.

Table B.8.2.1.2.1._CA-4: The numerical results of the examination of the indirect aqueous photolysis of Flufenacet in Stilwell pond water.

Irradiated samples – Suntest days**Graphical Summary:****Observations and Fitted Model:****Dark control – Suntest days****Graphical Summary:****Observations and Fitted Model:****Irradiated samples – Natural Sunlight Days****Graphical Summary:****Observations and Fitted Model:**

Figure B.8.2.1.2.2_CA-5: The graphical results of the examination of the indirect aqueous photolysis of Flufenacet in Stilwell pond water.

The fits obtained for irradiated samples can be considered reliable. The fit for the dark control bears a significant level of uncertainty, what can be attributed to virtually no degradation of the test compound observed in these samples. Therefore these results should be considered as indicative only. The determined kinetic endpoints were following:

- for irradiated sample using Suntest days $DT_{50} = 281$ days;
- for irradiated sample using Natural Sunlight days $DT_{50} = 822$ days;
- for the dark control sample using Suntest days $DT_{50} = 784$ days

Comparison of the results obtained for irradiated samples and the dark-control samples using the Suntest days showed that Flufenacet degraded much faster in irradiated samples. That in turn indicates that indirect photolysis played an important role in degradation of that compound. As practically no degradation of Flufenacet was observed in the dark control, in comparison to the irradiated samples, it may be assumed that the net degradation rate constant for photolysis $k_{\text{photol}} = k_{\text{irrad}}$. Therefore resulting $k_{\text{photol}} = 0.002467 \text{ [days}^{-1}\text{]}$. The DT_{50} for the net indirect aqueous photolysis of Flufenacet in Stilwell pond water is therefore following: **$DT_{50} = 160.08$ days** for Suntest days. As it was not necessary to correct the value provided by the modelling tool, also that expressed in Natural Sunlight Days may be left the same as returned by the kinetic model – **$DT_{50} = 822$ days** when expressed in Natral Sunlight Days.

Experiment 3 was performed using ultrapure water containing 15 ppm of Humic material.

The solution of humic material used in the experiment was prepared by dissolving 11.25 mg of humic acid in 2.5 mL of water.

To the foil-wrapped (with aluminium foil) test vessels, presented in the summary of the same study (as **Study 1**) under the point B.8.2.1.2.1. on figure B.8.2.1.2.1_CA-2, were introduced 60-mL portions of ultrapure water, to which 0.20 mL of the solution of humic material, characterised above, was added. Next, to each test vessel 0.6-mL portions of the **Test solution 2** were introduced and the test vessels sonicated for 5 minutes. The

number of so prepared test vessels was such to be sufficient for five single irradiation samples and three single dark-control samples including DAT-0 sample. The DAT 0 sample was analysed immediately after treatment by LSC and HPLC for the content of [^{14}C]-Flufenacet and radiochemical purity. The determined concentration of the test compound was 0.99 ppm with radiochemical purity of 98.6%. The concentration of the humic material was 15 ppm.

The remaining test vessels, irradiated samples and the dark-control samples, were placed in the Suntest irradiation unit and kept there for up to 10.01 days (corresponding to 29.3 Natural Sunlight Days; for the definition please refer to the summary of the *Study 1* presented under the point B.8.2.1.2.1.). In case of irradiated samples the foil wrapping vessels was removed, while the dark-control samples were kept wrapped with it.

At pre-designated time points irradiated samples and the dark-control samples were taken for the analysis.

The sampling points for the **dark-control samples** were set at the following time points, expressed as Natural Sunlight Days: 0, 23.4, and 29.3. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0, 8.00 (191.88 hours) and 10.01 (240.26 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit. The DAT 0 sample in the dark control can be also considered the DAT-0 irradiated sample.

The sampling points for the **irradiated samples** were set at the following time points, expressed as Natural Sunlight Days: 2.9, 11.7, 23.4 and 29.3. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0.99 (23.78 hours), 2.02 (48.38 hours), 5.02 (120.54 hours), 8.00 (191.88 hours) and 10.01 (240.26 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit.

At sampling intervals listed above single irradiated and dark control samples were removed from the Suntest unit. Vessels containing irradiated samples were immediately wrapped with aluminium foil to cut-off the light.

0.2-mL aliquots were analysed by LSC to quantify the [^{14}C] residues. Next 1-mL aliquots were analysed by HPLC to identify the compounds present in sample and quantify them. The example chromatograms for the irradiated and dark-control samples collected on DAT 10.01 (Suntest days) are presented below on figure B.8.2.1.2.2._CA-6.

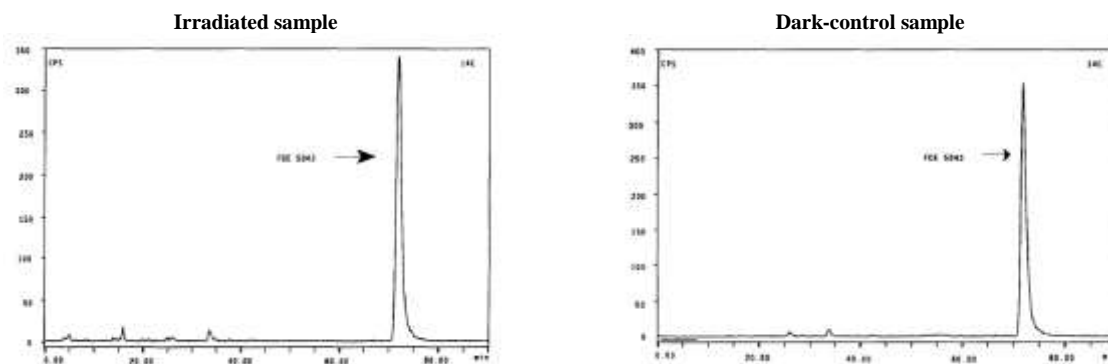

Figure B.8.2.1.2.2._CA-6: The DAT 10.01 (Suntest days; corresponding to 29.3 Natural Sunlight Days timepoint) HPLC chromatograms for irradiated and Dark-control samples (copied from the study report).

In all analysed samples Flufenacet was demonstrated to be the dominant compound. The numerical results of the analysis – the amounts of Flufenacet in each sample determined by HPLC, are presented below in the table B.8.2.1.2.2._CA-5. The time-points expressed in Suntest days and Suntest hours were recalculated by the RMS on the basis of the time-points expressed in Natural Sunlight Days provided in the study report.

Table B.8.2.1.2.2._CA-5: The concentration of Flufenacet in the irradiated and dark-control samples in function of time.

Time point			Content of Flufenacet [%] in:	
<i>Natural Sunlight Days</i>	<i>Suntest Days</i>	<i>Suntest hours</i>	<i>Irradiated sampels</i>	<i>Dark-control samples</i>
0	0	0	98.6	98.6
2.9	0.99	23.78	98.0	not determined

		k	0.002114	0.001263	-0.01394	0.018	0.1714		
Irradiated-Natural Sunlight days	SFO	M ₀	98.42	0.439	97.20	99.64	----	0.467	0.936
		k	0.002088	2.75 E-4	0.00136	0.003	8.02 E-4		

The fits obtained for irradiated samples can be considered reliable. The fit for the dark control bears a significant level of uncertainty, what can be attributed to small amount of experimental points (three) combined with very low level of degradation of the test compound observed in these samples. Therefore these results should be considered as indicative only. The determined kinetic endpoints were following:

- for irradiated sample using Suntest days DT₅₀ = 114 days;
- for irradiated sample using Natural Sunlight days DT₅₀ = 332 days;
- for the dark control sample using Suntest days DT₅₀ = 328 days

Due to the fact that the results of the fitting obtained for the dark-control samples bears significant level of uncertainty with regard to the rate degradation constant *k*, it was not possible to calculate the net degradation rate constant for photolysis *k*_{photol}. The results however indicate that the degradation of Flufenacet in solution containing humic material can be at least partly attributed to the indirect photolysis. It is therefore proposed to consider the values obtained for irradiated samples, presented above as good estimates of the rate of indirect photolysis of Flufenacet in water containing humic substances.

Experiment 4 was performed using ultrapure water containing 50 ppm of KNO₃.

The solution of KNO₃ used in the experiment was prepared by dissolving 45.0 mg of KNO₃ in 1.5 mL of water.

To the foil-wrapped (with aluminium foil) test vessels, presented in the summary of the same study (as **Study 1**) under the point B.8.2.1.2.1. on figure B.8.2.1.2.1._CA-2, were introduced 60-mL portions of ultrapure water, to which 0.10 mL of the solution of KNO₃, characterised above, was added. Next to each test vessel 0.6-mL portions of the **Test solution 3** were introduced and the test vessels sonicated for 5 minutes. The number of so prepared test vessels was such to be sufficient for four single irradiation samples and three single dark-control samples including DAT-0 sample. The DAT 0 sample was analysed immediately after treatment by LSC and HPLC for the content of [¹⁴C]-Flufenacet and radiochemical purity. The determined concentration of the test compound was 0.99 ppm with radiochemical purity of 99.4%. The concentration of KNO₃ was 50 ppm.

The remaining test vessels, irradiated samples and the dark-control samples, were placed in the Suntest irradiation unit and kept there for up to 10.01 days (corresponding to 29.3 Natural Sunlight Days; for the definition please refer to the summary of the **Study 1** presented under the point B.8.2.1.2.1.). In case of irradiated samples the foil wrapping vessels was removed, while the dark-control samples were kept wrapped with it.

At pre-designated time points irradiated samples and the dark-control samples were taken for the analysis.

The sampling points for the **dark-control samples** were set at the following time points, expressed as Natural Sunlight Days: 0, 23.4, and 29.3. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0, 8.00 (191.88 hours) and 10.01 (240.26 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit. The DAT 0 sample in the dark control can be also considered the DAT-0 irradiated sample.

The sampling points for the **irradiated samples** were set at the following time points, expressed as Natural Sunlight Days: 2.9, 11.7, 23.4 and 29.3. When recalculated by the RMS to the Suntest days, representing the real incubation time the sampling time-points, expressed as DAT (Days After Treatment), were following: 0.99 (23.78 hours), 4.00 (95.94 hours), 8.00 (191.88 hours) and 10.01 (240.26 hours). The calculations were based on the statement provided by the Applicant, that 1 Natural Sunlight Day is equivalent to 8.2 hours in the Suntest unit.

At sampling intervals listed above single irradiated and dark control samples were removed from the Suntest unit. Vessels containing irradiated samples were immediately wrapped with aluminium foil to cut-off the light.

0.2-mL aliquots were analysed by LSC to quantify the [^{14}C] residues. Next 1-mL aliquots were analysed by HPLC to identify the compounds present in sample and quantify them. The example chromatograms for the irradiated and dark-control samples collected on DAT 10.01 (Suntest days) are presented below on figure B.8.2.1.2.2._CA-8.

			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	r
					Lower	Upper			
Irradiated-Suntest days	SFO	M_0	101.0	2.168	94.11	107.9	----	2.08	0.933
		k	0.02519	0.003984	0.01251	0.038	0.004		
Dark control-Suntest days	SFO	M_0	99.37	0.174	97.16	101.6	----	0.093	0.997
		k	0.004401	2.41 E-4	0.001346	0.007	0.01737		
Irradiated-Natural Sunlight days	SFO	M_0	101.1	2.167	94.11	107.9	----	2.08	0.933
		k	0.008607	0.001361	0.004277	0.013	0.003993		

The obtained fits are reliable. They also returned the DT_{50} values, which are following:

- for irradiated sample using Suntest days $\text{DT}_{50} = 27.5$ days;
- for irradiated sample using Natural Sunlight days $\text{DT}_{50} = 158$ days;
- for the dark control sample using Suntest days $\text{DT}_{50} = 80.5$ days

Comparison of the results obtained for irradiated samples and the dark-control samples using the Suntest days showed that Flufenacet degraded much faster in irradiated samples. That in turn indicates that indirect photolysis played an important role in degradation of that compound. For that reason the net degradation rate constant for photolysis was calculated using the following equation: $k_{\text{photol}} = k_{\text{irrad}} - k_{\text{dark}}$. The resulting $k_{\text{photol}} = 0.020789$ [days^{-1}]. That value was subsequently used to calculate the DT_{50} for the net indirect aqueous

photolysis of Flufenacet in natural water containing salts (marine water, saline water). The calculated $DT_{50} = 33.34$ days for Suntest days. RMS additionally recalculated that value to Natural Sunlight Days, using assumption that 1 Natural Sunlight Day is equal to 8.2 Suntest hours. The resulting $DT_{50} = 97.59$ days when expressed in Natural Sunlight Days.

Conclusions:

The results of the study showed that Flufenacet in natural water will be prone to indirect photolysis and that process will be much faster than the direct aqueous photolysis of Flufenacet. It was also demonstrated that in presence of natural photosensitizer – humic substances, and inorganic salts generating hydroxyl radicals when exposed to solar radiation, the process of indirect aqueous photodegradation of Flufenacet may contribute to overall rate of degradation of that compound in surface water bodies.

The following study was carried out with aim to examine the indirect aqueous photolysis of FOE Thiadone – the major degradation product of Flufenacet in soil and aquatic environment.

Study 2:

Report: Stupp H.-P., Unold M., (2011): “[Thiadiazole-2-¹⁴C] BCS-AA41715 (FOE 5043-thiadone). Phototransformation in Natural Water.”; Bayer CropScience AG, Development, Environmental Safety, Metabolism /ADME and Environmental Fate, BCS-D-EnSDa-MeA/Efate, Alfred-Nobel-Str. 50, D-40789 Monheim am Rhein, Germany, study No. M 1121843-0, Report No. MEF-09/506; 21. 03. 2011; study reference number M-404931-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- EU Commission Directive 94/37/EC amending Council Directive 91/414/EEC, July 29, 1994;
- EU Commission Directive 95/36/EC amending Council Directive 91/414/EEC, July 14, 1995;
- US. Pesticide Assessment Guidelines, Subdivision N, Environmental Fate, EPA 161-2: Aqueous Photolysis Studies, 1982;

- Canada PMRA DACO Number 8.2.3.3.2.

GLP: Yes;

RMS comments: This is a newly submitted study, performed with aim to examine the indirect aqueous photolysis (photodegradation in natural water) of FOE Thiadone. For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- OECD Guideline 316: Phototransformation of Chemicals in Water – Direct Photolysis, Adopted 3 October 2008;
- US EPA Guideline OPPTS 835.2210 – Direct Photolysis Rate in Water by Sunlight; January 1998;
- US EPA Guideline OPPTS 835.2240 – Photodegradation in Water; October 2008;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-2, Aqueous Photolysis Studies (indicated as reference Guideline in the study report);
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals in Water – Direct and Indirect Photolysis, Draft Document August 2000 (additional reference document),
-

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable. It is summarised below.

Summary:

The aims of the study were:

- a) to determine the rate of photodegradation of FOE Thiadone in natural water exposed to UV-Vis light;
- b) to identify and quantify of major degradation products of that process.

The experiment was performed in two variants – as **Main Test 1** or **Main Test 2**, both characterised further down this summary.

The test compound used in the experiment was [^{14}C]- FOE Thiadone radiolabelled in position C2 of the thiadiazole ring, as shown below on figure B.8.2.1.2.2._CA-10. It had a specific radioactivity of 4.28 MBq/mg, radiochemical purity (determined by radio-HPLC) of >99% and chemical purity (determined by HPLC with UV detection) of >99%. To the test facility it was delivered in form of vacuum-dried solid. In the test facility the 2.59 mg of the test compound was dissolved in 3 mL of CH_3CN to obtain the solution having concentration of ~1 mg/mL, which was stored in the freezer in the dark until being used. That solution was further called **Stock solution (I12431)**. Its purity, determined chromatographically, was 100%.

Figure B.8.2.1.2.2._CA-10: The structural formula of the test compound – [^{14}C] FOE Thiadone, used in the study. The radiolabelling position is marked with an asterisk (*)
(copied from the study report).

The experiment was carried out using natural water sampled from the Rhine River in the vicinity of the test facility, at 717th-718th km of the river course. It was collected on the 31st March 2009 at a distance of ~1 m from the river bank, from the depth of 10-30 cm using 5-L plastic flask. After delivery to the test facility it was stored for 1 day at room temperature before being used. To justify the selection of the test medium – Rhine River water, it was stated that the river was well known to represent typical natural water in agricultural areas and that the amount of organic material was in range that did not influence the irradiation in the environmentally relevant wavelength range ($\lambda \geq 290$ nm) due to the absorption of light.

The characteristic of the test medium – river water, is presented in the table B.8.2.1.2.2._CA-9 and its UV-Vis absorption spectrum on figure B.8.2.1.2.2._CA-11. From that spectrum it can be clearly seen that the maximum absorption in test medium – natural river water, was observed for $\lambda < 290$ nm, while for $\lambda = 290$ nm it was only 0.056 and decreased for longer wavelengths.

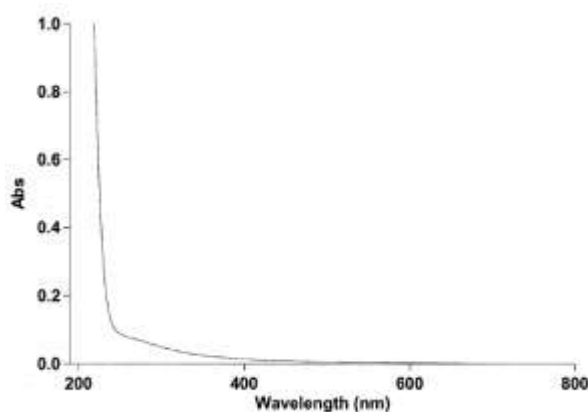

Figure B.8.2.1.2.2._CA-11: The UV-Vis absorption spectrum of the test medium – natural water, used in the experiment (copied from the study report).

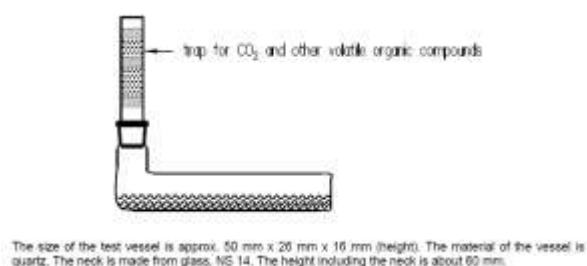

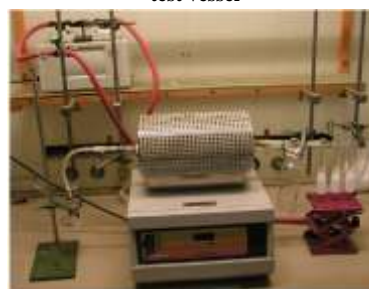

Table B.8.2.1.2.2._CA-9: The characteristic of the test medium – natural water, used in the experiment.

Parameter	Determined value
<i>Test medium</i>	River Rhine water
<i>pH</i>	8.0
<i>Suspended solids [mg/L]</i>	130
<i>Total evaporation residue [mg/L]</i>	370
<i>Oxygen saturation [%]</i>	95.3 at T = 22.5°C
<i>Conductivity [μS/cm]</i>	529
<i>Total Organic Carbon – TOC [mg/L]</i>	2
<i>Hardness [$^{\circ}$dH]</i>	10.5
<i>Total P [mg/L]</i>	0.0815
<i>Total NO₂⁻ and NO₃⁻ content [mg/L]</i>	3.1

The natural water used in the experiment was firstly filtered then sterilised by steam pressure sterilisation. The sterilisation of the test water was performed in order to avoid biological degradation of the test substance.

Its 540-mL portion was treated with 0.54 mL of the **Stock solution**, in the (sterile) Erlenmeyer flask, which afterwards was covered with aluminium foil to cut-off light and the solution was stirred under sterile conditions for ~1 hour to grant its appropriate aeration. So prepared solution was subsequently called **Test solution** and it contained 0.1% of the organic co-solvent – acetonitrile.

Next, the adequate portions of the **Test solution** – 20 mL in case of the **Main Test 1** and 19 mL in case of the **Main Test 2**, were placed in the quartz glass test vessels. Two kinds of the test vessels were prepared for the irradiated samples in the **Main Test 1** – vessels closed with the tower trap for the volatile compounds (**Test vessel type A**), shown below on figure B.8.2.1.2.2._CA-12, and those sealed with a crimped Teflon stopper (**Test vessel type B**), presented on figure B.8.2.1.2.2._CA-13. That second type of the test vessel was subsequently attached, by means of two needles piercing the Teflon stopper to the apparatus removing the volatile compounds formed in headspace and capturing them for further analysis. These samples were placed in the irradiation chamber and irradiated there, at constant temperature T = 25 ± 1°C for up to 14 days.

Test vessel with the trap tower for volatile compounds**The trap for volatile compounds in detail****Figure B.8.2.1.2.2._CA-12:** The **Test vessel type A** used in the experiment (copied from the study report).**Sealed test vessel with injection needles used to remove volatile compounds from headspace****The device for capturing the volatile compounds formed in the test vessel****Figure B.8.2.1.2.2._CA-13:** The **Test vessel type B** used in the experiment (copied from the study report).

In case of the dark control samples used in that experiment, the test vessels, same as shown on figure B.8.2.1.2.2._CA-12 (minus tower trap for volatiles) were sealed with a glass stopper. These samples were placed in the darkness, inside the climatic cabinet, and incubated at the constant temperature $T = 25 \pm 1^\circ\text{C}$ for up to 14 days.

The irradiated samples were kept in the Suntest chamber, presented below on figure B.8.2.1.2.2._CA-14, equipped with a Xenon lamp as the artificial light source. It had the following characteristic:

- emission wavelength spectrum $\lambda = 290 - 2450 \text{ nm}$, with the relevant range at $\lambda = 290 - 800 \text{ nm}$;
- light intensity: 975 W/m^2 for wavelength range $\lambda = 290 - 2450 \text{ nm}$ and 607 W/m^2 for wavelength range $\lambda = 290 - 800 \text{ nm}$;
- filters used: $<290\text{nm}$ cut-off UV filter;
- relationship to natural sunlight: constant 14-days exposure to light in suntest unit corresponded to ~38 days of natural solar irradiation (extreme conditions) in June at Phoenix, Arizona, USA – $33^\circ 26' \text{ N}$ (max daily irradiance: 31 MJ/m^2 , irradiance per 30 days: 930 MJ/m^2).

The temperature in the irradiation chamber was maintained at the constant level by using the cooling plate connected to a chiller. The device is also shown on the figure B.8.2.1.2.2._CA-14.

The Suntest unit – general view

The interior of the suntest unit with the cooling plate

Figure B.8.2.1.2.2._CA-14: The Suntest irradiation unit and its interior with the cooling plate (copied from the study report).

At the pre-designated time points the duplicate samples irradiated (one representing **Test vessels type A** and one representing **Test vessels type B**) were taken for the analysis. Those sampling points were on DAT (Days After Treatment) 1, 2, 5, 6, 8 and 14. At the same time points, and additional on DAT 0, the duplicate dark control samples were also taken for the analysis. The concentration of the test item in the solution was determined before and after introduction of the **Test solution** into the test vessels. That was done using three 0.1-mL aliquots of the solution, analysed by LSC.

The sample processing procedure used in the analysis of the irradiated samples is presented below on figure B.8.2.1.2.2._CA-15. Similar procedure was used for the dark control samples, with exception that the formation of the volatile compounds was not assessed and the solution remaining after analysis was stored in the dark in the freezer to be used as irradiated samples in the **Main Test 2**.

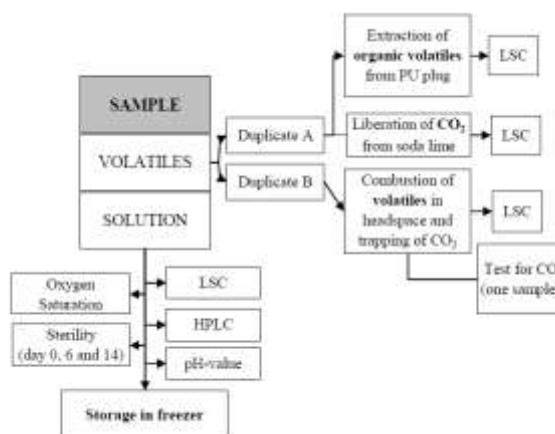

Figure B.8.2.1.2.2._CA-15: The sample-processing procedure used for irradiated samples in the **Main Test 1** (copied from the study report).

The **Main Test 2** was carried out using the test vessels containing samples that in the **Main Test 1** were used as the dark controls (as no degradation of the test item was observed in them). To carry out that experiment the vessels were sealed with crimped Teflon stopper, as were **Test vessels type B** used in the **Main Test 1**. So prepared duplicate samples were placed in the Suntest unit, shown on the figure B.8.2.1.2.2._CA-14, and irradiated for up to 14 days under the similar conditions as irradiated samples in the **Main Test 1**. The light source used in the experiment was Xenon lamp, having the following characteristic:

- emission wavelength spectrum $\lambda = 290 - 2450$ nm, with the relevant range at $\lambda = 290 - 800$ nm;
- light intensity: 958 W/m^2 for wavelength range $\lambda = 290 - 2450$ nm and 597 W/m^2 for wavelength range $\lambda = 290 - 800$ nm;
- filters used: <290nm cut-off UV filter;
- relationship to natural sunlight: constant 14-days exposure to light in suntest unit corresponded to 37.4 days of natural solar irradiation (extreme conditions) in June at Phoenix, Arizona, USA – $33^\circ 26' \text{ N}$ (max daily irradiance: 31 MJ/m^2 , irradiance per 30 days: 930 MJ/m^2).

Duplicate samples were taken for analysis at the following time points: after 1, 2, 5 8, 9 and 14 days of continuous irradiation. Additionally, prior to the start of irradiation, 2 aliquots of the test solution werer taken from one test vessel to be analysed. The samples taken for analysis at the time points listed above were processed using the procedure shown below on figure B.8.2.1.2.2._CA-16.

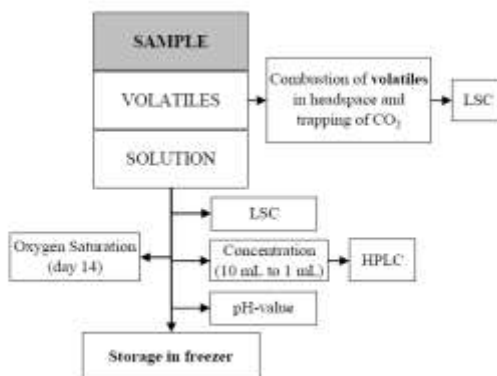

Figure B.8.2.1.2.2._CA-15: The sample-processing procedure used for irradiated samples in the **Main Test 2** (copied from the study report).

In all samples pH was determined using pH-meter Multi 340i (WTW) with a SenTix 62 electrode immediately after sampling. The sterility of the test solution was checked in DAT-0, DAT-6 and DAT-14 samples collected during the **Main Test 1**. For that purpose 20- μ L aliquots of the test solution were applied onto a sterile mixed culture medium and incubated for at least 14 days at $T = 25^{\circ}\text{C}$.

For sample collected during the **Main Test 2** such analysis was not performed as it was assumed that the sterile conditions of the samples were granted due to the high light intensity.

Samples were also monitored for aerobic conditions on DAT-0, DAT-6 and DAT-14 in case of the samples collected during the **Main Test 1** and at day 14 in case of samples collected during the **Main Test 2**. That was done using an oxygen meter Multi 340i (WTW) equipped with Celloxi 325 sensor.

All samples were analysed for radioactivity content using LSC. In case of individual liquid samples their three 0.1-mL aliquots were used in the analysis. Each was mixed with 2 mL of QuicksafeA + 5% water scintillation cocktail and analysed for radioactivity content using Beckman LS 6000LL/6500 scintillation counter. The counting time was 10 minutes, counting efficiency 86 – 92% and the background 13 – 15 cpm.

The radioactivity released from the test vessels in form of $^{14}\text{CO}_2$, either from the soda lime filling soda traps or as the combustion product of the volatile compounds present in the test vessels headspace, was absorbed in Carbosorb E/Permafluor E⁺ 1:1 scintillation cocktail. Next its 9-10-mL aliquots were analysed using LKB-Wallac 1219 LS counter. The counting time was ≤ 10 minutes, counting efficiency 74 – 90% and the background 26 – 28 cpm.

The test solutions were chromatographically analysed using RP-HPLC. The analysis was performed using Agilent 1200 HPLC system coupled with UV detector, set at $\lambda = 254$ nm, and Raytest Ramona Star radioactivity detector. Chromatographic separation was performed in a gradient mode on Purospher RP18E 250 • 4.6 mm, 5 μ m, chromatographic column placed in a chromatographic oven set at $T = 40^{\circ}\text{C}$.

The mobile phase used in the gradient elution consisted of:

- **Solvent A:** 0.1% HCOOH in Milli-Q water;
- **Solvent B:** 0.1% HCOOH in CH_3CN

The elution lasted for 34 minutes, the flow rate of the mobile phase was 1.0 mL/min and the gradient programm is shown below in the table B.8.2.1.2.2._CA-10. The volume of the sample injected was 0.15 – 0.5 mL. The identification of the test compound was performed by comparing the retention times of fractions in the analysed sample with those of the known standards. For FOE Thiadone the $R_t = \sim 23$ min.

Table B.8.2.1.2.2._CA-10: The gradient mode used in the RP-HPLC analysis.

Elution time [min]	Composition of the mobile phase	
	% Solvent A	% Solvent B
0.0	100	0
2.0	100	0
21.0	30	70
25.0	5	95
28.0	5	95
29.0	100	0
34.0	100	0

The **Stock solution** was chromatographically analysed using LC-MS method. The chromatographic analysis was carried out using Agilent HP1100 chromatographic station coupled to UV detector followed by Ramona Raytest radioactivity detector and TSQ 7000 MS Detector (Finnigan). The chromatographic separation was performed on Nucleodur C18 250 • 2, 3 μ m, chromatographic column working in the gradient mode. The mobile phase consisted of:

- **Solvent A:** 0.1% HCOOH in Milli-Q water;
- **Solvent B:** 0.1% HCOOH in CH_3CN

The elution lasted for 35 minutes, the flow rate of the mobile phase was 0.2 mL/min and the gradient programm is shown below in the table B.8.2.1.2.2._CA-11.

Table B.8.2.1.2.2._CA-11: The gradient mode used in the HPLC-MS analysis.

Elution time [min]	Composition of the mobile phase	
	% Solvent A	% Solvent B
0.0	95	5
1.0	95	5
25	5	95
35	5	95

The results – concentrations of the test compound, FOE Thiadone, in irradiated and dark-control samples in function of time, were kinetically examined in order to determine the rate of indirect photodegradation of FOE Thiadone in natural water. The analysis was performed in line with the recommendation of FOCUS Kinetics Guidance Document using KinGUI 1.1 kinetic modelling tool.

Results and their discussion:

The characteristic of artificial light used in the experiment is presented below on figure B.8.2.1.2.2._CA-16.

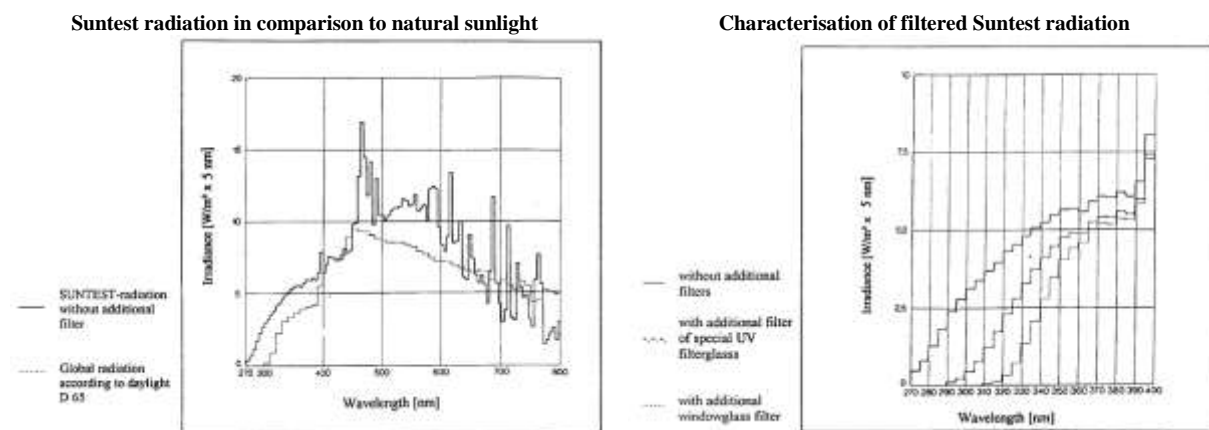

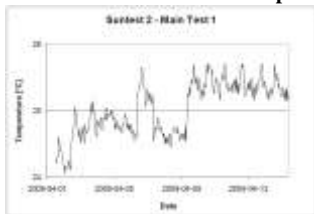

Figure B.8.2.1.2.2._CA-16: Characterisation of the artificial light used in the study (copied from the study report).

On figure B.8.2.1.2.2._CA-17 below are presented the experimental conditions – temperature, in irradiation/climatic chambers during irradiation/incubation of samples. On their basis it may be stated that:

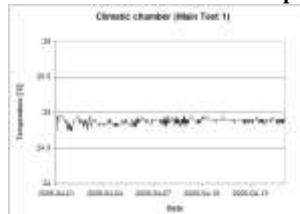

- in the Suntest chamber (irradiated samples) during the **Main Test 1** the average temperature was $T = 25.03^{\circ}\text{C}$, with min. $T = 24.05^{\circ}\text{C}$ and max. $T = 25.70^{\circ}\text{C}$;
- in the climatic chamber (dark control samples) during the **Main Test 1** the average temperature was $T = 24.90^{\circ}\text{C}$, with min. $T = 24.50^{\circ}\text{C}$ and max. $T = 25.45^{\circ}\text{C}$;
- in the Suntest chamber (irradiated samples) during the **Main Test 2** the average temperature was $T = 24.88^{\circ}\text{C}$, with min. $T = 24.75^{\circ}\text{C}$ and max. $T = 24.95^{\circ}\text{C}$.

On that basis it may be stated that during the whole study the temperature was maintained at the pre-defined level of $T = 25 \pm 1^{\circ}\text{C}$.

Main Test 1 – irradiated samples

Main Test 1 – dark-control samples

Main Test 2 – irradiated samples

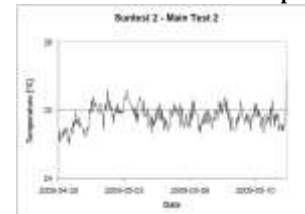

Figure B.8.2.1.2.2._CA-17: The experimental conditions – temperature, recorded in irradiation and incubation chambers during the experiment (copied from the study report).

The results of the determination of the test solution's pH, sterility and saturation with O₂ during the experiment are presented below in the table B.8.2.1.2.2._CA-12. On their basis it was stated that the samples were sterile throughout the study duration. The pH was of irradiated samples in range 7.8 – 9.0 and of the dark control ones 8.3 – 8.6. Oxygen was at the level >90%. In case of the Main Test 1 the replicate 1 of Irradiated samples represent the test vessels sealed with tower traps for volatiles, while replicate 2 – vessels capped with the crimped Teflon stopper.

Table B.8.2.1.2.2._CA-12: The results of the determination of pH, sterility and O₂ level in the test solution during experiment.

The verification of the application rate showed that:

- in the **Main Test 1** the initial amount of the test compound – FOE Thiadone, in individual vessel was 16.44 µg, what corresponded to the concentration 0.82 mg/L;
- in the **Main Test 2** the initial amount of the test compound – FOE Thiadone, in individual vessel was 15.62 µg, what corresponded to the concentration 0.82 mg/L.

The LOQ values (LOQ stands for Limit Of Quantification) for the LSC analysis was defined as the double average instrument background count rate, which was approx. 0.25 Bq for liquid samples and approx. 0.5 Bq for combusted headspace of **Test vessels type B** samples. In case of HPLC analysis with radioactivity detection the LOD = 0.4% AR (LOD stands for the Limit Of Detection) and the LOQ = 3 • LOD = 1.2% AR.

The verification of the performance of chromatographic procedure showed that the retention time – R_t , values were well reproducible, what indicated credibility of that method of identification of the test compounds, and the recovery of injected radioactivity was very good (100.9% of radioactivity determined by LSC).

The results of the experiment – the distribution of radioactivity in test solutions in function of time, are presented below in three tables. Table B.8.2.1.2.2._CA-13 contains the results obtained for irradiated samples in the **Main Test 1**, in the table B.8.2.1.2.2._CA-14 presents the results obtained in the **Main Test 1** for the dark-control samples, and the table B.8.2.1.2.2._CA-15 provides the results obtained for irradiated samples in the **Main Test 2**. Each table is followed by the bar graph presenting the results of the examination of the distribution of radioactivity between solution and volatile-compounds fraction (figures B.8.2.1.2.2._CA-18 – B.8.2.1.2.2._CA-20). In case of irradiated samples in the **Main Test 1** two bar graphs are provided, as the test vessels were in two different variants – as vessels sealed with tower trap for volatiles (**Replicate A**) and as vessels capped with crimped Teflon stoppers. In case of the dark control samples in the **Main Test 1** and irradiated samples in **Main Test 2** on the bar graphs are presented the averages obtained for the two replicates.

Analysing them in the study report the authors stated that in case of the **Main Test 1** the use of the **Test vessels type A** resulted in losses of the radioactivity in form of the volatile compounds, what indicated the formation of the non-absorbed volatiles. The recovery of the radioactivity in the same test from **Test vessels type B** was scattered, but on the basis of these results it was decided to use that design in the definitive test with irradiated samples.

Due to the insufficient recovery levels in these samples it was decided not to use the results in the kinetic analysis carried out for FOE Thiadone.

The qualitative analysis of the test solutions showed that they contained two radiolabelled compounds/fractions – FOE Thiadone and the degradation product M1. The concentrations of FOE Thiadone in both replicates decreased with time, what indicated that the compound was photodegraded. That was conformed by the increasing amounts of the degradate M1.

In the dark control samples collected during the **Main Test 1** the analysis showed that virtually whole radioactivity was in the solution. For that reason the analysis of the volatile fraction was not carried out. The profiling of the test solutions showed that the only constituent of the solution was FOE Thiadone. On that basis it was stated that in the dark control samples the compound was stable. The determined concentrations of FOE Thiadone were used in the kinetic analysis. The analysis was performed using the concentration for individual replicates as input values.

The solutions remaining in the dark-control samples from the **Main Test 1** after LSC and chromatographic analyses were subsequently used as the irradiated samples in the **Main Test 2**. In these samples a steady build-up of the volatile compounds fraction was demonstrated, correlated with the decrease of radioactivity in the solution. The recoveries of radioactivity were, with exception of the last time point (at which the leakage in the oxidiser was observed), at the level of >90% AR.

Three radioactivity fractions were detected in solution:

- FOE Thiadone, steadily decreasing with time;
- the M1 degradation product, reaching the maximum amount, in one of replicates, of 8.4% AR, and the peak concentration, as average of two replicates, of 7.5% AR; that fraction was not further characterised, being classified in the report as minor metabolite (RMS however noticed that in both replicates it was recorded in amounts >5% AR in at least two consecutive samples);
- the diffuse radioactivity fraction representing minor degradation products, not surpassing 1.1% AR during the study.

The results obtained in the **Main Test 2** for the individual compounds/fractions identified in the experiment were presented in the study report in the graphical form. That scheme is presented as the right-hand graph on figure B.8.2.1.2.2._CA-20.

Finally, it shall be indicated that it was stated in the study report that the formed volatile products could not have been trapped directly. For that reason they were determined as the $^{14}\text{CO}_2$ formed as the result of the combustion of the headspace. RMS noticed that FOE Thiadone may be classified as a volatile compound, with $V_p = 2.05 \text{ Pa}$ at $T = 20^\circ\text{C}$ and Henry's law constant $H = 0.012 \text{ Pa} \cdot \text{m}^3 \cdot \text{mol}^{-1}$. It may be therefore possible that part of radioactivity in the headspace may be attributed to that compound, what in turn could influence the results of the kinetic analysis. The results however obtained for the dark control samples in the **Main Test 1** do not seem to confirm that – all radioactivity applied was recovered in the test solution.

Table B.8.2.1.2.2._CA-13: The numerical results obtained for irradiated samples in the **Main Test 1**.

Total radioactivity recovered		1	98.4	96.2	93.2	91.7	95.0	94.9	67.4 ⁴⁾
		2	98.5	96.8	94.2	93.5	95.3	95.6	21.5 ⁴⁾
		Mean	98.5	96.5	93.7	92.6	95.2	95.2	44.4 ⁴⁾

Footnotes to the table:

- 1) n. d. – not detected;
- 2) n. e. – not examined;
- 3) The drop of radioactivity was caused by a leak in the oxidiser;
- 4) The lost of radioactivity recovered as volatile compounds (due to the leak in the oxidiser) was the reason for low total recovery level observed for this time point.

Figure B.8.2.1.2.2._CA-20: The graphical results obtained for irradiated samples (mean of two replicates) collected in the **Main Test 2** (copied from the study report).

On the basis of the results presented above in the study report was proposed the transformation scheme for the process of photodegradation of FOE Thiadone in the natural water (indirect aquatic photolysis). It is shown below on figure B.8.2.1.2.2._CA-21. It shall be indicated that it was derived only for the compound radiolabelled in C2 position within the thiadiazole ring, so it does not address the would-be products associated with the second carbon atom within the ring – C5. That may be considered as a data gap, minor however, as possibly the photodegradation products would be similar to detected for thiadiazole group radiolabelled in C5 position in the study examining the degradation of Flufenacet in aerobic soil.

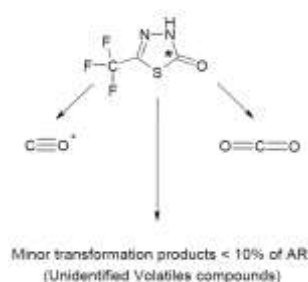

Figure B.8.2.1.2.2._CA-21: The proposed degradation pathway for FOE Thiadone radiolabelled in C2 position in the process of indirect aqueous photolysis (copied from the study report).

The data for FOE Thiadone presented in the tables B.8.2.1.2.2._CA-14 and B.8.2.1.2.2._CA-15 were subjected to the kinetic analysis carried out in line with the recommendations provided by the FOCUS Kinetics Guidance Document [Focus, 2005]. The assessment was performed using KinGUI 1.1 as a modelling tool. The data were fitted solely to the SFO kinetic model. The input data used in the analysis are presented below in the table B.8.2.1.2.2._CA-16.

Table B.8.2.1.2.2._CA-16: The input data used in the kinetic analysis of the results obtained for FOE Thiadone in the experiment examining its indirect aqueous photolysis.

Irradiated samples			Dark-control samples		
Sampling point [Days]	Concentration of FOE Thiadone [% AR]		Sampling point [Days]	Concentration of FOE Thiadone [% AR]

Figure B.8.2.1.2.2._CA-23: The rate of photodegradation of FOE Thiadone in natural water exposed to natural sunlight on different locations (latitudes) (copied from the study report).

Conclusions:

The results of the study demonstrate that FOE Thiadone is prone to photodegradation in natural water, i. e. to indirect aqueous photolysis. Light bearing characteristic identical to that of natural sunlight was demonstrated to be the main factor driving that process – the sterilisation of riverine water used in the experiment and lack of degradation observed in the dark control samples confirmed that. The degradation process, following 1st order kinetics (SFO), was relatively fast, with rate constant $k = 0.1194$ [days⁻¹] what corresponded to DT₅₀ = 5.8 days and DT₉₀ = 19.28 days in samples continuously exposed to artificial sunlight. That may indicate that FOE Thiadone could be efficiently removed in the processes of drinking water abstraction at the stage at which water is sterilised with UV radiation. The experiment was performed using the compound radiolabelled at C2 position,

for which it was possible to identify two degradation products – CO₂ and CO. There is no information about the would-be degradation products associated with the second carbon atom within the thiadiazole ring – C5, although it may be assumed that one of them could be TFA. That however may require further investigation.

When recalculated to natural conditions – exposure to sunlight at three different locations (representative), the half lives were following:

- for Phoenix, Arizona, USA, latitude 33° 26' N, in June (radiation intensity 31 MJ/m² per day and 930 MJ/m² for 30 days) **DT₅₀ = 15.8 days**;
- for Athens, Greece, EU, latitude 38° 08' N, in June (radiation intensity 20 MJ/m² per day and 600 MJ/m² for 30 days) **DT₅₀ = 24.4 days**;
- for Phoenix, Arizona, USA, latitude 33° 26' N, in July (radiation intensity 16 MJ/m² per day and 480 MJ/m² for 30 days) **DT₅₀ = 30.5 days**.

These results may indicate that the phototransformation in natural Surface Water bodies may be one of the mechanisms of the elimination of FOE Thiadone from that environmental compartment, although probably not a dominant one.

Summary – Indirect aqueous photolysis of Flufenacet

The indirect aqueous photolysis of Flufenacet was examined in four types of aqueous solutions:

- natural pond water having pH = 6.5, TOC = 20.7 mg/L and containing 160 mg/L of suspended solids (total), subsequently named Howe pond water;
- natural pond water having pH = 7.8, TOC = 1.55 mg/L and containing 9 mg/L of suspended solids, subsequently named Stilwell pond water;
- ultrapure water containing 15 ppm of humic material;
- ultrapure water containing 50 ppm KNO₃.

The samples were exposed to UV-Vis radiation generated by artificial light source, but bearing the characteristic of the natural sunlight. The irradiation conditions were similar to those recorded during the 30-days exposure to natural summer light in Phoenix, Arizona, USA. The experiment showed that Flufenacet was prone to indirect photolysis in water, although that process should not be regarded as one of the driving mechanisms in disappearance of Flufenacet from natural waters. The experiments were aimed on the determination of the kinetic parameters of the process – the rates of the indirect photodegradation of Flufenacet in water, therefore no attempt was made to identify and quantify the formed degradation products.

The calculated, net, half-lives for the indirect photodegradation of Flufenacet in water were following:

- for Howe pond water the experimentally derived (continuous irradiation) **DT₅₀ = 160.08 days**, what corresponded to **DT₅₀ = 468.53 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA);
- for Stilwell pond water the experimentally derived (continuous irradiation) **DT₅₀ = 281 days**, what corresponded to **DT₅₀ = 822 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA);
- for ultrapure water containing 15 ppm of Humic material the experimentally derived (continuous irradiation) **DT₅₀ = 114 days**, what corresponded to **DT₅₀ = 332 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA);
- for ultrapure water containing 50 ppm of KNO₃ the experimentally derived (continuous irradiation) **DT₅₀ = 27.5 days**, what corresponded to **DT₅₀ = 158 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA).

It shall be however indicated that these values were determined using the results obtained in non-GLP experiments (being an additional part of a GLP study aimed on the examination of the direct aqueous photolysis of Flufenacet). For that reason RMS decided to consider them as only indicative and not to include them into the EU List of Endpoints.

Additionally, in a separate experiment, was examined the indirect aqueous photolysis of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet. The test medium was sterilised natural (riverine) water. The samples were exposed to UV-Vis radiation generated by artificial light source, but bearing the characteristic of the natural sunlight. The irradiation conditions were similar to those recorded during the 30-days exposure to natural summer light in Phoenix, Arizona, USA. The experiment showed that FOE Thiadone was prone to indirect photolysis in water, although that process should not be regarded as one of the driving mechanisms in disappearance of Flufenacet from natural waters. The experiment was performed with the test compound radiolabelled at C2 position in thiadiazole ring, what resulted in identification only CO and CO₂ as degradation

products. Therefore it remains unknown what are the degradation products associated with the second carbon atom within the thiadiazole ring – C5. However, it may be assumed that one of such products could be TFA. The calculated, net, rate of indirect photodegradation of FOE Thiadone in water was $k = 0.1194 \text{ [days}^{-1}\text{]}$, corresponding to $\text{DT}_{50} = 5.8 \text{ days}$ in samples continuously irradiated with artificial sunlight. When recalculated to the natural conditions that value corresponded to:

- $\text{DT}_{50} = 15.8 \text{ days}$ determined for summer sunlight conditions (June) in Phoenix, Arizona, USA ($33^{\circ} 26' \text{N}$);
- $\text{DT}_{50} = 24.4 \text{ days}$ determined for summer sunlight conditions (June) in Athens, Greece, EU ($38^{\circ} 03' \text{N}$);
- $\text{DT}_{50} = 30.5 \text{ days}$ determined for summer sunlight conditions (July) in London, UK, EU ($51^{\circ} 30' \text{N}$).

These results were reported in the EU List of EndPoints for Flufenacet.

The results of the examination of the indirect aqueous photolysis of FOE Thiadone, in format recommended for reporting the regulatory endpoints in the EU, are presented below.

Aqueous photochemical degradation (Regulation (EU) N° 283/2013, Annex Part A, points 7.2.1.2 / 7.2.1.3)

Photolytic degradation of active substance and metabolites above 10 % - [results for Flufenacet, indirect photolysis](#)

B.8.2.2. – Route and rate of biological degradation in aquatic systems

The assessment in that area covered the following issues:

- examination of the ready biodegradability;
- examination of the aerobic mineralisation in surface water;
- examination of the fate and behaviour of Flufenacet in aerobic water/sediment systems;
- examination of the fate and behaviour of Flufenacet in irradiated aerobic water/sediment systems;
- examination of the degradation of Flufenacet in saturated zone (anaerobic water/sediment system).

Each of these problems is addressed below, under the relevant data point.

B.8.2.2.1. – Ready biodegradability

The Applicant has not submitted any study report presenting the results of the examination of ready biodegradability of Flufenacet. Instead the following justification for non-submission was provided:

“Flufenacet was stated to be not ready biodegradable. This was accepted by the European Commission (7469/VI/98-Final -3rd July 2003). Therefore no additional study was performed for the flufenacet renewal of approval.”

The justification for non-provision of the adequate study may be considered acceptable. RMS examining the submitted documentation stated that the Applicant submitted a study examining the degradation of Flufenacet in natural water. Also are available two studies examining the fate and behaviour of Flufenacet in aerobic water/sediment systems. These studies provided information on the mineralisation of Flufenacet in aquatic environment. Their results confirm that Flufenacet shall be classified as not readily biodegradable, hence the conclusion drawn during the previous evaluation of Flufenacet for its authorisation in the EU remains valid.

The outcome of that evaluation, in format recommended for reporting the regulatory endpoints in the EU, is presented below.

‘Ready biodegradability’ (Regulation (EU) N° 283/2013, Annex Part A, point 7.2.2.1)

Readily biodegradable
(yes/no)

<i>No data submitted, substance considered not readily biodegradable</i>
--

B.8.2.2.2. – Aerobic mineralisation in surface water

To address this data requirement the Applicant submitted two study reports, one examining the biotransformation of Flufenacet in natural water and the second one containing the results of the kinetic examination of the data obtained in the first study. Additionally was submitted the position paper presenting the compliance of the study examining the biological transformation of Flufenacet in water with the provisions of the OECD Guideline 309 – “Aerobic Mineralisation in Surface Water – Simulation Biodegradation Test.”.

All three submitted documents are summarised below as *Studies 1-3*.

Study 1:

Report: Schocken M. J., Yen P. Y., Widmer S. L., (1995): “[Phenyl-U-¹⁴C]FOE 5043 – Determination of Aerobic Aquatic Biotransformation at 25°C.”; Springborn Laboratories Inc., Environmental Sciences Division, 790 Main Street, Wareham, Massachusetts 02571-1075, USA (performing laboratory) for Bayer Corporation (formerly Miles Inc.), Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, MO 64120, USA; Springborn Laboratories Report No. 95-4-5785; study No. F3042404 (Bayer); Bayer Report No. BR106961; 27 December 1995; study reference number M-002210-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Canadian Guidelines T-1-255 for Determining Environmental Chemistry and Fate of Pesticides (Agriculture Canada), 30 October 1987.

GLP: Yes;

RMS comments: This is a newly submitted study. For the purpose of the present assessment it was evaluated for its compliance with the following Guidelines:

- OECD Guideline for the Testing of Chemicals No. 309: “Aerobic Mineralisation in Surface Water – Simulation Biodegradation Test.”, adopted 13 April 2004;

That evaluation of compliance was based on the results of the position paper submitted by the Applicant and summarised immediately after the summary of this study as *Study 2*.

RMS stated that, despite some deficiencies and deviations from the reference Guideline OECD 309, the study may be considered acceptable and used in the current assessment. It is summarised below.

Summary:

The aim of the study was to examine aerobic aquatic metabolism of Flufenacet (compound uniformly radiolabelled in phenyl ring) in order to:

- 1) determine the degradation kinetics of that compound;
- 2) to identify the major degradation products (>10% of the applied dose) and to establish their patterns of formation and decline over the course of one year.

The test compound used in the experiment was [Phenyl-U-¹⁴C]Flufenacet, having radiochemical purity of ≥ 99.0% and specific activity of 66.5 mCi/mmol. Its structural formula is shown below on figure B.8.2.2.2._CA-1. The radiolabelling position is indicated by an asterisk.

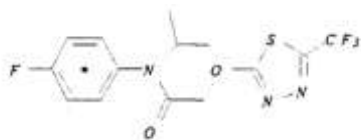

Figure B.8.2.2.2._CA-1: The structural formula of the test compound used in the study. Radiolabelling position is marked by an asterisk (copied from the study report).

The test compound was delivered in two separate vials, the content of which was used to prepare two stock solutions.

First vial, delivered on the 19 November 1993, was used to prepare the **Stock solution A**, used as application solution in an aborted study. That solution was prepared by dissolving the entire content of the vial with 100 mL of CH₃CN, what resulted in solution having the concentration of the test compound 0.165 mg/mL and specific activity of 406458 dpm/μL.

The second vial, received in the test facility on 18th February 1994, was used to prepare the **Stock solution B**. That was done by dissolving the entire content of that vial in 50 mL of CH₃CN and then combining so obtained solution with the remaining amount of the **Stock solution A**, in a volumetric flask. The so prepared solution had the concentration of the test compound 0.087 mg/mL and specific activity of 406358 dpm/μL (35211866 dpm/mL). It was used to prepare the application solution for fortification of the test samples. That was done by adding 3.177 mg of the non-radiolabelled Flufenacet with 77.151 mL of the **Stock solution B**. So prepared **Application solution** had the following estimated (calculated) parameters:

- concentration 0.128 mg/mL,
- radioactivity content 34861893 dpm/mL,
- specific activity 272614 dpm/μg.

The specific activity of the solution, determined experimentally (using HPLC), was 274661 dpm/μg and its radiochemical purity was 99.9%.

The experiment was performed using the natural pond water as a test medium. The test water was collected on the 25th October 1993 from a pond near Branchton/St. George, Ontario, Canada, from a depth of 30-60 cm below the surface. The sampling water body was representative for the areas of the intended use of Flufenacet. After delivery to the test facility the test water was stored at T = 5⁰C until being used. The characteristic of the non-sterilised test water is presented below in the table B.8.2.2.2._CA-1. It was carried out shortly before the initiation of the experiment.

Table B.8.2.2.2._CA-1: The characteristic of the tes water used in the experiment.

Determined parameter		Information/Value
<i>Data on sampling</i>	Location of the sampling site	Brachton/St. George, Ontario, Canada
	Type of water body	Pond
	Type of water sample	Pelagic water
	Sampling depth [cm below the surface]	30-60
<i>Physico-chemical properties of test water</i>	pH	7.5
	Total alkalinity [mg/L as CaCO ₃]	230
	Total hardness [mg/L as CaCO ₃]	329
	Specific conductivity [μmhos/cm]	500
	Dissolved oxygen [mg/L]	9.6
	Suspended solids [mg/L]	8.5
<i>Biological properties of test water – microbial activity</i>	Microbial population expressed as Colony Forming Units in 1 mL of test water [CFU/mL]	5.9 E3

The experiment was carried out in two variants – in sterile and non-sterile conditions. In case of sterile conditions the test water samples and all glassware used in the experiment was sterilised by autoclaving. Also sterilised in the same manner was glassware used in the experiment under non-sterile conditions.

The test system used in the experiment for individual samples was a flow-through system presented below on figure B.8.2.2.2._CA-2. It consisted of the 250-mL Erlenmeyer flask fitted with glass Dreschel cap equipped with inlet and outlet port, connected to a system delivering sterilised air (inlet port) and the system of trapping vessels to collect volatile compounds formed in the system during experiment (outlet port), at the end of which was placed a vacuum pump providing a flow of air through the system, for 30 minutes on each day of the experiment at rate 1-2 bubbles/second.

Each Erlenmayer flask was filled with 150 mL of sterilised or non-sterile test water. In total 36 such test systems were prepared – 24 for non-sterile experiment (2 replicates per each sampling point) and 12 for the sterile experiment (single replicates for each sampling point).

The test systems for sterile samples were assembled and treated with the test substance under the laminar-flow hood and those for non-sterile samples in an environmental fate laboratory.

After treatment all test systems were incubated under aerobic conditions in an environmental chamber at constant temperature T = 25 ± 1⁰C and standard daily light regime of 16 hours light and 8 hours darkness

(Sylvania GTE fluorescent lights of the type recommended for plant cultivation; light intensity 7.34 W/m^2 – 7.49 W/m^2) for up to 368 days.

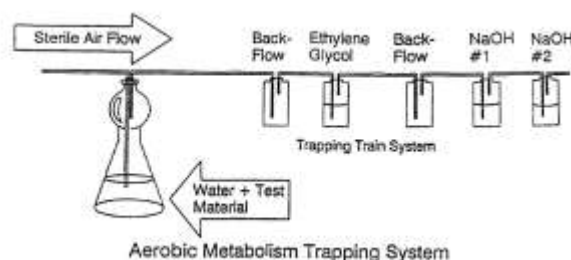

Figure B.8.2.2.2._CA-2: The test system for the individual samples used in the experiment (copied from the study report).

The test samples were treated with the test compound at application rate 1.3 mg/L , by adding 1.5 mL of the **Application solution** characterised above. That fortification rate was determined assuming the complete run-off from 1-acre field treated at application rate $1 \text{ kg Flufenacet/ha}$, soil bulk density of 1.5 g/cm^3 and the thickness of the treated soil layer of 5 cm . The **Application solution** was delivered using the gas-tight syringe below the surface of the test water in the given flask.

During the incubation period the water levels in all test vessels were constantly monitored and in non-sterile samples requiring the addition of water, that was done on day 102nd of incubation by addition of sterilised test water using 10-mL graduated pipet.

All test vessels were aerated by a daily purge, characterised above. The microbial activity of the test water was examined in non-sterile samples, by determining the size of microbial population, 7 days before the initiation of the experiment, on Day 0, day 278 and Day 368 (terminal) of the experiment. In case of the sterilised samples that was done on 7th day before the initiation of the experiment and on Days 278 and 368 of the incubation.

The non-sterile and sterilised samples were collected for the analysis on DAT (Days After Treatment with the test compound) 0, 4, 7, 15, 29, 60, 95, 188, 278 and 368. At these sampling points duplicate non-sterile samples and single sterilised samples were collected for analysis. The test systems collected for analysis were aerated for 30 minutes before being removed from the incubation chamber. Next each collected flask was gently swirled and, from pre-designated samples, $\sim 6\text{-mL}$ aliquot of the test water were taken for the analysis of microbial activity. The remaining sample was transferred to graduated cylinder and its volume recorded. Then three 1-mL aliquots were taken for LSC analysis, after mixing each of them with 15 mL of the scintillation cocktail, and 2-mL or 4-mL aliquots transferred to amber vials for radio-HPLC analysis. The remaining sample was stored in the freezer in Nalgene bottles.

At these sampling intervals the traps for volatile compounds – ethylene glycol- traps NaOH-traps, in all samples were replaced with fresh ones. Additional sampling of the traps for volatiles took place on DATs 153, 215, 243, 312 and 337.

The volumes of ethyl glycole and NaOH_{aq} from collected traps were recorded and duplicate 1-mL aliquots of each solution analysed, after mixing with 15 mL of the scintillation cocktail, by LSC.

Also, when it was necessary, the backflow traps were analysed for the radioactivity content.

The LSC analysis of all samples was performed using Beckman LS 1801 TD LS Counter or Packard 1600CA LS Counter. The maximum counting time was 5 minutes or until 2σ error of 5% was attained. The LOD was in range $30 - 60 \text{ cpm}$.

The chromatographic analysis was aimed at:

- the determination of the radiopurity and specific activity of the **Stock** and **Application** Solutions;
- the profiling of Flufenacet and its degradation products in collected samples (identification and quantitation);
- confirmatory analysis for the identification of degradation products of Flufenacet – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The determination of radiopurity and specific activity of the **Stock** and **Application** solutions was performed by means of HPLC analysis. It was carried out on Waters HPLC system, coupled with Beckman Model 171 radioactivity detector, equipped with Hamilton PRP-1 $250 \text{ mm} \times 4.1 \text{ mm}$, $10 \mu\text{m}$, chromatographic column working in the gradient mode.

The mobile phase consisted of: 0.4% CH₃COOH in HPLC-grade water as **Solvent A** and 0.4% CH₃COOH in CH₃CN as **Solvent B**. The flow rate of the mobile phase was 2.0 mL/minute and the gradient mode is presented below in the table B.8.2.2.2._CA-2. The elution lasted for 90 minutes.

Table B.8.2.2.2._CA-2: The gradient mode used in the analysis.

Elution time [min]	Composition of the mobile phase	
	% Solvent A	% Solvent B
0	100	0
15	70	30
65	40	60
70	0	100
80	0	100
81	100	0
90	100	0

The chromatographic profiling of Flufenacet and its degradation products in test water samples was performed by means of HPLC analysis, using Shimadzu SLC-6A HPLC system coupled with Raytest Ramona 90 radioactivity detector, equipped with Alltech Econsoil C18 250 mm • 4.6 mm chromatographic column working in the gradient mode.

The mobile phase consisted of: 0.1% CH₃COOH in HPLC-grade water as **Solvent A** and CH₃CN as **Solvent B**. The flow rate of the mobile phase was 1.0 mL/minute and the gradient mode is presented below in the table B.8.2.2.2._CA-3. The elution lasted for 45 minutes.

Table B.8.2.2.2._CA-3: The gradient mode used in the analysis.

Elution time [min]	Composition of the mobile phase	
	% Solvent A	% Solvent B
0	100	0
40	0	100
45	0	100

The identification was carried out by means of the comparison of the retention times of detected fractions with those of the known standards and the quantitative analysis by means of calibration curve.

The confirmatory analysis of the identity of the degradation compounds was performed in DAT-278 non-sterile samples and DAT-368 non-sterile samples.

The DAT-278 non-sterile samples were used to carry out the confirmatory analysis for FOE Alcohol and FOE Oxalate. The analysis was performed using GC-MS method. In case of FOE Alcohol the analysis was performed directly, without derivatisation, while FOE Oxalate was analysed after derivatisation as the methyl-ester.

The chromatographic analysis was performed on HP 5890 series II gas chromatograph coupled with HP 5970 MS detector. The GC column used in the analysis was Restec Rtx-1 GC column, 30-m long with 0.25 mm internal diameter and 0.5 df. The carrier gas was helium and the oven programme was following: start at T = 100°C, hold at that level for next 4 minutes then increase at rate 5°C/min up to T = 260°C and hold at that level for next 4 minutes. The ionisation mode was EI (electron impact) at 70 eV. The solvent delay was in case of Flufenacet 4 minutes, for FOE Alcohol – 10 minutes and for FOE Oxalate methyl ester – 14 minutes.

The confirmatory analysis for FOE Sulfonic acid was carried out in DAT-368 non-sterile samples using LC-TSP/MS method.

The chromatographic analysis was performed in a linear gradient mode on Varian HPLC system, coupled with Finnigan MAT 90 MS detector, equipped with Novapack C-18 150 mm • 3.9 mm, 5 µm, chromatographic column. The flow rate of the mobile phase was 0.8 mL/min. The gradient mode was defined as “5% methanol to 100% methanol in 20 minutes”. It was also indicated that the buffer solution – 0.1M CH₃COONH₄ in water was added “post column at a rate 0.5 mL/min.

The examination of the microbial activity in test water samples was carried out in the following way: each 6.0-mL sample of water vortexed twice: before diluting and after diluting, before placing on the plates. Next, serial dilutions 1:10 in 9.0 mL of the sterile water were performed. 0.1-mL aliquots of diluted water samples were placed in triplicate sterile 100 • 15 mm Petri plates and nutrient agar was poured. Then, when agar

solidified, plates were placed in the incubator set at $T = 35 - 37^{\circ}\text{C}$ and incubated there for 48 hours. The number of colony forming units per mL (cfu/mL) was determined by counting the visible colonies on each plate and dividing by dilution factor.

Finally, the obtained results – concentration of Flufenacet in solution in function of time, were kinetically examined using the linear regression method.

Results and their discussion:

The temperature in the incubation chamber during the experiment ranged from $T = 15.8^{\circ}\text{C}$ to $T = 28.8^{\circ}\text{C}$, with mean minimum $T = 23.1^{\circ}\text{C}$ and mean maximum $T = 24.4^{\circ}\text{C}$. In the study report it was indicated that that range was outside the protocol specification of $T = 25 \pm 1^{\circ}\text{C}$, but the deviation was not considered to have had an impact on the kinetics of the degradation of Flufenacet in water. The mean incubation temperature, estimated by the RMS, was $T = 23.75^{\circ}\text{C}$.

The intensity of light in the incubation chamber was determined to be 7.34 W/m^2 on the top shelf and 7.49 W/m^2 on the bottom shelf. The graphical results of the determination of that parameter are presented below on figure B.8.2.2.2._CA-3.

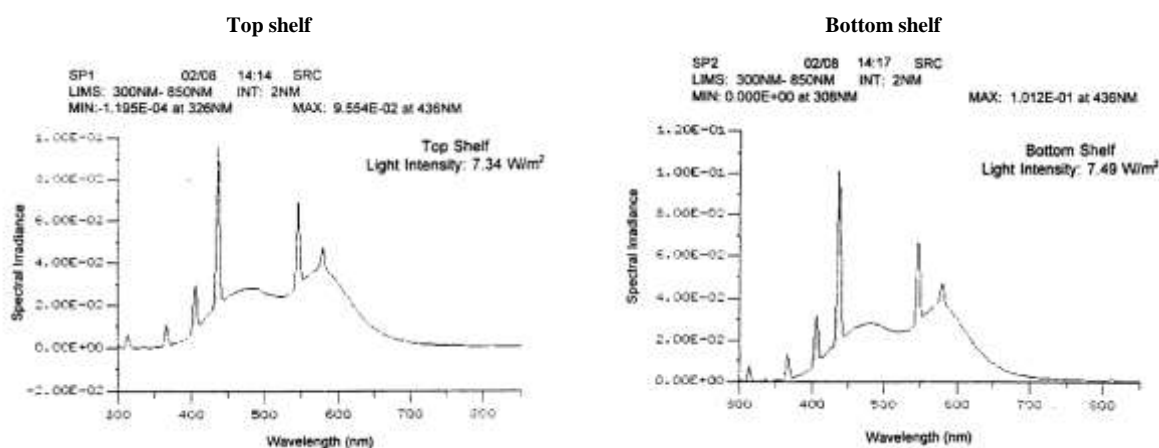

Figure B.8.2.2.2._CA-3: The results of the determination of the light intensity in the incubation chamber (copied from the study report).

The results of the examination of the biological viability of the non-sterile and sterilised pond water used in the experiment are presented below in the table B.8.2.2.2._CA-4. On their basis it may be stated that the non-sterile water retained its biological viability throughout the whole study period. The sterility of the sterilised water was compromised, what indicate the results obtained for DAT-278 sample of the test water, but it is not possible to determine when that occurred. However, according to the Applicant the results of the determination of radioactivity in the sterile samples may indicate that the lack of sterility detected in sterilised samples at the later time points had no significant impact on the results of the study (the degradation of Flufenacet in sterilised samples started to be observed on DAT 188, long after it was recorded for the first time in non-sterile samples – DAT 60).

Table B.8.2.2.2._CA-4: The results of the determination of the biological activity in the test medium – pond water, during the experiment.

Sampling time point (DAT = Days After Treatment)	Microbial viability of the test medium – pond water, determined in Colony Forming Units/mL [CFU/mL], of:		
	Non-sterilised test water		Sterilised test water
	Replicate 1	Replicate 2	
7 days before the test initiation	5.9 E3	----	0
DAT 7	3.0 E5	----	----
DAT 278	3.0 E3	3.0 E3	3.3 E2
DAT 368	1.7 E3	3.8 E2	2.0 E2

The results of the examination of the distribution and profiling of radioactivity in the non-sterilised samples are presented below in the table B.8.2.2.2._CA-5. In the next table – B.8.2.2.2._CA-6, are presented the results of the distribution and profiling of radioactivity obtained for the sterilised samples

Table B.8.2.2.2._CA-5: The results of the determination and profiling of radioactivity in the non-sterile samples collected during the experiment.

The results obtained for Flufenacet in the non-sterile samples (mean values) and sterilised ones were subsequently subjected to the kinetic analysis after being logarithmically transformed (ln was calculated). The kinetic analysis presented in the study report was not accepted by the RMS, and therefore not presented in the summary, as it was carried out using the linear regression. The Applicant repeated the kinetic analysis of the results using the approach recommended by FOCUS. The results of that analysis, presented in the separate study, are summarised as **Study 3**.

Analysing the obtained results the Applicant stated that the degradation of Flufenacet was predominantly biologically-mediated, while the abiotic processes, such as hydrolysis or photolysis, played only a minor role.

The level of mineralisation, determined on the basis of the amount of the radioactivity in the traps for volatile compounds, and that containing aqueous solution of sodium hydroxide in particular, was very low, not surpassing 3% in biologically viable samples. That may indicate that Flufenacet should be classified as not readily biodegradable.

Analysing the results the Applicant indicated that the degradation of Flufenacet in water was retarded – during initial 60 days no degradation was observed. The reasons however of that 60-days lag phase were not explained.

In non-sterile samples three degradation products were identified: FOE Alcohol (in amounts up to 4.4% of applied parent), FOE Oxalate (up to 24% of the applied parent) and FOE Sulfonic acid (up to 8.6% of the applied parent compound). It shall be indicated that while FOE Oxalate and FOE Alcohol were both observed since the estimated beginning of the process of degradation of Flufenacet (DAT 60), FOE Sulfonic acid was formed much later. The amounts of all three degradation products were increasing at the end of the experiment, what may indicate that all three degradates should be considered as potentially major transformation products of Flufenacet in natural water.

The Applicant stated that despite the low level of mineralisation it may be stated that Flufenacet in water will undergo the degradation, predominantly biologically mediated, although that process will be slow.

On the basis of the obtained results the transformation pathway of Flufenacet in natural water was postulated, which is presented below on figure B.8.2.2.2._CA-4. It should be indicated however that it fully covers only the part of the molecule containing fluorophenyl moiety, while the subsequent transformation of the part of the molecule containing thiadiazole moiety was not further examined.

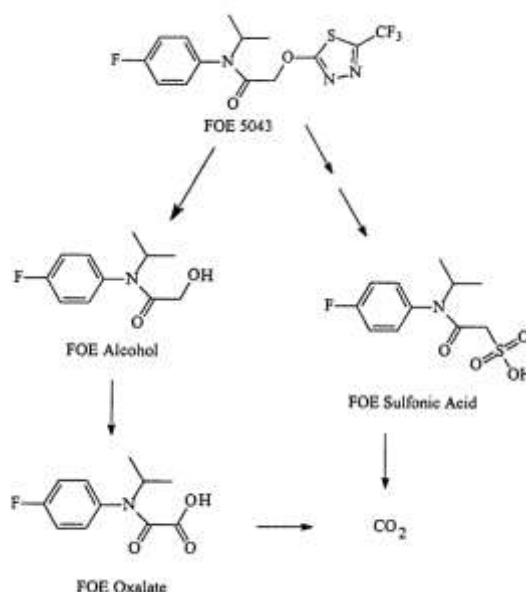

Figure B.8.2.2.2_CA-4: The proposed transformation pathway of Flufenacet, radiolabelled in fluorophenyl ring, in natural water (copied from the study report).

Conclusions:

The degradation of Flufenacet in natural water was examined using the test compound radiolabelled in fluorophenyl ring and non-sterilised pond water as the test medium. It was demonstrated that Flufenacet in natural water would undergo degradation, although that process would be slow. The postulated transformation pathway may indicate that the mechanism of the break-down of the molecule would be similar to that determined for Flufenacet in aerobic soil. The comparison of the results obtained in non-sterilised and sterilised samples demonstrated that the process of degradation of Flufenacet in water will be predominantly biologically-mediated. The identified degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, were specific for the radiolabelling position assumed in this study. It shall be indicated that no new degradation products for that specific radiolabelling position, other than those detected in aerobic soil, were identified, what clearly indicates that the transformation pathway of Flufenacet within the moiety containing fluorophenyl ring would be very similar to that determined in soil.

The process of degradation was demonstrated to be very slow, with the lag phase, what may indicate that in natural water bodies the degradation of Flufenacet in water phase may play only a secondary role in comparison to other dissipation processes, such as migration to the sediment.

The low level of mineralisation indicated that Flufenacet cannot be considered as readily biodegradable.

RMS is of the opinion that the study provides the relevant information in the area of the persistence of Flufenacet in water and its ready biodegradability. However it does not provide full information with regard to the transformation pathways in that compartment, as there is no information on the fate of the thiadiazole moiety.

Study 2:

Report: Hein E. – M., (2013): “Evaluation of the Study: [*Phenyl-U-¹⁴C*] FOE 5043 – Determination of Aerobic Aquatic Biotransformation at 25⁰C.”; Bayer CropScience AG, Environmental Fate, BCS AG – R&D-D-EnSa-Efate, Alfred-Nobel-Str. 50, D-40789 Monheim, Germany; unpublished report No. EnSa-13-0268; 03. 04. 2013; study reference number M-450131-01-1;

Guidelines: None declared, the study however examined the compliance of another study with the provisions of the following OECD Guideline:

- OECD Guideline for the Testing of Chemicals No. 309: “Aerobic Mineralisation in Surface Water – Simulation Biodegradation Test.”, adopted 13 April.

GLP: No, not required, the study is a position paper;

RMS comments: This is a new study, submitted in support of the study by [Schocken, Yen and Widmer; 1995] (study reference number M-002210-01-1) that examined the biological transformation of Flufenacet in natural water. It has a form of position paper presenting the compliance, in tabularised form, of the key features of the evaluated study with the provisions of the OECD Guideline 309. RMS examined that evaluation and found it acceptable. Therefore the study is summarised below, in format proposed by the Applicant, with comments to the assessment given by the RMS.

Summary:

The aim of the study was to evaluate the essential experimental facts of the study “[*Phenyl-U-¹⁴C*]FOE 5043 – Determination of Aerobic Biotransformation at 25⁰C.” by [Schocken, Yen and Widmer; 1995] against the requirements set by the OECD Test Guideline 309 “Aerobic Mineralisation in Surface Water – Simulation Biodegradation Test”. The results of the evaluation were presented in form of a table containing test parameter, requirement set by the OECD Guideline 309, solution in the study and evaluation by the Applicant. That table is reproduced below as the Table B.8.2.2.2._CA-6. RMS added one additional column containing RMS’s own remarks and assessment of the evaluated issue.

Table B.8.2.2.2._CA-6: The results of the evaluation of the study M-002210-01-1 for its compliance with the provisions of the OECD Guideline 309.

Test feature	Requirement of the OECD 309 Guideline	In the evaluated study	Evaluation by the Applicant	RMS's comments and evaluation
<i>Test Design</i>	Pelagic or Suspended Sediment	Pelagic	OK	Checked, conformed
<i>Lighting Conditions</i>	Dark (preferred) or diffuse light	16h light + 8h dark	The used lighting conditions are considered acceptable by BCS	RMS carried out the comparative analysis of the evaluated study with that examining the direct and indirect photolysis of Flufenacet. It was demonstrated that Flufenacet was not prone to direct photolysis in water, while indirect photolysis in natural pond water may play some role in the degradation of that compound in SW bodies. It was stated that the water used in the experiment bore similar characteristic to that from Stilwell pond used to examine the indirect aqueous photolysis. Additionally the intensity of light in the assessed experiment was much lower 7.34 -749 W/m ² v/s 680 W/m ² in the experiment examining the aqueous photolysis of Flufenacet. In the Stilwell pond water the rate of indirect photolysis was estimated to be DT ₅₀ = 822 Natural Sunlight Days. Therefore, on the basis of the similarity of the experimental solutions and intensity of light, RMS stated that light conditions will have a minimal influence on the overall rate of degradation of Flufenacet in that experiment, hence the justification provided by the Applicant may be considered valid.
<i>Temperature</i>	20-25°C (Keep constant at ± 2°C)	25 ± 1°C	OK	Checked, in the study report it was stated that the temperature during the experiment was in range 15.8 – 28.8°C (extremes) with averages in range 23.1 – 24.4°C. The mean incubation temperature, estimated by the RMS was T = 23.75°C.

Test feature	Requirement of the OECD 309 Guideline	In the evaluated study	Evaluation by the Applicant	RMS's comments and evaluation
<i>Study duration</i>	max. 60 days (up to max. 90 days, if degradation of test item starts within first 60 days)	1 year (368 days)	6 sampling intervals were taken within a period of 60 days and 7 sampling intervals were taken within a period of 95 days (degradation of test item starts between DAT-29 and DAT-60). Remark: Re-evaluation of the first study period possible, if required.	The study lasted for 1 year, significantly longer than recommended by the Guideline. RMS however noted that the analysis of the biological viability of the non-sterile samples, performed 7 days before the beginning of the experiment, on DAT 7, DAT 278 and DAT 368 confirmed its biological viability
<i>Sampling intervals</i>	Not stated	DAT-0, DAT-4, DAT-7, DAT-15, DAT-29, DAT-60, DAT-95, DAT-188, DAT-278, DAT-368		Number of sampling points and sampling intervals confirmed.
<i>Test item concentration</i>	Two different concentrations which represent the expected range in the environment (differ by factor of 5 to 10) e.g. 10 µg/L to 100 µg/L e.g. 1 µg/L to 10 µg/L	One concentration 1.3 mg/L	The used test item concentration is considered acceptable by BCS as it covers the following worst case scenario: - use of max. field application rate of 1 kg/ha - complete run-off - soil depth 5 cm, bulk density 1.5 g/cm ³ The prolonged study duration of 368 days combined with a higher test concentration enables to propose a valid degradation pathway of the test item and reflects also a worst case scenario referred to the kinetic behaviour of the test item under the tested conditions (DT ₅₀ values).	The concentration of the test item was an order of magnitude higher than that recommended by the Guideline. However, that enabled the identification and quantitation of the degradation products. Therefore RMS is of the opinion that that deviation should not have an impact on the validity and acceptability of the study. Also the justification provided by the Applicant is acceptable.
<i>Test system</i>	Flow through or static system	Flow-through system	OK	Checked, confirmed
<i>Traps for Volatiles</i>	Direct or indirect determination of carbon dioxide	Direct determination of volatiles using ethylene glycol (1x) and sodium hydroxide traps (2x)	OK	Checked, confirmed
<i>No of replicates</i>	Duplicate samples	Duplicate samples	OK	Checked, confirmed; RMS noticed that the only non-sterile samples were collected as duplicate samples per sampling point, while sterile samples were collected in single replicates per sampling point.
<i>Aeration</i>	By continuous stirring or shaking	By daily purge	The used method is considered acceptable for aeration of the test system.	Checked, confirmed – the system was aerated every day for 30 minutes with sterilised moist air
<i>Agitation</i>	By continuous stirring or shaking	By daily purge	Test systems were agitated by daily purge. However, this point is not assumed to have an impact on the validity of the study.	Checked, confirmed – the purging method caused agitation of the solution in the test vessels.

Test feature	Requirement of the OECD 309 Guideline	In the evaluated study	Evaluation by the Applicant	RMS's comments and evaluation
<i>Kinetics</i>	SFO	SFO	OK	Kinetic analysis of the results, in line of the provisions of the FOCUS Kinetics Guideline, in a separate report.
<i>Sterile samples</i>	Yes (autoclaving, HgCl ₂ or γ -irradiation)	Yes (autoclaving)	OK	Checked, confirmed; the initial sterility of test system confirmed, but the sterility during the experiment, in particular at later time points seems to be compromised; that deviation however does not seem to have an impact on the acceptability of the study.
<i>Reference substance</i>	Yes (aniline or sodium benzoate)	No	Microbial activity of the system was proven by plate count assay and by degradation of the test item (including total degradation/mineralization to carbon dioxide).	The design of the test system resulted in not meeting that requirement. RMS is of the opinion that that deviation from the OECD Guideline does not invalidate the study.
<i>Measurement of pH and O₂ concentration</i>	Yes	No	This point is not assumed to have an impact on the validity of the study.	Justification of that deviation provided by the Applicant is acceptable.
<i>Establish Material Balance</i>	Yes	Yes Non-sterile samples: 96.8 to 109.6% AR (mean 103.8% AR) Sterile samples 98.9 to 108.2% AR (mean 104.1% AR)	OK	Checked, confirmed
<i>Degradation Product Identification Trigger</i>	2 x >5% AR, 1 X >10% AR or >5% AR increasing at study end	2 x >5% AR, 1 X >10% AR or >5% AR increasing at study end	OK	Checked, confirmed

The Applicant, on the basis of the results of evaluation presented above stated that: “Bayer CropScience is of the opinion that the study “[Phenyl-U-¹⁴C]FOE 5043 – Determination of Aerobic Aquatic Transformation at 25⁰C” conducted according to the Canadian guideline T-1-255, is suitable to address the fate of Flufenacet in open water as required according to regulation (EC) No. 1107/2009, as the applied test conditions cover a worst case scenario.

RMS confirms the validity of that conclusion.

Study 3:

Report: Reinken G., Maassen K., (2014): “Kinetic Evaluation for Calculating Refined Half-life Times of [Phenyl-UL-¹⁴C]Flufenacet in Natural Pond-water According to FOCUS Kineitscs Using the KinGUI 2 Tool.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; Study report No. En-Sa-13-0970; 18. 02. 2014; study reference number: M-478212-01-1.

Guidelines: The study was performed to comply with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.”; Report of the Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005, version 2.0, 434 pp.;
- FOCUS (2011): “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies in EU Registration, version 1.0, 436 pp.

GLP: No, not required – modelling study;

RMS comments: This is a newly submitted study, evaluated for the purpose of the current assessment. RMS evaluated it for its compliance with the Guidelines listed as the reference Guidelines. That evaluation showed that the Applicant reduced the data base for which the assessment was performed by eliminating the time points after DAT 95. That was explained by the necessity to comply with the provisions of the OECD 309 Guideline, recommending that the study should not last longer than 60 days unless no degradation was observed within that period, and in such case it can be extended to 90 days. It shall be indicated that in the source study it was stated that the degradation of Flufenacet in non-sterilised water was delayed by at least 29 days after application of the test compound and the first time point at which the degradation of Flufenacet, demonstrating itself as the formation of the degradation products, was observed was DAT 60. That may indicate the lag-phase with the break-point occurring somewhere between DAT-29 and DAT-60 time points, the fact that was not taken into account by the Applicant in the performed kinetic analysis. It shall be pointed out that if the lag-phase indeed occurred the number of the data points for which the degradation of Flufenacet was observed, used by the Applicant in the kinetic analysis, was only two, a number too small to return the reliable kinetic endpoints.

It is also worth of noticing that the amounts of radioactivity recovered during the experiment in the non-sterilised samples were generally above 100% of the amount theoretically applied. These levels were in general within the acceptable range of 90 - 110%, therefore not having the influence on the validity of the study. However in terms of the kinetic analysis at early time points the recoveries of radioactivity >100% TAR, which was in addition identified as solely Flufenacet, caused some problems with fitting, in particular because the concentrations of that compound at the time points between DAT 0 and DAT 60 were higher than those recorded on DAT 0.

All that was not taken into account by the Applicant in the kinetic analysis.

Finally, it shall be indicated that in the study report only the results obtained for the non-sterilised samples, while for the sterile ones no such analysis was performed (which would be useful to demonstrate that in natural biologically viable water the degradation of that compound is indeed due to biologically-mediated transformation and abiotic processes play only minimal role.

As a result, RMS decided to repeat the kinetic analysis using for the non-sterile samples the whole data set and assuming that either lag phase occurred or such phenomenon was not observed. In parallel the data obtained for the sterilised samples were kinetically analysed using the same approach.

RMS decided, for comparative purpose, to present the kinetic analysis performed by the Applicant. It shall be indicated however that these results will not be further used in the assessment.

Summary:

The aim of the study was to kinetically examine the results obtained for Flufenacet in the study by [Schocken, Yen and Widmer; 1995], aimed on the examination of aerobic transformation of that compound in natural pelagic water. The kinetic analysis followed the procedure outlined in the FOCUS Kinetics Guidance Document

[FOCUS; 2006], [FOCUS; 2011]. As the initial step the data presented in the experimental data presented in the source study were pre-processed according to the recommendations of the FOCUS Kinetics Work Group. In particular:

- the DAT-0 values were included as provided in the study report, but for optimal goodness of fit they were allowed to be estimated by the model;
- values between LOD and LOQ were set to measured values (**N. b.:** RMS noticed that such values for Flufenacet did not appear in the study);
- values <LOD or the “non-detects” were processed in line with FOCUS recommendations (**N. b.:** once again RMS did not identify such values for Flufenacet in the analysed data set);
- to maintain the consistency with the provisions of the OCED test guideline No. 309 all values obtained after the time point DAT-95 were not used in the analysis.

The resulting data set used as input for the kinetic analysis is presented below in the table B.8.2.2.2._CA-7.

Table B.8.2.2.2._CA-7: The data set used in the kinetic analysis of the degradation of Flufenacet in the non-sterilised natural pelagic (pond) water.

Sampling time-point [Days After Treatment]		DAT						
		0	4	7	15	29	60	95
Concentration of Flufenacet [%TAR]	Replicate 1	100.0	106.6	107.5	103.5	105.0	104.0	88.0
	Replicate 2	99.7	108.5	107.3	106.9	102.4	100.4	97.3

The kinetic analysis was carried out using the single compartment approach (PI). The Applicant used two kinetic models – SFO and FOMC. The modelling tool used in the assessment was KinGUI version 2 software. The optimisation algorithm was IRLS (Iteratively Reweighed Nonlinear Least Squares).

The assessment of the acceptability of the kinetic analysis was based on:

- the assessment of the goodness of fit;
- the assessment of the reliability of the kinetic parameters.

The assessment of the goodness of fit was based on the results of the χ^2 -significance test and the visual assessment of the decline curve – conformity of the determined curve with the measured values and the levels and distribution of the residuals.

The assessment of the reliability of the kinetic parameters was indicated to be based on the examination of their statistical significance.

The whole assessment procedure was identical to that characterised for the kinetic assessment of the data obtained in soil, presented in details in this section of the Renewal Assessment Report report under the data point B.8.1.1.2.1.1.

The results of the kinetic assessment performed by the Applicant are presented below, in numerical form in the table B.8.2.2.2._CA-8 and in graphical form on figure B.8.2.2.2._CA-5. On their basis the Applicant proposed to consider the SFO as returning the reliable kinetic fit and the kinetic endpoints – DT₅₀ and DT₉₀ values.

Table B.8.2.2.2._CA-8: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	106.1	5.395	95.52	116.67	8.5 E-11	2.37	Good fit; R ² = 0.502
	k	0.001121	4.994 E-4	1.424 E-4	0.002	0.0222		
FOMC	M ₀	106.76	1.21	104.39	109.10	<2 E-16	2.63	Bad fit
	α	68.09	320.56	-560.18	696.40	0.418		
	β	50438.39	237614.71	-415277.88	516154.70	0.418		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

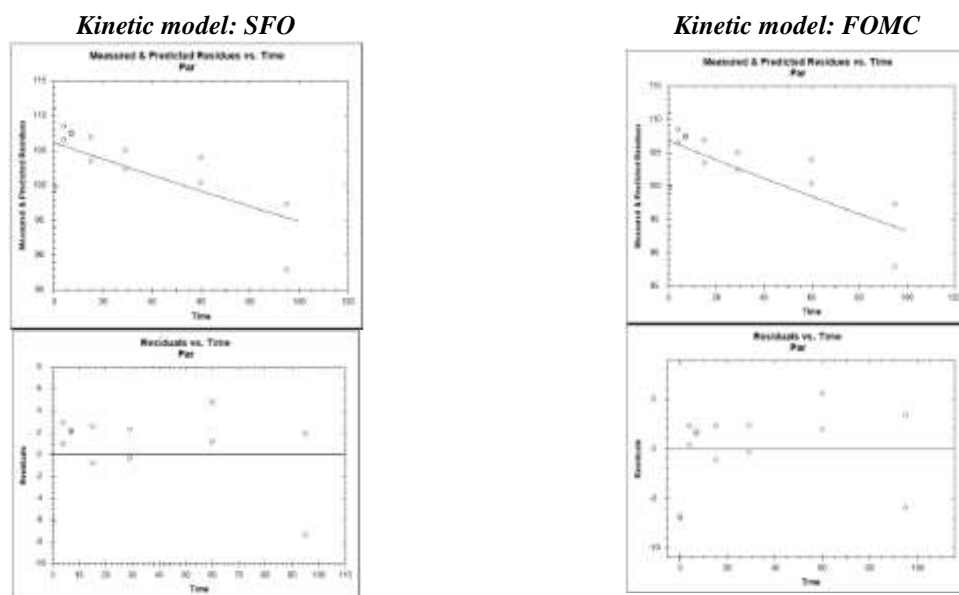

Figure B.8.2.2.2._CA-5: The graphical results of the kinetic analysis (copied from the study report).

The reliable kinetic endpoints determined in this analysis are: $k = 0.001121$ [days⁻¹], $DT_{50} = 618.25$ [days], $DT_{90} = 2053.8$ [days], kinetic model: **SFO**.

RMS however decided to repeat the kinetic analysis due to the fact that the approach adopted by the Applicant, consisting on the removal of the data obtained after the time point DAT-95, also in light of the postulated lag-phase observed in non-sterilised samples, does not seem appropriate, even though it may comply with the recommendations of the OECD test Guideline 309. The results of that analysis are presented below.

The kinetic analysis of the results of the study [Schocken, Yen and Widmer; 1995] performed by the RMS

The analysis was performed for the non-sterile and sterilised samples using the data sets presented below in the table B.8.2.2.2._CA-9. The pre-processing of the data followed the same procedure as used by the Applicant, with exception that the whole data sets generated in the study by [Schocken, Yen and Widmer; 1995] were used in the analysis.

Table B.8.2.2.2._CA-9: The data sets used in the repeated kinetic analysis performed by the RMS.

Sampling Time Point – Days After Treatment [DAT]	Concentration of Flufenacet – [% TAR ¹⁾] in:		
	Non-sterilised samples		Sterilised samples
	Replicate 1	Replicate 2	
0	100.0	99.7	98.9
4	107.5	108.5	105.3
7	103.5	107.3	107.3
15	105.0	106.9	103.2
29	104.0	102.4	105.2
60	88.0	100.4	107.2
95	---- ²⁾	97.3	101.9
188	77.0	87.0	99.8
278	71.4	71.4	95.5
368	57.2	57.5	93.1

Footnotes to the table:

- 1) TAR stands for Theoretically Applied Radioactivity;
- 2) For this sampling point in this replicate the Applicant indicated the inadvertent sample loss due to aeration, therefore, although the value was provided RMS decided not to use it in the kinetic analysis.

The values presented above were subjected to the kinetic analysis in order to determine the kinetic endpoints representing the degradation of Flufenacet in the non-sterile natural pelagic freshwater and the sterilised natural pelagic freshwater.

The kinetic analysis was performed using CAKE ver. 3.1 modelling tool, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The settings of the optimiser were the defaults of the tool:

- maximum iterations: 100,
- maximum reweighing: 10,
- SANN maximum iterations: 10000,
- convergence tolerance: 1 E-5,
- error variance tolerance: 1 E-5,
- extra solver: yes, if required.

The analysis performed for the data obtained in the non-sterilised samples was carried out in line of the procedure outlined in the FOCUS Kineitcs Guidance Document [FOCUS, 2006]. It consisted of two step. At first step the data were fitted as if no lag-phase occurred. Two kinetic models were used in that assessment – SFO and FOMC. At second step the kinetic analysis was performed with assumption that the lag-pahse, postulated in the source study report by [Schocken, Yen and Widmer; 1995] occurred. In this assessment, performed in line with the recommendations of the Guidance Document evoked above, RMS used the reversed HS model, with the k_l set to zero. The analysis was performed in two variants: with $k_l = 0.0$ not fixed but left to be optimised by the modelling tool and with $k_l = 0.0$ defined as a fixed value.

Additionally, parametrising the model, RMS assumed the $M_0 = 110.0$, what was in line with the values observed for the time points between DAT-4 and DAT-60. That value however was not defined as a fixed value, but was left to be optimised by the model. Finally, for each time point the values for individual replicates were used as the input data.

Exactly the same fitting procedure was used for the results obtained in sterilised samples. RMS decided to perform the analysis assuming the occurrence of the lag-phase, although that was not postulated for the sterilised samples in the source study report. That was done however to maintain the coherence of the performed kinetic analysis.

The results of the kinetic assessment are presented below.

1) Results of the kinetic analysis performed for the non-sterilised samples:

a) Analysis assuming no lag-phase:

The kinetic analysis was carried out using two kinetic models: SFO and FOMC – the same as used by the Applicant. RMS noticed that the concentrations of the test item – Flufenacet at the end of the experiment were well above the 10%, therefore FOMC model may not be fully appropriate. It was however used in order to verify whether other bi-phasic models should be checked in the analysis.

The results of the fitting are presented below, in the numerical form in table B.8.2.2.2._CA-10 and in the graphical form on figure B.8.2.2.2._CA-6. The kinetic endpoints obtained using each kinetic model tested are presented in the table B.8.2.2.2._CA-11.

Table B.8.2.2.2._CA-10: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment/ R value
				Lower	Upper			
SFO	M_0	107.2	1.352	104.9	109.6	----	3.22	Good fit; R = 0.934
	k	0.001464	1.09 E-4	0.001276	0.001653	8.12 E-11		
FOMC	M_0	108.4	1.494	105.8	111.0	----	3.40	Good fit; R = 0.934
	α	37.05	2.677	32.37	41.72	----		
	β	22500	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾	----		

Footnotes to the table:

- 1) n. d. = not determined – in the report returned by the modelling tools it was stated that these values “could not be calculated because the covariance matrix could not be created”.

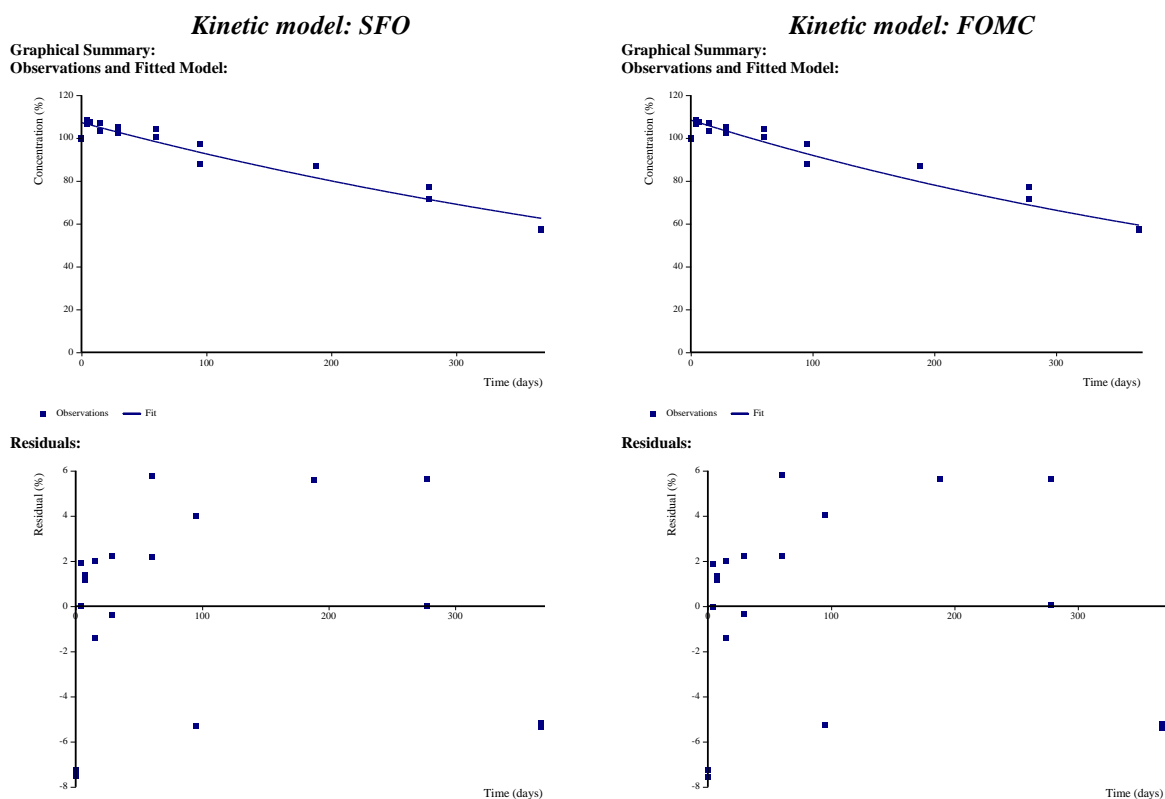

Figure B.8.2.2.2._CA-6: The graphical results of the kinetic analysis.

Table B.8.2.2.2._CA-11: The determined kinetic endpoints

Kinetic model	Determined parameters				
	Kinetic parameters		Kinetic endpoints		
			DT ₅₀ [days]	DT ₉₀ [days]	t_FOMC [days] (pseudo-SFO DT ₅₀)
<i>SFO</i>	$k = 0.001464$ [days ⁻¹]		473	1570	not applicable
<i>FOMC</i>	$\alpha = 37.05$	$\beta = 22500$	424	1440	434

Both kinetic models returned visually very similar fits. The value of χ^2 -error indicate that the SFO fit was statistically slightly better, therefore it should be selected as the first option. The analysis of the reliability of the kinetic parameters showed that while the rate constant k determined for the SFO model passed the reliability criteria, the kinetic parameters determined for FOMC model cannot be considered reliable – for β it was not possible to calculate either the error – σ , or the CI values. Finally, it shall be indicated that both models returned very similar kinetic endpoints, with DT₉₀ in FOMC being shorter than its SFO counterpart. Therefore SFO seems to be the appropriate kinetic model in this analysis.

b) Analysis assuming the occurrence of the lag-phase:

The kinetic analysis was carried in line with recommendations provided by the FOCUS Kinetics Guidance document, assuming the rate constant k_l set to 0.0. RMS decided to test two options:

- 1) with the rate constant k_l set to the value 0.0, but not fixed and left to be optimised by the modelling tool;
- 2) with k_l value fixed to the pre-defined value 0.0 and fixed, what resulted in switching off the optimisation performed by the modelling tool.

The second option was selected by the RMS because it simulated the lag-phase with no degradation of the test compound occurring, while the first option, assumed some, although minimal, level of degradation.

The results of the fitting are presented below, in the numerical form in table B.8.2.2.2._CA-12 and in the graphical form on figure B.8.2.2.2._CA-7. The kinetic endpoints obtained using each kinetic model tested are presented in the table B.8.2.2.2._CA-13.

Table B.8.2.2.2._CA-12: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment/ R value
				Lower	Upper			
HS, k_1 optimised	M_0	104.7	1.9	101.4	108.1	----	3.00	Good; R = 0.9494
	k_1	1.77 E-198	0.001206	-0.002114	0.002114	0.5		
	k_2	0.001654	1.51 E-4	0.00139	0.001918	7.15 E-4		
	t_b	40.81	25.78	-4.379	85.99	----		
HS, k_1 fixed	M_0	105.0	1.377	102.6	107.4	----	2.69	Good; R = 0.9511
	k_1	0.0	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾		
	k_2	0.001624	1.28 E-4	0.001401	0.001847	4.42 E-10		
	t_b	27.01	15.49	-0.02676	54.05	----		

Footnotes to the table:

1) n. d. = not determined – the k_1 value was fixed.

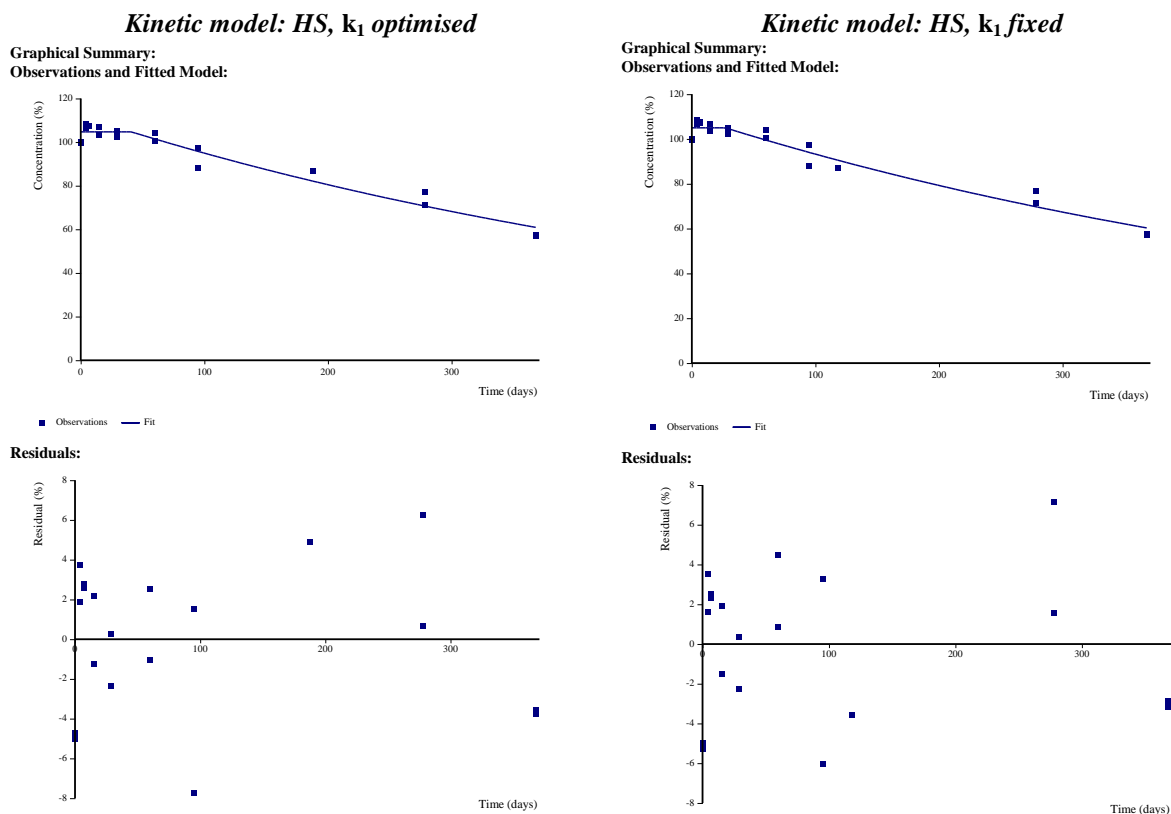

Figure B.8.2.2.2._CA-7: The graphical results of the kinetic analysis.

Table B.8.2.2.2._CA-13: The determined kinetic endpoints

Kinetic model	Determined parameters					
	Kinetic parameters		Kinetic endpoints			
	k_1 [days ⁻¹]	k_2 [days ⁻¹]	DT ₅₀ [days]	DT ₉₀ [days]	DT ₅₀ [days] for k_1	DT ₅₀ [days] for k_2
HS, k_1 optimised	1.77 E-198	0.001654	460	1430	> 10000	419
HS, k_1 fixed	----	0.001624	454	1440	> 10000	427

Both kinetic fits were visually very good and classified as good. The values of the χ^2 -error indicate that statistically slightly better fit was obtained when the k_1 value was fixed. Additionally it was noticed that the k_1

value optimised by the model lacked the reliability. As a result, the solution with fixed k_l value seems to be better fitting solution. At the same time it shall be indicated that the lack of reliability of the model-optimised k_l value may be due to the fact that it was extremely low, indicating this way virtually no degradation during the lag phase. That may indicate the appropriateness of the fixing of the k_l value in the repeated fitting.

The k_2 value was demonstrated to be reliable in both variants of the kinetic analysis.

The results of the determination of t_b value for the fit with fixed k_l value show that the lag phase was not very prolonged and it may be assumed that the degradation process was initiated already around DAT 29.

Finally, it shall be indicated that the DT_{50} values obtained for the second phase of HS kinetic curve, with both k_l value optimised by the model and fixed, are similar to those obtained for the SFO fit, without assuming the lag phase (they are even shorter). That may indicate that despite the postulated in the source study report lag phase, SFO model may be considered a good representation of the kinetic behaviour of Flufenacet in natural pelagic (pond) water.

Conclusion of the assessment:

The results of the performed analysis showed, that the degradation of Flufenacet in natural pelagic (pond) water was well described by the SFO kinetic model without assuming the lag phase. The analysis of the data assuming lag phase, performed using the reversed HS model returned the rate constant k and the kinetic parameters – DT_{50} and DT_{90} similar to those obtained using SFO model.

The average duration of the lag phase may be estimated to be around 29 days, however the longest possible value could be 40 days.

As the rate constant k and the kinetic parameters – DT_{50} and DT_{90} values obtained for the second phase of the reversed HS fit were shorter than their counterparts obtained with SFO model, it can be therefore stated that the results of the SFO fit without lag phase are the good representation of the degradation kinetics of Flufenacet in natural pelagic (pond) water. RMS proposes therefore to use them as the endpoint values in the assessment.

Therefore the proposed kinetic endpoints for the degradation of Flufenacet in the non-sterilised pelagic (pond) water are following: $k = 0.001464$ [days⁻¹], $DT_{50} = 473$ [days], $DT_{90} = 1570$ [days], kinetic model: **SFO**. The values were determined in the test system incubated at the mean temperature $T = 23.75^{\circ}\text{C}$. Therefore RMS decided to normalise them to the standard conditions – $T = 20^{\circ}\text{C}$. That was done using the Arrhenius equation, assuming the activation energy $E_a = 65.4$ kJ/mol (in line with the recommendations of EFSA PPR Panel). The normalised kinetic endpoints following: $k = 0.001044$ [days⁻¹], $DT_{50} = 664$ [days], $DT_{90} = 2204.1$ [days], kinetic model: **SFO**.

2) Results of the kinetic analysis performed for the sterilised samples:

a) Analysis assuming no lag-phase:

The kinetic analysis was carried out using two kinetic models: SFO and FOMC – the same as used by the Applicant. RMS noticed that the concentrations of the test item – Flufenacet at the end of the experiment were well above the 10%, therefore FOMC model may not be fully appropriate. It was however used in order to verify whether other bi-phasic models should be checked in the analysis.

The results of the fitting are presented below, in the numerical form in table B.8.2.2.2._CA-14 and in the graphical form on figure B.8.2.2.2._CA-8. The kinetic endpoints obtained using each kinetic model tested are presented in the table B.8.2.2.2._CA-15.

Table B.8.2.2.2._CA-14: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment/ R value
				Lower	Upper			
SFO	M_0	105.0	1.198	102.8	107.2	----	2.02	Acceptable; R = 0.6925
	k	3.11 E-4	7.50 E-5	1.71 E-4	4.50 E-4	0.001622		
FOMC	M_0	105.1	1.338	102.6	107.7	----	2.18	Acceptable; R = 0.6762
	α	0.296	0.07197	0.1596	0.4323	----		
	β	808.4	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾		

Footnotes to the table:

- 1) n. d. = not determined – in the report returned by the modelling tools it was stated that these values “could not be calculated because the covariance matrix could not be created”.

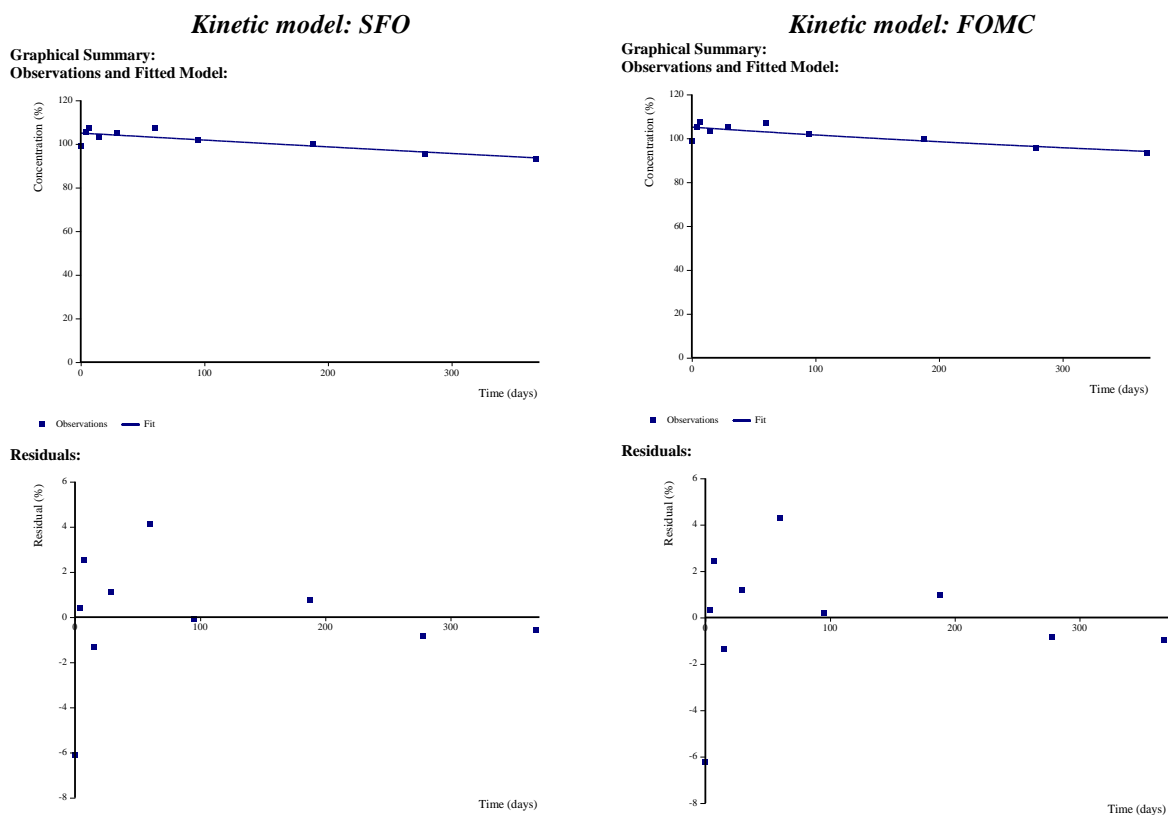

Figure B.8.2.2.2._CA-8: The graphical results of the kinetic analysis.

Table B.8.2.2.2._CA-15: The determined kinetic endpoints

Kinetic model	Determined parameters				
	Kinetic parameters	Kinetic endpoints			
		DT ₅₀ [days]	DT ₉₀ [days]	t_FOMC [days] (pseudo-SFO DT ₅₀)	
<i>SFO</i>	$k = 3.11 \text{ E-4} [\text{days}^{-1}]$	2230	7410	not applicable	
<i>FOMC</i>	$\alpha = 0.296$ $\beta = 808.4$	7600	> 10000	> 10000	

Both kinetic models returned visually very similar fits. The value of χ^2 -error indicate that the SFO fit was statistically slightly better, therefore it should be selected as the first option. The analysis of the reliability of the kinetic parameters showed that while the rate constant k determined for the SFO model passed the reliability criteria, the kinetic parameters determined for FOMC model cannot be considered reliable – for β it was not possible to calculate either the error – σ , or the CI values. Finally, it shall be indicated that both models returned very similar kinetic endpoints, with DT₉₀ in FOMC being shorter than its SFO counterpart. Therefore SFO seems to be the appropriate kinetic model in this analysis.

b) Analysis assuming the occurrence of the lag-phase:

The kinetic analysis was carried in line with recommendations provided by the FOCUS Kinetics Guidance document, assuming the rate constant k_l set to 0.0. RMS decided to test two options:

- 1) with the rate constant k_l set to the value 0.0, but not fixed and left to be optimised by the modelling tool;
- 2) with k_l value fixed to the pre-defined value 0.0 and fixed, what resulted in switching off the optimisation performed by the modelling tool.

The second option was selected by the RMS because it simulated the lag-phase with no degradation of the test compound occurring, while the first option, assumed some, although minimal, level of degradation.

The results of the fitting are presented below, in the numerical form in table B.8.2.2.2._CA-16 and in the graphical form on figure B.8.2.2.2._CA-9. The kinetic endpoints obtained using each kinetic model tested are presented in the table B.8.2.2.2._CA-17.

Table B.8.2.2.2._CA-16: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment/ R value
				Lower	Upper			
HS, k_l optimised	M_0	104.3	1.563	101.3	107.3	----	2.01	Good; R = 0.752
	k_l	9.95 E-6	3.78 E-4	-7.25 E-4	7.45 E-4	0.4899		
	k_2	3.96 E-4	1.17 E-4	1.69 E-4	6.22 E-4	0.00727		
	t_b	74.27	0.2369	73.81	74.73	----		
HS, k_l fixed	M_0	105.1	1.203	102.8	107.3	----	2.37	Poor; R = 0.0479
	k_l	0.0	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾	n. d. ¹⁾		
	k_2	8.99 E-5	1.33 e-4	-1.62 E-4	3.42 E-4	0.2603		
	t_b	151.3	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾		

Footnotes to the table:

1) n. d. = not determined – the k_l value was fixed.

2) n. d. = not determined – in the report returned by the modelling tools it was stated that these values “could not be calculated because the covariance matrix could not be created”.

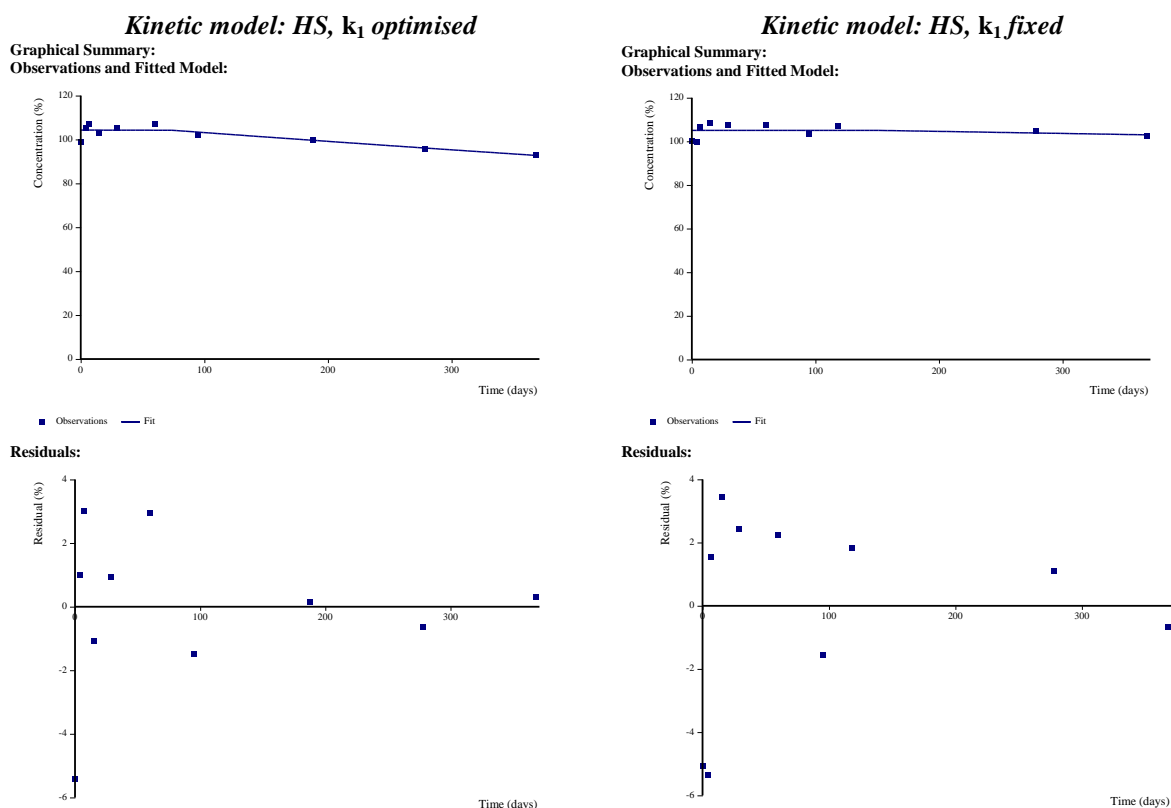

Figure B.8.2.2.2._CA-9: The graphical results of the kinetic analysis.

Table B.8.2.2.2._CA-17: The determined kinetic endpoints

Kinetic model	Determined parameters					
	Kinetic parameters		Kinetic endpoints			
	k_1 [days ⁻¹]	k_2 [days ⁻¹]	DT ₅₀ [days]	DT ₉₀ [days]	DT ₅₀ [days] for k_1	DT ₅₀ [days] for k_2
HS, k_1 optimised	9.95 E-6	3.69 E-4	1820	5890	> 10000	1750
HS, k_1 fixed	0.0	8.99 E-5	7860	> 10000	> 10000	7710

It was not possible to obtain fully reliable kinetic fits. Although visually fits seem to be acceptable, only the reversed HS fit with optimised k_1 value may be considered good, while that with fixed k_1 value is poor because of the low R value. Also the distribution of the residuals in this fit indicates its lack of appropriateness, because they are not distributed randomly, what is observed in case of the fit with the optimised k_1 value. Finally, it shall be indicated that, although the value of χ^2 -error was well <15%, it was higher for the fit with the fixed k_1 value. As a result, from the point of view of the appropriateness of the visual fit, only the reversed HS fit with the k_1 value can be considered acceptable.

At the same time it shall be indicated that also that fit cannot be considered acceptable because of the lack of reliability of the k_1 value, which did not pass the T-test (the *Prob.* > *t* is at the level 0.4899 therefore much higher than the recommended threshold value of 0.05).

As a result, it shall be indicated that the kinetic analysis of the data for Flufenacet in the sterilised natural pelagic (pond) water assuming the occurrence of the lag phase is not an appropriate option.

Conclusion of the assessment:

The results of the performed analysis showed, that the degradation of Flufenacet in sterilised natural pelagic (pond) water was well described by the SFO kinetic model without assuming the lag phase. The analysis of the data assuming lag phase, performed using the reversed HS model, showed that probably no lag phase occurred.

That also may indicate that the possible change of the conditions in the test system from sterile to the non-sterile, taking place at some point during the experiment, had no visible impact on the degradation kinetics of Flufenacet in sterilised test medium. It cannot be also excluded that the contamination of the test vessels occurred not during incubation, but during their processing.

RMS therefore proposes to consider that the degradation of Flufenacet in sterilised natural pelagic (pond) water follows the SFO kinetics and the proposed kinetic endpoints for the degradation of Flufenacet in the sterilised pelagic (pond) water are following: $k = 0.000311$ [days⁻¹], $DT_{50} = 2230$ [days], $DT_{90} = 7410$ [days], kinetic model: **SFO**. The values were determined in the test system incubated at the mean temperature $T = 23.75^{\circ}\text{C}$. Therefore RMS decided to normalise them to the standard conditions – $T = 20^{\circ}\text{C}$. That was done using the Arrhenius equation, assuming the activation energy $E_a = 65.4$ kJ/mol (in line with the recommendations of EFSA PPR Panel). The normalised kinetic endpoints following: $k = 0.0002214$ [days⁻¹], $DT_{50} = 3130.7$ [days], $DT_{90} = 10402.9$ [days], kinetic model: **SFO**.

Final conclusion of the assessment:

The data for Flufenacet obtained in the study by [Schocken, Yen and Widmer; 1995], examining the degradation of that compound in natural pelagic (pond) water, were subjected to the kinetic examination performed in line with the provisions of the FOCUS Work Group on the Degradation Kinetics.

That evaluation was first carried out by the Applicant, who, to comply with the provisions of the OECD Test Guideline No. 309, limited the analysed data base to the time points obtained until the DAT 95. The later time points were not included in the evaluation. Additionally, the kinetic analysis was performed only for the non-sterilised samples.

The performed kinetic analysis resulted in the identification of the SFO kinetic model as returning the reliable kinetic fit, with the following set of the kinetic endpoints: $k = 0.0001121$ [days⁻¹], $DT_{50} = 618.25$ [days] and $DT_{90} = 2053.80$ [days].

However, doing that assessment the Applicant did not take into account the fact that in the source study report for the biologically viable (not sterilised) water samples the lag phase was postulated on the basis of the observed formation profile of the degradation products – the two major degradation products: FOE Alcohol and FOE Oxalate, were observed on DAT 60 in the study.

In case the lag phase were taken into account the number of time points for which the degradation was observed was only two, in RMS's opinion too few to obtain the reliable kinetic curve.

Therefore RMS decided to repeat the kinetic assessment using the whole data base obtained for Flufenacet in the study by [Schocken, Yen and Widmer; 1995]. The additional justification for the correctness of such approach was the fact that the microbial viability of the non-sterilised samples determined was comparable to that measured at the beginning of the experiment.

The additional goal of the repeated assessment was to determine the degradation kinetics of Flufenacet in the sterilised samples and, if possible check whether the change of the conditions from the sterile to non-sterile, demonstrated itself somehow, and if yes, then when.

The analysis of the data sets was carried out in two variants:

- assuming no lag-phase;
- assuming the existence of the lag-phase.

The analysis of the data set assuming lag-phase was performed in line of the recommendations of the FOCUS Work Group on the Degradation Kinetics, using the reversed HS kinetic model.

For the non-sterilised samples it was demonstrated that the reliable fit in case the lag-phase was not included was obtained with the SFO kinetic model. Also the full reliable fit was obtained for the analysis assuming the lag-phase, with the k_l value set as a fixed parameter. The comparative analysis indicated that the results of the fitting with and without lag-phase were comparable, in case the lag-phase not being taken into account providing longer DT_{50}/DT_{90} values. RMS therefore decided to consider the SFO fit without lag phase as a good representation of the kinetic behaviour of Flufenacet in biologically viable pelagic (pond) water.

The kinetic analysis of the data obtained for Flufenacet in sterilised samples showed that the approach that assumed the occurrence of the lag-phase did not return reliable kinetic fit. Therefore it may be stated that in the sterilised samples the lag phase did not occur. It was also noticed that there was no break point, therefore it may be stated that either the lack of sterility might resulted from inappropriate handling and processing the samples after their removal from incubation chamber or, if occurred during the incubation, it had minimal impact on the degradation kinetics of Flufenacet in sterilised natural pelagic water.

The analysis resulted in the identification of SFO as the kinetic model adequately characterising the degradation kinetics in sterilised natural pelagic (pond) water.

The kinetic endpoints resulting from that assessment considered reliable by the RMS are presented below in the table B.8.2.2.2._CA-18.

Table B.8.2.2.2._CA-18: The definitive set of the kinetic endpoints obtained for Flufenacet as a result of the data set from the study by [Schocken, Yen and Widmer; 1995], examining the aerobic mineralisation of that compound in natural water.

Type of sample	Experimental conditions - temperature	Determined kinetic endpoints			Kinetic model
		k [days ⁻¹]	DT ₅₀ [days]	DT ₉₀ [days]	
<i>Natural pelagic freshwater (pond), not sterilised</i>	Mean incubation temperature 23.75°C (range 23.1 – 24.4°C)	0.001464	473	1570	SFO
	At standard T = 20°C	0.001044	664	2204.1	SFO
<i>Natural pelagic freshwater (pond), sterilised</i>	Mean incubation temperature 23.75°C (range 23.1 – 24.4°C)	0.000311	2230	7410	SFO
	At standard T = 20°C	0.0002214	3130.7	10402.9	SFO

Summary – Aerobic mineralisation in surface water

The aerobic mineralisation of Flufenacet in surface water was examined in pelagic (pond) freshwater collected from the pond representative for the agricultural area of the use of Flufenacet. The test water had the following characteristic:

- type of water sample: pelagic water (no associated sediment);
- pH: 7.5;
- total alkalinity: 230 mg CaCO₃/L;
- total hardness: 329 mg CaCO₃/L;
- specific conductivity: 500 µmhos/cm;
- [O₂]: 9.6 mg/L;
- Suspended solids: 8.5 mg/L;
- Microbial activity, expressed in number of the colony forming units (CFU): 5.9 E3 CFU/mL.

The examination of the degradation of Flufenacet in water was performed in irradiated test systems, under light regime similar to natural sunlight conditions. The mean temperature of incubation was in range 23.1 – 24.4 (mean estimated by the RMS is 23.75°C), therefore slightly deviating from the assumed T = 25 ± 1°C.

The experiment was performed with Flufenacet radiolabelled in only one position – in fluorophenyl ring, therefore the proposed transformation scheme cannot be considered as complete. In case of the biologically viable samples three degradation products were identified and quantified:

- FOE Alcohol, recorded for the first time on DAT 60, peaking at 4.4% of the applied amount of the parent compound on DAT 368 (end of the study) and that amount was still seemingly increasing;
- FOE Oxalate, recorded for the first time on DAT 60, peaking at 24.0% of the applied amount of the parent compound on DAT 368 (end of the study) and that amount was still increasing;
- FOE Sulfonic acid, recorded for the first time on DAT 278, peaking at 8.6% of the applied amount of the parent compound on DAT 368 (end of the study) and that amount was still increasing;

In sterilised samples only one degradation product was identified – FOE Alcohol, observed for the first time on DAT 278 and formed in amount up to 6.8% of the applied amount of the parent compound (value recorded at the end of the study – on DAT 368).

During that experiment, lasting for 368 days, it was stated that Flufenacet radiolabelled in fluorophenyl moiety, underwent very limited mineralisation – up to 3.0% of the applied dose was fully mineralised in the biologically viable samples. That indicates that Flufenacet cannot be considered ready biodegradable. In the sterilised samples the level of mineralisation was up to 0.8% at the end of incubation period – DAT 368.

The process of degradation of Flufenacet in pelagic water was slow, with DT₅₀ = 473 days and DT₉₀ = 1570 days in non sterilised water, and it followed the SFO kinetic model. When recalculated to the standard

temperature – $T = 20^{\circ}\text{C}$ (using Arrhenius activation energy $E_a = 65.4 \text{ kJ/mol}$) these values were: $DT_{50} = 664$ days and $DT_{90} = 2204.1$ days.

In sterilised water the rate of degradation, also following the SFO kinetics, was much slower, with $DT_{50} = 2230$ days and $DT_{90} = 7410$ days. When recalculated to the standard temperature – $T = 20^{\circ}\text{C}$ (using Arrhenius activation energy $E_a = 65.4 \text{ kJ/mol}$) these values were: $DT_{50} = 3130.7$ days and $DT_{90} = 10402.9$ days.

The kinetic examination of the results for any of the identified and quantified degradation products was not possible due to the fact that all they were still forming at the study end.

The results presented above demonstrated that the process of the degradation of Flufenacet in natural pelagic water was predominantly biologically mediated and that the abiotic degradation processes – hydrolysis and aqueous photolysis (direct and indirect) played only minor role, if any.

The results of the examination of aerobic mineralisation of Flufenacet in surface water, in format recommended for reporting the regulatory endpoints in the EU, are presented below. In that form the values will be inserted into the proposal for the EU List of End Points.

Aerobic mineralisation in surface water (Regulation (EU) N° 283/2013, Annex Part A, point 7.2.2.2 and Regulation (EU) N° 284/2013, Annex Part A, point 9.2.1)

B.8.2.2.3. – Water/sediment study

In order to cover that data requirement the Applicant submitted three study reports. Two of them examined the transformation pattern of Flufenacet radiolabelled in two different positions – in phenyl ring (first study) and in C2 position of Thiadiazole moiety (second study) in aerobic water/sediment systems. Both had already been evaluated for the purpose of the previous authorisation of Flufenacet in the EU. The third study, newly submitted, presented the results of the kinetic evaluation of the data obtained in the two studies referred to above.

RMS examining the data set stated that the examination of the fate and behaviour of Flufenacet in aerobic aquatic systems was performed for only two of the three possible radiolabelling positions – phenyl ring and C2 position in thiadiazole moiety. Not covered was the would-be transformation pathway for thiadiazole moiety radiolabelled in C5 position and, as a result there is no information about formation of two degradation products identified in soil as major – FOE 5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid. The lack of the data for that third radiolabelling position may be considered as a data gap.

The Applicant also submitted the study examining fate and behaviour of Flufenacet in anaerobic water/sediment system. That study, also submitted and evaluated for the purpose of the previous authorisation of Flufenacet in the EU, will be evaluated under this point after the evaluation of the aerobic water/sediment studies.

Study 1:

Report: Kelley I., Wood S., McKinney M., (1995): “Degradability and Fate of [Phenyl-UL-¹⁴C]FOE 5043 in Two Sediment/Water Systems.”; Bayer Corporation (formerly Miles Inc), Agriculture Division, Research and Development Department, 17745 S. Metcalf, Stilwell, Kansas 66085, USA (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120, USA; study No. F3042405; Report No. MR106928; 1 November 1995; study reference number: M-002213-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Official Testing of Plant Protectants Part IV, 5-1 (1990): Degradability and Fate of Plant Protectants in the Water/Sediment System;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-4, Aerobic Aquatic Metabolism.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.4.3.2.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. For the purpose of the current assessment the study was evaluated for its compliance with OECD Guideline 308 – Aerobic and Anaerobic Transformation in Aquatic Sediment Systems. The study was found acceptable and is summarised below. It shall be indicated however that in its part aimed on the kinetic evaluation of the results the study did not comply with the provisions of the current Guidelines, namely FOCUS Kinetics Guidance document. That assessment was performed separately and presented in the study report summarised further down this Renewal Assessment Report as **Study 3**.

Summary:

The aim of the study was to examine the fate and degradation rate of Flufenacet in two aerobic water/sediment systems.

The test compound used in the experiment was ¹⁴C-Flufenacet radiolabelled uniformly in fluorophenyl ring, as shown below on figure B.8.2.2.3._CA-1. It had a specific activity 66.5 mCi/mmol and radiochemical purity of 98.9%. It was used to prepare the application solutions with which the test systems were treated. It was delivered to the test facility as vial C-584, probably in form of solution in not specified organic solvent.

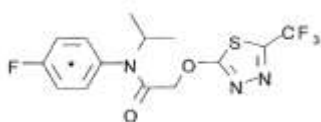

Figure B.8.2.2.3._CA-1: The structural formula of the test compound - [Phenyl-UL-¹⁴C]Flufenacet used in the experiment; radiolabelling position is indicated by an asterisk (copied from the study report).

Additionally, in the experiment the non-radiolabelled Flufenacet was used. That compound, delivered as vial K-597) had a declared chemical purity of 99.6%.

Other radiolabelled compounds used in the experiment were: FOE Methylsulfoxide (specific activity 21.0 mCi/mmole), FOE Methylsulfone (specific activity 21.0 mCi/mmole), FOE Thioglycolate sulfoxide (specific activity 21.0 mCi/mmole), FOE Sulfonic acid (specific activity 21.0 mCi/mmole), FOE Oxalate (specific activity 18.4 mCi/mmole), FOE Methylsulfide (specific activity 21.0 mCi/mmole), FOE Amine acetate (specific activity 115.8 mCi/mmole) and FOE Alcohol (specific activity 115.8 mCi/mmole). All these compounds were radiolabelled uniformly in the fluorophenyl ring. Their structural formulas were presented in the introductory part of this document (point B.8.0.), in the table B.8.0_CA-1. They were used as the reference compounds in the chromatographic analysis.

The examination of the fate and behaviour of Flufenacet in water/sediment systems was carried out using two freshwater sediments and water associated with them. The test matrices – sediment and associated water, were sampled from the ponds located in Kansas, USA, in areas representative for the intended use of Flufenacet.

One of the ponds, from which the test matrices were sampled, was located in Nelson Environmental Study Area near Lawrence, Kansas. It was positioned near the hilltop and was surrounded by the grassland. The test systems containing that set of the test matrices in the experiment bore the codename NESA.

The second sampling pond was located at Bayer Research Park in Stilwell, Kansas and was positioned in a valley surrounded by woods. The test systems containing that set of the test matrices were codenamed in the experiment BRP.

During the sampling several parameters of the pond water were determined. These are presented below in the table B.8.2.2.3._CA-1. In the original study report the depths were expressed in inches. For clarity the RMS recalculated them into standard, SI-related units (cm).

Table B.8.2.2.3._CA-1: The parameters of the test systems recorded on the sampling site.

Parameter		Test system	
		NESA	BRP
Location		Lawrence, KS, USA	Stilwell, KS, USA
Sampling depth [cm]		21.6	25.4
Temperature [°C]	On the surface	20	20
	5 cm above the sediment	19	19
Dissolved oxygen [ppm]	Near the surface	10.8	7.9
	5 cm above the sediment	9.2	7.9
pH		8.7	8.2
Conductivity [μMhos]		162	220
Redox potential [mV]		~365	409

The samples of sediment and associated water were taken to the test facility, where they were stored overnight at T = 4°C and the next day processed. The processing of the test matrices consisted on sieving the sediments through 2-mm sieve to remove larger skeletal elements and passing water through a 0.2-mm sieve to remove larger plant parts.

The subsamples of so prepared test matrices were taken for characterisation. Its results – the physicochemical and biological parameters of sediment and associated water for each test system, are presented below in the table B.8.2.2.3._CA-2.

Table B.8.2.2.3._CA-2: The physicochemical and biological parameters of water and sediment phases of each test system.

Matrix	Parameter	Test system	
		NESA	BRP
Water	<i>pH</i>	7.5	7.3
	<i>Conductivity [mmhos]</i>	0.17	0.24
	<i>Total dissolved solids [ppm]</i>	82	120
	<i>Turbidity [NTU]</i>	0.77	0.69
	<i>Ca content [ppm]</i>	5	11
	<i>Mg content [ppm]</i>	6	4
	<i>Hardness [mg equivalents CaCO₃/L]</i>	38	47
	<i>Redox potential [mV]</i>	259	296
	<i>total N [mg/L]</i>	13	13
	<i>total P [mg/L]</i>	0.04	0.04
	<i>Dissolved O₂ [ppm]</i>	9.2	8.5
Sediment	<i>Textural class (USDA)</i>	Silty clay loam	Silty clay loam
	<i>Particle size distribution</i>	Sand %	14
		Silt %	51
		Clay %	35
	<i>OC content [%]</i>	0.7	1.4
	<i>pH</i>	7.9	7.8
	<i>CEC [meq/100g]</i>	33.5	25.6
	<i>total N</i>	0.057	0.118
	<i>Microbial activity [mg CO₂/kg sediment •hour]</i>	17	8

The experiment was performed using 500-mL reagent bottles as the test vessels.

The test vessels for NESA system were prepared by weighing into each of them ~173 g of the moist sediment to obtain its 2.4-cm layer. It was carefully covered with 310 mL of the associated water to obtain 6-cm water layer.

The test vessels for BRP system were prepared by weighing into each of them ~173 g of the moist sediment to obtain its 2.5-cm layer. It was carefully covered with 325 mL of the associated water to obtain 6-cm water layer.

The amount of so prepared bottles was such to obtain two replicates for each sampling point, except those marked DAT 120 and DAT 157 (test spares) for which the test bottles were prepared in triplicate.

So prepared test vessels were allowed to equilibrate – until an aerobic/anaerobic gradient was established. During that period in selected bottles the following parameters were measured: pH, redox potential, conductivity and the O₂ content.

After pre-equilibration from each test bottle 10-mL samples of water were taken. The samples representing the given test system – NESA or BRP, were then pooled and sterilised by filtering them through 0.22-µm cellulose acetate filter. So prepared water samples were subsequently used to prepare two application solutions, each specific for the given test system. The preparation of the water samples, as well as that of the application solutions, was carried out using the glassware sterilised by autoclaving. The pre-equilibration was performed in a walk-in environmental chamber, in which the whole experiment was carried out, under the experimental conditions – in the darkness and at the incubation temperature $T = 20 \pm 1^{\circ}\text{C}$.

The application solution used to treat the samples of the test system NESA, further called **Application solution 1**, was prepared in a way described below.

Firstly 0.213 mL of the test compound from vial C-584 (2.562 mg using the declared in the study report concentration 12.028 mg/mL) was transferred to the 5-mL centrifuge tube. The solvent was evaporated and the residue redissolved in 1 mL of CH₃CN. So prepared solution was then added to 330 mL of sterilised water from NESA test system to obtain the **Application solution 1** having a nominal concentration of the test compound of 7.8 mg/L. The concentration of the test compound in so prepared solution was verified by LSC using three 100-µL aliquot samples. The concentration of ¹⁴C-Flufenacet in the solution was determined on the basis of the determination of radioactivity content using the calculated specific radioactivity of ¹⁴C-Flufenacet equal to 0.18 µCi/µg, corresponding to 6.8 kBq/µg. On that basis the concentration of ¹⁴C-Flufenacet in solution was determined to be 349575 dpm/100 µL, what corresponded to 8.7 mg/L. RMS noticed that the measured concentration was by 0.9 mg/L higher than the declared nominal concentration. The radiochemical purity of the **Application solution 1**, determined by radio-HPLC, was 95.3%.

The application solution to treat the samples of the test system BRP, further called **Application solution 2**, was prepared in a way described below.

Firstly 3.32 mL of the test compound from vial C-584 (2.686 mg using the declared in the study report concentration 0.809 mg/mL) was transferred to the 5-mL centrifuge tube. The solvent was evaporated and the

residue redissolved in 1 mL of CH₃CN. So prepared solution was then added to 330 mL of sterilised water from NESA test system to obtain the **Application solution 1** having a nominal concentration of the test compound of 8.1 mg/L. The concentration of the test compound in so prepared solution was verified by LSC using three 100-μL aliquot samples. The concentration of ¹⁴C-Flufenacet in the solution was determined on the basis of the determination of radioactivity content using the calculated specific radioactivity of ¹⁴C-Flufenacet equal to 0.18 μCi/μg, corresponding to 6.8 kBq/μg. On that basis the concentration of ¹⁴C-Flufenacet in solution was determined to be 348238 dpm/100 μL, what corresponded to 8.7 mg/L. RMS noticed that the measured concentration was by 0.6 mg/L higher than the declared nominal concentration. The radiochemical purity of the **Application solution 2**, determined by radio-HPLC, was 98.1%.

RMS's comment:

RMS analysing the description of the preparation of the **Application solution 1** and **Application solution 2** provided in the study report noticed the significant discrepancies in the description. Although taken from the same vial the volumes of the test compound solution and its amount in the solution's volume unit were different. Additionally the radiochemical purities of the so prepared application solutions were different by about 3%. Assuming that the source of the test compound for both application solutions was the same vial – C584 and that the compound was homogenous (what shall be true, taking into account that it was, as indicate the description, delivered as a liquid not a solid) and stable during storage (what was confirmed by the results of the adequate analyses), that puts a questionmark over the procedure of the preparation of the application solutions and subsequent treatment of the individual test systems. Therefore in RMS's opinion, although this is not a factor invalidating the study rendering it unreliable, the Applicant should clarify the problem.

Additionally the application solution with non-radiolabelled Flufenacet was prepared. That was done by weighing 10 mg of the material from the vial K-597 into 500-mL volumetric flask, to which 2 mL of CH₃CN were firstly added (to improve the solubility of the test item) and then the appropriate amount of the sterile, distilled water (flask was filled up to the calibration mark). The so prepared solution was used to treat the control samples set to determine the biomass in the test systems during the experiment.

Another set of control samples – sterile control samples, was treated with the modified **Application solution 1** or **Application solution 2**. The modification consisted on addition to the 40-mL aliquots of the application solutions 1 g of HgCl₂ used as a sterilising agent.

The test vessels were treated at application rate 750 g/ha, assuming 30-cm depth of the water column, corresponding to the theoretical rate 0.25 ppm Flufenacet in the water phase of the individual test vessel. For that purpose to each individual test vessel containing the given water/sediment test system was introduced 10 mL of the adequate **Application solution** containing radiolabelled test substance (**Application solution 1** or **Application solution 2**) was added. The given **Application solution** was introduced to the test vessel by evenly applying it to the water surface using pipette. The verification of the application rate showed that in case of the NESA test system it was 0.28 ppm and for BRP system – 0.27 ppm. These application rates were slightly higher than the assumed application rate of 0.25 ppm.

In the similar way, using the same as above amounts of the adequate **Application solutions** to obtain the target application rate of 0.25 ppm, were treated the control samples for the determination of biomass (using the **Application solution** containing non-radiolabelled Flufenacet) and the so-called sterile control samples (using the appropriate **Application solution** containing HgCl₂ as sterilising agent).

Additionally were prepared the blank control samples for each test systems – the vessels not treated with the test compound, neither radiolabelled nor non-radiolabelled one.

The fortification of all test vessels was performed in such way to minimise the access of light. After treatment the test vessels were connected to the flow-through system, presented below (for each individual test vessel) on figure B.8.2.2.3._CA-2, and incubated for the pre-defined amount of time in the climatic walk-in chamber, in the darkness under the constant temperature $T = 20 \pm 1^{\circ}\text{C}$. The exact maximum incubation time for each type of sample was:

- 120 days for the test vessels (both systems);
- 157 days for the spare samples (both systems) to provide enough material for metabolite profiling;
- 120 days for the control samples for determination of biomass;
- 162 days for the sterile control samples;

The maximum incubation time for the blank control samples was not defined.

The test vessels were aerated with continuous air-flow from a pressurized air tank. The air administered to each test vessel were sterilised and moisturised before reaching it.

The main trap for volatile compound in each flow-through system was filled with 3:7 v/v mixture of monoethanolamine:ethylene glycol. It was followed by the secondary trap, containing the same filling, set to trap the volatiles in case of the oversaturation or overflow of the primary trap.

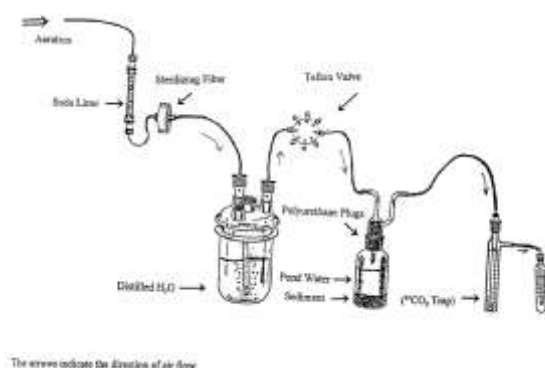

Figure B.8.2.2.3._CA-2: The schematic presentation of the incubation flow-through system used in the experiment (copied from the study report).

At pre-designated sampling points the duplicate test vessels for each water/sediment test system and each type of samples were taken for the analysis. In case of the test samples the sampling points were set at DAT (DAT stands for Days After Treatment): 0, 0.25 (6 hours after treatment), 1, 2, 7, 14, 30, 100 and 120. The DAT 120 samples were taken in triplicate. Additionally triplicate test samples (initially set as spares) were taken for the metabolite profiling analysis.

In case of the control samples for biomass determination the sampling points were set to DAT 0, DAT 43 and DAT 120. Finally the sterile control samples were taken for the analysis on DAT 120 and DAT 162.

After removal from the incubation chamber each test vessel was purged for 1 hour with a gentle stream of N_2 administered at a rate 40-55 mL/min to transfer all volatile compounds remaining in the head space into the traps for volatile compounds. Then the samples were processed in line with the procedure presented below on figure B.8.2.2.3._CA-3.

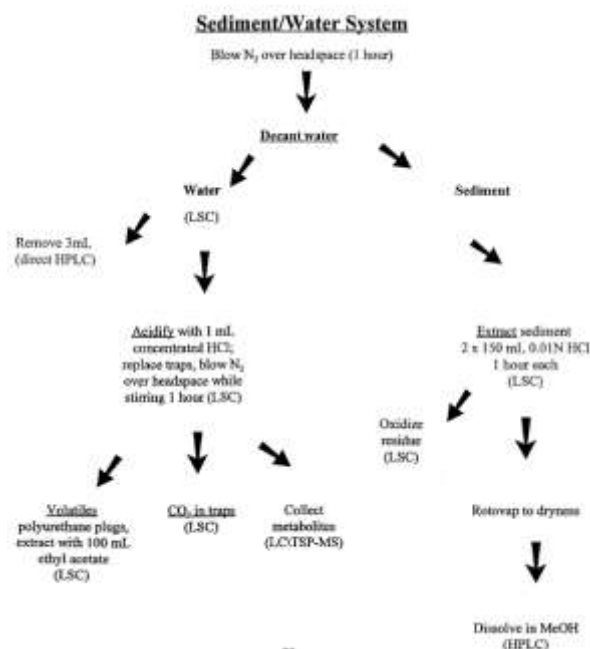

Figure B.8.2.2.3._CA-3: The conceptual scheme of the sample processing procedure (copied from the study report).

The radioactivity in samples was quantified by LSC. The measurements were performed using a Packard Tri-Carb Model 4640 LS counter.

In case of liquid samples the volume of aliquot taken for analysis was 0.1 – 1.0 mL and that of the liquid scintillation cocktail – Ultima Gold, 15 – 20 mL. The detailed parameters were presented for the 0.5-mL aliquots of liquid samples, mixed with 15 mL of Ultima Gold LS cocktail. The minimum sensitivity of LSC analysis for those samples was 1.8 E-4 ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 70 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 35 cpm, assuming average background (BCGK) of 35 cpm (LAGC = 2*BCGK and LANC = LAGC – BCGK). The greatest probable error GPE = 8.83%. The counting lasted for 5 minutes.

In case of the solid samples, the amount taken for analysis was 0.1g, pelleted with cellulose. It was oxidised and the formed $^{14}\text{CO}_2$ absorbed in a mixture of 6 mL Carbo-sorb and 15 mL Perma Fluor E⁺. The minimum sensitivity of LSC analysis for those samples was 9.1 E-4 ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 70 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 35 cpm, assuming average background (BCGK) of 35 cpm (LAGC = 2*BCGK and LANC = LAGC – BCGK). The greatest probable error GPE = 8.83%. The counting lasted for 5 minutes.

The chromatographic methods used in the study were HPLC, TLC and LC/TPS-MS (Liquid Chromatography/Thermospray – Mass Spectrometry)

The HPLC method was used to analyse pond water and sample extracts for the content of the parent compound and its degradation products.

It was carried out on HP 1090 chromatograph coupled with an UV-detector set to $\lambda = 254$ nm and radioactivity detector (Raytest Ramona). The chromatographic separation was performed in a gradient mode on the Spherisorb 3 μ ODS, 70 • 10 mm, chromatographic column. The mobile phase used in the elution consisted of:

- **Solvent A:** 0.4% CH_3COOH in water;
- **Solvent B:** 0.4% CH_3COOH in CH_3CN ;

The gradient mode used in the analysis was linear from 0% to 100% of **Solvent B** over 60 minutes. The flow rate was 1.0 mL/min. The quantitative analysis was performed by means of the external standards of known concentration and the identification of the fractions by comparing their retention times – R_t , with those of the known standards. The R_t values of the standards are presented in the table B.8.2.2.3._CA-3.

The TLC (Thin-Layer Chromatography) was used as a conformatory method for metabolite identification. The chromatographic separation was performed on pre-coated silica gel plates, 0.25-mm thick, with fluorescent indicator. The TLC plates were developed first in the solvent system $\text{CHCl}_3/\text{CH}_3\text{COOC}_2\text{H}_5$ (3:1 v/v) and then in the solvent system $\text{CH}_3\text{CN}/(\text{CH}_3)_2\text{CHOH}/\text{CH}_3\text{COOH}/\text{H}_2\text{O}$ (20:3:2:1 v/v/v/v). The identification of the bands was performed by means of the comparison of their R_f values with those of the known standards. The R_f values of the standards are presented in the table B.8.2.2.3._CA-3.

Table B.8.2.2.3._CA-3: The R_t (HPLC) and R_f (TLC) values of the standard compounds used as the reference values in identification of the fractions in chromatographic analysis.

Chromatographic fraction	Chromatographic characteristic		Identity of the fraction
	Retention time R_t [min] – HPLC	R_f value – TLC	
Parent	45	0.94	Flufenacet
Metabolite 1	16 – 18	0.54	FOE Sulfonic acid
Metabolite 2	18 – 20	0.36	FOE Oxalate
Metabolite 3	26	0.28	FOE Thioglycolate sulfoxide
Metabolite 4	30	0.62	Foe Methylsulfoxide
Metabolite 5	34	0.85	FOE Methylsulfone
Metabolite 6	38	0.81	FOE Amine acetate
Metabolite 7	40.5 – 42	0.62	FOE Methylsulfide
Metabolite 8	----	0.74	FOE Alcohol

The LC/TPS-MS analysis was performed to conform the identity of Flufenacet and its degradation products. It was carried out using Varian 540 HPLC coupled with Finnigan-MAT 90 thermospray MS detector. The chromatographic separation was performed in a gradient mode on the C18 Novapak, 150 • 3.9 mm, 5 μ , chromatographic column. The mobile phase used in the elution consisted of:

- **Solvent A:** 0.1% CH₃COOH in water;
- **Solvent B:** CH₃OH;

The gradient mode used in the analysis was linear from 0% to 100% of **Solvent B** over 30 minutes. The flow rate was 1.0 mL/min.

The identification was performed by means of the identification of characteristic peaks in the mass spectrum. These are presented, for each compound expected to be present in samples, in the table B.8.2.2.3._CA-4.

Table B.8.2.2.3._CA-4: Identification of the Flufenacet and its degradation products in samples using LC-MS method – the characteristic MS peaks for each compound

Compound	Characteristic MS peak	
	Position m/z	Description
<i>Flufenacet</i>	364	Protonated pseudo-molecular ion $[M + H]^+$
	381	Peak for ammonia adduct $[M + NH_4]^+$
<i>FOE Oxalate</i>	226	Pseudo-molecular ion $[M + H]^+$
	243	Peak for ammonia adduct $[M + NH_4]^+$
<i>FOE Methylsulfide</i>	242	Pseudo-molecular ion $[M + H]^+$
<i>FOE Methylsulfone</i>	274	Protonated molecular ion $[M + H]^+$
	291	Peak for ammonia adduct $[M + NH_4]^+$
<i>FOE Methylsulfoxide</i>	258	Protonated molecular ion $[M + H]^+$
	275	Peak for ammonia adduct $[M + NH_4]^+$
<i>FOE Thioglycolate sulfoxide</i>	302	Protonated molecular ion $[M + H]^+$
<i>FOE Thioglycolate sulfide</i>	286	Pseudo-molecular ion $[M + H]^+$
	308	Sodium adduct $[M + Na]^+$
<i>FOE Alcohol</i>	212	Pseudo-molecular ion $[M + H]^+$
	229	Peak for ammonia adduct $[M + NH_4]^+$

Results and their discussion:

The test vessels containing the given systems were equilibrated in order to establish the stable aerobic/anaerobic gradient. In case of NESA test system the process lasted for 10 days and at its end the following parameters were recorded:

- temperature of the test system: $T = 20^\circ\text{C}$;
- the dissolved O₂ near surface (2 cm below water surface): 5.4 – 7.1 [mg/L];
- pH: 7.1 – 7.3;
- conductivity measured in water phase: 313 – 677 μMHO ;
- redox potential of water phase: 142 – 246 mV;
- redox potential of the sediment phase: -124 – -153 mV.

The equilibration of the vessels containing BRP test systems lasted for 6 days. At its end the following parameters were recorded:

- temperature of the test system: $T = 20^\circ\text{C}$;
- the dissolved O₂ near surface (2 cm below water surface): 5.6 – 7.0 [mg/L];
- pH: 7.0 – 7.3;
- conductivity measured in water phase: 417 – 437 μMHO ;
- redox potential of water phase: 126 – 138 mV;
- redox potential of the sediment phase: -191 – -199 mV.

The results indicate that while the conditions in the water phase were aerobic, in the sediment they were rather anaerobic.

The temperature was constantly monitored and results recorded in 7-days periods. It was demonstrated that it was on the constant level throughout the study – $T = 20 \pm 1^\circ\text{C}$. All samples were incubated without the access of light and during the sampling periods they were additionally protected by covering them with heavy demin cover pulled over the shelves.

The results of the determination of microbial activity in the test systems is presented below in the table B.8.2.2.3._CA-5. On their basis it was stated that for the NESA test system during 120-days lasting incubation in blank systems it dropped by 50% while in those treated with Flufenacet (“cold” material) by 15%. In case of the BRP test systems the decrease in microbial activity over 120-days period of incubation was 37% for the blank

systems and 12% in those treated with Flufenacet (“cold” material). On that basis it was stated that the test systems maintained their biological viability during the experiment.

Table B.8.2.2.3._CA-5: The results of the determination of the microbial viability of the test systems during the incubation period.

Kind of sample	Microbial activity in [mg CO ₂ /kg sediment • hour] obtained for the sediment of the test system:			
	NESA		BRP	
	Blank	Treated with flufenacet	Blank	Treated with flufenacet
<i>Fresh after sampling</i>	17	Not applicable	8	Not applicable
<i>DAT 0, after initial equilibration</i>	13 – 14	Not applicable	9 – 10	Not applicable
<i>DAT 120</i>	8 – 9	12 – 17	4 – 6	7

The analysis of the samples of NESA test system showed that the total recovery of radioactivity was in range 92.9 – 100.9% of the applied.

The level of mineralisation was 3.4% AR after 157 days of incubation. The NER fraction in sediment at the end of the experiment (DAT 157) in that system was 23.2% AR. Additionally at that time point 22.7% AR was the fraction extractable from the sediment while 38.1% AR was in water.

The concentration of Flufenacet in that test system declined steadily from ~100% AR at the beginning of the experiment to 27.7% AR at its end – on DAT 157. The following degradation products were detected in the whole system:

- FOE Oxalate, reaching max. 4.6% AR on DAT 157;
- FOE Sulfonic acid, reaching max. of 1.7% AR on DAT 157;
- FOE Alcohol, reaching max. of 0.7% AR on DAT 120;
- FOE Methylsulfide, reaching max. of 11.4% on DAT 157;
- FOE Methylsulfone, reaching max. of 6.4% AR on DAT 100;
- FOE Methylsulfoxide, reaching max. of 3.2% AR on DAT 157;
- FOE Thioglycolate sulfoxide, reaching max. of 2.0% AR on DAT 157.

Also recorded were eight minor fractions, of which only those having $t_R \approx 6$ min (max 3.5% AR), $t_R \approx 29$ min (max 1.8% AR) and $t_R \approx 43$ min (max 1.1% AR), surpassed 1% AR at any sampling point.

The detailed results of the analysis are presented below in numerical form in the table B.8.2.2.3._CA-6 and additionally on two figures – B.8.2.2.3._CA-4, showing the distribution of radioactivity in the test system, and B.8.2.2.3._CA-5 presenting the results of the profiling of extractable radioactivity in the system. The values reported in the table are the averages of the two replicates. RMS noticed some inconsistencies between the values reported as total for the given compartment and their counterparts representing the sums of the individual constituents. That may be due to the fact that the values reported as representing the mass balance and those that are the sums of the individual components of radioactivity in the given component were determined using different analytical method: those for the mass balance were measured using LSC, while the profiling of radioactivity was performed using chromatographic methods.

The results obtained for the sterilized samples showed that the major constituent of the extractable fraction, accounting for 75.5% AR on DAT 120 and 67.0% AR on DAT 157, was Flufenacet – 86.8% of extracted on DAT 120 and 84.2% of extracted on DAT 157.

On that basis, after comparison with the results obtained for analogous test samples, it was stated that the mechanism of transformation of Flufenacet in NESA water/sediment system was predominantly biologically-mediated. The amount of radioactivity recovered as bound residues was 23.2% AR on DAT 120 and 26.4% AR on DAT 157 what may indicate that the formation of NER fraction contributes to some extent to the dissipation of Flufenacet from the water/sediment system. Finally, the level of mineralization was very low – 0.3% AR on DAT 120 and 0.5% AR on DAT 157 what additionally indicates that the process of the degradation of Flufenacet in NESA water/sediment system is biologically mediated (it shall be indicated that in the study report it was clearly stated that the sterility of the sterilized samples was not checked during the experiment).

Table B.8.2.2.3._CA-6: The numerical results of the examination of transformation of Flufenacet in NESA water/sediment test system.

Radioactivity in the test system		% AR recorded on DAT										
		0	0.25	1	2	7	14	30	60	100	120	157

Figure B.8.2.2.3_CA-4: The distribution of radioactivity in NESA test system in function of time (copied from the study report).

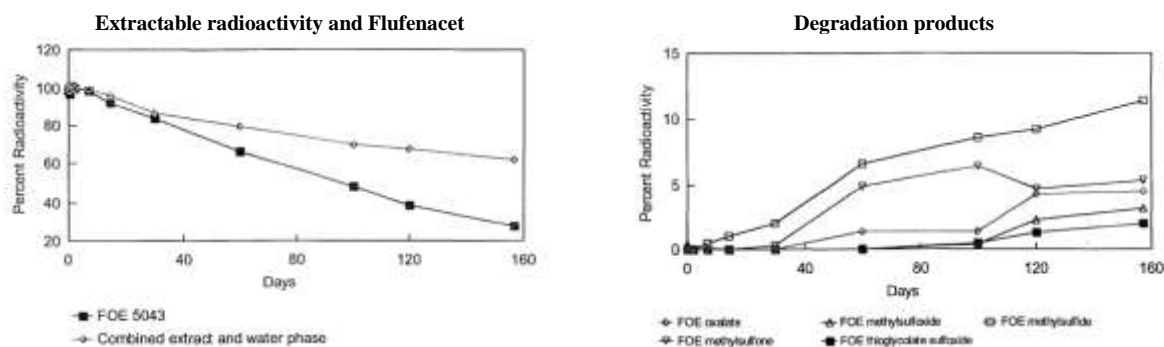

Figure B.8.2.2.3_CA-5: The results of the profiling of extractable radioactivity in NESA test system in function of time (copied from the study report).

The results obtained for Flufenacet were subjected to the kinetic analysis in order to derive the kinetic endpoints – DT_{50} and DT_{90} values for the dissipation/degradation of Flufenacet in the whole system and water phase.

The kinetic analysis was carried out using the approach developed by Timme and Frehse. As that approach is no longer considered valid in the EU for the purpose of the deriving the regulatory endpoints, RMS decided not to present the results of that analysis in the summary. The analysis of the same data, performed in line with the recommendation of FOCUS workgroup of the degradation kinetics, are presented in the **Study 3**.

The results obtained for the identified degradation products were not subjected to the kinetic analysis due to the fact that their levels were too low and some of them were still forming at the end of the study.

The analysis of the samples of BRP test system showed that the total recovery of radioactivity was in range 93.4 – 100.6% of the applied.

The level of mineralisation was 1.5% AR after 157 days of incubation. The NER fraction in sediment at the end of the experiment (DAT 157) in that system was 46.4% AR. Additionally at that time point 24.9.7% AR was the fraction extractable from the sediment while 21.9% AR was in water.

The concentration of Flufenacet in that test system declined steadily from ~100% AR at the beginning of the experiment to 22.3% AR at its end – on DAT 157. The following degradation products were detected in the whole system:

- FOE Oxalate, reaching max. 5.4% AR on DAT 157;
- FOE Sulfonic acid, reaching max. of 3.2% AR on DAT 157;
- FOE Alcohol, reaching max. of 1.3% AR on DAT 157;
- FOE Methylsulfide, reaching max. of 4.5% on DAT 157;
- FOE Methylsulfone, reaching max. of 7.2% AR on DAT 120;
- FOE Methylsulfoxide, reaching max. of 2.2% AR on DAT 120;
- FOE Thioglycolate sulfoxide, reaching max. of 1.9% AR on DAT 60.

Also recorded were eight minor fractions, none of them surpassing 1.5% AR at any sampling point.

The detailed results of the analysis are presented below in numerical form in the table B.8.2.2.3._CA-7 and additionally on two figures – B.8.2.2.3._CA-6, showing the distribution of radioactivity in the test system, and B.8.2.2.3._CA-7 presenting the results of the profiling of radioactivity in water and sediment extracts. RMS noticed some inconsistencies between the values reported as total for the given compartment and their counterparts representing the sums of the individual constituents. That may be due to the fact that the values reported as representing the mass balance and those that are the sums of the individual components of radioactivity in the given compartment were determined using different analytical method: those for the mass balance were measured using LSC, while the profiling of radioactivity was performed using chromatographic methods.

The results obtained for the sterilized samples showed that the major constituent of the extractable fraction, accounting for 67.5% AR on DAT 120 and 59.0% AR on DAT 157, was Flufenacet – 100% of extracted on DAT 120 and 94.9% of extracted on DAT 157.

On that basis, after comparison with the results obtained for analogous test samples, it was stated that the mechanism of transformation of Flufenacet in BRP water/sediment system was predominantly biologically-mediated. The amount of radioactivity recovered as bound residues was 28.2% AR on DAT 120 and 37.4% AR on DAT 157 what may indicate that the formation of NER fraction contributes to some extent to the dissipation of Flufenacet from the water/sediment system. Finally, the level of mineralization was very low – 0.1% AR on both DAT 120 and DAT 157 what additionally indicates that the process of the degradation of Flufenacet in BRP water/sediment system is biologically mediated (it shall be indicated that in the study report it was clearly stated that the sterility of the sterilized samples was not checked during the experiment).

Table B.8.2.2.3._CA-7: The numerical results of the examination of transformation of Flufenacet in BRP water/sediment test system.

Radioactivity in the test system		% AR recorded on DAT

Figure B.8.2.2.3_CA-6: The distribution of radioactivity in BRP test system in function of time (copied from the study report).

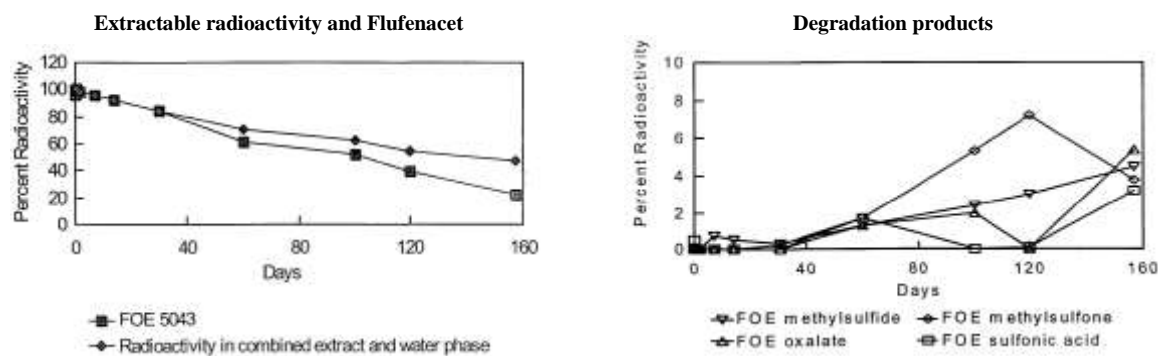

Figure B.8.2.2.3_CA-7: The results of the profiling of extractable radioactivity in BRP test system in function of time (copied from the study report).

The results obtained for Flufenacet were subjected to the kinetic analysis in order to derive the kinetic endpoints – DT_{50} and DT_{90} values for the dissipation/degradation of Flufenacet in the whole system and water phase.

The kinetic analysis was carried out using the approach developed by Timme and Frehse. As that approach is no longer considered valid in the EU for the purpose of the deriving the regulatory endpoints, RMS decided not to present the results of that analysis in the summary. The analysis of the same data, performed in line with the recommendation of FOCUS workgroup of the degradation kinetics, are presented in the *Study 3*.

The results obtained for the identified degradation products were not subjected to the kinetic analysis in this study report. Such analysis was performed by the Applicant in the *Study 3* for the identified major degradation product – FOE Methylsulfide. In RMS's opinion however it cannot be considered fully reliable (that concerns in particular the kinetic endpoints representing degradation) because of the lack of decline in one test system – NESA and only one data point representing the decline phase in the second test system – BRP. As for the other identified degradation products the kinetic analysis of the data obtained for them was not carried out due to the fact that their levels were too low and some of them were still forming at the end of the study.

Conclusions of the study:

The examination of the transformation of Flufenacet in aerobic water/sediment system showed that that compound quite quickly degraded in that environment, forming several degradation products. The mechanism of dissipation from the water phase was mixed – the compound partly degraded in that phase, but also quite significant migration to the sediment phase, where it was degraded, was observed. The degradation products, the same as identified in other studies examining the transformation of Flufenacet in the environment, were detected. One new degradation product was identified – FOE Methylsulfide, the metabolite specific only for the aquatic

environment. The degradation products were found predominantly in water phase, but their presence in the sediment phase as well may indicate that they could be formed also, if not predominantly, in sediment and from there released to the water phase.

The data for Flufenacet was kinetically examined, but that assessment was performed not in line with the current requirements, so its results were not reported. The data were kinetically re-examined, in line with the current recommendations, in a separate study.

The kinetic analysis of the data for the degradation products could not be carried out because, even when sufficient amount of data points was available, the metabolite was either still forming or its decline was in its initial phase.

On the basis of the results of the metabolite profiling the transformation scheme of Flufenacet in water/sediment system, determined for the part of the molecule containing the fluorophenyl ring was proposed. It is shown below on figure B.8.2.2.3._CA-8. The FOE Cysteine conjugate presented on the scheme in brackets is an hypotesized intermediate, postulated on the basis of the analysis of the structural formulae of the identified degradation products, in particular that of FOE Thioglycolate sulfoxide.

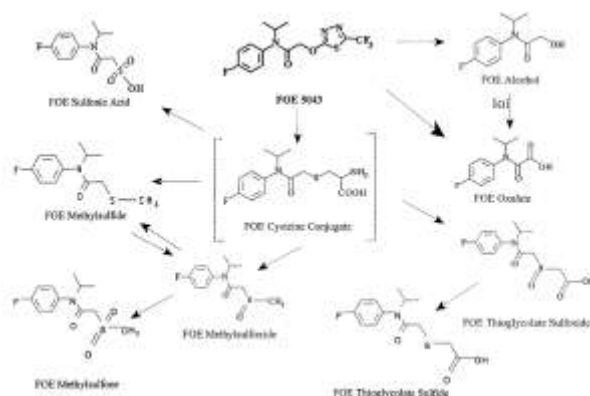

Figure B.8.2.2.3. CA-8: The postulated transformation pathway of Flufenacet in water/sediment system, determined for the part of the molecule containing the fluorophenyl ring (copied from the study report).

Study 2:

Report: Halarnkar P. P., Irwin D. W., (1997): “Degradability and Fate of [Thiadiazole-2-¹⁴C]FOE 5043 in Two Water/Sediment Systems.”; Bayer Corporation, Agriculture Division, Environmental Research, 17745 S. Metcalf, Stilwell, Kansas 66085, USA (performing laboratory) for Bayer Corporation, Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120, USA; study No. F3042406; Report No. 107822; 6 October 1997; study reference number: M-004595-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Society of environmental Toxicology and Chemistry (SETAC-Europe) Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides, March 1995;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-4, Aerobic Aquatic Metabolism.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found in the Addenda to the Monograph for Flufenacet, e. g. Addendum to the Volume 3, Annex B issued in January 2003, under the the point B.7.4.3.2.2. These documents were prepared by the then-RMS – France, for Flufenacet. For the purpose of the current assessment the study was evaluated for its compliance with OECD Guideline 308 – Aerobic and Anaerobic Transformation in Aquatic Sediment Systems. The study was found acceptable and is summarised below. It shall be indicated however that in its part aimed on the kinetic evaluation of the results the study did not comply with the provisions of the current Guidelines, namely FOCUS Kinetics Guidance document. That assessment was performed separately and presented in the study report summarised further down this Renewal Assessment Report as *Study 3*.

Summary:

The aim of the study was to examine the fate and degradation rate of Flufenacet in two aerobic water/sediment systems.

The test compound used in the experiment was ¹⁴C-Flufenacet radiolabelled in C-2 position in the thiadiazole moiety, as shown below on figure B.8.2.2.3._CA-9. It had a specific activity 18.47 mCi/mmol. It was delivered to the test facility as vial C-573A, probably in form of solution in a not specified organic solvent.

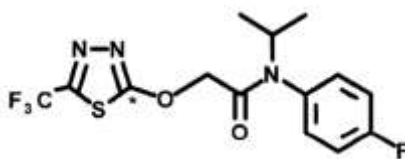

Figure B.8.2.2.3._CA-9: The structural formula of the test compound - [Thiadiazole-2-¹⁴C]Flufenacet used in the experiment; radiolabelling position is indicated by an asterisk (copied from the study report).

The test substance was used to prepare the application solution, which in turn was used to treat the test systems. The application solution was prepared by transferring the appropriate amount of the test compound into a vessel. The solvent was evaporated under the gentle stream of N₂ and the residue redissolved in the appropriate amount of CH₃CN to obtain the solution having a radiochemical purity of 98.8%.

The examination of the fate and behaviour of Flufenacet in water/sediment systems was carried out using two freshwater sediments and water associated with them. The test matrices – sediment and associated water, were sampled from the ponds located in Kansas, USA, in areas representative for the intended use of Flufenacet.

One of the ponds, from which the test matrices were sampled, was located in Nelson Environmental Study Area near Lawrence, Kansas. It was positioned near the hilltop and was surrounded by the grassland. The test systems containing that set of the test matrices in the experiment bore the codename NESA.

The second sampling pond was located at Bayer Research Park in Stilwell, Kansas and was positioned in a valley surrounded by woods. The test systems containing that set of the test matrices were codenamed in the experiment BRP.

During the sampling several parameters of the pond water were determined. These are presented below in the table B.8.2.2.3._CA-8.

Table B.8.2.2.3._CA-8: The parameters of the sampled water recorded on the sampling site.

Parameter	Test system	
	NESA	BRP
<i>Location</i>	Lawrence, KS, USA	Stilwell, KS, USA
<i>Temperature [°C]</i>	12	15
<i>Dissolved oxygen [ppm]</i>	5.6	10.0
<i>pH</i>	8.8	7.6
<i>Redox potential [mV]</i>	150	158

The samples of sediment and associated water were taken to the test facility, where they were stored overnight at $T = 4^{\circ}\text{C}$ and the next day processed. The processing of the test matrices consisted on sieving the sediments through 2-mm sieve to remove larger skeletal elements and passing water through a 0.2-mm sieve to remove larger plant parts.

The subsamples of so prepared test matrices were taken for characterisation. Its results – the physicochemical and biological parameters of sediment and associated water for each test system, are presented below in the table B.8.2.2.3._CA-9.

Table B.8.2.2.3._CA-9: The physicochemical and biological parameters of water and sediment phases of each test system.

Matrix	Parameter	Test system	
		NESA	BRP
Water	<i>pH</i>	7.2	6.9
	<i>Conductivity [mmhos]</i>	0.32	0.48
	<i>Total dissolved solids [ppm]</i>	220	300
	<i>Turbidity [NTU]</i>	15.6	2.96
	<i>Ca content [ppm]</i>	30	71
	<i>Mg content [ppm]</i>	9	5
	<i>Hardness [mg equivalents CaCO_3/L]</i>	114	197
	<i>Redox potential [mV]</i>	379.9	308.1
	<i>total N [ppm]</i>	8	10
	<i>total P [ppm]</i>	2	2
	<i>OC content [ppm]</i>	331	415
	<i>Dissolved O_2 [ppm]</i>	8.0	8.5
Sediment	<i>Textural class (USDA)</i>	Silty Clay	Silty clay loam
	<i>Particle size distribution</i>	Sand %	3.6
		Silt %	56.0
		Clay %	40.4
	<i>OM content [%]</i>	0.65	2.66
	<i>OC content [%] (recalculated by RMS)</i>	0.38	1.54
	<i>pH (measured in H_2O)</i>	7.8	7.8
	<i>CEC [meq/100g]</i>	22.00	13.02
	<i>Bulk density [g/cm^3]</i>	1.37	1.19
	<i>Moisture content at $\frac{1}{3}$ bar [%]</i>	39.41	37.57
	<i>Microbial activity [mg C/100 g sediment]</i>	1.18	21.41

Analysing the properties of each test system RMS noticed that the sediment in NESA test system displayed very low OC content – below the lower limit of 0.5% recommended for the sediments with low OC content. That however had probably no significant impact on the results of the study, therefore the stated deviation is acceptable.

The experiment was performed using 500-mL reagent bottles as the test vessels. To each of them 75-g (d.w.) aliquot of the given sediment was weighed. Next, it was carefully covered with 300 mL of the associated water. The so prepared test bottles were closed and attached to the flow-through system, presented below (for each individual test vessel) on figure B.8.2.2.3._CA-10. They were then preincubated for 7 days before being treated with the test compound, in the climatic walk-in chamber, in the darkness under the constant temperature $T = 20 \pm 1^\circ\text{C}$.

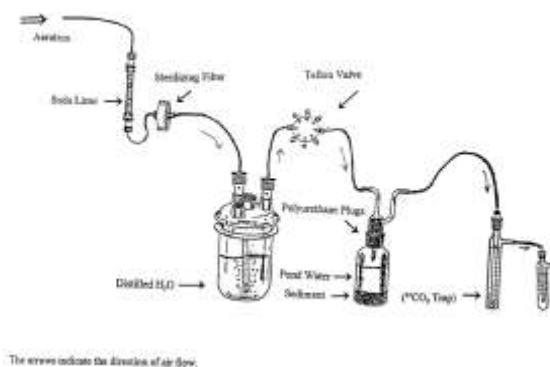

Figure B.8.2.2.3._CA-10: The schematic presentation of the incubation flow-through system used in the experiment (copied from the study report).

After pre-equilibration 25 test vessels containing NESAs water/sediment system and another 25 test vessels with BRP water/sediment system were treated with the application solution of ^{14}C -Flufenacet at application rate 0.250 ppm in water, what corresponded to a field application rate of 750 g/ha, assuming 30-cm depth of the water column. That was done by adding 438 μL of the application solution, containing 75 μg of ^{14}C -Flufenacet onto the water surface in each test vessel. After treatment the test vessels were re-attached to their flow-through systems in the incubation chamber and incubated there for up to 156 days.

Additionally, for each test system 5 test vessels were treated with the non-radiolabelled Flufenacet at application rate 75 μg /test vessels for biomass control. 5-7 vessels containing the same test systems were incubated alongside the treated vessels as blank controls.

The test vessels were aerated with continuous air-flow from a pressurized air tank. The air administered to each test vessel were sterilised and moisturised before reaching it.

The main trap for volatile compound in each flow-through system was filled with 3:7 v/v mixture of monoethanolamine:ethylene glycol. It was followed by the secondary trap, containing the same filling, set to trap the volatiles in case of the oversaturation or overflow of the primary trap.

At pre-designated sampling points the duplicate test vessels for each water/sediment test system and each type of samples were taken for the analysis. In case of the test samples the sampling points were set at DAT (DAT stands for Days After Treatment): 0, 7, 14, 28, 55, 100 and 156.

In case of the control samples for biomass determination the sampling points were set to DAT 0, DAT 65 and DAT 156.

After removal from the incubation chamber each test vessel was purged for 15 – 20 minutes with a gentle stream of N_2 administered at a rate 40 mL/min to transfer all volatile compounds remaining in the head space into the traps for volatile compounds. Then the samples were processed in line with the procedure presented below on figure B.8.2.2.3._CA-11.

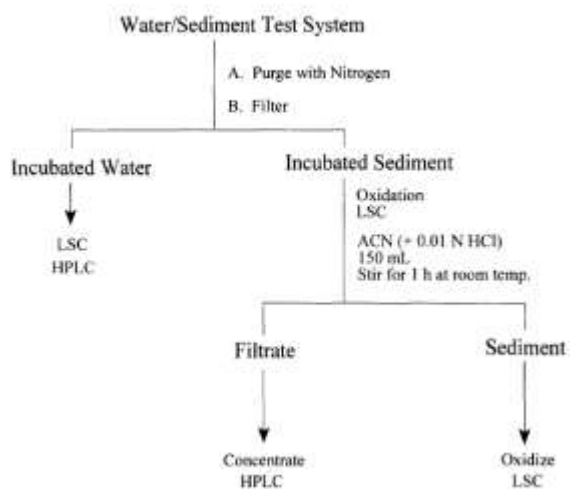

Figure B.8.2.2.3._CA-11: The conceptual scheme of the sample processing procedure (copied from the study report).

The radioactivity in samples was quantified by LSC. The measurements were performed using a Packard Tri-Carb Model 4640 LS counter.

The average volume of analysed sample was 0.5-mL and it was mixed with 10 mL of Ultima Gold LS cocktail and 2 mL of water. The minimum sensitivity of LSC analysis for those samples was 6.0 E-4 ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm (LAGC = 2*BCGK and LANC = LAGC – BCGK). The greatest probable error GPE = 9.2%. The counting lasted for 5 minutes.

In case of the solid samples, the amount taken for analysis was 0.2 g. It was oxidised and the formed $^{14}\text{CO}_2$ absorbed in a mixture of 6 mL Carbo-sorb and 15 mL Perma Fluor E⁺. The minimum sensitivity of LSC analysis for those samples was 1.6 E-3 ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm (LAGC = 2*BCGK and LANC = LAGC – BCGK). The greatest probable error GPE = 9.2%. The counting lasted for 5 minutes.

The chromatographic methods used in the study were HPLC and LC-MS/ESI.

The HPLC method was used to analyse pond water and sample extracts for the content of the parent compound and its degradation products.

It was carried out on HP 1090 chromatograph coupled with an UV-detector set to $\lambda = 254$ nm and radioactivity detector (Raytest Ramona). The chromatographic separation was performed in a gradient mode on the RP ODS chromatographic column (Phenomenex, Econex-sil, 10 μ , 250 • 4.6 mm), preceded by an RP-18, 30 • 4.6 mm, guard column. The mobile phase used in the elution consisted of:

- **Solvent A:** 0.4% CH_3COOH in water;
- **Solvent B:** 0.4% CH_3COOH in CH_3CN ;

The gradient mode used in the analysis is presented below in the table B.8.2.2.3._CA-10. The flow rate was 1.0 mL/min.

Table B.8.2.2.3._CA-10: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH_3COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH_3COOH</i>
0	80	20
50	0	100
60	0	100

The quantitative analysis was performed by means of the external standards of known concentration and the identification of the fractions by comparing their retention times – R_t , with those of the known standards. They were following:

- for Flufenacet the $R_t = 32.2$ min;
- for FOE-Thiadone the $R_t = 16.3$ min.

The LC-MS/ESI analysis was performed on the CONSTAMETRIC 3500/3200 HPLC coupled with TSQ 700 triple quadrupole mass spectrometer. The chromatographic separation was performed in a gradient mode on the Zorbax ODS, 150 • 4.6 mm chromatographic column. The mobile phase used in the elution consisted of:

- **Solvent A:** 0.1% HCOOH in water;
- **Solvent B:** CH₃OH;

The gradient mode used in the analysis is presented below in the table B.8.2.2.3._CA-11. The flow rate was 0.8 mL/min.

Table B.8.2.2.3._CA-11: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% HCOOH</i>	<i>Solvent B – CH₃OH</i>
0	95	5
1	95	5
15	0	100
22	0	100
23	95	5
30	95	5

The identification was performed by means of the identification of characteristic peaks in the mass spectrum, which were following:

- for Flufenacet m/z 364 [amu] - Protonated [M + 1] molecular ion;
- for FOE-Thiadone m/z 169 – deprotonated [M-1] molecular ion.

Additionally, at each sampling point the content of the dissolved oxygen, pH and the redox potential was determined in the collected samples.

Results and their discussion:

The results of the measurements of pH, dissolved O₂ and redox potential in samples are presented below in the table B.8.2.2.3._CA-12. On their basis it was stated that the aerobic conditions were maintained in the test systems throughout the study duration. The temperature was maintained at the constant level throughout the study – $T = 20 \pm 1^\circ\text{C}$. All samples were incubated without the access of light and during the sampling periods they were additionally protected.

Table B.8.2.2.3._CA-12: The results of the monitoring of pH, redox potential and O₂ content in incubated samples during the experiment.

Sampling time point	Replicate	Results obtained in NESA test system			Results obtained in BRP test system		
		pH	Redox potential [mV]	Dissolved O ₂ [mg/L]	pH	Redox potential [mV]	Dissolved O ₂ [mg/L]
0	1	7.4	171	3.2	7.3	155	3.1

	2	6.3	203	3.7	6.8	220	1.3

The results of the determination of microbial activity in the test systems are presented below in the table B.8.2.2.3._CA-13. On their basis it was stated that the test systems maintained their biological viability during the experiment.

Table B.8.2.2.3._CA-13: The results of the determination of the microbial viability of the test systems during the incubation period.

Sampling time point	Microbial biomass in [mg C/100 g sediment] obtained for the sediment of the test system:			
	NESA		BRP	
	Blank	Treated with flufenacet	Blank	Treated with flufenacet
DAT 0	1.18	Not applicable	21.41	Not applicable
DAT 65	6.83	7.19	16.41	18.97
DAT 156	5.15	6.97	17.29	25.77

The analysis of the samples of NESA test system showed that the total recovery of radioactivity was in range 89.6 – 99.0% of the applied.

The level of mineralisation was 15.3% AR after 156 days of incubation. The NER fraction in sediment at the end of the experiment (DAT 156) in that system was 2.2% AR. Its maximum level was 3.3% AR recorded on DAT 55.

The concentration of Flufenacet in that test system declined steadily from 94.2% AR at the beginning of the experiment to 0.6 – 0.9% AR at its end. One degradation product was identified – FOE-Thiadone, reaching maximum of 84.3% AR on DAT 55.

The detailed results of the analysis are presented below in numerical form in the table B.8.2.2.3._CA-14. The values reported in the table are the averages of the two replicates. Additionally RMS recalculated the concentrations of Flufenacet and FOE Thiadone in water and sediment extracts to express them in % AR as in the study report they were presented as % in the fraction.

Table B.8.2.2.3._CA-14: The numerical results of the examination of transformation of Flufenacet in NESA water/sediment test system.

The results obtained for Flufenacet were subjected to the kinetic analysis in order to derive the kinetic endpoints – DT₅₀ and DT₉₀ values for the dissipation/degradation of Flufenacet in the whole system and water phase.

The kinetic analysis was carried out using the approach developed by Timme and Frehse. As that approach is no longer considered valid in the EU for the purpose of the deriving the regulatory endpoints, RMS decided not to present the results of that analysis in the summary. The analysis of the same data, performed in line with the recommendation of FOCUS workgroup of the degradation kinetics, are presented in the *Study 3*.

The results obtained for the identified degradation products were not subjected to the kinetic analysis, neither performed by the Applicant nor by the RMS. That was due to the fact that the decline phase consisted only of the two data points, in RMS's opinion too few to obtain the reliable kinetic endpoints.

The analysis of the samples of BRP test system showed that the total recovery of radioactivity was in range 82.7 – 100.5% of the applied.

The level of mineralisation was 15.0% AR after 156 days of incubation. The NER fraction in sediment at the end of the experiment (DAT 156) in that system was 7.5% AR. Its maximum level was 9.6% AR recorded on DAT 100.

The concentration of Flufenacet in that test system declined steadily from 96.3% AR at the beginning of the experiment to 3.3% AR at its end – on DAT 156. One degradation product was identified – FOE-Thiadone, reaching maximum of 63.8% AR on DAT 100.

The detailed results of the analysis are presented below in numerical form in the table B.8.2.2.3._CA-15. The values reported in the table are the averages of the two replicates. Additionally RMS recalculated the concentrations of Flufenacet and FOE Thiadone in water and sediment extracts to express them in % AR as in the study report they were presented as % in the fraction.

The results obtained for Flufenacet were subjected to the kinetic analysis in order to derive the kinetic endpoints – DT₅₀ and DT₉₀ values for the dissipation/degradation of Flufenacet in the whole system and water phase.

The kinetic analysis was carried out using the approach developed by Timme and Frehse. As that approach is no longer considered valid in the EU for the purpose of the deriving the regulatory endpoints, RMS decided not to present the results of that analysis in the summary. The analysis of the same data, performed in line with the recommendation of FOCUS workgroup of the degradation kinetics, are presented in the *Study 3*.

The results obtained for the identified major degradation product – FOE Thiadone were not subjected to the kinetic analysis performed by the Applicant. RMS however is of the opinion that that analysis, and the kinetic endpoints in particular, is of the limited reliability because of too few data points representing the decline phase – one or two after maximum was reached, depending on the test system.

Conclusions of the study:

The examination of the transformation of Flufenacet in aerobic water/sediment system showed that that compound quite quickly degraded in that environment, forming one degradation degradation product – FOE Thiadone – the same as identified in other studies with Flufenacet radiolabelled in that position. The mechanism of dissipation from the water phase was mixed – the compound partly degraded in that phase, but also quite significant migration to the sediment phase, where it was degraded, was observed.

FOE Thiadone was found predominantly in water phase, but its presence in the sediment phase as well may indicate that it was possibly formed also, if not predominantly, in sediment and from there released to the water phase.

The data for Flufenacet was kinetically examined, but that assessment was performed not in line with the current requirements, so its results were not reported. The data were kinetically re-examined, in line with the current recommendations, in a separate study.

The kinetic analysis of the data for the identified degradation product – FOE Thiadone, could not be carried out because of the too few data points at the decline phase (one or two, depending on the test system).

On the basis of the results of the metabolite profiling the transformation scheme of Flufenacet in water/sediment system, determined for the part of the molecule containing the thiadiazole moiety was proposed. It is shown below on figure B.8.2.2.3._CA-12. It shall be indicated that the proposed transformation pathway may not fully cover all processes occurring within the thiadiazole moiety. That is due to the fact that the thiadiazole ring contains two possible radiolabelling positions – C2, examined in this study does, and C5, which was not covered by this study.

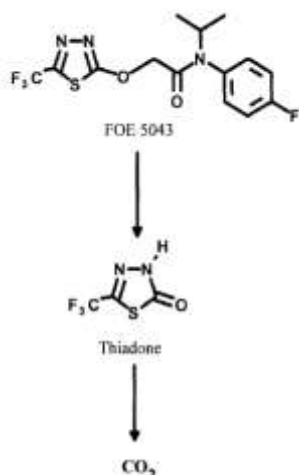

Figure B.8.2.2.3._CA-12: The postulated transformation pathway of Flufenacet in water/sediment system, determined for the part of the molecule containing the thiadiazole moiety (copied from the study report).

RMS, further analysing the proposed metabolic pathway, also in light of the results obtained in other studies aimed on the elucidation of the transformation pattern of Flufenacet within the thiadiazole moiety, came to the conclusions presented below.

It may be assumed, with high probability, that radiolabelling at C5 position would lead to the identification of at least one other major degradation product – TFA (Trifluoroacetic acid). That compound, as indicated by the results of the study on the degradation of Flufenacet at C5 in the thiadiazole ring, could be formed either directly from Flufenacet or from FOE Thiadone as its immediate precursor. That second option seems to be more probable in light of the results of this study – FOE Thiadone was observed in amounts well above 50% AR, up to ~85% AR. Therefore, on the analysis of the available results it may be anticipated that were the fate and behaviour in water/sediment system of [Thiadiazole-5-¹⁴C]Flufenacet examined using the same test systems, for the same study duration up to 50% AR could be observed in form of TFA. It cannot be excluded that for the study lasting longer than 156 days the amount of TFA formed in the test system could be even higher, up to 100% of the applied amount of the parent compound.

Also, taking into consideration the results of the transformation in water/sediment systems obtained for Flufenacet radiolabelled in phenyl ring, it cannot be excluded the formation of another, possibly major degradation product – TFESA.

However, all that theoretical analysis needs to be confirmed by the experimental data, hence in RMS's opinion the lack of the examination of the fate and behavior of [Thiadiazole-5-¹⁴C]Flufenacet (or FOE-Thiadone radiolabelled in the same position) should be considered as a potential data gap.

Study 3:

Report: Reinken G., Maassen K., (2014): “Kinetic Evaluation of Degradation and Dissipation Behaviour of Flufenacet and its Degradation Products in Water/Sediment Systems According to FOCUS Kineitics Using the KinGUI 2 Tool. Flufenacet (FOE 5043); FOE Methylsulfide; FOE-thiadone.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; Study report No. En-Sa-13-0973; 17. 02. 2014; study reference number: M-477845-01-1.

Guidelines: The study was performed to comply with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.”; Report of the Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005, version 2.0, 434 pp.;
- FOCUS (2011): “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies in EU Registration, version 1.0, 436 pp.

GLP: No, not required – modelling study;

RMS comments: This is a newly submitted study, evaluated for the purpose of the current assessment. RMS evaluated it for its compliance with the Guidelines listed as the reference Guidelines. The analysis was performed in line with the recommendations given by FOCUS Work Group on Degradation Kinetics. In case of the parent compound – Flufenacet, it was performed on the Level P-I for the whole system and for each compartment individually. That analysis was verified and was found acceptable by the RMS.

Due to the fact that the results of the kinetic analysis performed at Level P-I individually for each compartment were subsequently used as supporting information in the decision making process aimed on the determination of the appropriate kinetic endpoints to be used as input data in SW modelling, RMS decided to repeat the analysis at the Level P-II in order to verify the correctness of the Applicant’s proposal.

The results of the additional kinetic examination of the data performed by the RMS will be presented immediately below the presentation of the results of the kinetic analysis performed by the Applicant.

The kinetic analysis of the data for the two identified major degradation products – FOE Methylsulfide and FOE Thiadone, were performed at the Level M-I and for the whole system only. The fitting was performed for parent compound – Flufenacet, and for the given degradation product. The results of that analysis will be presented further down the summary, below the whole set of the results of the analysis for the parent compound performed by the Applicant and RMS.

The study, after the thorough examination, was found acceptable and is summarised below.

Summary:

The aim of the study was to perform the kinetic analysis of the data obtained for Flufenacet and its two major aquatic degradation products – FOE Methylsulfide and FOE Thiadone, in water/sediment systems examined in two different studies – by [Kelley et al; 1995] and by [Halarankar and Irwin; 1997], to obtain the kinetic endpoints representing persistence and those suitable for modelling exposure assessment.

The assessment was carried out for Flufenacet at the Level P-I and was aimed on the determination of the persistence endpoints as well as those suitable for SW modelling. The kinetic analysis of the data for the degradation products was performed at the Level M-I and was aimed on the determination of the kinetic endpoints for them.

The brief characteristic of the water/sediment test systems used in the source studies is presented below in the table B.8.2.2.3._CA-16.

Table B.8.2.2.3._CA-16: The brief characteristic of the water/sediment test systems used in data-source studies.

Compartment	Parameter	Study by [Kelley et al.; 1995]		Study by [Halarnkar and Irwin; 1997]	
		Test system: NESAs	Test system: BRP	Test system: NESAs	Test system: BRP

Footnotes to the table:

1) DAT stands for “Days After Treatment”;

The data presented in the above tables were subjected to a multistep evaluation procedure performed in line with the recommendations of FOCUS Kinetics Guidelines [FOCUS; 2006].

For the parent compound it was performed at the Level P-I and consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data, separately for each compartment, using following, 1st - order, kinetic models: SFO, FOMC, DFOP and HS, and KinGUI 2 as a modelling tool. That step consisted of the three sub-steps:
 - **Sub-step 1:** kinetic evaluation of the data for the whole system;
 - **Sub-step 2:** kinetic evaluation of the data for the water phase alone;
 - **Sub-step 3:** kinetic evaluation of the data for the sediment phase alone using the top-down approach and the data set limited to the time points after the maximum was reached;
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The raw input data for Flufenacet, presented in tables B.8.2.2.3._CA-17 – B.8.2.2.3._CA-20, were processed following the recommendations given by FOCUS. In general terms it looked as follows:

- The total AR recovery recorded in DAT-0 samples was used as concentration of Flufenacet at that time point, but the M_0 value was allowed to be estimated by the model;
- Values between LOD and LOQ were set to measured values;
- All single values <LOD or the non-detects (n. d.) were set to ½LOD. The same procedure was applied to the first appearances. However, when the values <LOD/n.d. appeared consecutively for second and next times, the kinetic curve was cut off until the appearance of the first value >LOQ;
- Sampling times for sediment phases were shifted, starting with the time point DAT 0 at the day of the maximum measured concentration of Flufenacet.
- For the whole system the pre-processed values in water and sediment compartments were summed up and used as the input.

The processed values used as input data for the kinetic examination are presented below in two separate tables – in the table B.8.2.2.3._CA-21 for the results from the study by [Kelley et al.; 1995] and in the table B.8.2.2.3._CA-22 for those obtained in the study by [Halarnkar and Irwin; 1997]. In case of the values <LOD they were set to NaN (“Not a Number” – KinGUI default when numbers are not available).

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure was a two-stage one. At first stage – **Step 1**, the performance of the two kinetic models – SFO and FOMC, was examined. In case the SFO returned visually and statistically better results than FOMC, the fitting exercise was stopped at that stage. In case however FOMC returned better fit The Applicant passed to the second stage – **Step 2**. At this stage two additional bi-phasic models – DFOP and HS, were tested.

It shall be indicated that the analysis at both stages was performed in order to derive the persistence endpoints, while the determination of the modelling endpoints focused rather on the results of **Step-1** analysis.

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis, comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

Characterising the whole procedure the Applicant stated at the beginning that it is generally preferred to select the simplest kinetic model with a high goodness of fit. That principle was followed when the assessment of the results obtained at the **Step 1** of kinetic analysis of the data was carried out.

Characterising the adopted approach to the visual assessment of the fit, considered to be the first step in the evaluation, the Applicant stated that it focused on the following features:

- the conformity of the fitted decline curve with measured residue concentrations;
- the distribution of the residuals, which should be random and not systematic;
- level of residuals, which should be as small as possible – in such case even if their distribution is rather systematic, the fit may be still qualified as acceptable.

Based on these criteria the fit could be classified as:

- **good fit**, when the conformity of the kinetic curve and measured residues was good, levels of residuals were low, they were randomly scattered and no obvious systematic deviation in residual plot was visible;
- **acceptable fit**, when the conformity of the kinetic curve and measured residues was acceptable, levels of residuals were medium and they were more-or-less randomly scattered, and the absolute level of residuals was low;
- **poor fit**, when the fitted decline curve significantly deviated from the measured residues and did not match the observed pattern, the level of residuals was high and they were clearly not randomly scattered around zero line.

Characterising the next component of the assessment – χ^2 -error statistics, the Applicant indicated that 15% threshold value was not considered to be an absolute cut-off criterion. It was therefore indicated that in some cases, even though χ^2 -error > 15%, the fit may be acceptable, in particular for the deradation products.

Finally, characterising the t-test, the Applicant stated that the t-test probability of 0.05 was sufficiently small and should be used as acceptability criterion, in case however of degradation products, or the results of field dissipation studies the $prob > t$ value of 0.10 or even higher may be still acceptable.

On that basis the following multistep assessment procedure was followed:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in as persistence and modelling endpoints, two kinetic models were tested – SFO and FOMC for passing the acceptance criteria (visually acceptable, χ^2 -error not exceeding, or not significantly exceeding, 15%, $prob. > t$ value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the SFO model passed the acceptance criteria and returned statistically and visually better fit than FOMC, it was considered the appropriate fit and the fitting procedure was terminated there;
- **Step 3:** if at the **Step-2** FOMC model was identified as returning better fit than SFO two additional bi-phasic models were introduced; these were DFOP and, possibly HS; they were then assessed for passing the acceptance criteria (visually acceptable, χ^2 -error not exceeding, or not significantly exceeding, 15%, $prob. > t$ value in t-test less than 0.05). The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved and fully reliable fit, SFO model was selected if visually acceptable. That was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test system.

- 1) The kinetic evaluation of the data obtained in the test system NESA treated with [Phenyl-U-¹⁴C]Flufenacet (study by [Kelley et al.; 1995]):

The results of the fitting are presented below, individually for each compartment.

a) Whole system:

The kinetic analysis of the whole-system data for Flufenacet was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-13 and the numerical results in the table B.8.2.2.3._CA-23. Additionally, in the table B.8.2.2.3._CA-24 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

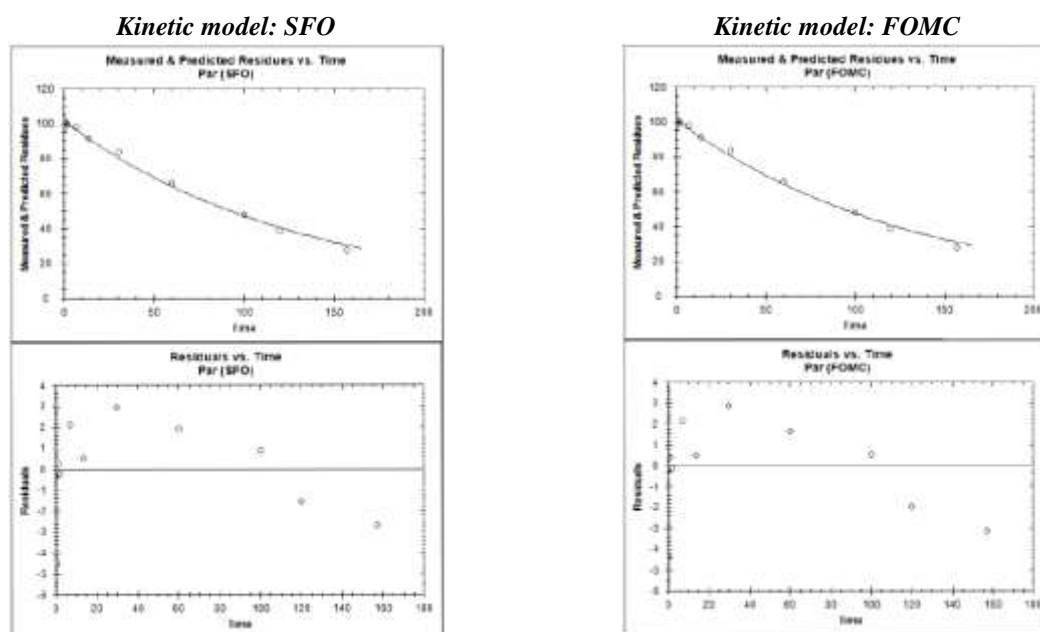

Figure B.8.2.2.3._CA-13: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-23: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	101.30	0.979	99.39	103.23	1.87 E-15	2.185	Good fit
	k	0.00767	2.72 E-4	0.00714	0.008	2.13 E-10		
FOMC	M ₀	101.15	1.065	99.07	103.20	8.42 E-14	2.306	Good fit
	α	331.79	329.80	-314.61	978.20	0.172		
	β	43732.09	43494.68	-41515.92	128980.10	0.172		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-24: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	90.34	91.46
	DT ₉₀ [days]	300.10	304.60

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in the whole water/sediment system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the whole water/sediment system and suitable to derive the input values for modelling, is following: the rate of degradation $k = 0.00767$ [days⁻¹], $DT_{50} = 90.34$ days, $DT_{90} = 300.10$ [days], kinetic model: **SFO**.

b) Water phase:

The kinetic analysis of the data for Flufenacet in the water phase was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-14 and the numerical results in the table B.8.2.2.3._CA-25. Additionally, in the table B.8.2.2.3._CA-26 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

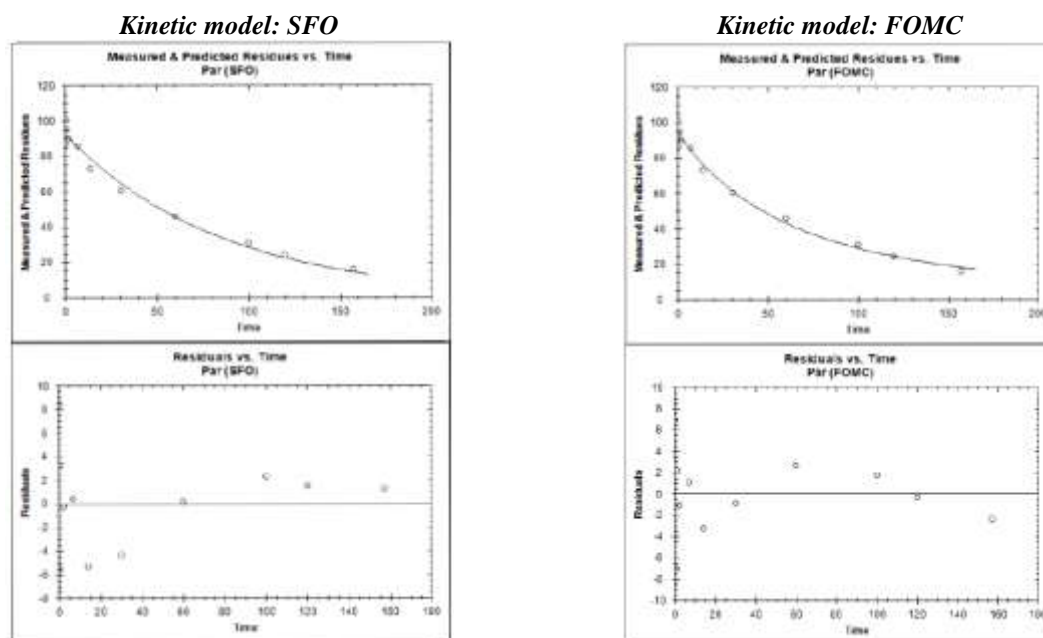

Figure B.8.2.2.3._CA-14: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-25: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	92.45	1.925	88.68	96.23	1.84 E-12	4.936	Good fit
	k	0.0118	0.000868	0.0101	0.014	1.31 E-7		
FOMC	M_0	93.96	2.351	89.36	98.57	8.44 E-11	4.519	Good fit
	α	2.179	1.599	-0.954	5.313	0.105		
	β	139.359	131.199	-117.787	396.504	0.160		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-26: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	58.72	52.18
	DT ₉₀ [days]	195.10	261.50

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in the water phase of the test system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase, is following: the rate of degradation $k = 0.0118 \text{ [days}^{-1}\text{]}$, DT₅₀ = **58.72 days**, DT₉₀ = **195.10 [days]**, kinetic model: **SFO**. The Applicant also proposed to consider them as reliable modelling endpoints. RMS however noticed that the dissipation of Flufenacet from the water phase comprised both degradation of that compound and its migration to the sediment phase. The experiments on abiotic degradation of Flufenacet in water – aqueous hydrolysis and photolysis, showed that these processes contributed only to the limited extent to the degradation of Flufenacet in water, the only really relevant process being indirect photolysis. Also the biologically-mediated degradation in that compartment was demonstrated to be slow. On that basis it shall be indicated that without further verification the Applicant's proposal with regard to the suitability of the derived kinetic endpoints for modelling cannot be accepted. That verification was performed by the RMS and its results are presented further down this summary.

c) Sediment:

The kinetic analysis of the data for Flufenacet in the sediment phase was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-15 and the numerical results in the table B.8.2.2.3._CA-27. Additionally, in the table B.8.2.2.3._CA-28 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

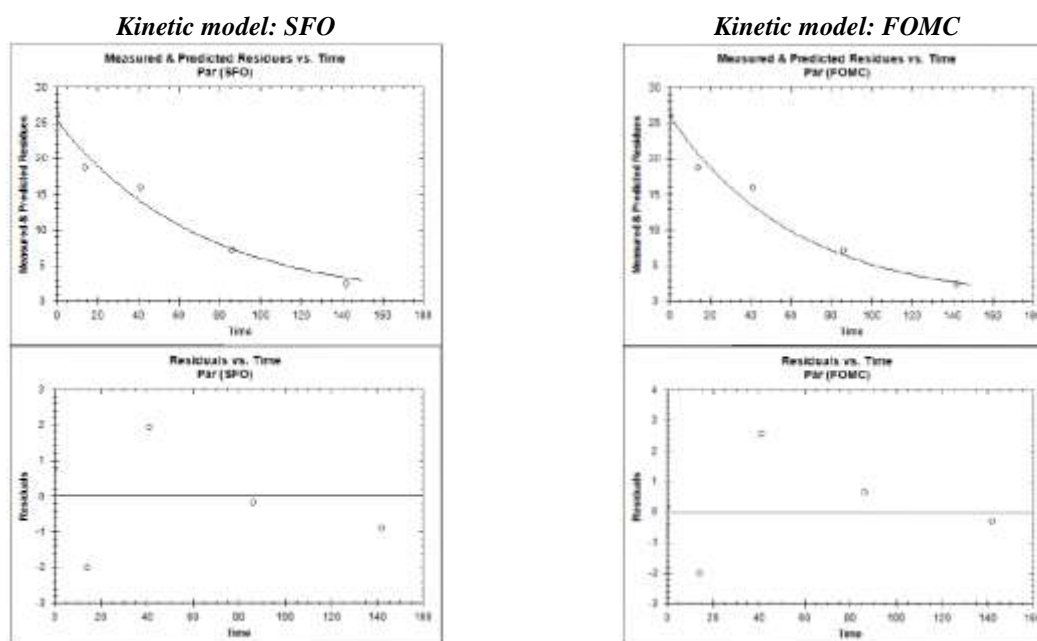

Figure B.8.2.2.3._CA-15: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-27: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	23.23	0.491	22.27	24.19	1.04 E-4	2.079	Good fit
	k	0.00493	0.000343	0.00426	0.006	0.000366		
FOMC	M ₀	23.66	0.585	22.51	24.80	0.000305	2.925	Poor fit
	α	371.30	811.200	-1219.00	1961.28	0.3460		
	β	6921.00	151300.00	-227400.00	365801.00	0.3461		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-28: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	140.50	129.30
	DT ₉₀ [days]	466.80	430.50

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in sediment phase of the test system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS conforms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase, is following: the rate of degradation $k = 0.00493$ [days⁻¹], DT₅₀ = 140.50 days, DT₉₀ = 466.80 [days], kinetic model: SFO. The Applicant also proposed to consider them as reliable modelling endpoints. RMS however is of the opinion that that proposal may require further verification. That verification was performed by the RMS and its results are presented further down this summary.

Conclusions:

The kinetic analysis performed at the Level P-I of the data obtained for Flufenacet, radiolabelled in fluorophenyl ring, in the NESA water sediment system resulted in the following set of the kinetic endpoints:

- for the whole system: the rate of degradation $k = 0.00767$ [days⁻¹], DT₅₀ = 90.34 days, DT₉₀ = 300.10 [days], kinetic model: SFO; the kinetic endpoints represent the persistence of Flufenacet in that compartment and are suitable to derive the input values for SW modelling;
- for the water phase: the rate of degradation $k = 0.0118$ [days⁻¹], DT₅₀ = 58.72 days, DT₉₀ = 195.10 [days], kinetic model: SFO; the kinetic endpoints represent the persistence of Flufenacet in that compartment;
- for the sediment phase: the rate of degradation $k = 0.00493$ [days⁻¹], DT₅₀ = 140.50 days, DT₉₀ = 466.80 [days], kinetic model: SFO; the kinetic endpoints represent the persistence of Flufenacet in that compartment.

- 2) The kinetic evaluation of the data obtained in the test system **BRP** treated with [Phenyl-U-¹⁴C]Flufenacet (study by [Kelley et al.; 1995]):

The results of the fitting are presented below, individually for each compartment.

- a) Whole system:

The kinetic analysis of the whole-system data for Flufenacet was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-16 and the numerical results in the table B.8.2.2.3._CA-29. Additionally, in the table B.8.2.2.3._CA-30 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

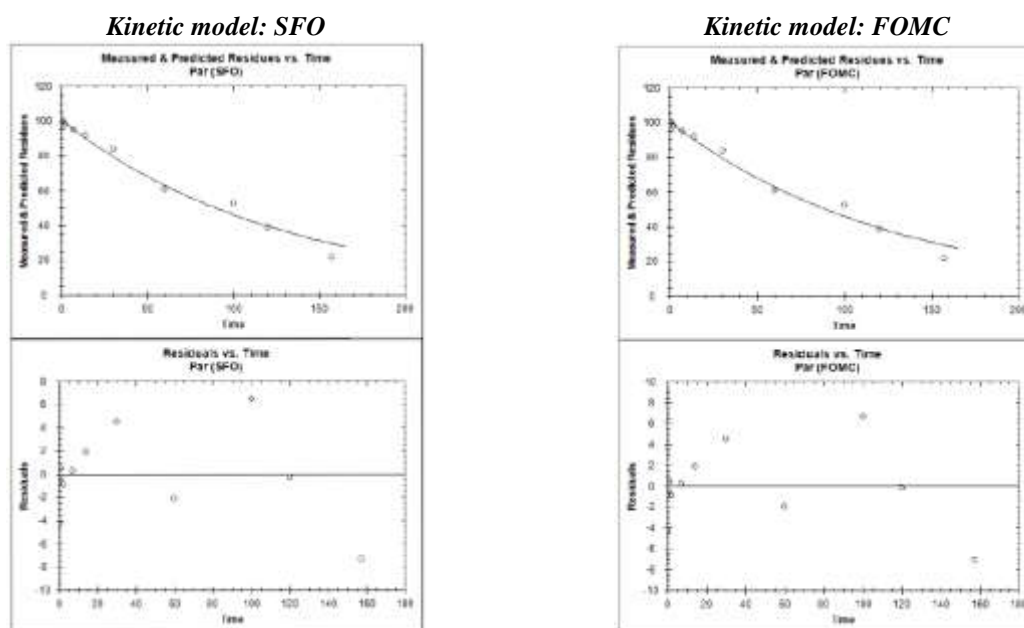

Figure B.8.2.2.3._CA-13: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-29: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-30: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	89.00	88.48
	DT ₉₀ [days]	295.70	294.80

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in the whole water/sediment system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the whole water/sediment system and suitable to derive the input values for modelling, is following: the rate of degradation $k = 0.00779$ [days⁻¹], $DT_{50} = 89.00$ days, $DT_{90} = 295.70$ [days], kinetic model: **SFO**.

b) Water phase:

The kinetic analysis of the data for Flufenacet in the water phase was carried out using all four models – SFO, FOMC, DFOP and HS. Its graphical results are presented on figure B.8.2.2.3._CA-17 and the numerical results in the table B.8.2.2.3._CA-31. Additionally, in the table B.8.2.2.3._CA-32 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-32: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
Flufenacet	DT_{50} [days]	40.89	31.23	31.50	35.94
	DT_{90} [days]	135.80	211.00	171.60	156.80

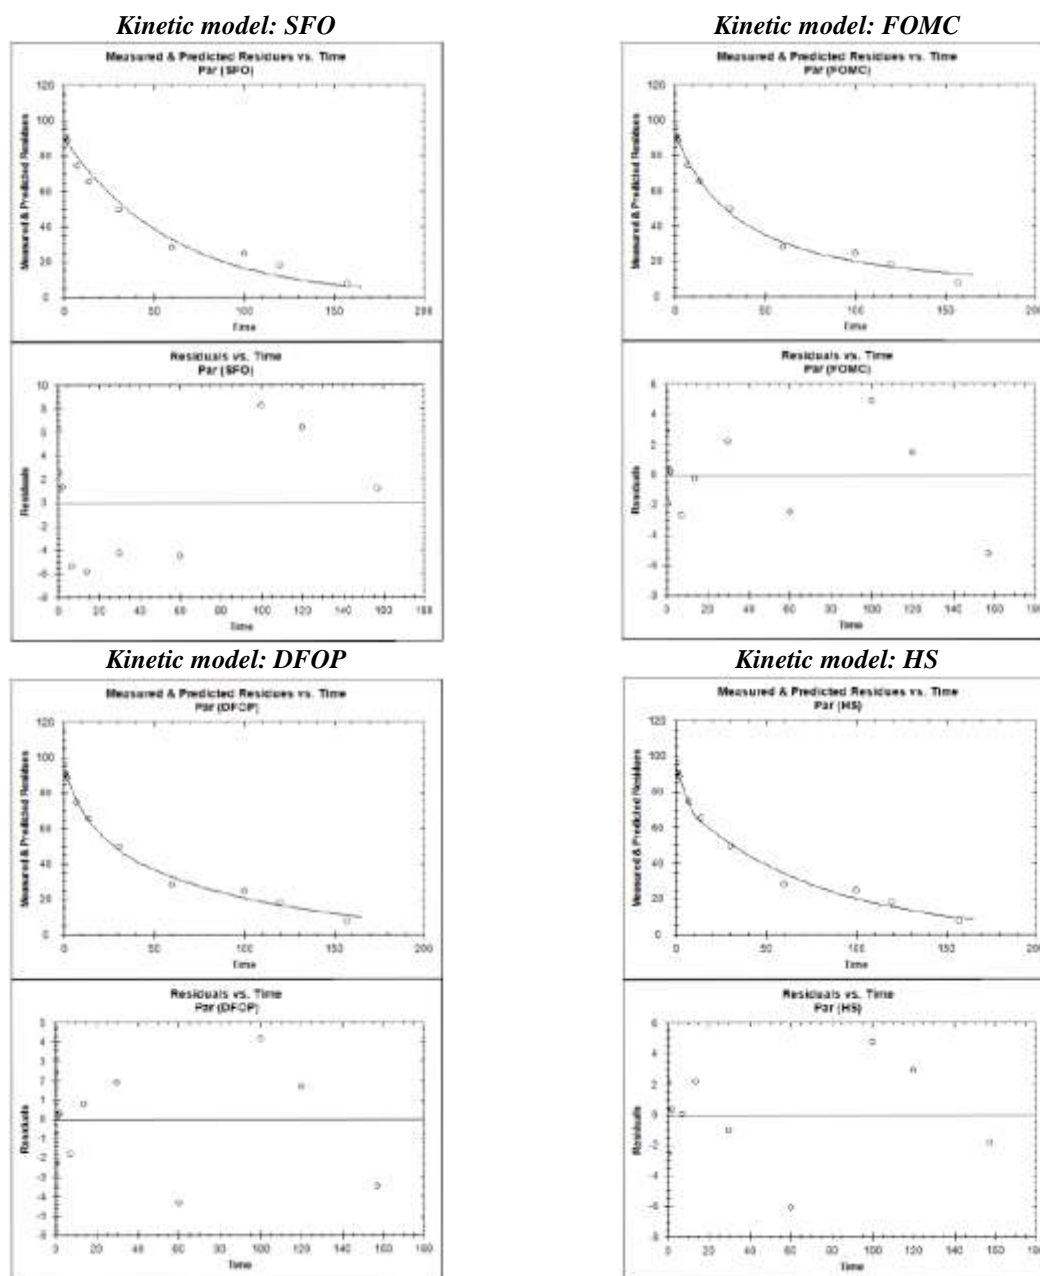

Figure B.8.2.2.3_CA-17: The graphical results of the kinetic analysis (copied from the study report).

Evaluation:

The Applicant stated when the data were fitted using the SFO and FOMC models, FOMC returned statistically better results – the χ^2 error was lower. It shall be indicated that both models tested returned reliable kinetic parameters. As a result, two additional bi-phasic models were tested – DFOP and HS. They both returned statistically better fits, that with the lowest χ^2 error being DFOP. However, the kinetic parameters returned by DFOP model were not fully reliable – the rate constant k_1 did not pass the acceptability criterion of the t-test. In case of the remaining kinetic fits the determined kinetic parameters were fully reliable. Therefore, although the Applicant indicated it as returning the best fit because of the lowest value of the χ^2 error, it cannot be considered such.

The analysis of the results performed by the RMS showed that of the three, the best in statistical terms was FOMC fit with χ^2 error being the lowest – 4.041. The Applicant indicated that the FOMC cannot be used in case

the final concentration is >10% of the initial. RMS checked that and stated that at the last time point – DAT 157, the concentration of Flufenacet in water phase was 7.53% AR. Therefore the FOMC fit shall be considered as returning the best fit.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase is following: parameters of the kinetic curve – $\alpha = 1.339$, $\beta = 46.0745$, **DT₅₀ = 31.23 days**, **DT₉₀ = 211.00 [days]**, kinetic model: **FOMC**. These parameters represent solely the dissipation of Flufenacet from the water phase.

c) Sediment:

The kinetic analysis of the data for Flufenacet in the sediment phase was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-18 and the numerical results in the table B.8.2.2.3._CA-33. Additionally, in the table B.8.2.2.3._CA-34 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

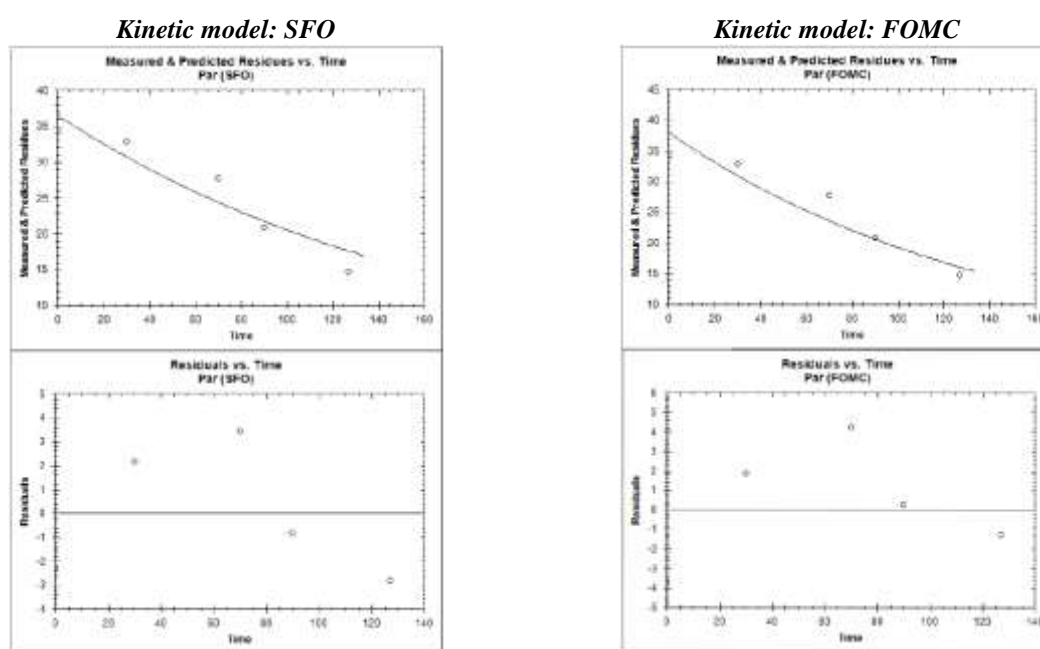

Figure B.8.2.2.3._CA-18: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-33: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	36.45	2.666	31.22	41.67	0.000423	7.534	Not given (RMS: intermediate)
	k	0.00575	0.00122	0.00336	0.008	0.009191		
FOMC	M ₀	37.94	2.630	32.79	43.09	0.00238	9.553	Not given (RMS: intermediate)
	α	354.24	839.61	-1291.36	1999.84	0.3571		
	β	52143.93	123698.30	-190300.00	294588.00	0.3572		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-34: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	120.50	102.10
	DT ₉₀ [days]	400.20	340.00

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in sediment phase of the test system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase, is following: the rate of degradation $k = 0.005754$ [days⁻¹], $DT_{50} = 120.50$ days, $DT_{90} = 400.20$ [days], kinetic model: **SFO**. The Applicant also proposed to consider them as reliable modelling endpoints. RMS however is of the opinion that that proposal may require further verification. That verification was performed by the RMS and its results are presented further down this summary.

Conclusions:

The kinetic analysis performed at the Level P-I of the data obtained for Flufenacet, radiolabelled in fluorophenyl ring, in the BRP water sediment system resulted in the following set of the kinetic endpoints:

- for the whole system: the rate of degradation $k = 0.00779$ [days⁻¹], $DT_{50} = 89.00$ days, $DT_{90} = 295.70$ [days], kinetic model: **SFO**; the kinetic endpoints represent the persistence of Flufenacet in that compartment and are suitable to derive the input values for SW modelling;
- for the water phase: parameters of the kinetic curve – $\alpha = 1.339$, $\beta = 46.0745$, $DT_{50} = 31.23$ days, $DT_{90} = 211.00$ [days], kinetic model: **FOMC**; the kinetic endpoints represent the persistence of Flufenacet in that compartment;
- for the sediment phase: the rate of degradation $k = 0.005754$ [days⁻¹], $DT_{50} = 120.50$ days, $DT_{90} = 400.20$ [days], kinetic model: **SFO**; the kinetic endpoints represent the persistence of Flufenacet in that compartment.

- 3) The kinetic evaluation of the data obtained in the test system NESA treated with [Thiadiazole-2-¹⁴C]Flufenacet (study by [Halarnkar and Irwin; 1997]):

The results of the fitting are presented below, individually for each compartment.

a) Whole system:

The kinetic analysis of the whole-system data for Flufenacet was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-19 and the numerical results in the table B.8.2.2.3._CA-35. Additionally, in the table B.8.2.2.3._CA-36 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

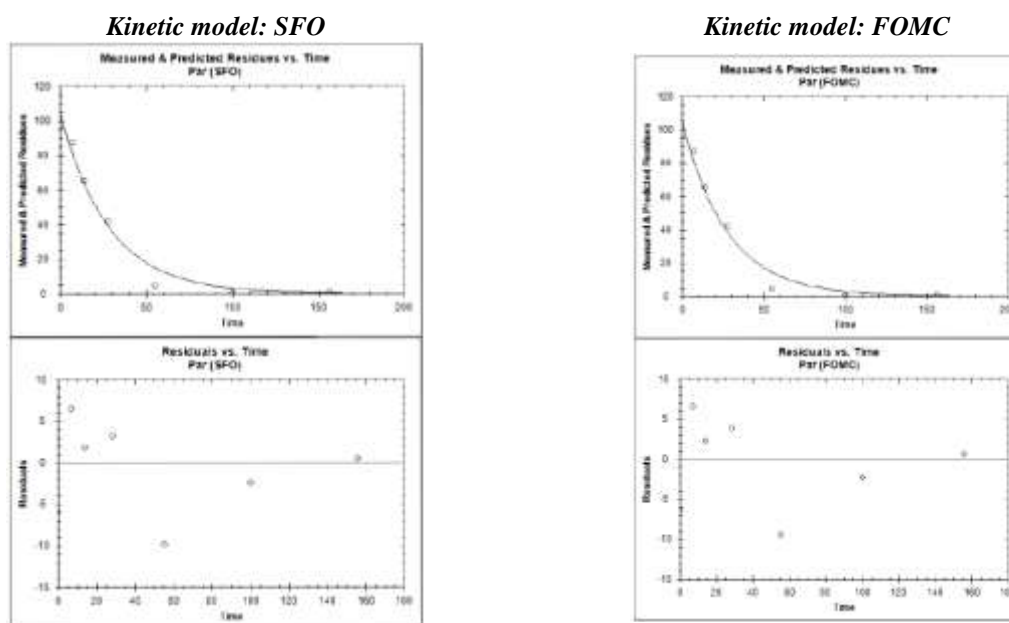

Figure B.8.2.2.3._CA-19: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-35: The numerical results of the kinetic analysis.

SFO	M ₀	103.80	5.138	93.74	113.88	2.75 E-6	9.836	Good
	k	0.03525	0.00408	0.02726	0.043	0.000171		
FOMC	M ₀	104.30	4.097	96.26	112.30	7.07 E-6	10.67	Good
	α	853.00	3829.00	-6652.00	8357.50	0.417		
	β	23710.00	106600.00	-185200.00	232598.50	0.417		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-36: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	19.67	19.28
	DT ₉₀ [days]	65.33	64.09

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in the whole water/sediment system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the whole water/sediment system and suitable to derive the input values for modelling, is following: the rate of degradation $k = 0.03525$ [days⁻¹], $DT_{50} = 19.67$ days, $DT_{90} = 65.33$ [days], kinetic model: SFO.

b) Water phase:

The kinetic analysis of the data for Flufenacet in the water phase was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-20 and the numerical results in the table B.8.2.2.3._CA-37. Additionally, in the table B.8.2.2.3._CA-38 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

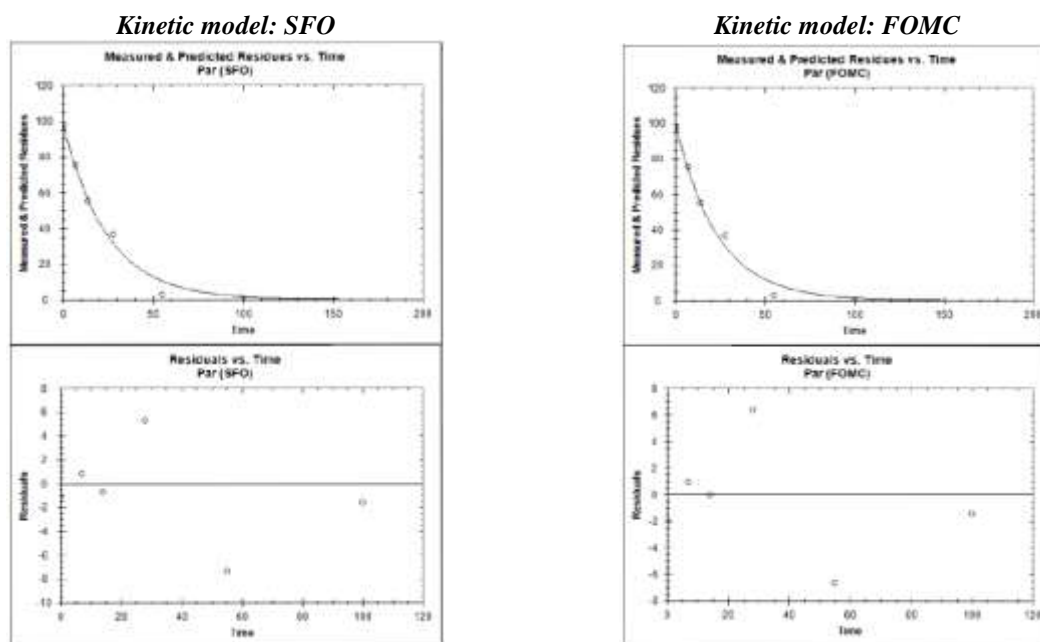

Figure B.8.2.2.3._CA-20: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-37: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	98.98	4.047	91.04	106.91	8.29 E-6	6.823	Good fit
	k	0.04083	0.003883	0.03321	0.048	0.000231		
FOMC	M_0	99.88	3.887	92.26	107.50	6.45 E-5	7.673	Good fit
	α	1272.00	9015.00	-16400.00	18941.80	0.448		
	β	29990.00	212700.00	-386800.00	446782.70	0.448		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-38: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	16.98	16.34
	DT ₉₀ [days]	56.40	54.33

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in the water phase of the test system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase, is following: the rate of degradation $k = 0.04083 \text{ [days}^{-1}\text{]}$, DT₅₀ = 16.98 days, DT₉₀ = 56.40 [days], kinetic model: SFO. The Applicant also proposed to consider them as reliable modelling endpoints. RMS however noticed that the dissipation of Flufenacet from the water phase comprised both degradation of that compound and its migration to the sediment phase. The experiments on abiotic degradation of Flufenacet in water – aqueous hydrolysis and photolysis, showed these processes contributed only to the limited extent to the degradation of Flufenacet in water, the only really relevant process being indirect photolysis. Also the biologically-mediated degradation in that compartment was demonstrated to be slow. On that basis it shall be indicated that without further verification the Applicant's proposal with regard to the suitability of the derived kinetic endpoints for modelling cannot be accepted. That verification was performed by the RMS and its results are presented further down this summary.

c) Sediment:

The kinetic analysis of the data for Flufenacet in the sediment phase was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-21 and the numerical results in the table B.8.2.2.3._CA-39. Additionally, in the table B.8.2.2.3._CA-40 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

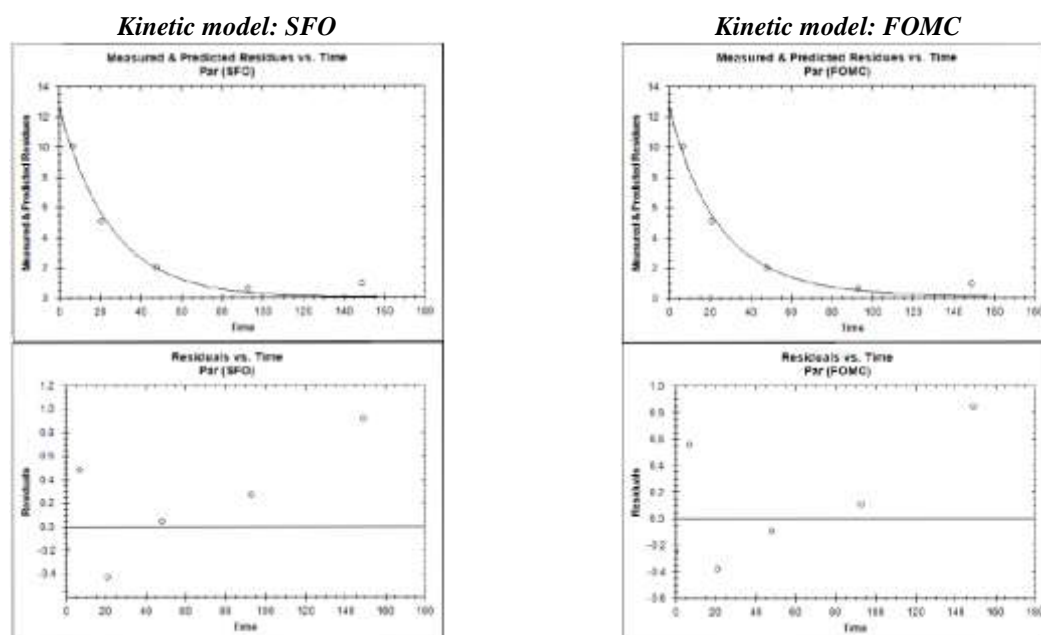

Figure B.8.2.2.3._CA-21: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-33: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	12.61	0.516	11.60	13.63	8.3 E-6	7.312	Good
	k	0.03929	0.004253	0.03095	0.048	0.000382		
FOMC	M ₀	12.67	0.571	11.55	13.79	0.0010	7.726	Good
	α	9.590	1.094	7.446	11.73	0.001564		
	β	230.119	0.9171	228.322	231.92	6.98 E-8		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-34: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	17.64	17.25
	DT ₉₀ [days]	58.61	62.45

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in sediment phase of the test system. RMS analysing the results stated that both fits returned fully reliable parameters and very similar kinetic curves, therefore the factor indicating the prevalence of SFO over FOMC is the level of the χ^2 error, slightly lower in case of SFO fit (7.312 for SFO and 7.726 for FOMC). Using that criterion, in line with the recommendations of FOCUS, RMS is of the opinion that the decision made by the Applicant is correct.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase, is following: the rate of degradation $k = 0.03929$ [days⁻¹], DT₅₀ = 17.64 days, DT₉₀ = 58.61 days, kinetic model: SFO. The Applicant also proposed to consider them as reliable modelling endpoints. RMS however is of the opinion that that proposal may require further verification. That verification was performed by the RMS and its results are presented further down this summary.

Conclusions:

The kinetic analysis performed at the Level P-I of the data obtained for Flufenacet, radiolabelled at C2 in the thiadiazole ring, in the NESA water sediment system resulted in the following set of the kinetic endpoints:

- for the whole system: the rate of degradation $k = 0.03525$ [days⁻¹], DT₅₀ = 19.67 days, DT₉₀ = 65.33 [days], kinetic model: SFO; the kinetic endpoints represent the persistence of Flufenacet in that compartment and are suitable to derive the input values for SW modelling;
- for the water phase: the rate of degradation $k = 0.04083$ [days⁻¹], DT₅₀ = 16.98 days, DT₉₀ = 56.40 [days], kinetic model: SFO; the kinetic endpoints represent the persistence of Flufenacet in that compartment;
- for the sediment phase: the rate of degradation $k = 0.03929$ [days⁻¹], DT₅₀ = 17.64 days, DT₉₀ = 58.61 [days], kinetic model: SFO; the kinetic endpoints represent the persistence of Flufenacet in that compartment.

- 4) The kinetic evaluation of the data obtained in the test system **BRP** treated with [Thiadiazole-2-¹⁴C]Flufenacet (study by [Halarnkar and Irwin; 1997]):

The results of the fitting are presented below, individually for each compartment.

a) Whole system:

The kinetic analysis of the whole-system data for Flufenacet was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-22 and the numerical results in the table B.8.2.2.3._CA-41. Additionally, in the table B.8.2.2.3._CA-42 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

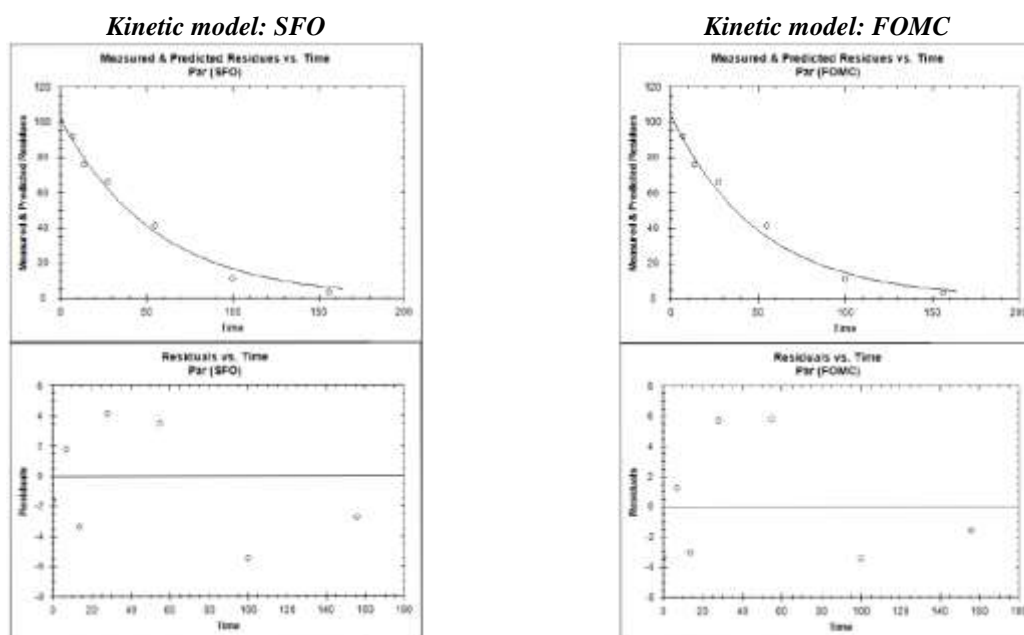

Figure B.8.2.2.3._CA-22: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-41: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	102.10	2.916	96.43	107.86	1.78 E-7	4.933	Good
	k	0.01819	0.001368	0.01551	0.021	2.15 E-5		
FOMC	M ₀	103.90	3.133	97.73	110.00	2.47 E-6	5.894	Good
	α	1685.00	3272.00	-4727.00	8097.30	0.317		
	β	85590.00	166200.00	-240200.00	411424.00	0.317		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-42: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT ₅₀ [days]	38.11	35.22
	DT ₉₀ [days]	126.60	117.00

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in the whole water/sediment system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the whole water/sediment system and suitable to derive the input values for modelling, is following: the rate of degradation $k = 0.01819$ [days⁻¹], $DT_{50} = 38.11$ days, $DT_{90} = 126.60$ [days], kinetic model: **SFO**.

b) Water phase:

The kinetic analysis of the data for Flufenacet in the water phase was carried out using all four models – SFO, FOMC, DFOP and HS. Its graphical results are presented on figure B.8.2.2.3._CA-23 and the numerical results in the table B.8.2.2.3._CA-43. Additionally, in the table B.8.2.2.3._CA-44 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

Table B.8.2.2.3._CA-43: The numerical results of the kinetic analysis.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
Flufenacet	DT_{50} [days]	23.84	18.86	18.55	19.76
	DT_{90} [days]	79.20	100.30	94.25	91.63

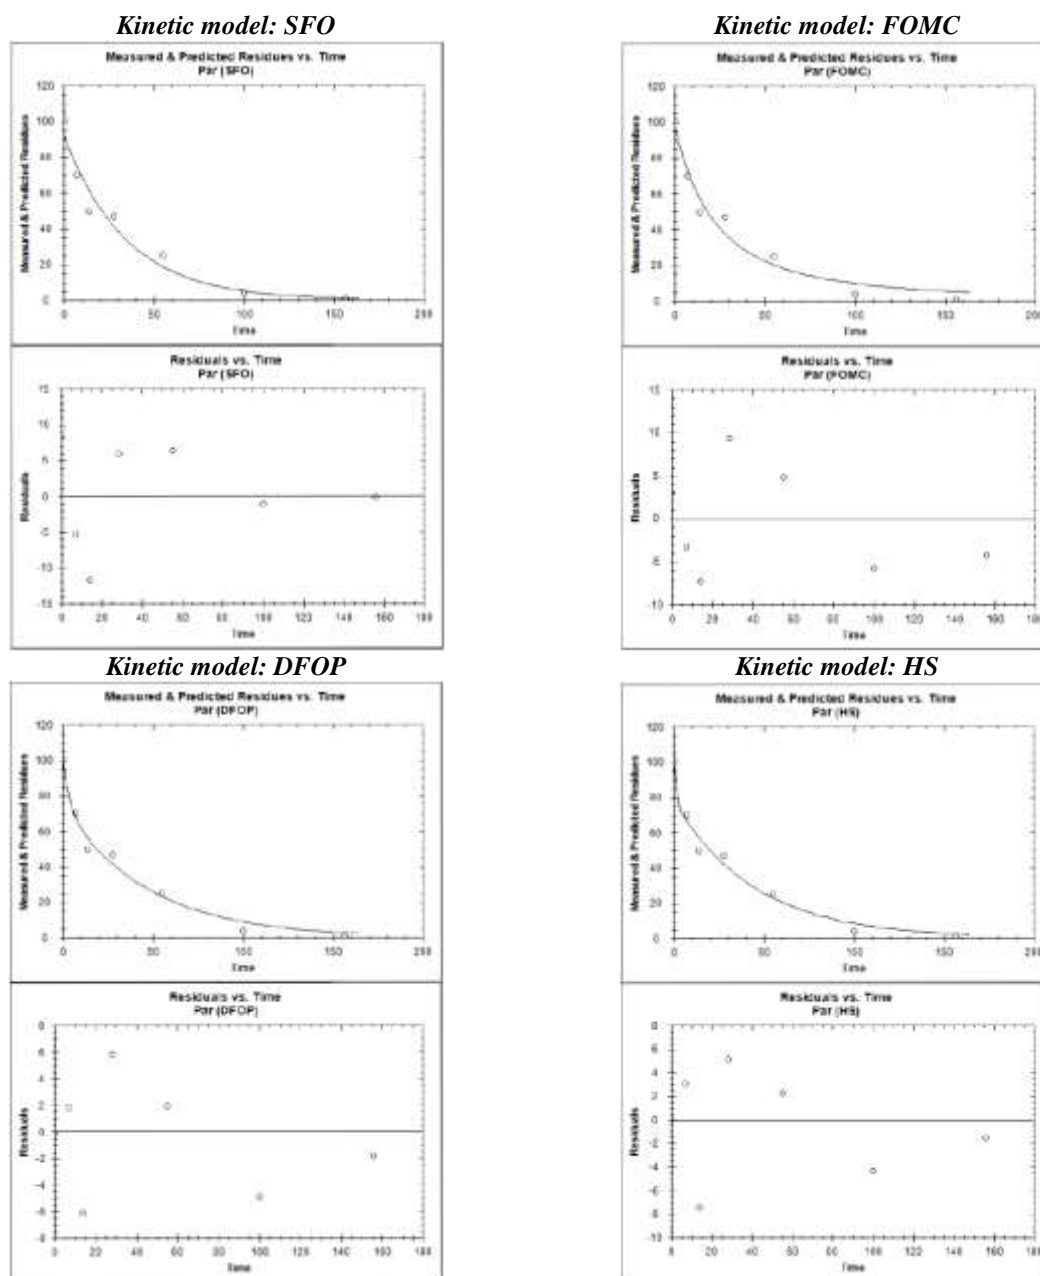

Figure B.8.2.2.3_CA-23: The graphical results of the kinetic analysis (copied from the study report).

Evaluation:

The Applicant stated when the data were fitted using the SFO and FOMC models, FOMC returned statistically better results – the χ^2 error was lower. For that reason the Applicant tested two additional bi-phasic models – DFOP and HS. RMS analysing the results of the fitting noticed that although all bi-phasic models returned statistically better fits than SFO none of them can be considered acceptable because of the lack of reliability of the kinetic parameters. In case of FOMC fit for both α and β the CI passed through zero. DFOP cannot be considered acceptable because of the lack of reliability of k_1 and g – they did not pass the acceptability criterion of the t-test. Similar problem was observed for HS fit in which of k_1 and t_b did not pass the acceptability criterion of the t-test.

Therefore the fit adequately characterising the persistence of Flufenacet in the water phase in that experiment is SFO. The Applicant proposed to consider as such the DFOP displaying the good visual fit and the lowest χ^2 error, but that fit cannot be taken into account because the lack of reliability of the kinetic parameters.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase is following: the rate of degradation $k = 0.02908 \text{ [days}^{-1}\text{]}$, $DT_{50} = 23.84 \text{ days}$, $DT_{90} = 79.20 \text{ [days]}$, kinetic model: **SFO**. These parameters represent solely the dissipation of Flufenacet from the water phase.

c) Sediment:

The kinetic analysis of the data for Flufenacet in the sediment phase was carried out using two kinetic models – SFO and FOMC. Its graphical results are presented on figure B.8.2.2.3._CA-24 and the numerical results in the table B.8.2.2.3._CA-45. Additionally, in the table B.8.2.2.3._CA-46 are provided the kinetic endpoints returned by the modelling tool for each kinetic model.

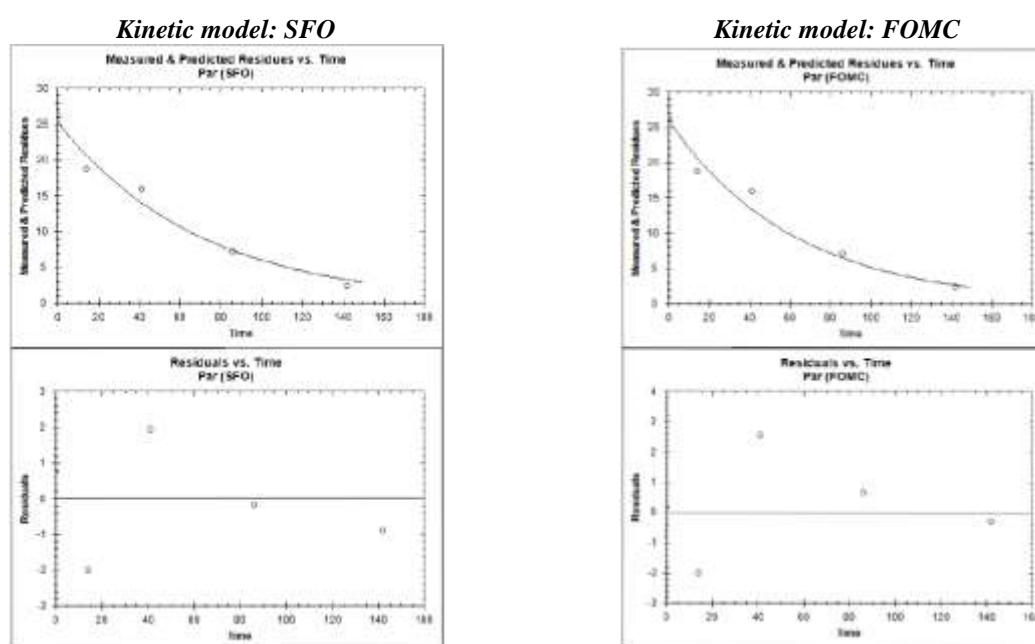

Figure B.8.2.2.3._CA-24: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-45: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	25.35	1.445	22.52	28.18	0.000202	7.738	Good
	k	0.01447	0.002028	0.01049	0.018	0.002835		
FOMC	M_0	25.94	1.677	22.66	29.23	0.00208	9.698	Good
	α	304.90	1069.00	-1790.00	2399.51	0.4011		
	β	18870.00	66290.00	-111100.00	148797.30	0.4014		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-46: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
Flufenacet	DT_{50} [days]	47.91	42.94
	DT_{90} [days]	159.10	143.00

Evaluation:

The Applicant stated that the SFO model returned visually and statistically better fit, therefore it was selected as adequately representing the kinetic behaviour of Flufenacet in sediment phase of the test system. RMS analysing the result noticed that FOMC fit cannot be considered acceptable, because it returned the kinetic parameters that were not reliable – for both α and β the CI passed through zero. Therefore RMS confirms the correctness of the decision made by the Applicant.

The definitive set of the kinetic endpoints determined for this experiment, representing the persistence of Flufenacet in the water phase, is following: the rate of degradation $k = 0.01447$ [days⁻¹], $DT_{50} = 47.91$ days, $DT_{90} = 159.10$ [days], kinetic model: **SFO**. The Applicant also proposed to consider them as reliable modelling endpoints. RMS however is of the opinion that that proposal may require further verification. That verification was performed by the RMS and its results are presented further down this summary.

Conclusions:

The kinetic analysis performed at the Level P-I of the data obtained for Flufenacet radiolabelled in fluorophenyl ring in the BRP water sediment system resulted in the following set of the kinetic endpoints:

- for the whole system: the rate of degradation $k = 0.01819$ [days⁻¹], $DT_{50} = 38.11$ days, $DT_{90} = 126.60$ [days], kinetic model: **SFO**; the kinetic endpoints represent the persistence of Flufenacet and are suitable to derive the input values for SW modelling;
- for the water phase: the rate of degradation $k = 0.02908$ [days⁻¹], $DT_{50} = 23.84$ days, $DT_{90} = 79.20$ [days], kinetic model: **SFO**; the kinetic endpoints represent the persistence of Flufenacet;
- for the sediment phase: the rate of degradation $k = 0.01447$ [days⁻¹], $DT_{50} = 47.91$ days, $DT_{90} = 159.10$ [days], kinetic model: **SFO**; the kinetic endpoints represent the persistence of Flufenacet.

The Applicant indicated that the persistence endpoints determined for Flufenacet in water and sediment phases of each test system may also be considered the modelling endpoints.

As subsequently the Applicant proposed to consider for SW model exposure assessment the geomean whole system DT_{50} values as representing the degradation of Flufenacet in water phase, attributing the default value $DT_{50} = 1000$ days to degradation in sediment phase, RMS performed the additional kinetic analysis of the data for Flufenacet in water and sediment phases in line with the principles of the Level P-II analysis. The aim of that additional kinetic analysis was to check whether dissipation from the water phase can be attributed wholly to degradation, or it is a mixed process in which migration to the sediment phase plays an important role. It is presented below.

Additional kinetic analysis of the data for Flufenacet performed by the RMS

The aim of the kinetic analysis was to determine, by means of the kinetic examination of the data, which processes are responsible for the dissipation of Flufenacet from the water phase in water/sediment studies. The analysis was carried out in a way characterised as Level P-II analysis in the FOCUS Kinetics Guidance Document – the results for water phase and sediment phase were kinetically examined in one fitting exercise.

The not-processed input data used in that analysis were presented in this summary, in the tables B.8.2.2.3._CA-17 – B.8.2.2.3._CA-20. For the purpose of the fitting they were processed in line with the procedure outlined on pp. 1231 – 1233. For completeness the non-processed and processed data used as the input in the kinetic analysis are presented below in the table B.8.2.2.3._CA-47. As the concentrations in sediment in the fitting corresponded to the “A 1” compartment, RMS set the DAT-0 concentration to zero. The concentration in water phase was adjusted to the whole-system concentration on DAT 0. These values are:

- for NESA test system in the study by [Kelley et al.; 1995]: 98.4% AR;
- for BRP test system in the study by [Kelley et al.; 1995]: 95.5% AR;
- for NESA test system in the study by [Halarnkar and Irwin; 1997]: 94.2% AR;
- for BRP test system in the study by [Halarnkar and Irwin; 1997]: 96.3% AR;

Table B.8.2.2.3._CA-47: The not processed and pre-processed data obtained in the studies examining degradation in water/sediment systems, used as input in kinetic analysis.

Footnotes to the table:

1) DAT stands for “Days After Treatment”;

The pre-processed data presented in the tables above were subjected to the kinetic analysis in line with the recommendations of FOCUS Kinetics Guideline [FOCUS; 2006] for the fitting of the data at the Level P-II. The kinetic analysis was performed using CAKE ver. 3.1 modelling tool, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The settings of the optimiser were the defaults of the tool:

- maximum iterations: 100,
- maximum reweighing: 10,
- SANN maximum iterations: 10000,
- convergence tolerance: 1 E-5,
- error variance tolerance: 1 E-5,
- extra solver: yes, if required.

The whole analysis consisted of the following steps:

- **Step 1:** Processing of the raw input data, presented above;
- **Step 2:** Kinetic evaluation of the processed data for water and sediment phases kinetically fitted together, the using CAKE ver. 3.1 modelling tool; for water phase, representing in the fitting the “Parent” compartment, three kinetic models – SFO, FOMC and DFOP, were used, while for the sediment,

representing in the fitting the “A1” compartment, only SFO model was tested; the conceptual scheme used in the fitting (copied as a screenshot from the modelling tool) is presented below on figure B.8.2.2.3_CA-25;

- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results.

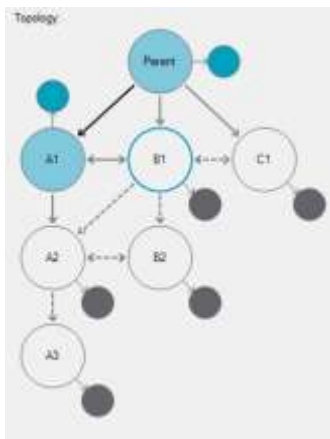

Figure B.8.2.2.3_CA-25: The conceptual scheme used in the kinetic analysis of the data for Flufenacet obtained in the water/sediment studies, performed by the RMS.

The obtained results of the kinetic analysis of the data were evaluated by means of a detailed statistical analysis, comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

It followed the principles outlined on pages 1231-1233.

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test system.

- 1) The results of the kinetic analysis of the data for Flufenacet at the Level P-II obtained for NESA test system treated with [Phenyl- $U-^{14}C$]Flufenacet (study by [Kelley et al.; 1995]):

The kinetic analysis was performed for the results obtained in water and sediment compartments fitted together, as shown on figure B.8.2.2.3_CA-25. For the results obtained in water phase, defined in the fitting as “parent” compartment, the fitting was performed using three kinetic models – SFO, FOMC and DFOP. The results obtained in the sediment phase were kinetically analysed using solely SFO kinetic model, due to the fact that in the conceptual model within the tool they were defined as the compartment “A1”. The results of the fitting are presented below, individually for each combination of the kinetic models.

a) Fitting using the SFO as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-26 and in the numerical form in the table B.8.2.2.3._CA-48.

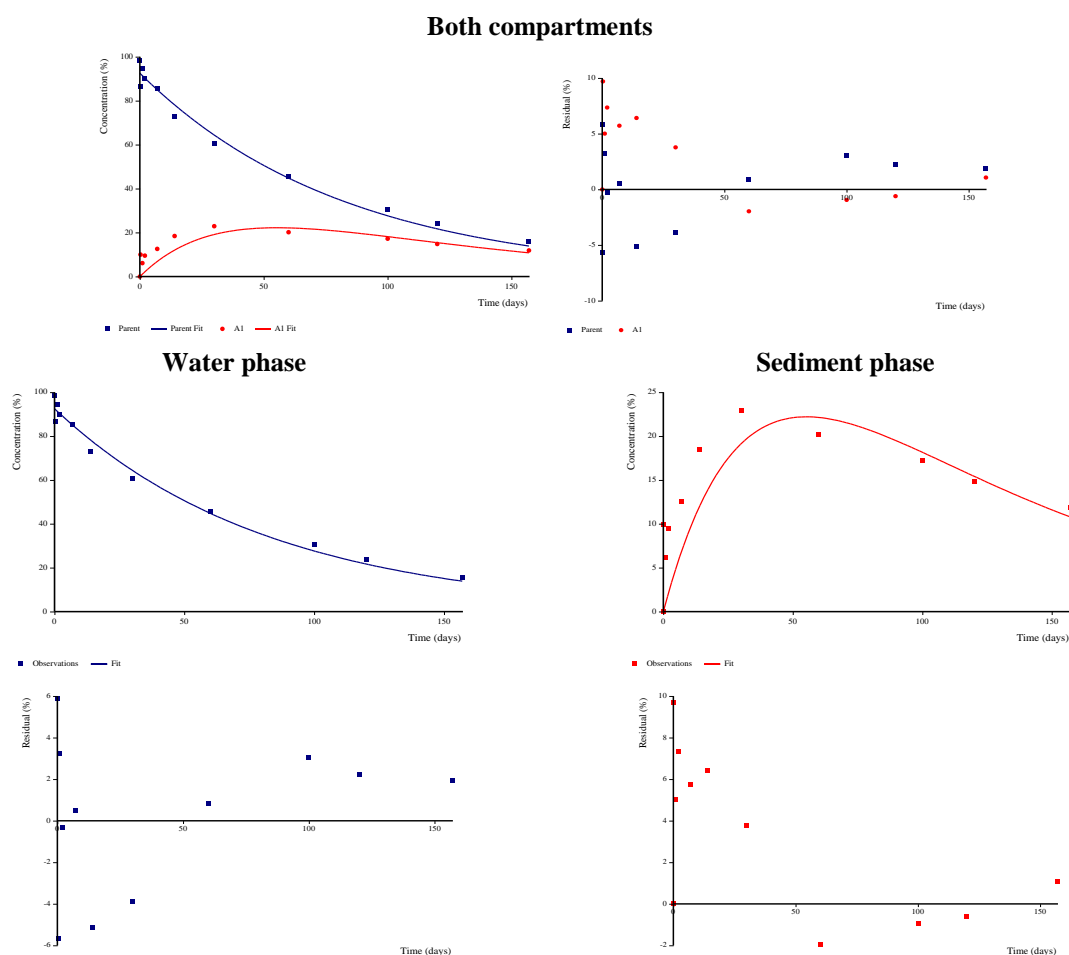

Figure B.8.2.2.3._CA-26: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Kelley et al.; 1995], using SFO model for water phase.

Table B.8.2.2.3._CA-48: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Kelley et al.; 1995], using SFO model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	SFO	M_0	92.53	1.767	89.46	95.6	----	4.44	Good fit; R = 0.986
		k	0.01208	7.91 E-4	0.01071	0.01346	1.16 E-11		
Sediment phase	SFO	M_0	0.00	----	----	----	----	28.9	Acceptable fit; R = 0.780
		k	0.02581	9.72 E-3	8.90 E-3	0.04272	8.33 E-3		
		ff	1.00	0.311	0.4586	1.541	----		

b) Fitting using the FOMC as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-27 and in the numerical form in the table B.8.2.2.3._CA-49.

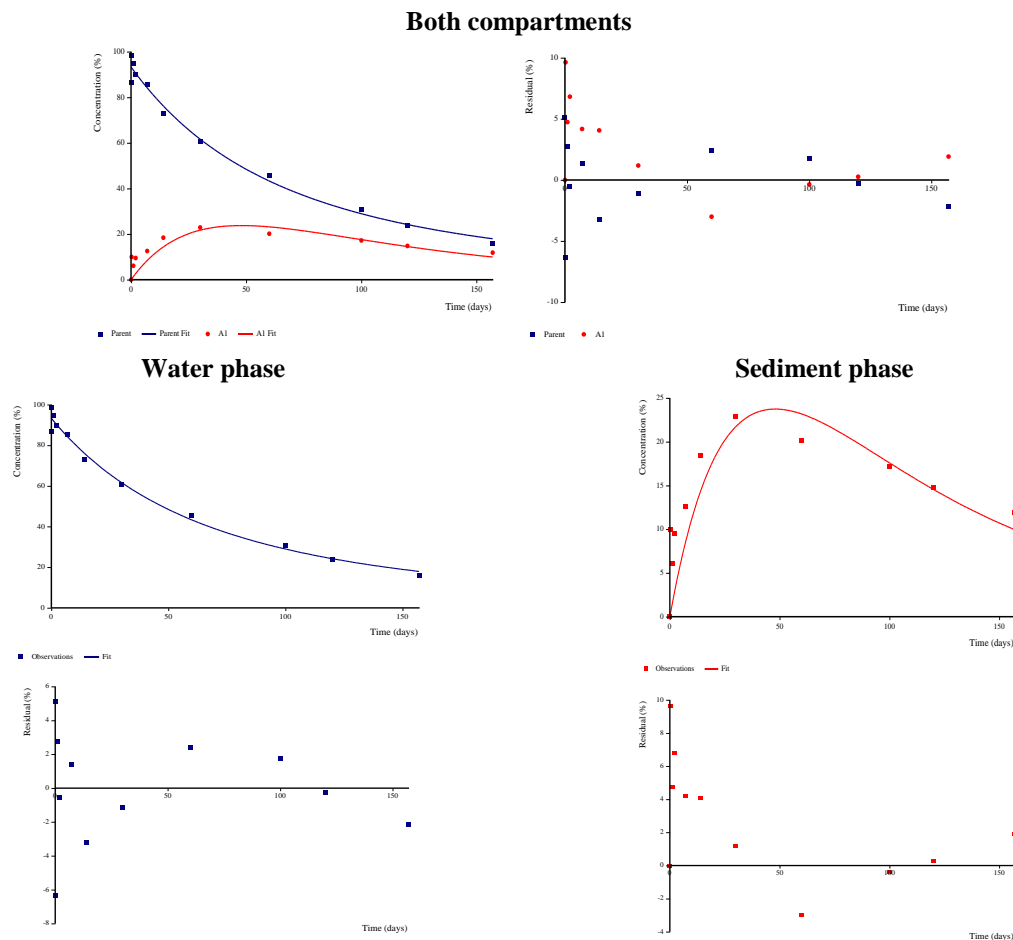

Figure B.8.2.2.3._CA-27: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Kelley et al.; 1995], using FOMC model for water phase.

Table B.8.2.2.3._CA-49: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Kelley et al.; 1995], using FOMC model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	FOMC	M_0	93.31	1.778	90.21	96.41	----	3.98	Good fit; R = 0.9891
		α	2.404	1.474	-0.1689	4.978	----		
		β	159.4	121.8	-53.23	372.1	----

		ff	0.9998	0.2801	0.5108	1.489	----		

c) Fitting using the DFOP as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-28 and in the numerical form in the table B.8.2.2.3._CA-50.

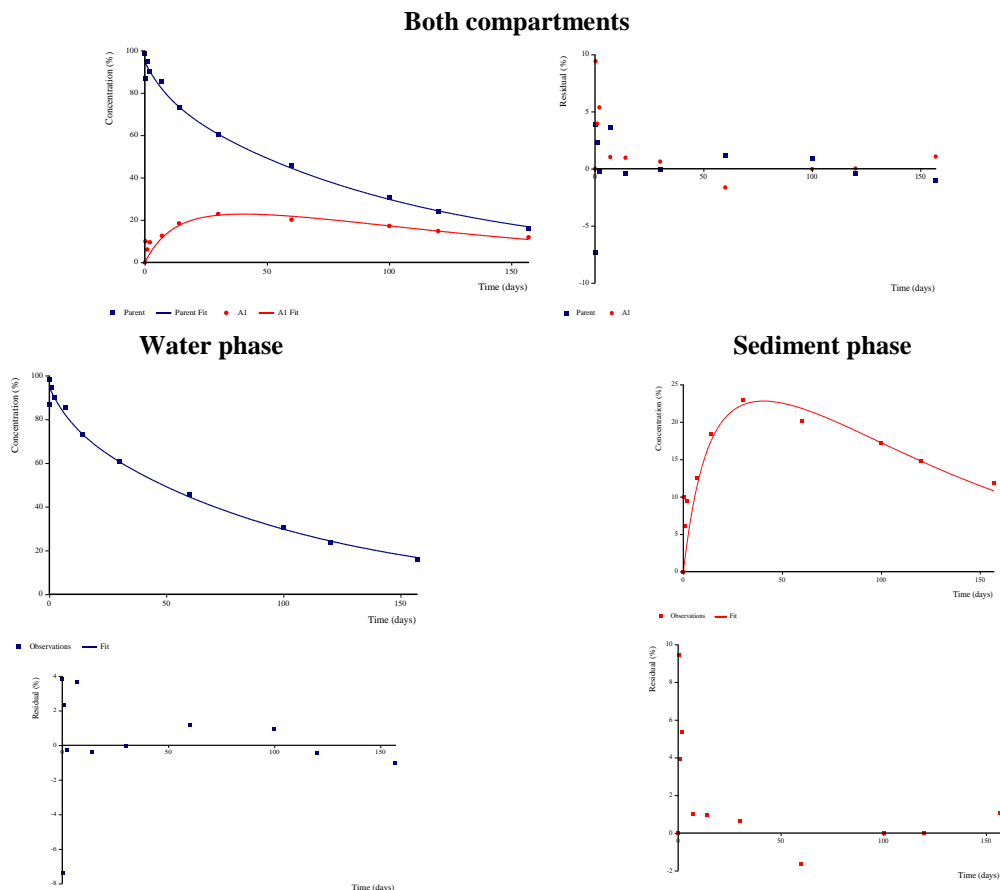

Figure B.8.2.2.3._CA-28: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Kelley et al.; 1995], using DFOP model for water phase.

Table B.8.2.2.3._CA-50: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Kelley et al.; 1995], using DFOP model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	DFOP	M_0	94.54	2.008	91.02	98.05	----	3.98	Good fit; $R = 0.990$
		k_1	0.1089	0.09423	-0.05628	0.2741	0.1329		
		k_2	0.01002	1.266 E-3	7.801 E-3	0.01224	4.89 E-7		
		g	0.1421	0.0821	-1.83 E-3	0.286	----		
Sediment phase	SFO	M_0	0.00	----	---	----	----	20.9	Good fit; $R = 0.876$
		k	0.02452	7.35 E-3	0.01164	0.03741	2.256 E-3		
		ff	1.00	0.2408	0.5779	1.422	----		

Evaluation of the fits:

Of the three tested options DFOP-SFO returned the best fits for both phases in visual and statistical terms. The improvement was observed already for the combination FOMC-SFO, what may indicate that the dissipation of Flufenacet from water phase may follow bi-phasic pattern. While the kinetic fit for the water phase was visually and statistically acceptable for all three kinetic models used, it was not possible to obtain the fully acceptable fit, mainly in statistical terms, for any of the options tested. The lowest χ^2 error for the fit representing the kinetic behaviour of Flufenacet in sediment phase, also the best visually, was obtained in combination with DFOP for water phase. It shall be indicated that none of the bi-phasic models tested for water phase returned reliable kinetic parameters. Therefore SFO-SFO fit shall be regarded as appropriate description of kinetic behaviour of Flufenacet in water and sediment compartments. For the water phase the kinetic model identified as returning the best fit is the same as indicated by the Applicant in the kinetic examination carried out at the Level P-I.

The kinetic endpoints obtained for each tested combination are presented below in the table B.8.2.2.3._CA-51.

Table B.8.2.2.3._CA-51: The kinetic endpoints obtained in the fitting for each combination of the kinetic models.

Compartment	Kinetic endpoint	Kinetic model tested for water phase:		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>Water phase</i>	DT ₅₀ [days]	57.4	53.3	54.0
	DT ₉₀ [days]	191	256	215
<i>Sediment phase (SFO model used only)</i>	DT ₅₀ [days]	26.9	28.7	28.3
	DT ₉₀ [days]	89.2	95.2	93.9
	Kinetic formation fraction <i>ff</i>	1.00	0.9998	1.00

Analysing the values of the kinetic formation fractions – *ff*, representing here the flow from water to the sediment phase, RMS noticed that for all three combinations of the kinetic models tested they were very close or equal to 1. That may indicate that the dominant mechanism of dissipation of Flufenacet from water phase is its migration to sediment. Therefore the kinetic parameters determined for Flufenacet in water phase in that test system should be regarded as persistence endpoints not to be used in modelling.

The comparison of the results obtained for Flufenacet in water phase by RMS and the Applicant showed, that they were very similar. For that reason RMS decided to keep as reliable the values determined by the Applicant.

The kinetic endpoints determined in this fitting exercise for the sediment phase lacked the reliability due to the rather poor fitting. For that reason RMS decided to consider the values determined by the Applicant as reliable kinetic characteristic of the persistence of Flufenacet in sediment phase.

Finally, in RMS's opinion the results of this fitting, and in particular that of *ff* (representing the flow from water to sediment compartment), clearly indicate that the whole system DT₅₀ value is more appropriate for SW modelling at higher tiers as representing the degradation in the sediment phase. Therefore the appropriate value for SW modelling at higher tiers as representing the degradation in water will be DT₅₀ = 1000 days (FOCUS default).

- 2) The results of the kinetic analysis of the data for Flufenacet at the Level P-II obtained for BRP test system treated with [Phenyl-U-¹⁴C]Flufenacet (study by [Kelley et al.; 1995]):

The kinetic analysis was performed for the results obtained in water and sediment compartments fitted together, as shown on figure B.8.2.2.3._CA-25. For the results obtained in water phase, defined in the fitting as “parent” compartment, the fitting was performed using three kinetic models – SFO, FOMC and DFOP. The results obtained in the sediment phase were kinetically analysed using solely SFO kinetic model, due to the fact that in the conceptual model within the tool they were defined as the compartment “A1”. The results of the fitting are presented below, individually for each combination of the kinetic models.

a) Fitting using the SFO as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-29 and in the numerical form in the table B.8.2.2.3._CA-52.

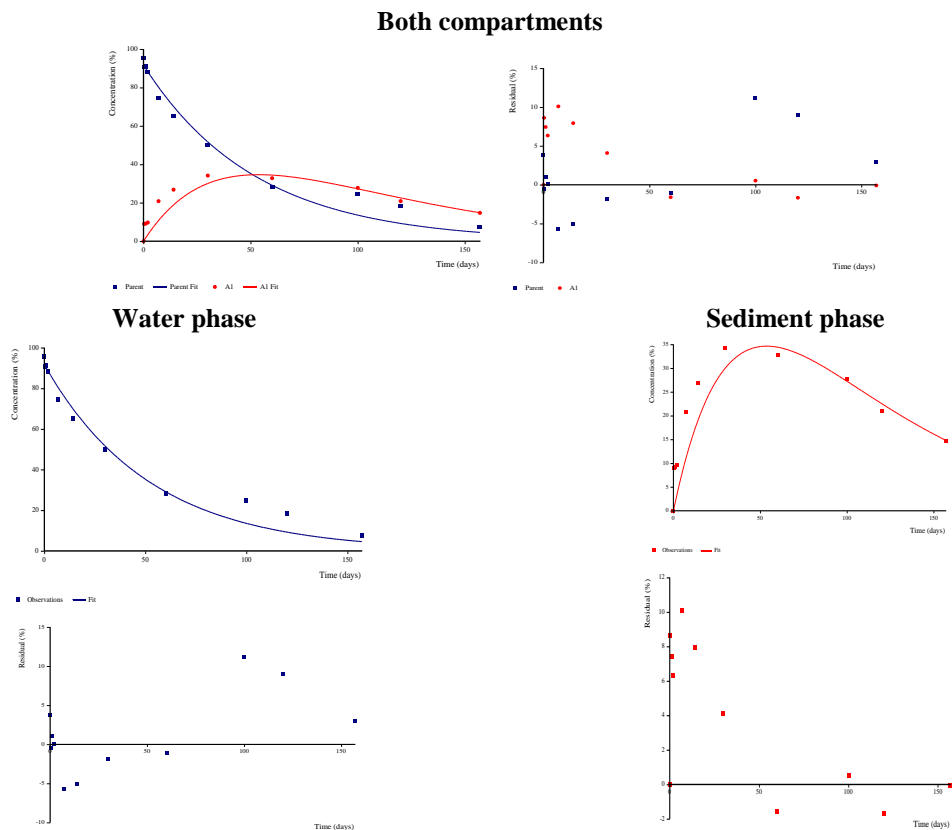

Figure B.8.2.2.3._CA-29: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Kelley et al.; 1995], using SFO model for water phase.

Table B.8.2.2.3._CA-52: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Kelley et al.; 1995], using SFO model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	SFO	M_0	91.69	2.728	86.94	96.43	----	12.1	Good fit; R = 0.983
		k	0.001911	2.02 E-3	0.01559	0.02262	1.73 E-8		
Sediment phase	SFO	M_0	0.00	----	----	----	----	23.3	Acceptable fit; R = 0.879
		k	0.01811	5.21 E-3	9.04 E-3	0.02718	0.001457		
		ff	1.00	0.229	0.6012	1.399	----		

b) Fitting using the FOMC as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-30 and in the numerical form in the table B.8.2.2.3._CA-53.

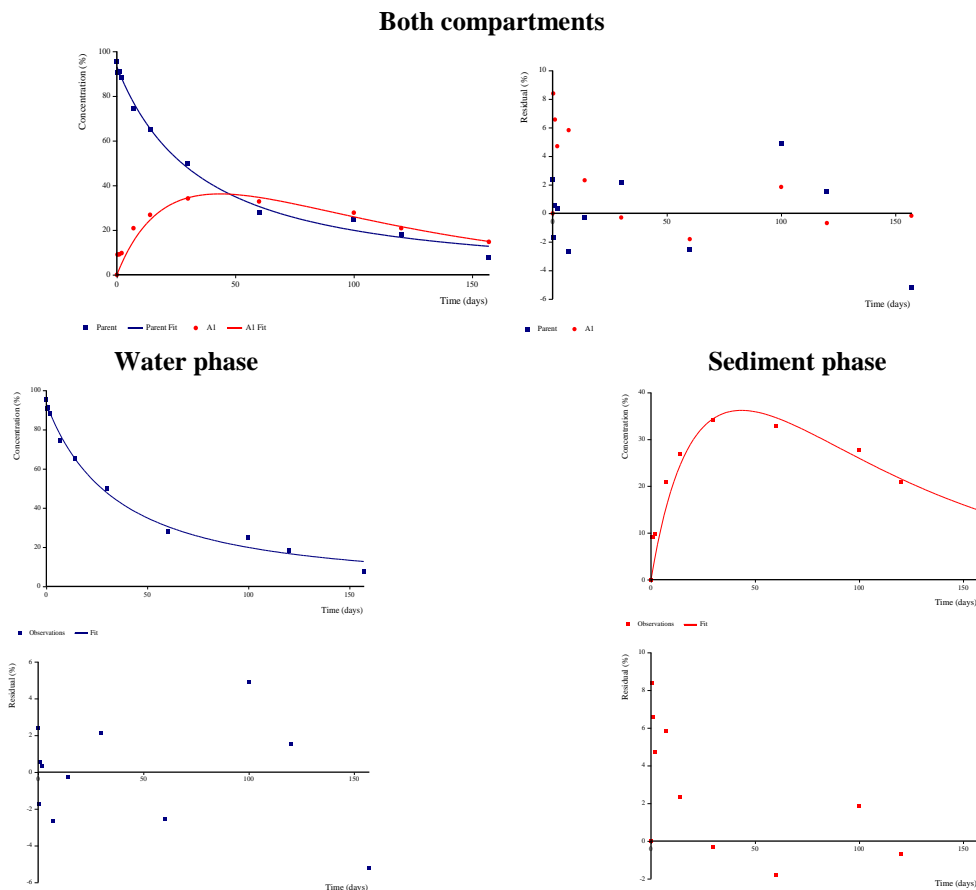

Figure B.8.2.2.3._CA-30: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Kelley et al.; 1995], using FOMC model for water phase.

Table B.8.2.2.3._CA-53: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Kelley et al.; 1995], using FOMC model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	FOMC	M_0	93.1	1.706	90.12	96.08	----	3.96	Good fit; $R = 0.9902$
		α	1.357	0.344	0.7558	1.958	----		
		β	47.19	17.98	15.8	78.57	----

		k	0.01589	3.355 E-3	0.01003	0.02175	1.12 E-4		
		ff	1.00	0.151	0.7364	1.264	----		

c) Fitting using the DFOP as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-31 and in the numerical form in the table B.8.2.2.3._CA-54.

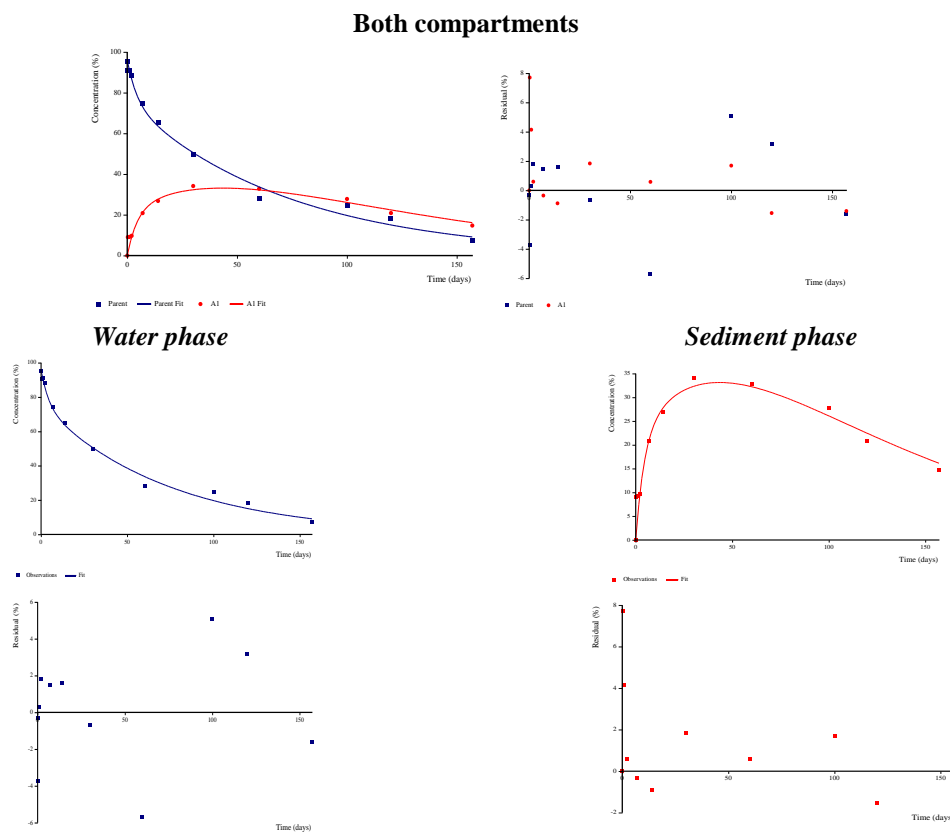

Figure B.8.2.2.3._CA-31: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Kelley et al.; 1995], using DFOP model for water phase.

Table B.8.2.2.3._CA-54: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Kelley et al.; 1995], using DFOP model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	DFOP	M_0	95.79	2.155	92.01	99.57	----	4.47	Good fit; $R = 0.992$
		k_1	0.2243	0.1009	0.04744	0.4011	0.02099		
		k_2	0.01346	0.00135	0.01109	0.01583	2.60 E-8		
		g	0.2103	0.05249	0.1183	0.3023	----		
Sediment phase	SFO	M_0	0.00	----	----	----	----	11.6	Good fit; $R = 0.951$
		k	0.01714	0.002905	0.01204	0.02223	1.46 E-5		
		ff	1.00	0.1323	0.7681	1.232	----		

Evaluation of the fits:

Of the three tested options DFOP-SFO returned the best fits for both phases in visual and statistical terms. The improvement was observed already for the combination FOMC-SFO, what may indicate that the dissipation of Flufenacet from water phase may follow bi-phasic pattern. While the kinetic fit for the water phase was visually and statistically acceptable for all three kinetic models used, it was not possible to obtain the fully acceptable fit, mainly in statistical terms, for the combinations SFO-SFO and FOMC-SFO. Only the combination DFOP-SFO returned visually and statistically acceptable fits for both water and sediment phase. At the same time it shall be indicated that the DFOP fit for water phase cannot be considered acceptable because of the lack of reliability of the determined kinetic parameters – k_1 in particular. Therefore, as the combination FOMC-SFO returned the fits visually and statistically better than the combination SFO-SFO, and the kinetic parameters of the fits were acceptable, it shall be regarded as appropriate description of kinetic behaviour of Flufenacet in water and sediment compartments. For the water phase the kinetic model identified as returning the best fit is the same as indicated by the Applicant in the kinetic examination carried out at the Level P-I.

The kinetic endpoints obtained for each tested combination are presented below in the table B.8.2.2.3._CA-55.

Table B.8.2.2.3._CA-55: The kinetic endpoints obtained in the fitting for each combination of the kinetic models.

Compartment	Kinetic endpoint	Kinetic model tested for water phase:		
		SFO	FOMC	DFOP
Water phase	DT ₅₀ [days]	36.3	31.5	34
	DT ₉₀ [days]	121	210	154
Sediment phase (SFO model used only)	DT ₅₀ [days]	38.3	43.6	40.5
	DT ₉₀ [days]	127	145	134
	Kinetic formation fraction ff	1.00	1.00	1.00

Analysing the values of the kinetic formation fractions – ff , representing here the flow from water to the sediment phase, RMS noticed that for all three combinations of the kinetic models tested they were equal to 1. That may indicate that the dominant mechanism of dissipation of Flufenacet from water phase is its migration to sediment. Also that is indicated by the fact that FOMC – bi-phasic model, returned the best fit, statistically and visually, with fully reliable kinetic parameters. Therefore the kinetic parameters determined for Flufenacet in water phase in that test system should be regarded as persistence endpoints not to be used in modelling.

The comparison of the results obtained for Flufenacet in water phase by RMS and the Applicant showed, that they were similar. For that reason RMS decided to keep as reliable the values determined by the Applicant.

As for the kinetic endpoints for the sediment phase, RMS decided to consider the values determined by the Applicant as reliable kinetic characteristic of the persistence of Flufenacet in sediment phase. That was due to the fact that they displayed higher reliability.

Finally, in RMS's opinion the results of this fitting, and in particular that of ff (representing the flow from water to sediment compartment), clearly indicate that the whole system DT₅₀ value is more appropriate for SW modelling at higher tiers as representing the degradation in the sediment phase. Therefore the appropriate value for SW modelling at higher tiers as representing the degradation in water will be DT₅₀ = 1000 days (FOCUS default).

- 3) The results of the kinetic analysis of the data for Flufenacet at the Level P-II obtained for NESA test system treated with [Thiadiazole-2-¹⁴C]Flufenacet (study by [Halarnkar and Irwin, 1997]):

The kinetic analysis was performed for the results obtained in water and sediment compartments fitted together, as shown on figure B.8.2.2.3._CA-25. For the results obtained in water phase, defined in the fitting as “parent” compartment, the fitting was performed using all four kinetic models – SFO, FOMC, DFOP and HS. The results obtained in the sediment phase were kinetically analysed using solely SFO kinetic model, due to the fact that in the conceptual model within the tool they were defined as the compartment “A1”. The results of the fitting are presented below, individually for each combination of the kinetic models.

a) Fitting using the SFO as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-32 and in the numerical form in the table B.8.2.2.3._CA-56.

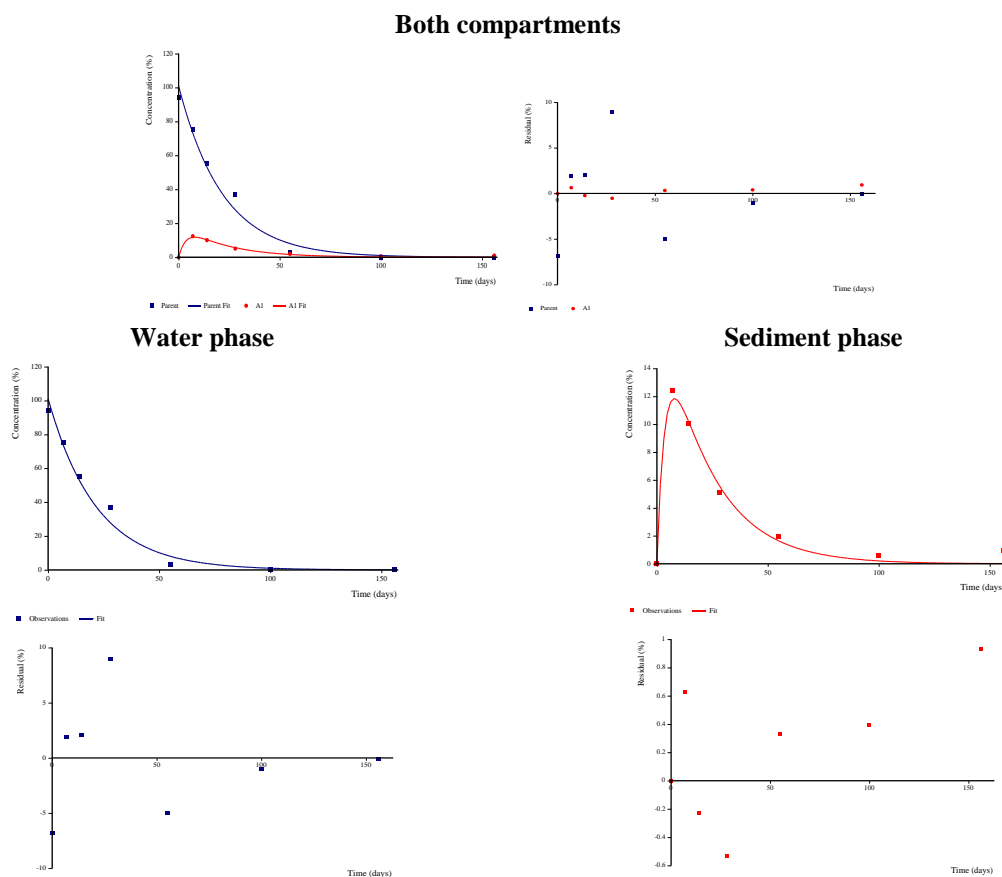

Figure B.8.2.2.3._CA-32: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESAsystem, study by [Halarnkar and Irwin; 1997], using SFO model for water phase.

Table B.8.2.2.3._CA-56: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESAsystem, study by [Halarnkar and Irwin; 1997], using SFO model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	SFO	M_0	101.0	5.072	91.72	110.3	----	10.1	Good fit; R = 0.983
		k	0.04594	0.00483	0.03709	0.05479	2.71 E-6		
Sediment phase	SFO	M_0	0.00	----	----	----	----	8.57	Good fit; R = 0.990
		k	0.2731	0.07009	0.1464	0.4016	0.001818		
		ff	1.00	0.2948	0.4596	1.540	----		

b) Fitting using the FOMC as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-33 and in the numerical form in the table B.8.2.2.3._CA-57.

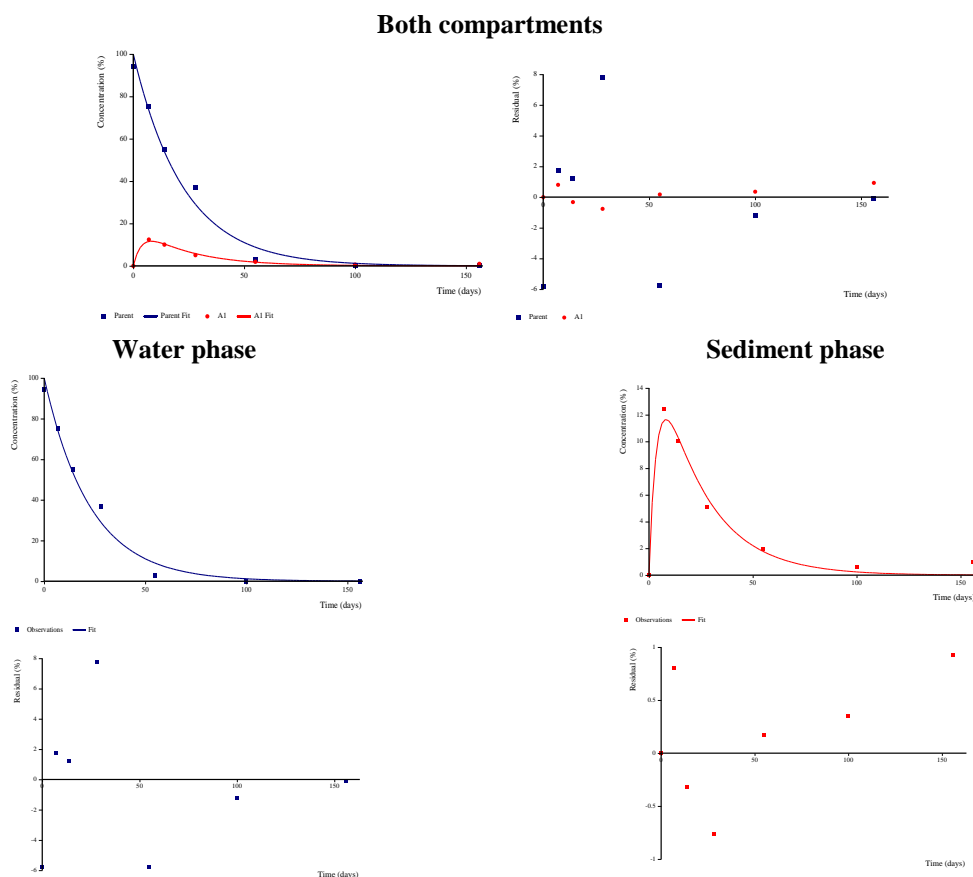

Figure B.8.2.2.3._CA-33: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESAs system, study by [Halarnkar and Irwin; 1997], using FOMC model for water phase.

Table B.8.2.2.3._CA-57: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESAs system, study by [Halarnkar and Irwin; 1997], using FOMC model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	FOMC	M_0	100.0	4.379	91.85	108.1	----	9.93	Good fit; $R = 0.985$
		α	6900	321.7	6300	7500	----		
		β	1.57 E5	305.2	1.56 E5	1.57 E5	----		
Sediment phase	SFO	M_0	0.00	----	----	----	----	9.61	Acceptable fit; $R = 0.986$
		k	0.2644	0.02255	0.2224	0.3063	1.28 E-6		
		ff	1.00	7.07 E-4	0.9987	1.001	----		

c) Fitting using the DFOP as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-34 and in the numerical form in the table B.8.2.2.3._CA-58.

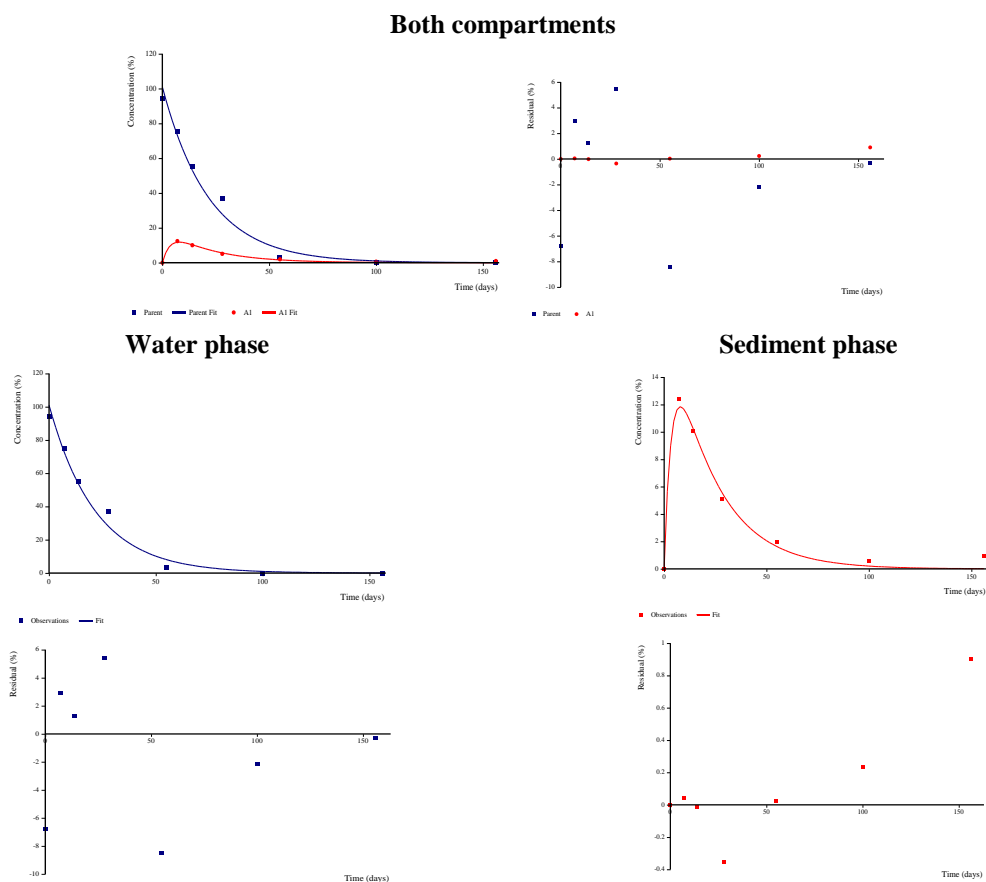

Figure B.8.2.2.3._CA-34: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Halarnkar and Irwin; 1997], using DFOP model for water phase.

Table B.8.2.2.3._CA-58: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in NESA system, study by [Halarnkar and Irwin; 1997], using DFOP model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	DFOP	M_0	101.0	5.09	91.37	110.7	----	12.1	Good fit; R = 0.983
		k_1	0.1902	0.177	-0.1452	0.5255	0.1591		
		k_2	0.04594	0.00896	0.02896	0.06291	6.79 E-4		
		g	6.9 E-7	0.1764	-0.3343	0.3343	----		
Sediment phase	SFO	M_0	0.00	----	---	----	----	6.27	Good fit; R = 0.995
		k	0.2731	0.0275	0.221	0.3252	1.12 E-5		
		ff	1.00	7.56 E-4	0.9986	1.001	----		

Evaluation of the fits:

Of the three tested options SFO-SFO returned the best fits for both phases in visual and statistical terms. The combination FOMC-SFO returned statistically slightly better fit for water phase, but worse, in both statistical and visual terms, for the sediment phase. Finally, the use of the combination of DFOP-SFO kinetic models resulted in the best fit for the sediment phase, but the worst of the three for water phase. Additionally, while combinations SFO-SFO and FOMC-SFO returned reliable sets of the kinetic parameters, the same cannot be stated for the combination DFOP-SFO – the k_i in the DFOP fit for the water phase did not pass the acceptability criteria of the t-test.

Therefore, on the basis of the weight of evidence, SFO-SFO fit shall be regarded as appropriate description of kinetic behaviour of Flufenacet in water and sediment compartments. For the water phase the kinetic model identified as returning the best fit is the same as indicated by the Applicant in the kinetic examination carried out at the Level P-I.

The kinetic endpoints obtained for each tested combination are presented below in the table B.8.2.2.3._CA-59.

Table B.8.2.2.3._CA-59: The kinetic endpoints obtained in the fitting for each combination of the kinetic models.

Compartment	Kinetic endpoint	Kinetic model tested for water phase:		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>Water phase</i>	DT ₅₀ [days]	15.1	15.7	15.1
	DT ₉₀ [days]	50.1	52.2	50.1
<i>Sediment phase</i> (<i>SFO model used only</i>)	DT ₅₀ [days]	2.54	2.62	2.54
	DT ₉₀ [days]	8.43	8.71	8.43
	Kinetic formation fraction ff	1.00	1.00	1.00

Analysing the values of the kinetic formation fractions – ff , representing here the flow from water to the sediment phase, RMS noticed that for all three combinations of the kinetic models tested they were equal to 1. That may indicate that the dominant mechanism of dissipation of Flufenacet from water phase is its migration to sediment. Therefore the kinetic parameters determined for Flufenacet in water phase in that test system should be regarded as persistence endpoints not to be used in modelling.

The comparison of the results obtained for Flufenacet in water phase by RMS and the Applicant showed, that they were very similar. For that reason RMS decided to keep as reliable the values determined by the Applicant.

As for the kinetic endpoints for the sediment phase, RMS decided to consider the values determined by the Applicant as reliable kinetic characteristic of the persistence of Flufenacet in sediment phase. That was due to the fact that they displayed higher reliability.

Finally, in RMS's opinion the results of this fitting, and in particular that of ff (representing the flow from water to sediment compartment), clearly indicate that the whole system DT₅₀ value is more appropriate for SW modelling at higher tiers as representing the degradation in the sediment phase. Therefore the appropriate value for SW modelling at higher tiers as representing the degradation in water will be DT₅₀ = 1000 days (FOCUS default).

- 4) The results of the kinetic analysis of the data for Flufenacet at the Level P-II obtained for NESA test system treated with [Thiadiazole-2-¹⁴C]Flufenacet (study by [Halarnkar and Irwin; 1997]):

The kinetic analysis was performed for the results obtained in water and sediment compartments fitted together, as shown on figure B.8.2.2.3._CA-25. For the results obtained in water phase, defined in the fitting as “parent” compartment, the fitting was performed using all four kinetic models – SFO, FOMC, DFOP and HS. The results obtained in the sediment phase were kinetically analysed using solely SFO kinetic model, due to the fact that in the conceptual model within the tool they were defined as the compartment “A1”. The results of the fitting are presented below, individually for each combination of the kinetic models.

a) Fitting using the SFO as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-35 and in the numerical form in the table B.8.2.2.3._CA-60.

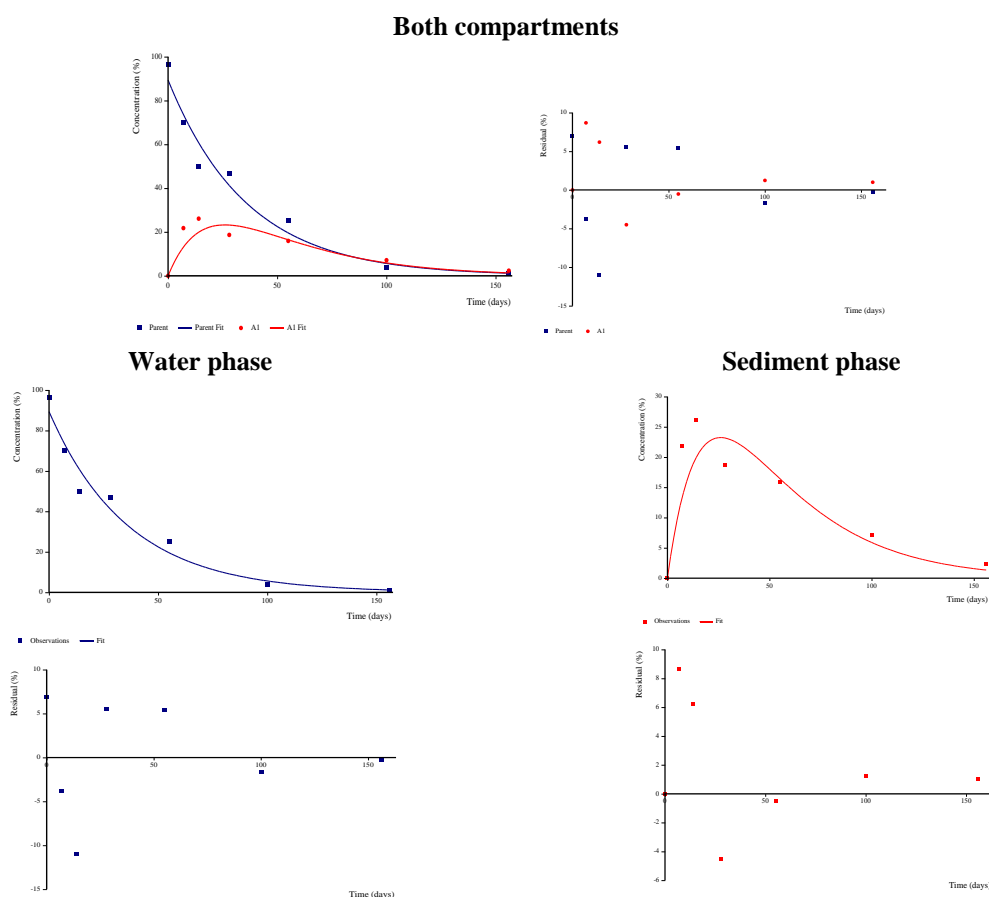

Figure B.8.2.2.3._CA-35: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Halarncar and Irwin; 1997], using SFO model for water phase.

Table B.8.2.2.3._CA-60: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Halarncar and Irwin; 1997], using SFO model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R
					Lower	Upper			
Water phase	SFO	M_0	89.37	5.936	78.49	100.3	----	11.3	Acceptable fit; $R = 0.966$
		k	0.02759	0.00468	0.01901	0.03617	1.15 E-4		
Sediment phase	SFO	M_0	0.00	----	----	----	----	24.8	Acceptable fit; $R = 0.809$
		k	0.05172	0.02361	8.44 E-3	0.09501	0.0281		
		ff	1.00	0.387	0.2913	1.709	----		

b) Fitting using the FOMC as kinetic model for water phase:

The results of the fitting are presented below in graphical form on the figure B.8.2.2.3._CA-36 and in the numerical form in the table B.8.2.2.3._CA-61.

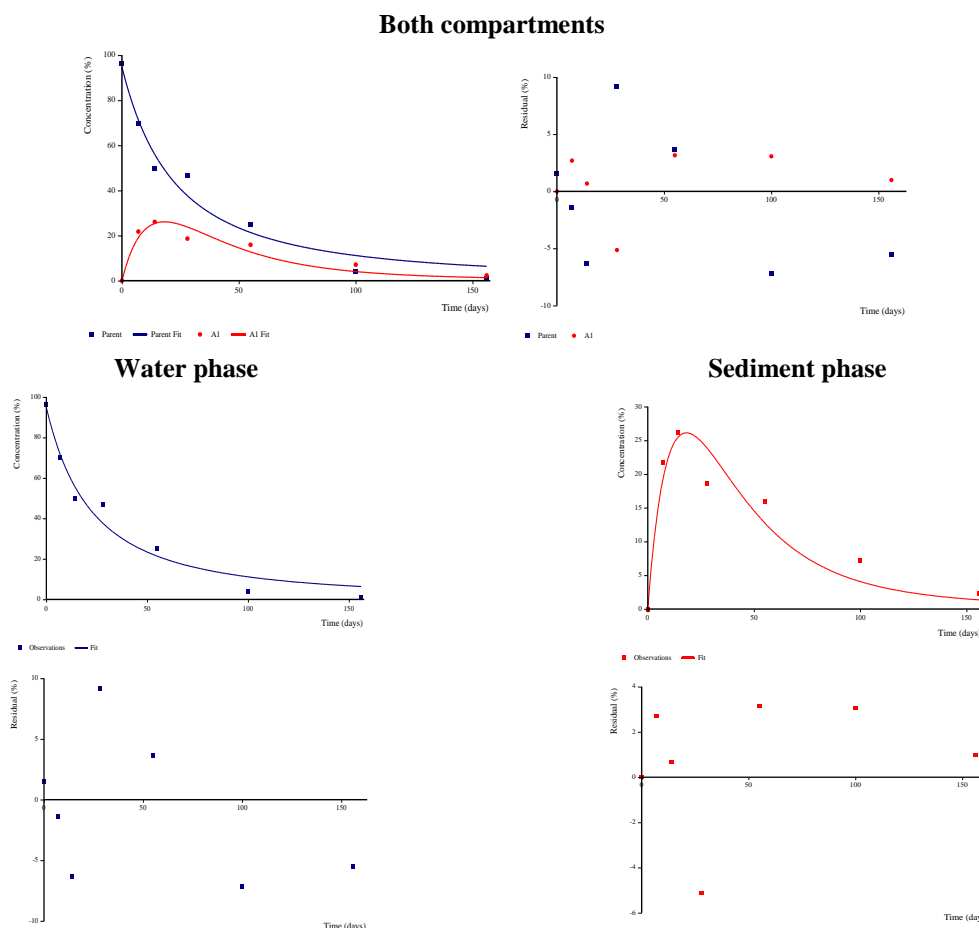

Figure B.8.2.2.3._CA-36: The graphical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Halarikar and Irwin; 1997], using FOMC model for water phase.

Table B.8.2.2.3._CA-61: The numerical results of the kinetic fitting of the data for Flufenacet in water and sediment phases obtained in BRP system, study by [Halarikar and Irwin; 1997], using FOMC model for water phase.

Compartment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment; R

		ff	0.8566	0.2072	0.4641	1.249	----		

Evaluation of the fits:

Of the three tested options DFOP-SFO returned the best fits for both phases in visual and statistical terms. The improvement of the fit for the sediment phase was observed already for the combination FOMC-SFO. dissipation of Flufenacet from water phase may follow bi-phasic pattern. The kinetic fit for the water phase was visually and statistically acceptable for all three kinetic models used, but it was not possible to obtain the fully acceptable fit, mainly in statistical terms, for the combinations SFO-SFO and FOMC-SFO. It shall be indicated that none of the bi-phasic models tested for water phase returned reliable kinetic parameters. Therefore SFO-SFO fit shall be regarded as appropriate description of kinetic behaviour of Flufenacet in water and sediment compartments. For the water phase the kinetic model identified as returning the best fit is the same as indicated in the kinetic examination carried out at the Level P-I.

The kinetic endpoints obtained for each tested combination are presented below in the table B.8.2.2.3._CA-63.

Table B.8.2.2.3._CA-63: The kinetic endpoints obtained in the fitting for each combination of the kinetic models.

Compartment	Kinetic endpoint	Kinetic model tested for water phase:		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>Water phase</i>	DT ₅₀ [days]	25.1	19.5	19.9
	DT ₉₀ [days]	83.5	115	103
<i>Sediment phase (SFO model used only)</i>	DT ₅₀ [days]	13.4	12.4	15.6
	DT ₉₀ [days]	44.5	41.2	51.9
	Kinetic formation fraction <i>ff</i>	1.00	1.00	0.8566

Analysing the values of the kinetic formation fractions – *ff*, representing here the flow from water to the sediment phase, RMS noticed that for all three combinations of the kinetic models tested they were very close or equal to 1. That may indicate that the dominant mechanism of dissipation of Flufenacet from water phase is its migration to sediment. Therefore the kinetic parameters determined for Flufenacet in water phase in that test system should be regarded as persistence endpoints not to be used in modelling.

The comparison of the results obtained for Flufenacet in water phase by RMS and the Applicant showed, that they were similar. For that reason RMS decided to keep as reliable the values determined by the Applicant.

As for the kinetic endpoints for the sediment phase, RMS decided to consider the values determined by the Applicant as reliable kinetic characteristic of the persistence of Flufenacet in sediment phase. That was due to the fact that they displayed higher reliability.

Finally, in RMS's opinion the results of this fitting, and in particular that of *ff* (representing the flow from water to sediment compartment), clearly indicate that the whole system DT₅₀ value is more appropriate for SW modelling at higher tiers as representing the degradation in the sediment phase. Therefore the appropriate value for SW modelling at higher tiers as representing the degradation in water will be DT₅₀ = 1000 days (FOCUS default).

Final conclusion of the kinetic analysis:

On the basis of the obtained results it may be stated that the kinetic endpoints determined for the dissipation of Flufenacet from water phase shall be regarded only as persistence endpoints and cannot be considered as modelling endpoints. Additionally, it was demonstrated that the kinetic endpoints determined for the whole system in each experiment shall be regarded, for the modelling purpose, as representing the degradation of Flufenacet in sediment compartment. Therefore, for degradation in water compartment the default value of DT₅₀ = 1000 days should be used.

Finally, RMS is of the opinion that the kinetic parameters determined by the Applicant the the Level P-I for the whole system, water phase and sediment phase shall be regarded as reliable kinetic endpoints characterising persistence of Flufenacet in water/sediment system. Additionally the whole-system DT₅₀ values shall be used to derive the geomean value to be used as input parameter in SW model exposure assessment.

Finally, the Applicant performed the kinetic analysis of the data for the parent compound and identified major degradation products – FOE Methylsulfide and FOE Thiadone. That was done in order to derive the kinetic endpoints for these two compounds that could be subsequently used in SW modelling assessment.

The kinetic analysis of the data for the major degradation products (performed by the Applicant)

In the water/sediment studies two major degradation products – formed in the whole test system at any time point in amount >10% AR, were identified. In case of the study by [Kelley et al.; 1995] it was FOE Methylsulfide and in that by [Halarnkar and Irwin; 1997] FOE Thiadone. The Applicant performed their kinetical analysis in attempt to derive the kinetic endpoints suitable for deriving kinetic input parameters for the SW modelling.

The kinetic analysis was carried out in line with the recommendations of FOCUS Kinetics Guidelines ([FOCUS; 2006], [FOCUS; 2011]) at the Level M-I using the whole-system data. It was a multi-stage procedure consisting of the following steps:

- **Step 1:** Processing of the raw input data for parent – Flufenacet, and the given degradation product;
- **Step 2:** Kinetic evaluation of the processed data for the using the SFO kinetic model for both parent compound and the given degradation product and KinGUI 2 as a modelling tool; the fitting was carried out using the transformation schemes for Flufenacet → FOE Methylsulfone and Flufenacet → FOE Thiadone presented on figure B.8.2.2.3._CA-38.
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters (not normalised) recommended for modelling.

The raw input data for Flufenacet were processes following the recommendations given by FOCUS. In general terms it looked as follows:

- The total AR recovery recorded in DAT-0 samples was used as concentration of Flufenacet at that time point, but the M_0 value was allowed to be estimated by the model;
- Values between LOD and LOQ were set to measured values;
- All single values <LOD or the non-detects (n. d.) were set to $\frac{1}{2}$ LOD. The same procedure was applied to the first appearances. However, when the values <LOD/n.d. appeared consecutively for second and next times, the kinetic curve was cut off until the appearance of the first value >LOQ;
- Sampling times for sediment phases were shifted, starting with the time point DAT 0 at the day of the maximum measured concentration of Flufenacet.
- For the whole system the pre-processed values in water and sediment compartments were summed up and used as the input.

The pre-processing of the raw input data for the degradation products followed the similar pattern, and looked as follows:

- The initial (DAT-0) concentration was set to 0. That value, unlike the free-fitted M_0 concentration for the parent compound, was a fixed value;
- The values for subsequent time points, if reported as <LOD or non-detects were also set to 0 until the last time point before the first detectable amount was recorded;
- The value reported as <LOD/n.d. appearing just before the first detectable amount was recorded was set to $\frac{1}{2}$ LOD.
- Values between LOD and LOQ were set to measured values;
- In the decline phase the first values <LOD/n.d. were also set $\frac{1}{2}$ LOD. For the consecutive second and next such appearances the kinetic curve was cut off until, eventually, the first value >LOQ appeared;
- Data sets with insufficient number of data points (less than 4 after peak concentration) were not further processed.

The raw and pre-processed data, used as input data for the kinetic examination, are presented below in two tables: the table B.8.2.2.3._CA-64 for the experiment in which FOE Methylsulfide was identified and table B.8.2.2.3._CA-65 for the experiment in which FOE Thiadone was detected. In case the values were the non-detects occurring before or after the value >LOD appeared for the first/last time (except DAT-0 time point) they were set to NaN (“Not a Number” – KinGUI default when numbers are not available).

Table B.8.2.2.3._CA-64: The not processed and pre-processed whole-system data for Flufenacet and FOE Methylsulfide used as input in kinetic analysis.

Study	Test system/test compound	The whole-system concentrations – the not processed data			The whole-system concentrations – the pre-processed data

Footnotes to the table:

1) DAT stands for “Days After Treatment”;

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting was performed assuming the transformation schemes presented below on figure B.8.2.2.3._CA-38.

Transformation pathway for kinetic examination of the data for Flufenacet and FOE Methylsulfide

Transformation pathway for kinetic examination of the data for Flufenacet and FOE Thiadone

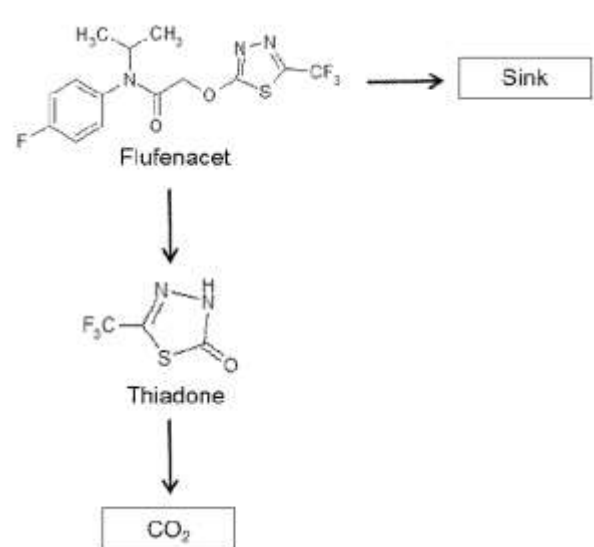

Figure B.8.2.2.3_CA-38: The transformation pathways assumed in the kinetic analysis of the whole-system data for Flufenacet and its major degradation products at the Level M-I (copied from the study report).

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis, comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

Characterising the adopted approach to the visual assessment of the fit, considered to be the first step in the evaluation, the Applicant stated that it focused on the following features:

- the conformity of the fitted decline curve with measured residue concentrations;
- the distribution of the residuals, which should be random and not systematic;
- level of residuals, which should be as small as possible – in such case even if their distribution is rather systematic, the fit may be still qualified as acceptable.

Based on these criteria the fit could be classified as:

- **good fit**, when the conformity of the kinetic curve and measured residues was good, levels of residuals were low, they were randomly scattered and no obvious systematic deviation in residual plot was visible;
- **acceptable fit**, when the conformity of the kinetic curve and measured residues was acceptable, levels of residuals were medium and they were more-or-less randomly scattered, and the absolute level of residuals was low;
- **poor fit**, when the fitted decline curve significantly deviated from the measured residues and did not match the observed pattern, the level of residuals was high and they were clearly not randomly scattered around zero line.

Characterising the next component of the assessment – χ^2 -error statistics, the Applicant indicated that 15% threshold value was not considered to be an absolute cut-off criterion, especially in case of the degradation products. That was indicated to be due to the fact that that threshold value is strictly appropriate for optimal experimental conditions only. It was therefore indicated that in some cases, even though χ^2 -error > 15%, the fit may be acceptable. Additionally, for degradation products it was indicated that for them usually measurements in comparison to the mean of all measurements are low, what strongly influences the χ^2 test.

Finally, characterising the t-test, the Applicant stated that the t-test probability of 0.05 was sufficiently small and should be used as acceptability criterion, in case however of degradation products, or the results of field dissipation studies the $prob > t$ value of 0.10 or even higher may be still acceptable.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test system.

- 1) The kinetic evaluation of the whole-system data for Flufenacet and FOE Methylsulfide obtained in the test system NESA treated with [Phenyl- $U-^{14}C$]Flufenacet (study by [Kelley et al.; 1995]):

The kinetic analysis of the whole-system data for Flufenacet and FOE Methylsulfide was carried out SFO kinetic model for both compounds. Its graphical results are presented on figure B.8.2.2.3._CA-39 and the numerical results in the table B.8.2.2.3._CA-66. Additionally, in the table B.8.2.2.3._CA-67 are provided the kinetic endpoints returned by the modelling tool for each compound.

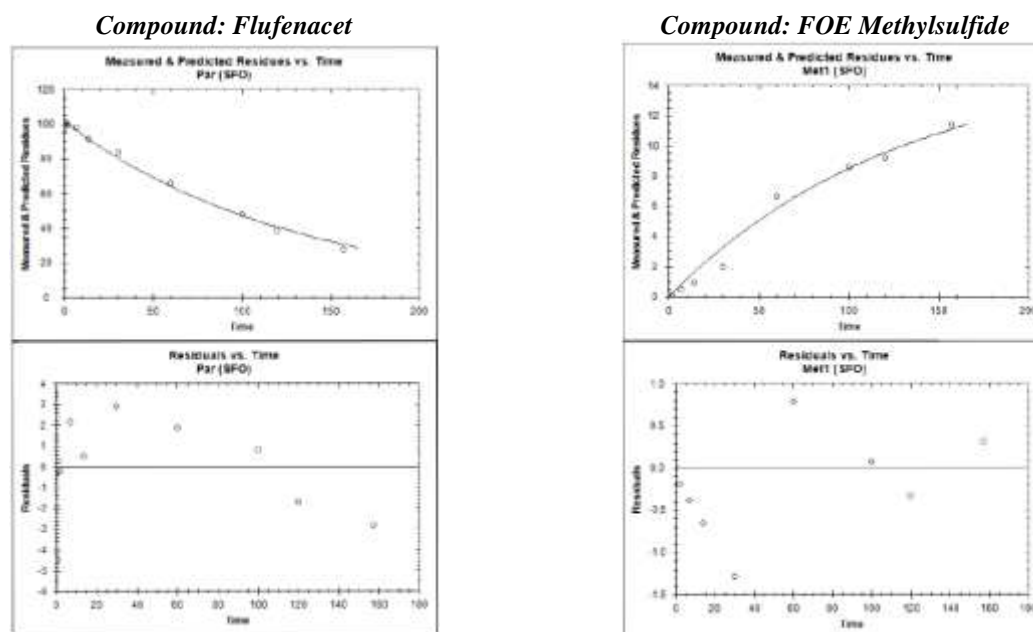

Figure B.8.2.2.3._CA-39: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-66: The numerical results of the kinetic analysis.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M_0	101.30	0.991	99.32	103.21	<2 E-16	2.186	Not provided
		k	7.65 E-3	2.74 E-4	7.11 E-3	0.008	2.73 E-15		
FOE Methylsulfide	SFO	M_0	0.0	----	----	----	----	10.076	Good
		k	4.51 E-9	1.54 E-3	-3.03 E-3	0.003	0.5		
		ff	0.1568	0.01854	----	----	----		

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-67: The kinetic endpoints obtained as a result of the fitting.

Determined parameter	Compound	
	<i>Flufenacet</i>	<i>FOE Methylsulfide</i>
DT ₅₀ [days]	90.64	Reliable value not determined
DT ₉₀ [days]	301.10	Reliable value not determined
Kinetic formation fraction <i>ff</i>	Not applicable – parent compound	0.157 ± 0.0185
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	FOMC	SFO

Evaluation:

The values obtained for the parent compound are very similar to those obtained for Flufenacet fitted alone. In case of the degradation product – FOE Methylsulfide it was not possible to obtain the reliable kinetic endpoints for degradation because the concentrations were still increasing at the study's end.

- 2) The kinetic evaluation of the whole-system data for Flufenacet and FOE Methylsulfide obtained in the test system **BRP** treated with [Phenyl-U-¹⁴C]Flufenacet (study by [Kelley et al.; 1995]):

The kinetic analysis of the whole-system data for Flufenacet and FOE Methylsulfide was carried out SFO kinetic model for both compounds. Its graphical results are presented on figure B.8.2.2.3._CA-40 and the numerical results in the table B.8.2.2.3._CA-68. Additionally, in the table B.8.2.2.3._CA-69 are provided the kinetic endpoints returned by the modelling tool for each compound.

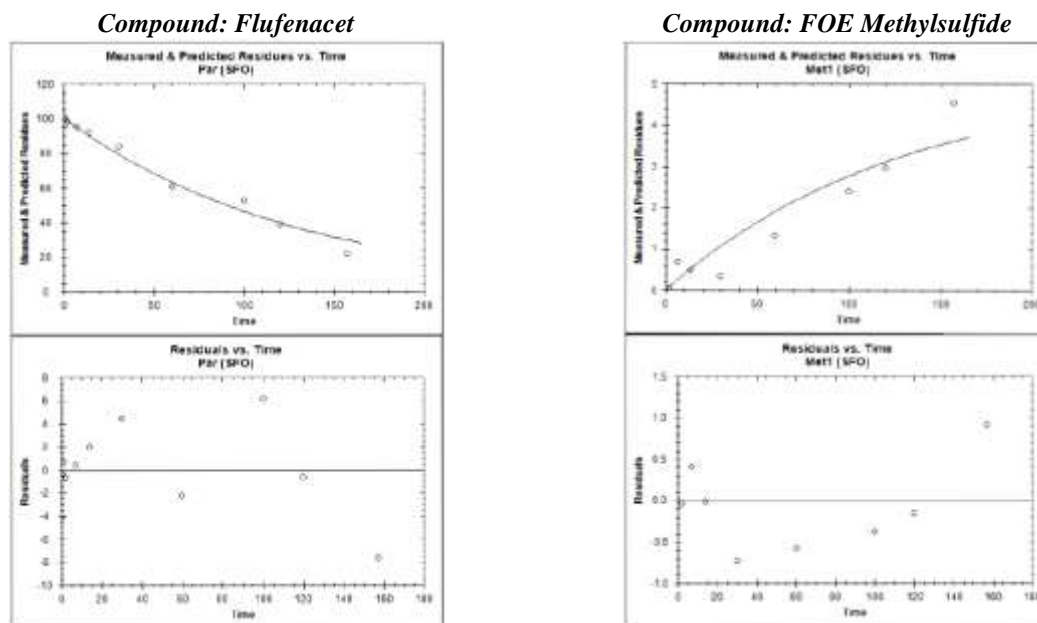

**Figure B.8.2.2.3._CA-40:** The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-68: The numerical results of the kinetic analysis.

		k	7.71 E-3	4.78 E-4	6.77 E-3	0.009	1.29 E-11		
FOE Methylsulfide	SFO	M ₀	0.0	----	----	----	----	25.098	Poor
		k	3.49 E-9	4.35 E-3	-8.53 E-3	0.009	0.5		
		ff	0.0514	0.0156	----	----	----		

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-69: The kinetic endpoints obtained as a result of the fitting.

Determined parameter	Compound	
	Flufenacet	FOE Methylsulfide
DT ₅₀ [days]	89.91	Reliable value not determined
DT ₉₀ [days]	298.70	Reliable value not determined
Kinetic formation fraction ff	Not applicable – parent compound	0.051 ± 0.0043
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	FOMC	SFO

Evaluation:

The values obtained for the parent compound are very similar to those obtained for Flufenacet fitted alone. In case of the degradation product – FOE Methylsulfide it was not possible to obtain the reliable kinetic endpoints for degradation because the concentrations were still increasing at the study's end.

- 3) The kinetic evaluation of the whole-system data obtained for Flufenacet and FOE Thiadone in the test system **NESA** treated with [Thiadiazole-2-¹⁴C]Flufenacet (study by [Halarnkar and Irwin; 1997]):

The kinetic analysis of the whole-system data for Flufenacet and FOE Thiadone was carried out SFO kinetic model for both compounds. Its graphical results are presented on figure B.8.2.2.3._CA-41 and the numerical results in the table B.8.2.2.3._CA-70. Additionally, in the table B.8.2.2.3._CA-71 are provided the kinetic endpoints returned by the modelling tool for each compound.

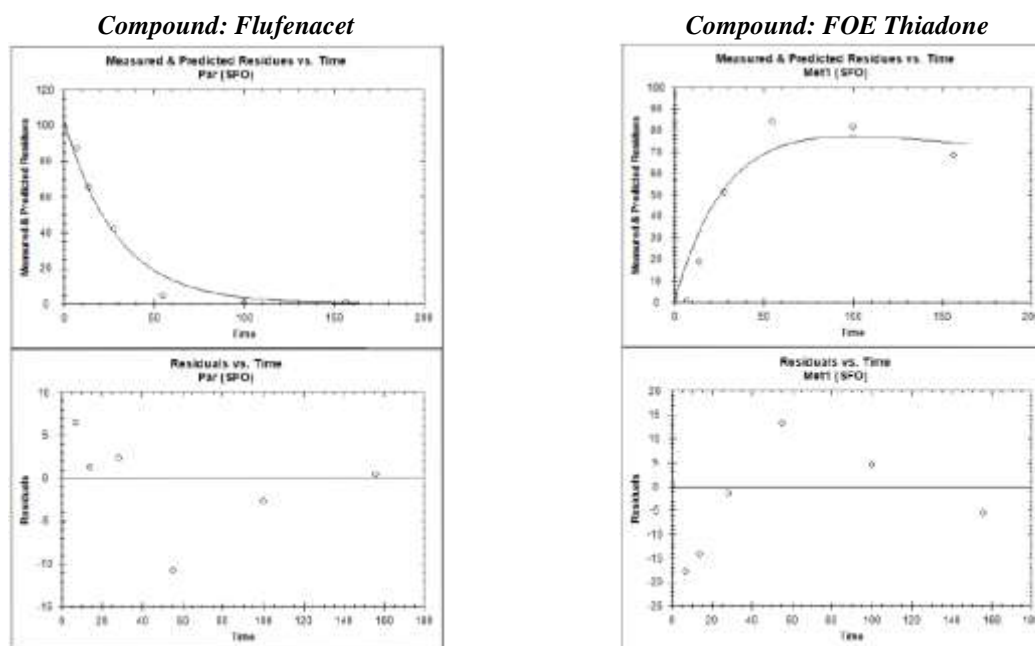

Figure B.8.2.2.3_CA-41: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3_CA-70: The numerical results of the kinetic analysis.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M ₀	102.99	5.151	92.90	113.089	1.08 E-9	9.905	Not provided
		k	0.03411	0.00392	0.02643	0.042	2.80 E-6		
FOE Thiadone	SFO	M ₀	0.0	----	----	----	----	17.448	Poor
		k	1.26 E-3	2.02 E-3	-2.71 E-3	0.005	0.2736		
		ff	0.8504	----	----	----	----		

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3_CA-71: The kinetic endpoints obtained as a result of the fitting.

Determined parameter	Compound	
	Flufenacet	FOE Thiadone
DT ₅₀ [days]	89.91	Reliable value not determined
DT ₉₀ [days]	298.70	Reliable value not determined
Kinetic formation fraction ff	Not applicable – parent compound	0.850
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	FOMC	SFO

Evaluation:

The values obtained for the parent compound are very similar to those obtained for Flufenacet fitted alone. In case of the degradation product – FOE Thiadone it was not possible to obtain the reliable kinetic endpoints for degradation because of the too few data points after the maximum was reached and the poor fitting results.

- 4) The kinetic evaluation of the whole-system data obtained for Flufenacet and FOE Thiadone in the test system **BRP** treated with [Thiadiazole-2-¹⁴C]Flufenacet (study by [Halarikar and Irwin; 1997]):

The kinetic analysis of the whole-system data for Flufenacet and FOE Thiadone was carried out SFO kinetic model for both compounds. Its graphical results are presented on figure B.8.2.2.3._CA-42 and the numerical results in the table B.8.2.2.3._CA-72. Additionally, in the table B.8.2.2.3._CA-73 are provided the kinetic endpoints returned by the modelling tool for each compound.

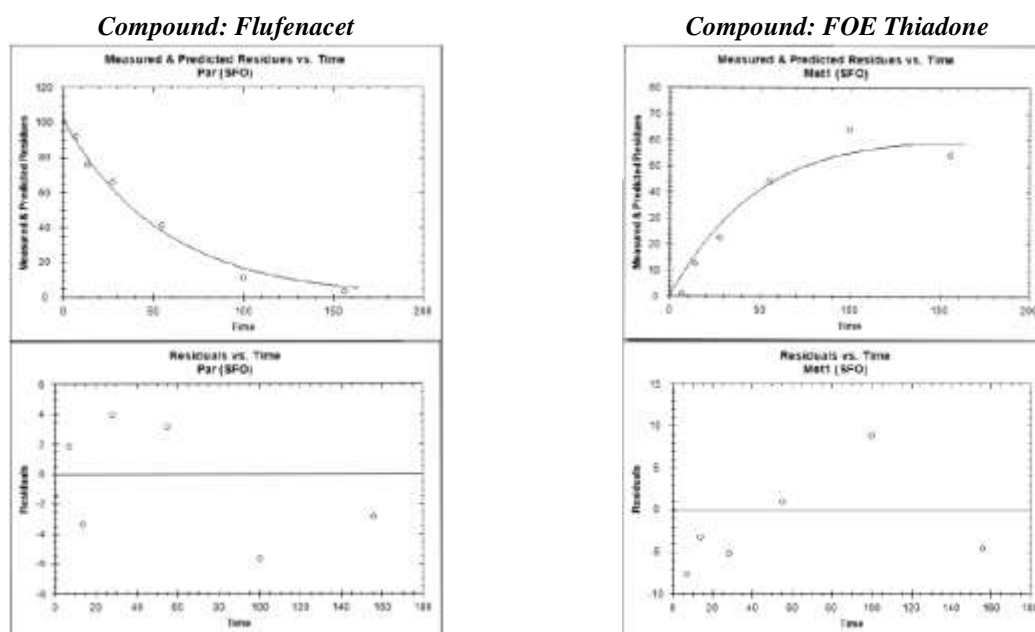

Figure B.8.2.2.3._CA-42: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.2.2.3._CA-72: The numerical results of the kinetic analysis.

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.2.2.3._CA-73: The kinetic endpoints obtained as a result of the fitting.

Determined parameter	Compound	
	Flufenacet	FOE Thiadone
DT ₅₀ [days]	38.47	Reliable value not determined
DT ₉₀ [days]	127.80	Reliable value not determined
Kinetic formation fraction ff	Not applicable – parent compound	0.6949
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	FOMC	SFO

Evaluation:

The values obtained for the parent compound are very similar to those obtained for Flufenacet fitted alone. In case of the degradation product – FOE Thiadone it was not possible to obtain the reliable kinetic endpoints for degradation because of the too few data points after the maximum was reached.

Conclusions of the fitting:

The kinetic examination of the whole-system data for Flufenacet and its identified major degradation products – either FOE Methylsulfide or FOE Thiadone, showed that it was not possible to derive reliable kinetic endpoints for both metabolites. In case of FOE Methylsulfide that was due to the fact that by the end of the study the maximum of formation and decline phase were not reached. For FOE Thiadone such maximum was reached in both test systems, but the decline phase that followed comprised too few data points – two for NESA test system and only one for BRP test system, to obtain the reliable kinetic endpoints.

Additionally it was demonstrated that neither for FOE Methylsulfide nor FOE Thiadone it was possible to obtain fully reliable kinetic fits using the available data sets.

Final conclusions of the study:

The Applicant presented the kinetic evaluation of the data on the fate and behaviour of Flufenacet in water/sediment systems obtained in two separate studies: by [Kelley et al.; 1995] using [Phenyl-U-¹⁴C]Flufenacet and by [Halarnkar and Irwin; 1997] using [Thiadiazole-2-¹⁴C]Flufenacet. In these studies two major degradation products were identified – FOE Methylsulfide in the experiment by [Kelley et al.; 1995] and FOE Thiadone in that by [Halarnkar and Irwin; 1997]. The kinetic analysis was performed for the data obtained for Flufenacet in the whole test systems as well as in water and sediment phases of each test system and was carried out on the Level P-I. Its aim was, in case of the whole-system data to determine the persistence endpoints for Flufenacet and the modelling endpoints. In case of water and sediment phases the kinetic analysis was aimed on the determination of the persistence endpoints. The analysis was performed in line with the recommendations given by FOCUS Kineits Guidance document [FOCUS; 2006].

The key results of that examination are presented below in the table B.8.2.2.3._CA-74.

Table B.8.2.2.3._CA-74: The key results of the kinetic examination at the Level P-I of the data obtained for Flufenacet in water/sediment studies.

Study	Test system	Compartment	Kinetic model	Evaluation of fit		Kinetic parameter(s)		Kinetic endpoints	
				Visual	χ^2 % error	Parameter	Value	DT ₅₀ [days]	DT ₉₀ [days]

		Sediment	SFO – top down	Good	7.738	<i>k</i>	0.01447	47.91	159.10

The calculated geomean values for the kinetic endpoints – DT₅₀ and DT₉₀, determined in the whole system are following **DT₅₀ = 49.54 days**, **DT₉₀ = 164.59 days**. These values are determined by the RMS. The geomean

whole-system DT_{50} value given in the study report is following: **$DT_{50} = 49.6$ days**. The difference between the two values is minimal and can be attributed to the rounding procedure used by the Applicant. Therefore the value proposed by the Applicant may be considered a reliable kinetic endpoint to be used as input parameter in SW model exposure assessment.

For water and sediment phases at the Level P-I the Applicant derived two sets of the kinetic endpoints – those representing persistence and those suitable for modelling. RMS however noticed that Flufenacet displayed quite high adsorption potential onto soil, with the geomean $K_{fOC} = 245.9$ mL/g (range 161.6 – 643.48 mL/g) and rather low solubility in water – 56 mg/L. That may indicate that the compound would display substantial affinity to the sediment phase. The examination of degradation of Flufenacet in natural water, not containing suspended sediment, showed that that process take long – more than 600 days. Additionally, studies on abiotic degradation of Flufenacet in water showed that only indirect photolysis may substantially contribute to the dissipation of Flufenacet from water, while abiotic hydrolysis is not a relevant degradation mechanism for Flufenacet. All that taken into account, also bearing in mind that the water/sediment studies were performed in absence of light, it may be assumed that the process of dissipation of Flufenacet from water column is, at least of mixed nature, partly being degradation and to some extent, if not predominantly, migration to the sediment, where the proper degradation occurs.

In order to verify that RMS decided to perform additional kinetic examination of the data for Flufenacet using the procedure corresponding to the Level P-II assessment. In that fitting the data for Flufenacet in water phase were treated as those for the parent compound, while the sediment phase was defined as the metabolite A1 compartment.

Unlike at the Level P-I for the sediment phase whole data set was fitted together with that for water phase.

The results obtained for water phase were comparable to those obtained for that compartment by the Applicant at the Level P-I. The kinetic endpoints obtained for the sediment phase were usually shorter than those obtained by the Applicant at the Level P-I, what also reflected differences in the kinetic approach. It shall be indicated that the fits obtained for Flufenacet in the sediment phase were also not always fully reliable, but of sufficient quality to draw the conclusions.

Finally, it was noticed that the values of the kinetic formation fraction – ff , characterising the flux from water to sediment phases were in all cases very close or equal to 1. That may indicate that the dominant mechanism of dissipation from water column is migration to the sediment.

On that basis the RMS stated that the geomean whole-system DT_{50} value when used in the modelling should be considered as representing the degradation of Flufenacet in sediment, not in the water column.

The Applicant also made an attempt to derive the kinetic endpoints for the two identified major degradation products – FOE Methylsulfide and FOE Thiadone. The kinetic analysis aimed on that was performed at the Level M-I using the whole-system data for Flufenacet and related degradation products kinetically fitted together. The results obtained for Flufenacet were very similar to those obtained for the same compound fitted alone at the Level P-I. However, it was not possible to obtain the reliable kinetic endpoints for the degradation products, due to the fact that the concentrations stillm increased at the end of the experiment – which was the case for FOE Methylsulfide, or the number of data point after maximum was reached was too low to obtain the reliable decline curve, what was observed in case of FOE Thiadone. Additionally, it shall be indicated that due to the poor fitting results the kinetic formation fractions determined for both degradation products shall be considered with care.

Study 4:

Report: Pangilinan N. C., Smith D. M., (1995): “Anaerobic Aquatic Metabolism of [Thiadiazole-2-¹⁴C]FOE 5043.”; Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; (performing laboratory) *for* Miles Inc., Agriculture Division, 17745 South Metvcalf Avenue, Stilwell, Kansas 66085, USA; study No. F3042102; unpublished Miles Report No. MR 106440; 24 February 1995; study reference number: M-002215-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-3, Anaerobic Aquatic Metabolism.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.4.3.2.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. The study was evaluated for its compliance with OECD Guideline 308 – Aerobic and Anaerobic Transformation in Aquatic Sediment Systems. RMS stated that the study deviated from the reference Guideline in the following areas:

- **selection of sediment:** in the study soil was used instead of anaerobic sediment; the water overlying “sediment layer” was not that associated with it, but taken from pond located at the test facility, in the vicinity of the soil sampling area;
- **number of water/sediment systems:** the Guideline recommends at least two types of water/sediment systems to be used in experiment; in this case only one type was used;
- **duration of the experiment:** Guideline recommends that the study should usually not be longer than 100 days; in this case the study lasted for 388 days;
- the anaerobic conditions were not maintained throughout the incubation period and there is no indication in the study report when the change occurred; although in the study report it is declared that anaerobic conditions for ~99 days of incubation there is no experimental evidence conforming that statement;
- although the study lasted for 388 days and the test soil, used as a surrogate for sediment, was known, from other studies, to have problems with maintaining biological viability, in the study report the biological viability of the test system was not reported.

As a result, RMS stated that the study cannot be considered as complying with the provisions of the reference Guideline, hence it cannot be considered acceptable for the present assessment. It shall be indicated that the fully reliable study in aerobic water/sediment system for Flufenacet radiolabelled in exactly the same position as used here is summarised above as **Study 2**. Therefore RMS decided not to summarise it in order not to overburden the report, nor include its results into the List of End Points. The former summary can be found in the Draft Assessment Report prepared by the then-RMS – France, for the previous authorisation of Flufenacet in the EU.

Summary:

The evaluation of the study performed by the RMS showed that it was not acceptable. For that reason, in order not to overburden the Renewal Assessment Report, RMS decided not to summarise it.

Additionally the search of the open literature resulted in identifying a paper containing the data relevant for the determination of fate and behaviour of Flufenacet in water/sediment system. The paper is characterising the fate and behaviour of Trifluoroacetic acid (TFA) in water/sediment systems, the issue not covered by any of water/sediment studies submitted for Flufenacet for regulatory purposes. It is summarised below as **Study 5**.

Study 5:

Report: Ellis D. A.^{a)}, Hanson M. L.^{b)}, Sibley P. K.^{b)}, Shahid T.^{a)}, Fineberg N. A.^{a)}, Solomon K. R.^{b)}, Muir D. C. G.^{c)}, Mabury S. A.^{a)}, (2001): "The fate and persistence of trifluoroacetic and chloroacetic acids in pond water."; Department of Chemistry, University of Toronto, Toronto, Canada (a), Department of Environmental Biology, University of Guelph, Guelph, Canada (b), National Water Research Institute, Environment Canada, Burlington, Canada (c); published study - published in: "Chemosphere", vol. 42, 2001, pp 309-318.

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper

RMS comments: The paper presents the results of the examination of fate of selected haloacetic acids, including trifluoroacetic acid in the aquatic environment. The investigation was carried out using the outdoor aquatic mesocosms (artificial ponds) and laboratory water/sediment systems. In the paper it was not indicated that the experiments were performed in line with any relevant guidelines. However, the study protocol is well characterised, what enables the evaluation of the validity of the study for regulatory purposes. The study may be considered valid, and therefore is summarised below, in its part dealing specifically with the examination of the fate and behaviour of TFA in aquatic, water/sediment, systems. The study provides the pieces of information giving the good insight into the persistence of TFA in SW water bodies and its behaviour there. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and should not be used as a source of regulatory endpoints.

Summary:

The paper contains an abstract, outlining the aims of the experiment and its key results, which was made available on-line. However, due to the copyright restrictions RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to investigate the fate of four haloacetic acids (HAAs) – three chloroacetic acids (monochloroacetic acid – MCA, Dichloroacetic acid – DCA and trichloroacetic acid – TCA) and Trifluoroacetic acid (TFA) in the aquatic environment – field and laboratory microcosms. That was done in order to demonstrate that the degradation of chloroacetic acids is the biologically mediated process and to establish the degradation pathways and the residence times of the test HAAs in natural (pond) water.

The selected HAAs are common pollutants belonging to that group, for which the routes of entering the environment as well as concentrations in various environmental compartments was extensively examined. However, prior to that study little was known about their fate and behaviour in the environment, and in particular in SW water bodies.

The outdoor part of the experiment was performed at the University of Guelph Microcosm Facility, located at the Guelph Turfgrass Institute (Canada) and consisting of 30 artificial ponds. The microcosms were each 1.2 m deep, 3.9 m in diameter, having a surface area of 11.95 m² and a capacity of holding approx. 12 m³ of water. The water layer in each of them had a depth of 1 m. In order to avoid the potential run-off from precipitation the ponds were located on the top of a raised mound. The surface of water layer in each pond was on the same level as the surrounding ground and the its rim was elevated 5-10 cm above that level.

The microcosm systems were created using galvanized steel panels and support struts to provide a basic frame and food grade PVC to create the closed system relative to other microcosm.

The sediment layer in each mesocosm was created by placing at the bottom 46 trays, 52-cm long and 25-cm wide, having the depth of 7cm. They were filled with a sediment consisting of a mixture of sand and loam in even amounts and in 20% of organic matter. The so prepared sediment was sieved thorough ½ in. mesh screen. The so prepared trays covered approx. 50% of the total bottom surface of the microcosm. Water filling

microcosm during pre-treatment period originated from an irrigation pond located on the trial site and supplied from the on-site located well. It was circulated among all microcosm at rate 12 m³/24 hours for at least two weeks prior to the treatment with any test compounds. To each microcosm were introduced at least five potted macrophytes – *Myriophyllum spicatum* in order to provide the habitat for juvenile fish and zooplankton. Additionally individual plants of *Myriophyllum spicatum* and *Myriophyllum sibiricum* were introduced for toxicity testing. In each microcosm cages with breeding pairs (four pairs per cage) of fish – fathead minnow (*Pimephales promelas*) were introduced. In some studies the additional fish species – pumpkinseed sunfish (*Lepomis gibbosus*) were introduced in hanging mesh cages. Microcosms were open to aerial colonisation by insects and PVC sides allowed for periphyton growth.

The circulation of water in microcosms was stopped before the treatment with the test compounds, each administered individually.

The HAA were administered as a solution in bi-distilled deionised water, adjusted to pH = 8.5, prepared on the day of treatment. The treatment solutions were injected to the microcosms using a low-pressure high-volume pump system. After treatment water in each microcosm, including the untreated controls was circulated for 15 minutes.

The experiments with TFA, each lasting one year, were performed in two periods – in years 1997-1998 and 1998-1999. The treatment rates in 1997 were following: 10 µg/L – four microcosms, 100 µg/L – another four microcosms, 300 µg/L – two microcosms, 1000 µg/L – another two microcosms. In 1998 the treatment rates were: 100 µg/L, 1000 µg/L, 3000 µg/L and 10000 µg/L, each applied to three individual microcosms. The experiment for each year comprised also three untreated microcosms as controls.

The experiments lasted 1 year each.

During the experiment the maximum and minimum temperature and dissolved O₂ were measured on the daily basis. Additionally, on selected sampling days other water parameters, such as pH hardness, alkalinity, DOC total N and total P, were measured.

Water samples for the determination of the content of the given HAA were taken one day before treatment, on the day of the treatment, 1 hour after introduction of the test compound, on DAT 1 (Days After Treatment), DAT 2, DAT 4, DAT 7 and from that time point in one- or two-week intervals. They were taken using the metal integrated water column sample, characterised in one of the previous publications by Solomon. From each microcosm at least four samples were collected, having a total volume of 250, 500 or 1000 mL. They were stored at T = 4°C until being analysed by IC.

The indoor experiment, in design similar to water/sediment study, was carried out in 120-mL clear narrow-mouth Boston round bottles to which 5-g aliquots of the dried sediment, characterised above, were introduced. Next, to each bottle the appropriate amount of the test solution, containing 20 µg/mL of the given HAA, was added in such way to not disturb the sediment. The bottles were then loosely capped and placed on the windowsill facing north to be exposed to sunlight – 12-14 hours in June-July 1999. At predefined sampling points 5-mL water samples were taken for the analysis. The experiment for TFA lasted for 2880 hours (120 days).

The quantitative analysis of TFA was performed by means of the Ion Chromatography (IC), on Dionex Ionopac AS14 IC column. The chromatographic separation was performed in isocratic mode using an aqueous solution of 3.5 mmol NaHCO₃/0.5 mmol Na₂CO₃ as a mobile phase.

In case of the low-concentration samples – <100 µg/L a pre-concentration step was used. Firstly 50-mL aqueous samples were filtered through 0.45-µm paper filter and then passed sequentially through an IC-Ba cartridge and two 500-mg SAX columns. Next cartridges were eluted with 2M NaOH_{aq}, the eluates combined and analysed using IC. For these samples the standard solutions, containing the known amounts of TFA, were prepared in a similar way.

In the field studies with TFA no global change in concentration of that compound over the period of one experimental year was observed. As the results of the concurrent project showed the input of TFA from precipitation was negligible (in amounts of ng/L), it was stated that no degradation of TFA occurred. However, the temporal fluctuations in concentration were recorded. During the period June – October no change in concentrations of TFA in water column was observed, from November to the end of January they dropped by 35%. Then in February and March it gradually returned to the initial levels.

The possible explanation of that phenomenon was the forced partition to the not identified phase, possibly enhanced by low temperatures. It was noticed that formation of ice caused the increase of the concentration of TFA in water phase due to its thermodynamic exclusion from ice. That phenomenon however was observed for one 1-year experimental period, while in the second experiment no such decrease was observed. For that reason further experiments were conducted.

One of the possible explanation of the phenomenon, provided in the paper were the observed differences in the content of biotic and/or suspended organic matter content, what could have indicated that TFA partitioned to that phase.

In the laboratory water/sediment experiments with TFA no degradation of that compound was observed in the course of experiment, conforming its high persistence.

It shall be indicated that unlike TFA all chlorinated HAAs used in the experiment underwent degradation, at rate specific for the given compound. TFA was not degraded even in solutions previously containing TCA, so pre-adapted to degradation of HAAs. That indicated that TFA is very resistant to microbial transformation.

On the basis of the obtained results it was stated that TFA was demonstrated to be persistent in natural SW water bodies, but its concentrations may be subjected to the temporal fluctuations related to the changes of the temperature. It was indicated however that the nature of that phenomenon required further examination.

RMS comments:

The results of this study demonstrate the high persistence of TFA in SW water bodies under natural conditions. Therefore they may be considered as fully supporting the default $DT_{50} = 1000$ days values for TFA in the whole system. water and sediment, proposed to be used as the input values in the SW modelling.

Summary – Water/sediment studies

The transformation pattern of Flufenacet in aerobic water/sediment systems was examined in two separate studies, using Flufenacet radiolabelled at two different positions – uniformly in fluorophenyl ring as [Phenyl-U- ^{14}C]Flufenacet – one of the studies ([Kelley et al.; 1995]), and in C2 position of Thiadiazole moiety as [Thiadiazole -2- ^{14}C]Flufenacet – second study ([Halarnkar and Irwin; 1997]). In each study two water/sediment systems were used, bearing codenames (common for both studies) NESA and BRP. It shall be indicated however that, although sampled on the same locations, the test systems did not bear the same characteristics, therefore shall be considered as individual test systems and not the replicates. RMS examining the data set noticed that the examination of the transformation of the thiadiazole moiety of Flufenacet was performed for only C2 radiolabelling position, while C5 radiolabelling position was not covered. That resulted in the lack of data concerning the potential formation of TFA and, possibly (if the degradation pattern was similar to that observed in aerobic soil) FOE TFESA. RMS considers this to be a potential data gap with regard to the full examination of the transformation of Flufenacet in the water/sediment systems.

In the study with [Phenyl-U- ^{14}C]Flufenacet two water/sediment systems were used:

- NESA test system (NESA), containing silty clay loam sediment, having pH = 7.9, OC content of 0.7% and CEC of 33.5 meq/100 g, and associated water, having pH = 7.5, dissolved O_2 content of 9.2 ppm and the content of total dissolved solids of 82 ppm;
- BRP test system (BRP), containing silty clay loam sediment, having pH = 7.8, OC content of 1.4% and CEC of 25.6 meq/100 g, and associated water, having pH = 7.3, dissolved O_2 content of 8.5 ppm and the content of total dissolved solids of 120 ppm.

The experiment lasted for 156 days and the samples were incubated in the darkness at constant temperature $T = 20^{\circ}C$.

In the study with [Thiadiazole-2- ^{14}C]Flufenacet two water/sediment systems were used:

- NESA test system (NESA 1), containing silty clay sediment, having pH = 7.8, OC content of 0.38% and CEC of 22.0 meq/100 g, and associated water, having pH = 7.2, dissolved O_2 content of 9.2 ppm and the OC content of 331 ppm;
- BRP test system (BRP 1), containing silty clay loam sediment, having pH = 7.8, OC content of 1.54% and CEC of 13.02 meq/100 g, and associated water, having pH = 6.9, dissolved O_2 content of 10.0 ppm and the OC content of 415 ppm.

The experiment lasted for 156 days and the samples were incubated in the darkness at constant temperature $T = 20^{\circ}C$.

The key results of both studies with regard to the distribution of radioactivity in the test systems are presented below in the table B.8.2.2.3._CA-75. The detailed results of the profiling of radioactivity in the test water/sediment systems are presented in the table B.8.2.2.3._CA-76.

Footnotes to the table:

- 1) DAT 0 for all experiments;
- 2) DAT 157 for experiments with [Phenyl-U-¹⁴C] Flufenacet and DAT 156 for experiments with [Thiadiazole-2-¹⁴C] Flufenacet;
- 3) FOE TGS = FOE Thioglycolate sulfoxide.

The results obtained in the water/sediment systems confirm that Flufenacet cannot be considered readily biodegradable. It was also stated that the transformation pathway of Flufenacet in aerobic water/sediment systems was very similar to that determined in aerobic soil. It is presented below on figure B.8.2.2.3._CA-43. As already stated that transformation scheme cannot be considered complete due to the fact that the transformation of the thiadiazole moiety was not fully examined. In particular not examined was the formation of TFA from FOE Thiadone, the mechanism indicated in some literature studies (please refer to the point **B.8.2.6. – Impact on water treatment procedures**). That would result in the underestimation of the exposure in SW compartment based on the model calculations.

RMS was able to identify one open literature study examining the fate of several halogenoacetic acids, including TFA, in the test systems similar to the design used in water/sediment studies. On that basis it may be concluded that TFA, when formed from FOE Thiadone, will not undergo any substantial transformation in natural SW bodies and it will occur predominantly in water column.

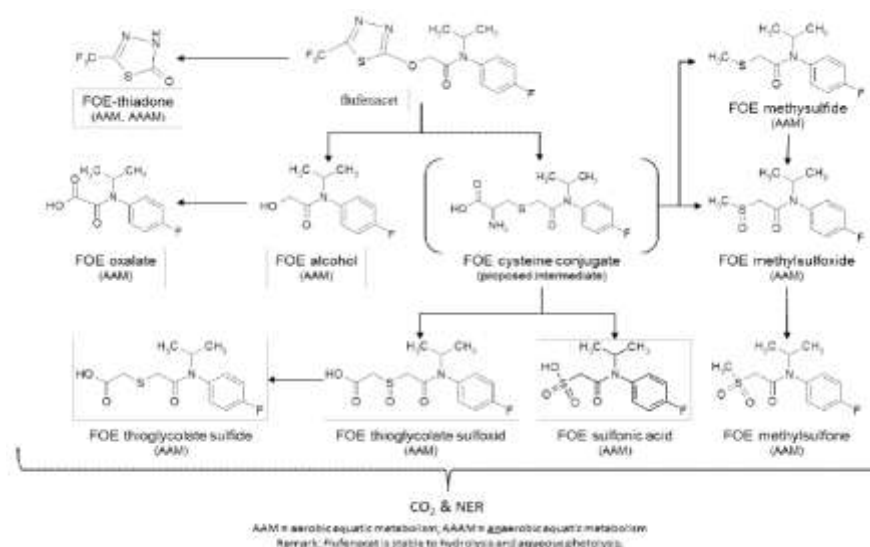

Figure B.8.2.2.3_CA-43: The transformation pathway of Flufenacet determined in aerobic water/sediment system (copied from the Applicant's report).

The results of the regulatory water/sediment studies were subjected to the kinetic examination in a separate study.

The kinetic analysis was performed for the data obtained for Flufenacet in the whole test systems as well as in water and sediment phases of each test system and was carried out on the Level P-I. Its aim was, in case of the whole-system data to determine the persistence endpoints for Flufenacet and the modelling endpoints. In case of water and sediment phases the kinetic analysis was aimed on the determination of the persistence endpoints. The analysis was performed in line with the recommendations given by FOCUS Kinetics Guidance document [FOCUS; 2006].

The key results of that examination are presented below in the table B.8.2.2.3_CA-77.

Table B.8.2.2.3_CA-77: The key results of the kinetic examination at the Level P-I of the data obtained for Flufenacet in water/sediment studies.

Study	Test system	Compartment	Kinetic model	Evaluation of fit		Kinetic parameter(s)		Kinetic endpoints	
				Visual	χ^2 % error	Parameter	Value	DT ₅₀ [days]	DT ₉₀ [days]

The calculated geomean values for the kinetic endpoints – DT₅₀ and DT₉₀, determined in the whole system are following **DT₅₀ = 49.54 days**, **DT₉₀ = 164.59 days**. These values are determined by the RMS. The geomean

whole-system DT_{50} value given in the study report is following: $DT_{50} = 49.6$ days. The difference between the two values is minimal and can be attributed to the rounding procedure used by the Applicant. Therefore the value proposed by the Applicant may be considered a reliable kinetic endpoint to be used as input parameter in SW model exposure assessment.

For water and sediment phases at the Level P-I the Applicant derived two sets of the kinetic endpoints – those representing persistence and those suitable for modelling. RMS however noticed that Flufenacet displayed quite high adsorption potential onto soil, with the geomean $K_{fOC} = 245.9$ mL/g (range 161.6 – 643.48 mL/g) and rather low solubility in water – 56 mg/L. That may indicate that the compound would display substantial affinity to the sediment phase. The examination of degradation of Flufenacet in natural water, not containing suspended sediment, showed that that process take long – more than 600 days. Additionally, studies on abiotic degradation of Flufenacet in water showed that only indirect photolysis may substantially contribute to the dissipation of Flufenacet from water, while abiotic hydrolysis is not a relevant degradation mechanism for Flufenacet. All that taken into account, also bearing in mind that the water/sediment studies were performed in absence of light, it may be assumed that the process of dissipation of Flufenacet from water column is, at least of mixed nature, partly being degradation and to some extent, if not predominantly, migration to the sediment, where the proper degradation occurs.

In order to verify that RMS decided to perform additional kinetic examination of the data for Flufenacet using the procedure corresponding to the Level P-II assessment. In that fitting the data for Flufenacet in water phase were treated as those for the parent compound, while the sediment phase was defined as the metabolite A1 compartment.

Unlike at the Level P-I for the sediment phase whole data set was fitted together with that for water phase.

The results obtained for water phase were comparable to those obtained for that compartment by the Applicant at the Level P-I. The kinetic endpoints obtained for the sediment phase were usually shorter than those obtained by the Applicant at the Level P-I, what also reflected differences in the kinetic approach. It shall be indicated that the fits obtained for Flufenacet in the sediment phase were also not always fully reliable, but of sufficient quality to draw the conclusions.

Finally, it was noticed that the values of the kinetic formation fraction – ff , characterising the flux from water to sediment phases were in all cases very close or equal to 1. That may indicate that the dominant mechanism of dissipation from water column is migration to the sediment.

On that basis the RMS stated that the geomean whole-system DT_{50} value when used in the modelling should be considered as representing the degradation of Flufenacet in sediment, not in the water column.

The Applicant also made an attempt to derive the kinetic endpoints for the two identified major degradation products – FOE Methylsulfide and FOE Thiadone. The kinetic analysis aimed on that was performed at the Level M-I using the whole-system data for Flufenacet and related degradation products kinetically fitted together. The results obtained for Flufenacet were very similar to those obtained for the same compound fitted alone at the Level P-I. However, it was not possible to obtain the reliable kinetic endpoints for the degradation products, due to the fact that the concentrations stillm increased at the end of the experiment – which was the case for FOE Methylsulfide, or the number of data point after maximum was reached was too low to obtain the reliable decline curve, what was observed in case of FOE Thiadone. Additionally, it shall be indicated that due to the poor fitting results the kinetic formation fractions determined for both degradation products shall be considered with care.

Also was submitted the study examining the fate and behaviour of Flufenacet in anaerobic water/sediment system. The study was evaluated for its compliance with OECD Guideline 308 – Aerobic and Anaerobic Transformation in Aquatic Sediment Systems. RMS stated that the study deviated from the reference Guideline in the following areas:

- **selection of sediment:** in the study soil was used instead of anaerobic sediment; the water overlying “sediment layer” was not that associated with it, but taken from pond located at the test facility, in the vicinity of the soil sampling area;
- **number of water/sediment systems:** the Guideline recommends at least two types of water/sediment systems to be used in experiment; in this case only one type was used;
- **duration of the experiment:** Guideline recommends that the study should usually not be longer than 100 days; in this case the study lasted for 388 days;
- the anaerobic conditions were not maintained throughout the incubation period and there is no indication in the study report when the change occurred; although in the study report it is declared that anaerobic conditions for ~99 days of incubation there is no experimental evidence conforming that statement;
- although the study lasted for 388 days and the test soil, used as a surrogate for sediment, was known, from other studies, to have problems with maintaining biological viability, in the study report the biological viability of the test system was not reported.

As a result, RMS stated that the study could not be considered as complying with the provisions of the reference Guideline, hence it was found not acceptable for the present assessment. Therefore RMS decided not to summarise it and use its results in the evaluation.

The results of the examination of fate and behaviour of Flufenacet in aerobic water/sediment systems, in format recommended for reporting the regulatory endpoints in the EU, are presented below. In that form the values will be inserted into the proposal for the EU List of End Points.

Water / sediment study (Regulation (EU) N° 283/2013, Annex Part A, point 7.2.2.3 and Regulation (EU) N° 284/2013, Annex Part A, point 9.2.2)

B.8.2.2.4. – Irradiated water/sediment study

The Applicant did not submit any study report specifically covering this data point. However, in the Document M-II, Section 7: Fate and behaviour in the environment, it was stated that such data were provided in the study, also submitted for the purpose of the previous authorisation of Flufenacet in the EU, examining fate and biological effects of that, formulated, compound in aquatic indoor mesocosm. The results obtained in that study with regard to the fate of Flufenacet in the test system were kinetically examined and the results presented in the study report submitted specifically for the purpose of the current evaluation.

The evaluation of both studies performed by the RMS is presented below.

Study 1:

Report: Foekema E. M., Jak R. G., (1999): “The fate and biological effects of Flufenacet WG 60 in aquatic indoor microcosms.”; TNO Institute of Environmental Sciences, Energy Research and Process Innovation, Business Part E. T. V., Laan van Westenenk 501, P. O. Box 342, 7300 AH Apeldoorn, The Netherlands (performing laboratory) for Bayer AG, Crop Protection, Institute for Environmental Biology, Agricultural Centre Monheim, D-51368 Leverkusen, Germany; study No. 30210 (TNO), TNO report No. TNO-MEP-R99/423; 29 November 1999; study reference number: M-023412-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guidance document “Freshwater Lentic Field Tests”, July 1996 (Draft);
- Guidance document on Testing Procedures for Pesticides in Freshwater Mesocosm (SETAC-Europe Workshop, Monks Wood, UK, July 1991).

GLP: Yes;

RMS comments: The study is indicated by the Applicant as an existing mesocosm study, evaluated for the previous authorisation of Flufenacet in the EU, but it was then evaluated only as ecotox study. Therefore as the study aimed on the examination of fate and behaviour of Flufenacet in the aquatic systems it may be considered as a newly submitted study, and hence evaluated specifically for the purpose of the current assessment. It shall be indicated that it was not listed by the Applicant as one of the studies examining the fate and behaviour of Flufenacet in aquatic system. RMS however decided to include it, because it was a data-source study for the next study, aimed on the kinetic examination of its results, presented further down this data point as **Study 2**.

It was evaluated for its compliance with the provisions of the OECD 308 Guideline – “Aerobic and Anaerobic Transformation in Aquatic Sediment Systems”, in line with the provisions of the Commission Regulation (EU) No. 283/2013 and the European Commission Communication 2013/C95/01, indicating that Guideline as the reference test guideline for the experiments carried out under the data requirement set by the point 7.2.2.4. of the Annex to the Commission Regulation (EU) No. 283/2013. The examination of the study report for its compliance with the evoked test Guideline showed that:

- the study was performed in the test system containing water phase and sediment sampled at two different locations – sediment from Geesteambach lake located in Northern Holland (mesotrophic lake) and water from lake Markermeer, which is a southwestern part of the lake IJsselmeer located in central part of the Netherlands (eutrophic lake); the OECD Guideline, in point 28, recommends to use sediment and water associated with it (from the same SW body) and at the same period;
- sediment used in the experiment was only characterised for its texture while other parameters required by the reference Guideline, such as CEC, pH, WHC, content of macro- and microelements, were not provided;
- the experiment was performed in open polyethylene containers (test tanks), while OECD 308 Guideline recommends the use of glass containers attached to the trap system for volatile compounds;
- The sediment layer used in the experiment was 10-cm thick, while the guideline recommends 2.5 ± 0.5 cm-layer, and the height of the water column above it was 50 cm;
- OECD 308 Guideline recommends to use radiolabelled test compound, what enables the determination of the mass balance as well as identification and quantitation of the degradation products, while in the experiment the non-radiolabelled Flufenacet was used;

- The experiment was performed using several initial concentrations of the test compound: 0 µg/L, 0.75 µg/L, 1.5 µg/L, 3.0 µg/L, 6.0 µg/L, 12.0 µg/L and 24.0 µg/L, while OECD 308 Guideline recommends one test concentration of the given compound should be used, reflecting the would-be maximum environmental concentration resulting from the use of the test compound in maximum label-recommended rate; it is admissible to use second concentration in case it is expected that the compound may reach the SW bodies via different migration routes and at significantly different concentrations;
- The test compound was applied as formulated product – WG 60 formulation, while OECD 308 states that “*The use of formulated products is not routinely recommended as formulation ingredients may affect the distribution of the test substance and/or transformation products between water and sediment phases.*” The use of formulated products is indicated as an alternative for poorly water-soluble products, which is not a case of Flufenacet;
- The average temperature of the test vessels during the experiment was $T = 16.4^{\circ}\text{C}$, but it varied from 15.3°C to 18.0°C ; the OECD 308 states that the experiment shall be performed at constant temperature within the range $10 - 30^{\circ}\text{C}$, but preferably (indicated appropriate temperature) at $T = 20 \pm 2^{\circ}\text{C}$;
- The concentration of Flufenacet in the test system was determined only in the water phase, by taking the representative samples from each test tank, while sediment was not analysed for the content of Flufenacet at the given time point (OECD 308 Guideline recommends the analysis of both water and sediment phase); as a result from that experiment solely the information on the dissipation of Flufenacet from water phase, including the uptake by plants introduced to the test tanks.

On the basis of the assessment presented above RMS stated that the experiment did not comply with the provisions of the OECD 308 Guideline and therefore cannot be considered acceptable as representing irradiated water/sediment study. It shall be also indicated that the study was also not considered acceptable, for the purpose of the current assessment, as a microcosm study (for more details please refer to the B.9 section of this Renewal Assessment Report). Therefore it was decided not to summarise the study report in its part relevant for the elucidation of the fate and behaviour of Flufenacet in water/sediment system, in order not to overburden the report.

Summary:

The evaluation of the study performed by the RMS showed that it was not acceptable. For that reason, in order not to overburden the Renewal Assessment Report, RMS decided not to summarise it.

Study 2:

Report: Reinken G., Maassen K., (2014): “Kinetic Evaluation of the Dissipation Behaviour of Flufenacet in Aquatic Microcosm Systems According to FOCUS Kinetics Using the KinGUI 2 Tool. Flufenacet (FOE 5043).”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; Report No. En-Sa-14-0127; 2014. 02. 18; study reference number: M-478447-01-1

Guidelines: The study was performed to comply with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.”; Report of the Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005, version 2.0, 434 pp.;
- FOCUS (2011): “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies in EU Registration, version 1.0, 436 pp.

GLP: No, not applicable – this is a modelling study;

RMS comments: This is a newly submitted study, providing the kinetic examination of the results of the determination of concentration of Flufenacet in water phase of the indoor microcosms, presented in the study by [Foekema and Jak; 1999]. RMS, for the purpose of the current

assessment evaluated the study for its compliance with the Guidelines evoked above. It can be stated that the kinetic assessment presented in the study was in line with the provisions of the FOCUS Kinetics Guidance Document. The Applicant justifying the submission of the study in LCA-Section-7 document provided the following statement: *“Additional data: Kinetic analysis of the dissipation of flufenacet in aquatic indoor microcosm system for modelling purpose and trigger evaluation.”* It shall be indicated that RMS, having evaluated the source study stated that it cannot be considered acceptable. As a result also the kinetic analysis of its results cannot be considered acceptable for registration purposes. Therefore RMS decided not to summarise this study report in order not to overburden the Renewal Assessment Report.

Summary:

The evaluation of the study performed by the RMS showed that although it was acceptable from the methodological point of view, it was aimed on the assessment of the data presented in the study report that was found not acceptable. Therefore the study cannot be considered as providing the reliable kinetic endpoints. For that reason, in order not to overburden the Renewal Assessment Report, RMS decided not to summarise it.

B.8.2.4 – Degradation in the saturated zone

The problem of the degradation of Flufenacet in the saturated zone was not examined for the purpose of the present evaluation. Instead the Applicant in the document MCA for the Section 7: Environmental Fate and Behaviour, in order to address the problem, made the following statement: *“The degradation of flufenacet in the saturated zone was not studied since flufenacet is not expected to reach the saturated zone after its use according to good agricultural practices.”*. That statement may be considered justified as long as it concerns GW recharge, however it cannot be excluded that the problem of the degradation of Flufenacet in the saturated zone may be relevant with regard to other issues, in particular bank filtration as a first stage of drinking water abstraction from the surface water (riverine). The problem is discussed in a more detailed way under the point B.8.2.6 of this document, therefore RMS is of the opinion that it does not require more extensive consideration under this point.

It shall be indicated that for the purpose of the former evaluation of Flufenacet for its authorisation in the EU the then-RMS – France, made the following statement in this area (please also refer to the point B.7.4.4 of the Annex B.7 of the Assessment Report): *“No special studies were performed on the degradation of FOE 5043 and its metabolites in the saturated zone. However, this requirement is considered to be covered by the lysimeter studies under the point 7.2.4. Additional information can be derived from the studies on the metabolism in soil (section 7.1.1.) and on hydrolytic degradation (section 7.4.1.).”*.

RMS – Poland, is of the opinion that for the purpose of the current assessment this statement may be considered valid.

Finally, it shall be indicated that the results of the examination of the transformation pathways of Flufenacet in the aquatic systems, in particular water/sediment studies, showed that it should be very similar, if not identical, to that determined in soil. Therefore RMS is of the opinion that there is no need for more extensive examination of that problem and that it may be covered by the data obtained in the other areas of the assessment.

B.8.2.5 – Summary of persistence in surface water and degradation in the saturated zone

The determination of transformation pathways and persistence of Flufenacet in the aquatic environment was performed by examining potentially relevant abiotic and biologically-mediated processes.

The examination of abiotic degradation of Flufenacet in the aquatic environment comprised the following processes:

- abiotic aqueous hydrolysis;
- direct aqueous photolysis;
- indirect aqueous photolysis.

The **abiotic hydrolysis of Flufenacet** was examined at three different pH – pH = 5, pH = 7 and pH = 9 (environmentally relevant pH range) and T = 25°C. The results of that examination, presented in one study report, demonstrated that Flufenacet was hydrolytically stable within the whole examined pH range. The determined in that experiment half-lives at T = 25°C were: DT₅₀ > 1000 days for pH 5-7 and DT₅₀ = 655 days for pH = 9.

Additionally the results presented in the open source paper identified as a relevant for the evaluation of Flufenacet showed that the pH of the aqueous solution, and hence the hydrolysis, had only minimal influence on the rate of dissipation/degradation of Flufenacet from water (biologically viable). The results of that study were considered however only as indicative and were not used to derive the regulatory endpoints.

Also stable to abiotic hydrolysis in the aquatic environment, for the same environmentally relevant conditions, was demonstrated to be the major soil and aquatic major degradation product of Flufenacet – FOE Thiadone. The determined half-lives were DT₅₀ > 1000 days for the whole tested range pH = 5-9 and T = 25°C.

The **direct aqueous photolysis of Flufenacet** was examined in a sterile buffer solution having pH = 5 and T = 21°C. The samples were exposed to UV-Vis radiation generated by the artificial light source. The irradiation conditions were similar to those recorded during 30-days exposure to natural summer sunlight in Phoenix, Arizona, USA. The results demonstrated that Flufenacet was not prone to the direct aqueous photolysis – practically no photodegradation of Flufenacet, in comparison to what was observed in the dark control samples, was stated. The determined half-lives were: for irradiated sample DT₅₀ = 7430 days when expressed in Natural Sunlight days, and for the dark control samples DT₅₀ = 4160 days.

In a separate experiment the quantum yield of the process of direct photodegradation of Flufenacet in water was determined. The quantum yield value determined in that experiment was $\phi = 0.00096$ [mol/Einstein]. The calculated using that value environmental photolytical half-lives for Flufenacet, calculated using GC-Solar method in water were:

- for the latitude 30°N in range DT₅₀ = 126 – 308 days;
- for the latitude 40°N in range DT₅₀ = 131 – >365 days;
- for the latitude 50°N in range DT₅₀ = 142 – >365 days;
- for the latitude 60°N in range DT₅₀ = 160 – >365 days;

Additionally, in a separate study, was examined the direct aquatic photolysis of the major soil and aquatic degradation product of Flufenacet – FOE Thiadone. The experiment was performed in a sterile buffer solution having pH = 7 and T = 25°C. The samples were exposed to UV-Vis radiation generated by the artificial light source. The irradiation conditions were similar to those recorded during 30-days exposure to natural summer sunlight in Phoenix, Arizona, USA. The results demonstrated that FOE Thiadone not prone to the direct aqueous photolysis – practically no photodegradation of that compound was observed in either irradiated samples or in dark control and it was not possible to determine the reliable DT₅₀ values.

The **indirect aqueous photolysis of Flufenacet** was examined in four types of aqueous solutions:

- natural pond water having pH = 6.5, TOC = 20.7 mg/L and containing 160 mg/L of suspended solids (total), subsequently named Howe pond water;
- natural pond water having pH = 7.8, TOC = 1.55 mg/L and containing 9 mg/L of suspended solids, subsequently named Stilwell pond water;
- ultrapure water containing 15 ppm of humic material;
- ultrapure water containing 50 ppm KNO₃.

The samples were exposed to UV-Vis radiation generated by artificial light source, but bearing the characteristic of the natural sunlight. The irradiation conditions were similar to those recorded during the

30-days exposure to natural summer light in Phoenix, Arizona, USA. The experiment showed that Flufenacet was prone to indirect photolysis in water, although that process should not be regarded as one of the driving mechanisms in disappearance of Flufenacet from natural waters. The experiments were aimed on the determination of the kinetic parameters of the process – the rates of the indirect photodegradation of Flufenacet in water, therefore no attempt was made to identify and quantify the formed degradation products.

The calculated, net, half-lives for the indirect photodegradation of Flufenacet in water were following:

- for Howe pond water the experimentally derived (continuous irradiation) **DT₅₀ = 160.08 days**, what corresponded to **DT₅₀ = 468.53 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA);
- for Stilwell pond water the experimentally derived (continuous irradiation) **DT₅₀ = 281 days**, what corresponded to **DT₅₀ = 822 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA);
- for ultrapure water containing 15 ppm of Humic material the experimentally derived (continuous irradiation) **DT₅₀ = 114 days**, what corresponded to **DT₅₀ = 332 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA);
- for ultrapure water containing 50 ppm of KNO₃ the experimentally derived (continuous irradiation) **DT₅₀ = 27.5 days**, what corresponded to **DT₅₀ = 158 days** for exposure to natural summer sunlight at 33° 26' N (in June at Phoenix, Arizona, USA).

It shall be however indicated that these values were determined using the results obtained in non-GLP experiments (being an additional part of a GLP study aimed on the examination of the direct aqueous photolysis of Flufenacet). For that reason RMS decided to consider them as only indicative and not to include them into the EU List of Endpoints.

Additionally, in a separate experiment, was examined the indirect aqueous photolysis of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet. The test medium was sterilised natural (riverine) water. The samples were exposed to UV-Vis radiation generated by artificial light source, but bearing the characteristic of the natural sunlight. The irradiation conditions were similar to those recorded during the 30-days exposure to natural summer light in Phoenix, Arizona, USA. The experiment showed that FOE Thiadone was prone to indirect photolysis in water, although that process should not be regarded as one of the driving mechanisms in disappearance of Flufenacet from natural waters. The experiment was performed with the test compound radiolabelled at C2 position in thiadiazole ring, what resulted in identification only CO and CO₂ as degradation products. Therefore it remains unknown what are the degradation products associated with the second carbon atom within the thiadiazole ring – C5. However, it may be assumed that one of such products could be TFA. The calculated, net, rate of indirect photodegradation of FOE Thiadone in water was **k = 0.1194 [days⁻¹]**, corresponding to **DT₅₀ = 5.8 days** in samples continuously irradiated with artificial sunlight. When recalculated to the natural conditions that value corresponded to:

- **DT₅₀ = 15.8 days** determined for summer sunlight conditions (June) in Phoenix, Arizona, USA (33° 26' N);
- **DT₅₀ = 24.4 days** determined for summer sunlight conditions (June) in Athens, Greece, EU (38° 03' N);
- **DT₅₀ = 30.5 days** determined for summer sunlight conditions (July) in London, UK, EU (51° 30' N).

These results were reported in the EU List of Endpoints for Flufenacet.

The assessment of biologically-mediated transformation of Flufenacet in the aquatic environment covered the following issues:

- examination of the ready biodegradability;
- examination of the aerobic mineralisation in surface water;
- examination of the fate and behaviour of Flufenacet in aerobic water/sediment systems;
- examination of the fate and behaviour of Flufenacet in irradiated aerobic water/sediment systems;
- examination of the degradation of Flufenacet in saturated zone (anaerobic water/sediment system).

The Applicant has not submitted any study report presenting the results of the examination of **ready biodegradability of Flufenacet**. Instead the following justification for non-submission was provided:

“Flufenacet was stated to be not ready biodegradable. This was accepted by the European Commission (7469/VI/98-Final -3rd July 2003). Therefore no additional study was performed for the flufenacet renewal of approval.” The justification for non-provision of the adequate study may be considered acceptable. RMS examining the submitted documentation stated that the Applicant submitted a study examining the degradation of Flufenacet in natural water. Also are available two studies examining the fate and behaviour of Flufenacet in aerobic water/sediment systems. These studies provided information on the mineralisation of Flufenacet in

aquatic environment. Their results confirm that Flufenacet shall be classified as not readily biodegradable, hence the conclusion drawn during the previous evaluation of Flufenacet for its authorisation in the EU remains valid.

The **aerobic mineralisation of Flufenacet in surface water** was examined in pelagic (pond) freshwater collected from the pond representative for the agricultural area of the use of Flufenacet. The test water had the following characteristics:

- type of water sample: pelagic water (no associated sediment);
- pH: 7.5;
- total alkalinity: 230 mg CaCO₃/L;
- total hardness: 329 mg CaCO₃/L;
- specific conductivity: 500 µmhos/cm;
- [O₂]: 9.6 mg/L;
- Suspended solids: 8.5 mg/L;
- Microbial activity, expressed in number of the colony forming units (CFU): 5.9 E3 CFU/mL.

The examination of the degradation of Flufenacet in water was performed in irradiated test systems, under light regime similar to natural sunlight conditions. The mean temperature of incubation was in range 23.1 – 24.4 (mean estimated by the RMS is 23.75°C), therefore slightly deviating from the assumed $T = 25 \pm 1^\circ\text{C}$.

The experiment was performed with Flufenacet radiolabelled in only one position – in fluorophenyl ring, therefore the proposed transformation scheme cannot be considered as complete. In case of the biologically viable samples three degradation products were identified and quantified:

- FOE Alcohol, recorded for the first time on DAT 60, peaking at 4.4% of the applied amount of the parent compound on DAT 368 (end of the study) and that amount was still seemingly increasing;
- FOE Oxalate, recorded for the first time on DAT 60, peaking at 24.0% of the applied amount of the parent compound on DAT 368 (end of the study) and that amount was still increasing;
- FOE Sulfonic acid, recorded for the first time on DAT 278, peaking at 8.6% of the applied amount of the parent compound on DAT 368 (end of the study) and that amount was still increasing;

In sterilised samples only one degradation product was identified – FOE Alcohol, observed for the first time on DAT 278 and formed in amount up to 6.8% of the applied amount of the parent compound (value recorded at the end of the study – on DAT 368).

The proposed, partial, transformation scheme for Flufenacet in natural, microbiologically viable water, resulting from that examination, is presented below on figure B.8.2.5._CA-1.

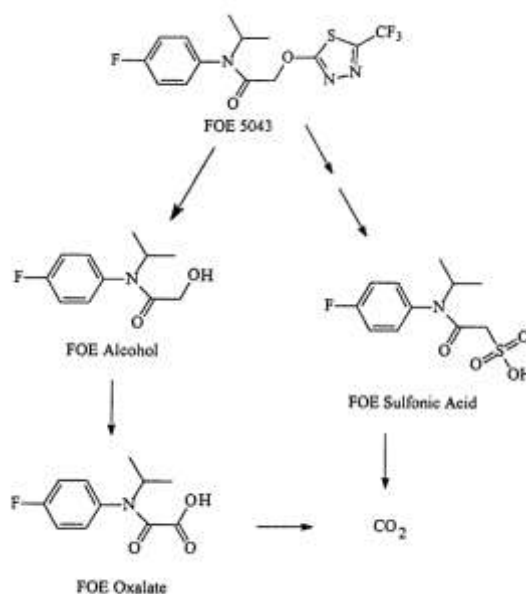

Figure B.8.2.5._CA-1: The proposed, partial transformation pathway of Flufenacet in natural, microbiologically viable water (copied from the study report).

During that experiment, lasting for 368 days, it was stated that Flufenacet radiolabelled in fluorophenyl moiety, underwent very limited mineralisation – up to 3.0% of the applied dose was fully mineralised in the biologically viable samples. That indicates that Flufenacet cannot be considered ready biodegradable. In the sterilised samples the level of mineralisation was up to 0.8% at the end of incubation period – DAT 368.

It shall be pointed out that the so determined transformation pathway of Flufenacet was only partial, as it fully covered only one moiety within the molecule – that comprising fluorophenyl ring and attached to it n-alkyl chain. At the same time however it shall be indicated that the main functional group within that moiety – fluorophenyl ring, displayed high persistence, what enabled to estimate with quite good accuracy not only persistence of Flufenacet in natural, microbiologically viable water, but also overall level of mineralisation of the molecule.

The process of degradation of Flufenacet in pelagic water was slow, with $DT_{50} = 473$ days and $DT_{90} = 1570$ days in non sterilised water, and it followed the SFO kinetic model. When recalculated to the standard temperature – $T = 20^{\circ}\text{C}$ (using Arrhenius activation energy $E_a = 65.4$ kJ/mol) these values were: $DT_{50} = 664$ days and $DT_{90} = 2204.1$ days.

In sterilised water the rate of degradation, also following the SFO kinetics, was much slower, with $DT_{50} = 2230$ days and $DT_{90} = 7410$ days. When recalculated to the standard temperature – $T = 20^{\circ}\text{C}$ (using Arrhenius activation energy $E_a = 65.4$ kJ/mol) these values were: $DT_{50} = 3130.7$ days and $DT_{90} = 10402.9$ days.

The kinetic examination of the results for any of the identified and quantified degradation products was not possible due to the fact that all they were still forming at the study end.

These results demonstrated that the process of the degradation of Flufenacet in natural pelagic water was predominantly biologically mediated and that the abiotic degradation processes – hydrolysis and aqueous photolysis (direct and indirect) played only minor role, if any.

The transformation pattern of Flufenacet in aerobic water/sediment systems was examined in two separate studies, using Flufenacet radiolabelled at two different positions – uniformly in fluorophenyl ring as [Phenyl- $U\text{-}^{14}\text{C}$]Flufenacet – one of the studies ([Kelley et al.; 1995]), and in C2 position of Thiadiazole moiety as [Thiadiazole - $2\text{-}^{14}\text{C}$]Flufenacet – second study ([Halarnkar and Irwin; 1997]). In each study two water/sediment systems were used, bearing codenames (common for both studies) NESAs and BRPs. It shall be indicated however that although sampled on the same locations the test systems did not bear the same characteristics, therefore shall be considered as individual test systems and not the replicates. RMS examining the data set noticed that the examination of the transformation of the thiadiazole moiety of Flufenacet was performed for only C2 radiolabelling position, while C5 radiolabelling position was not covered. That resulted in the lack of data concerning the potential formation of TFA and, possibly (if the degradation pattern was similar to that observed in aerobic soil) FOE TFESA. RMS considers this to be a potential data gap with regard to the full examination of the transformation of Flufenacet in the water/sediment systems.

In the study with [Phenyl- $U\text{-}^{14}\text{C}$]Flufenacet two water/sediment systems were used:

- NESAs test system (NESAs), containing silty clay loam sediment, having $\text{pH} = 7.9$, OC content of 0.7% and CEC of 33.5 meq/100 g, and associated water, having $\text{pH} = 7.5$, dissolved O_2 content of 9.2 ppm and the content of total dissolved solids of 82 ppm;
- BRPs test system (BRPs), containing silty clay loam sediment, having $\text{pH} = 7.8$, OC content of 1.4% and CEC of 25.6 meq/100 g, and associated water, having $\text{pH} = 7.3$, dissolved O_2 content of 8.5 ppm and the content of total dissolved solids of 120 ppm.

The experiment lasted for 156 days and the samples were incubated in the darkness at constant temperature $T = 20^{\circ}\text{C}$.

In the study with [Thiadiazole- $2\text{-}^{14}\text{C}$]Flufenacet two water/sediment systems were used:

- NESAs test system (NESAs 1), containing silty clay sediment, having $\text{pH} = 7.8$, OC content of 0.38% and CEC of 22.0 meq/100 g, and associated water, having $\text{pH} = 7.2$, dissolved O_2 content of 9.2 ppm and the OC content of 331 ppm;
- BRPs test system (BRPs 1), containing silty clay loam sediment, having $\text{pH} = 7.8$, OC content of 1.54% and CEC of 13.02 meq/100 g, and associated water, having $\text{pH} = 6.9$, dissolved O_2 content of 10.0 ppm and the OC content of 415 ppm.

The experiment lasted for 156 days and the samples were incubated in the darkness at constant temperature $T = 20^{\circ}\text{C}$.

The key results of both studies with regard to the distribution of radioactivity in the test systems are presented below in the table B.8.2.5._CA-1. The detailed results of the profiling of radioactivity in the test water/sediment systems are presented in the table B.8.2.5._CA-2.

Footnotes to the table:

- 1) DAT 0 for all experiments;
- 2) DAT 157 for experiments with [Phenyl-U-¹⁴C] Flufenacet and DAT 156 for experiments with [Thiadiazole-2-¹⁴C] Flufenacet;
- 3) FOE TGS = FOE Thioglycolate sulfoxide.

The results obtained in the water/sediment systems conform that Flufenacet cannot be considered readily biodegradable. It was also stated that the transformation pathway of Flufenacet in aerobic water/sediment systems was very similar to that determined in aerobic soil. It is presented below on figure B.8.2.5._CA-2. As already stated that transformation scheme cannot be considered complete due to the fact that the transformation of the thiadiazole moiety was not fully examined. In particular not examined was the formation of TFA from FOE Thiadone, the mechanism indicated in some literature studies (please refer to the point **B.8.2.6. – Impact on water treatment procedures**). That would result in the underestimation of the exposure in SW compartment based on the model calculations.

RMS was able to identify one open literature study examining the fate of several halogenoacetic acids, including TFA, in the test systems similar to the design used in water/sediment studies. On that basis it may be concluded that TFA, when formed from FOE Thiadone, will not undergo any substantial transformation in natural SW bodies and it will occur predominantly in water column.

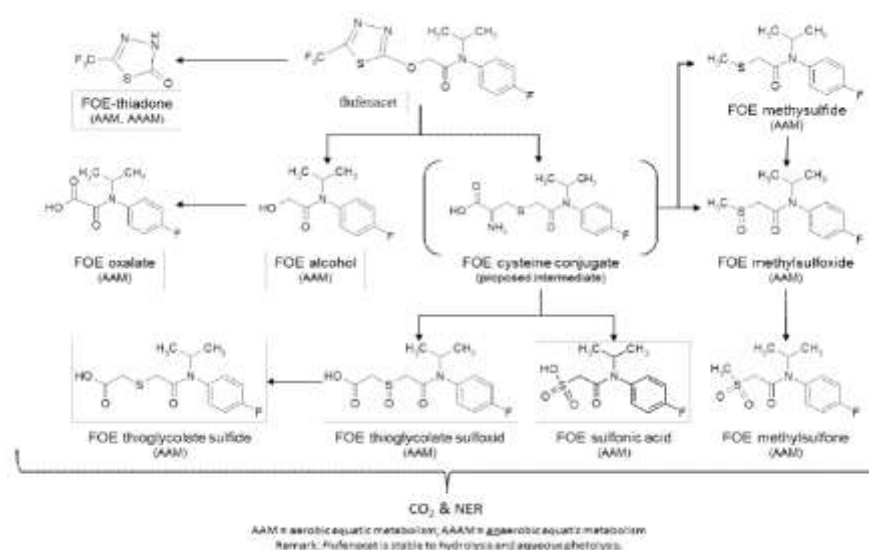

Figure B.8.2.5_CA-2: The transformation pathway of Flufenacet determined in aerobic water/sediment system (copied from the Applicant's report).

The results of the regulatory water/sediment studies were subjected to the kinetic examination in a separate study.

The kinetic analysis was performed for the data obtained for Flufenacet in the whole test systems as well as in water and sediment phases of each test system and was carried out on the Level P-I. Its aim was, in case of the whole-system data to determine the persistence endpoints for Flufenacet and the modelling endpoints. In case of water and sediment phases the kinetic analysis was aimed on the determination of the persistence endpoints. The analysis was performed in line with the recommendations given by FOCUS Kineitics Guidance document [FOCUS; 2006].

The key results of that examination are presented below in the table B.8.2.5_CA-3.

Table B.8.2.5_CA-3: The key results of the kinetic examination at the Level P-I of the data obtained for Flufenacet in water/sediment studies.

Study	Test system	Compartment	Kinetic model	Evaluation of fit		Kinetic parameter(s)		Kinetic endpoints	
				Visual	χ^2 % error	Parameter	Value	DT ₅₀ [days]	DT ₉₀ [days]

The calculated geomean values for the kinetic endpoints – DT₅₀ and DT₉₀, determined in the whole system are following **DT₅₀ = 49.54 days**, **DT₉₀ = 164.59 days**. These values are determined by the RMS. The geomean

whole-system DT_{50} value given in the study report is following: $DT_{50} = 49.6$ days. The difference between the two values is minimal and can be attributed to the rounding procedure used by the Applicant. Therefore the value proposed by the Applicant may be considered a reliable kinetic endpoint to be used as input parameter in SW model exposure assessment.

For water and sediment phases at the Level P-I the Applicant derived two sets of the kinetic endpoints – those representing persistence and those suitable for modelling. RMS however noticed that Flufenacet displayed quite high adsorption potential onto soil, with the geomean $K_{fOC} = 245.9$ mL/g (range 161.6 – 643.48 mL/g) and rather low solubility in water – 56 mg/L. That may indicate that the compound would display substantial affinity to the sediment phase. The examination of degradation of Flufenacet in natural water, not containing suspended sediment, showed that that process take long – more than 600 days. Additionally, studies on abiotic degradation of Flufenacet in water showed that only indirect photolysis may substantially contribute to the dissipation of Flufenacet from water, while abiotic hydrolysis is not a relevant degradation mechanism for Flufenacet. All that taken into account, also bearing in mind that the water/sediment studies were performed in absence of light, it may be assumed that the process of dissipation of Flufenacet from water column is, at least of mixed nature, partly being degradation and to some extent, if not predominantly, migration to the sediment, where the proper degradation occurs.

In order to verify that RMS decided to perform additional kinetic examination of the data for Flufenacet using the procedure corresponding to the Level P-II assessment. In that fitting the data for Flufenacet in water phase were treated as those for the parent compound, while the sediment phase was defined as the metabolite A1 compartment.

Unlike at the Level P-I for the sediment phase whole data set was fitted together with that for water phase.

The results obtained for water phase were comparable to those obtained for that compartment by the Applicant at the Level P-I. The kinetic endpoints obtained for the sediment phase were usually shorter than those obtained by the Applicant at the Level P-I, what also reflected differences in the kinetic approach. It shall be indicated that the fits obtained for Flufenacet in the sediment phase were also not always fully reliable, but of sufficient quality to draw the conclusions.

Finally, it was noticed that the values of the kinetic formation fraction – ff , characterising the flux from water to sediment phases were in all cases very close or equal to 1. That may indicate that the dominant mechanism of dissipation from water column is migration to the sediment.

On that basis the RMS stated that the geomean whole-system DT_{50} value when used in the modelling should be considered as representing the degradation of Flufenacet in sediment, not in the water column.

The Applicant also made an attempt to derive the kinetic endpoints for the two identified major degradation products – FOE Methylsulfide and FOE Thiadone. The kinetic analysis aimed on that was performed at the Level M-I using the whole-system data for Flufenacet and related degradation products kinetically fitted together. The results obtained for Flufenacet were very similar to those obtained for the same compound fitted alone at the Level P-I. However, it was not possible to obtain the reliable kinetic endpoints for the degradation products, due to the fact that the concentrations still increased at the end of the experiment – which was the case for FOE Methylsulfide, or the number of data point after maximum was reached was too low to obtain the reliable decline curve, what was observed in case of FOE Thiadone. Additionally, it shall be indicated that due to the poor fitting results the kinetic formation fractions determined for both degradation products shall be considered with care.

Also was submitted the study examining the **fate and behaviour of Flufenacet in anaerobic water/sediment system**. The study was evaluated for its compliance with OECD Guideline 308 – Aerobic and Anaerobic Transformation in Aquatic Sediment Systems. RMS stated that the study deviated from the reference Guideline in the following areas:

- **selection of sediment:** in the study soil was used instead of anaerobic sediment; the water overlying “sediment layer” was not that associated with it, but taken from pond located at the test facility, in the vicinity of the soil sampling area;
- **number of water/sediment systems:** the Guideline recommends at least two types of water/sediment systems to be used in experiment; in this case only one type was used;
- **duration of the experiment:** Guideline recommends that the study should usually not be longer than 100 days; in this case the study lasted for 388 days;
- the anaerobic conditions were not maintained throughout the incubation period and there is no indication in the study report when the change occurred; although in the study report it is declared that anaerobic conditions for ~99 days of incubation there is no experimental evidence conforming that statement;
- although the study lasted for 388 days and the test soil, used as a surrogate for sediment, was known, from other studies, to have problems with maintaining biological viability, in the study report the biological viability of the test system was not reported.

As a result, RMS stated that the study could not be considered as complying with the provisions of the reference Guideline, hence it was found not acceptable for the present assessment. Therefore RMS decided not to summarise it and use its results in the evaluation.

The issue of the determination of **fate and behaviour of Flufenacet in irradiated water/sediment system** was covered by the Applicant by submitting a study report presenting the kinetic evaluation of the results obtained in the indoor mesocosm study. The indoor mesocosm study ([Foekema and Jak.; 1999]) was indicated by the Applicant as the study covering the problem of transformation in irradiated water/sediment systems. RMS evaluated the study and stated that it displayed several deficiencies not enabling to consider it a reliable regulatory study addressing the problem of fate and behaviour in irradiated water/sediment systems. As a result also the study presenting the kinetic analysis of its results cannot be considered valid for regulatory purposes. At the same time it shall be indicated that the kinetic analysis it presents was performed in line with the recommendations of the FOCUS Work Group on the Degradation Kinetics ([FOCUS; 2006]), therefore formally meeting the acceptability criteria.

It shall be however indicated that the lack of the proper regulatory study examining the problem of the transformation of Flufenacet in the irradiated water/sediment systems does not result in the data gap, as the issue is satisfactorily covered by the other studies submitted for this assessment.

The problem of the **degradation of Flufenacet in the saturated zone** was not examined for the purpose of the present evaluation. Instead the Applicant in the document MCA for the Section 7: Environmental Fate and Behaviour, in order to address the problem, made the following statement: *“The degradation of flufenacet in the saturated zone was not studied since flufenacet is not expected to reach the saturated zone after its use according to good agricultural practices.”*. That statement may be considered justified as long as it concerns GW recharge, however it cannot be excluded that the problem of the degradation of Flufenacet in the saturated zone may be relevant with regard to other issues, in particular bank filtration as a first stage of drinking water abstraction from the surface water (riverine). The problem is discussed in a more detailed way under the point B.8.2.6 of this document, therefore RMS is of the opinion that it does not require more extensive consideration under this point.

It shall be indicated that for the purpose of the former evaluation of Flufenacet for its authorisation in the EU the then-RMS – France, made the following statement in this area (please also refer to the point B.7.4.4 of the Annex B.7 of the Assessment Report): *“No special studies were performed on the degradation of FOE 5043 and its metabolites in the saturated zone. However, this requirement is considered to be covered by the lysimeter studies under the point 7.2.4. Additional information can be derived from the studies on the metabolism in soil (section 7.1.1.) and on hydrolytic degradation (section 7.4.1.).”*.

RMS – Poland, is of the opinion that for the purpose of the current assessment this statement may be considered valid.

Finally, it shall be indicated that the results of the examination of the transformation pathways of Flufenacet in the aquatic systems, in particular water/sediment studies, showed that it should be very similar, if not identical, to that determined in soil. Therefore RMS is of the opinion that there is no need for more extensive examination of that problem and that it may be covered by the data obtained in the other areas of the assessment.

Summarising the data presented above it may be stated that in the aquatic compartment of the environment Flufenacet is expected to be moderately persistent, with half life in water $DT_{50} = 29.4$ days (geomean; range 16.9 – 58.8 days) and that in sediment $DT_{50} = 61.5$ days (geomean; range 17.6 – 140.5 days). The half life in the whole compartment (water and sediment together) is estimated to be $DT_{50} = 49.6$ days (geomean; range 19.6 – 90.3 days). The dissipation from water column was demonstrated to occur mainly by migration to sediment, where the compound will be degraded to several degradation products, identical to those identified in soil.

The degradation of Flufenacet in the aquatic environment was demonstrated to be biologically-mediated process, while the abiotic processes – abiotic hydrolysis and direct photolysis were shown to be not relevant degradation mechanism for Flufenacet in that component of the environment. Of the abiotic degradation processes only indirect aqueous photolysis may be considered relevant, contributing to degradation of Flufenacet in water column (understood as the decomposition of the molecule) to similar extent as the microbial transformation.

Flufenacet was demonstrated to be not readily biodegradable.

B.8.2.6 - Impact on water treatment procedures

In the documentation submitted by the Applicant this issue was not addressed. Therefore the whole assessment presented below is based on the results of the repeated literature search performed by the RMS.

The analysis performed by the RMS focused mainly on the potential impact of Flufenacet and its identified major degradation products on drinking water abstraction procedures. The identified publications also enabled to briefly evaluate the possible impact of the residues of Flufenacet on wastewater treatment processes. However, as the problem is also dealt with, and to greater extent in section B.9. – Ecotoxicology, of this Renewal Assessment Report, RMS decided to signalise the issue instead of examining it thoroughly.

The assessment of the impact on the processes of abstraction of drinking water consisted of the following steps:

- a) examination of the available data resulting from the assessment of the documentation provided by the Applicant in order to determine the possibility of Flufenacet and its identified major degradation products of reaching drinking water abstraction plants and estimation of their fate during the various stages of the process,
- b) analysis of the structural formula of Flufenacet in order to examine the possibility of the formation of the unwanted/toxic by-products of the water abstraction processes, in particular disinfection using halogenated (chlorinated) compounds and UV light; the analysis was focused on the halogenated by-products, such as haloacetic acids, and nitrosamines;
- c) analysis of the identified publications in order to determine the potential of generating nitrosamines from Flufenacet and/or its degradation products present in the substrate after filtration;
- d) characterisation, on the basis of the available literature data, of the processes leading to the effective elimination of Flufenacet from the treated substrate during the abstraction of drinking water;
- e) characterisation, on the basis of the available literature data, the impact of the degradation products of Flufenacet on the process and the risk they may pose to the consumers.

The analysis of the data available in the documentation submitted by the Applicant showed that Flufenacet is not mobile in soil, with average $K_{fOC} = 245$ mL/g. That in turn may indicate that when reaching the drinking water abstraction plants in substrate – surface water, it should be effectively eliminated at early stages – bank filtration, filtration on sand and gravel filters and finally on GAC (Granular Activated Carbon) filters. Similar statement can be made in case of wastewater treatment plants, where it is expected that the compound should be efficiently removed at early stages – during mechanical and chemical treatment (filtration, sedimentation using coagulants and/or flocculants, e. t. c.). Therefore, it can be estimated that in wastewater treatment plants only small fraction of the initial amount of Flufenacet present in the “substrate” would reach the biological stage of the process. The problem of the impact on biological treatment of wastewater is dealt with in more detailed way in section B.9. – Ecotoxicology of this Renewal Assessment Report, therefore it is recommended to consult the relevant point in that section. However, the literature search performed by the RMS enabled the identification of at least one publication examining the impact of Flufenacet on the performance of typical, small biological wastewater treatment installation, designed to deal with wastewater generated on the farm and containing the residues of Plant Protection Products. That publication will be summarised further down this part of the Report.

Flufenacet was demonstrated to be not prone to abiotic hydrolysis and direct photolysis. Therefore it may be stated that at later stages of the process of abstraction of drinking water – the disinfection of the product using UV light, it is not expected that any potentially harmful transformation products, if Flufenacet is present at that stage, may be formed.

The indirect photolysis is not expected to be of any relevance at this stage, as the compounds considered to be photosensitizers shall be removed from the processed substrate at earlier stages of the whole process.

As the trace amounts of Flufenacet may still be present in the treated substrate – water processed with aim to obtain drinking water, after filtration, it is necessary to assess would it pose any threat to the consumer, via formation of unwanted/toxic by-products of chemical disinfection through chlorination or ozonation. As such may be considered various nitrosamines or low-weight haloorganic compounds. On the basis of the data presented by the Applicant such assessment was not possible. As a result it had to be based fully on the structural examination of Flufenacet and available literature data. That assessment is presented further down this chapter.

Finally, it shall be indicated that the results of both model exposure assessment and the lysimeter studies showed that Flufenacet is not expected to leach to the groundwater compartment in any significant amounts and

hence pose a risk to that compartment. As a result, it will not be a compound of concern in case drinking water is abstracted from that source.

As a result of the examination of fate and behaviour of Flufenacet in soil and aquatic environment seven degradation products were identified that were classified as major in soil, in water or in both components. These are:

- FOE Oxalate, observed forming in soil and aquatic environment, but only in soil classified as a major degradation/transformation product;
- FOE Sulfonic acid observed forming in soil and aquatic environment, but only in soil classified as a major degradation/transformation product;
- FOE Methylsulfone observed forming in soil and aquatic environment, but only in soil classified as a major degradation/transformation product;
- FOE Methylsulfide observed forming only in the aquatic environment and there classified as a major degradation/transformation product;
- FOE Thiadone observed forming in soil and aquatic environment, and in both environmental compartments classified as a major degradation/transformation product;
- FOE 5043-Trifluoroethanesulfonic acid (FOE TFESA) observed forming only in soil and there classified as a major degradation/transformation product; it was not observed in the aquatic environment in any amounts probably because the relevant experiments using the appropriately labelled active substance (C5 in the thiadiazole moiety) were not performed (as a result its formation in water cannot be ruled out);
- Trifluoroacetic acid (TFA) observed forming only in soil and there classified as a major degradation/transformation product; it was not observed in the aquatic environment in any amounts probably because the relevant experiments using the appropriately labelled active substance (C5 in the thiadiazole moiety) were not performed (as a result its formation in water cannot be ruled out);

The examination of the data available in the documentation provided by the Applicant showed that:

- FOE Oxalate was demonstrated to be very mobile in soil, with average $K_{fOC} = 10.60$ mL/g, therefore it would probably not be efficiently removed from the substrate – raw water, during the filtration stage of the drinking water abstraction procedure; it may also be a compound of concern, as testify the results of the GW model exposure assessment, in case drinking water is abstracted from groundwater resources;
- FOE Sulfonic acid was demonstrated to be very mobile in soil, with average $K_{fOC} = 11.10$ mL/g, therefore it would probably not be efficiently removed from the substrate – raw water, during the filtration stage of the drinking water abstraction procedure; it will also be a compound of concern, as testify the results of the GW model exposure assessment and lysimeter studies, in case drinking water is abstracted from groundwater resources;
- FOE Methylsulfone was demonstrated to be moderately mobile in soil, with average $K_{fOC} = 61.03$ mL/g, therefore it would probably be only partly removed from the substrate – raw water, during the filtration stage of the drinking water abstraction procedure during filtration; it may also be a compound of concern, as testify the results of the GW model exposure assessment, in case drinking water is abstracted from groundwater resources (although the associated risk is in this case lower than that estimated for FOE Oxalate);
- FOE Methylsulfide was estimated to be strongly sorbed onto organic carbon – the calculated $K_{OC} = 598.0$ mL/g, therefore, if present in raw processed water abstracted for drinking water, it should be efficiently removed from the treated substrate during filtration; the problem of risk related to its presence in groundwater as a source of drinking water is not relevant as this is an aquatic degradation/transformation product, hence not expected to occur in any amounts in Groundwater recharge;
- FOE Thiadone Methylsulfone was demonstrated to be moderately mobile in soil, with average $K_{fOC} = 42.10$ mL/g, therefore it would probably be only partly removed from the substrate – raw water, during the filtration stage of the drinking water abstraction procedure; the compound was demonstrated to be not expected to leach to GW compartment, hence the problem of risk related to its presence in groundwater as a source of drinking water is not relevant;
- FOE TFESA was demonstrated to be very mobile in soil, with average $K_{fOC} = 0.0$ mL/g, therefore it would not be efficiently removed from the substrate – raw water, during the filtration stage of the drinking water abstraction procedure; it may also be a compound of concern, as testify the results of the GW model exposure assessment, in case drinking water is abstracted from groundwater resources;

- TFA was demonstrated to be very mobile in soil, with average $K_{FOC} = 0.0$ mL/g, therefore it would not be efficiently removed from the substrate – raw water, during the filtration stage of the drinking water abstraction procedure; it may also be a compound of concern, as testify the results of the GW model exposure assessment, in case drinking water is abstracted from groundwater resources;

The abiotic hydrolysis and direct and indirect photolysis as degradation mechanisms in aquatic environment were examined by the Applicant only for FOE Thiadone. The compound was demonstrated not to be prone to either abiotic hydrolysis or direct photolysis in water. It may be therefore stated, as it was in case of Flufenacet, that at later stages of the process of abstraction of drinking water – the disinfection of the product using UV light, it is not expected that any potentially harmful transformation products, if FOE Thiadone is present at that stage, may be formed. The analysis of the possible formation of any unwanted/toxic by-products of disinfection by chlorination or ozonation has to be based, due to the lack of any experimental data or other assessment provided by the Applicant, on the results of the literature search carried out by the RMS.

As a next step, because it could not be ruled out that Flufenacet may reach later stages of substrate-processing during abstraction of drinking water, the structural formula of that compound was inspected in search of potentially alarming structures, that theoretically may lead to the formation of unwanted/toxic by-products.

Three such groups were identified. They are indicated below on the figure B.8.2.6._CA-1 by circling them red and marking with letters **a**, **b** and **c**.

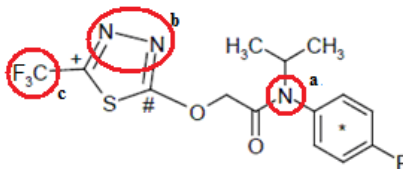

Figure B.8.2.6._CA-1: The structural formula of Flufenacet with the potentially alarming structures it contains marked by red circles and indicator letters **a**, **b** or **c** (the structural formula copied from the documentation submitted by the Applicant).

The groups marked **a** and **b** contain nitrogen atoms so may possibly be precursors of nitrosoamines. The group **c** – trifluoromethyl, was selected because it was demonstrated to form, during the breakdown of the thiadiazole moiety, trifluoroacetic acid. It may also be a component of other haloorganic compounds formed from either Flufenacet or FOE Thiadone during the breakdown of these molecules

To estimate the would be fate of the potentially alarming group marked **b** present in both Flufenacet and FOE Thiadone RMS consulted the following publication:

- Bond T., Tempelton M. R., Graham N. “Precursors of nitrogenous disinfection byproducts in drinking water – A Critical review and analysis.”; Journal of Hazardous Materials 2012, **235-236**, 1 – 16.

The data presented in that paper do not indicate that the group of concern may yield in any compound considered to be unwanted in the terminal product of drinking water abstraction, such as nitrosoamines, haloacetonitriles, cyanogen halides or halonitromethanes. RMS therefore decided not to continue the examination for that group.

The F₃C- group in Flufenacet and FOE Thiadone is known to be transformed into trifluoroacetic acid in soil. Similar process may occur in natural waters as well. Therefore it cannot be excluded (and the literature data which will be presented further down this chapter suggest that such process indeed will occur) that the compound will be formed from Flufenacet or FOE Thiadone during the drinking water abstraction. To estimate its toxic potential RMS consulted the following publications:

- Boorman G. A., Dellarco V., Dunnick J. K., Chapin R. E., Hunter S., Hauchman F., Gardner H., Cox M., Sills R. C., “Drinking Water Disinfection Byproducts: Review and Approach to Toxicity Evaluation.”; Environmental Health Perspectives, 1999, **107 Supplement 1**, 207 – 217;

- Richardson S. D., Postigo C., “Drinking Water Disinfection By-products” in Barcelo D. (ed.) “Emerging Organic Contaminants and Human Health”, “Handbook of Environmental Chemistry”, 2012, Springer Verlag, 93 – 138;
- Toxicological data sheet for TFA published on TOXNET – Toxicology Data Network, site of US NIH National Library of Medicine; available on-line at <http://toxnet.nlm.nih.gov/index.html> as a record CASRN: 76-05-1;

TFA was not listed in any of the publications cited above as a potential by-product of drinking water disinfection. Additionally it was not considered, if present in water very diluted and totally dissociated, to pose any serious risk to human health.

It shall also be indicated that TFA, being quite widely used compound, may be present in drinking water from other sources than Flufenacet and the contribution of either Flufenacet or/FOE Thiadone to the presence of that compound in drinking water may not be substantial in comparison to other sources.

As a result, RMS decided that that group as well, as well as TFA formed from Flufenacet in soil/natural water bodies, may not be a compound of special concern with regard to drinking water abstraction procedures.

The third group, marked **a** structurally, abstracted from the surrounding groups, is a ternary amino- group and as such may be a precursor of nitrosamines. Therefore RMS consulted several publications characterizing the formation of that group of compounds, i. e. :

- Boorman G. A., Dellarco V., Dunnick J. K., Chapin R. E., Hunter S., Hauchman F., Gardner H., Cox M., Sills R. C., “Drinking Water Disinfection Byproducts: Review and Approach to Toxicity Evaluation.”; Environmental Health Perspectives, 1999, **107 Supplement 1**, 207 – 217;
- Richardson S. D., Postigo C., “Drinking Water Disinfection By-products” in Barcelo D. (ed.) “Emerging Organic Contaminants and Human Health”, “Handbook of Environmental Chemistry”, 2012, Springer Verlag, 93 – 138;
- Le Roux J., Gallard H., Croué J.-P., “Chloramination of nitrogenous contaminants (pharmaceuticals and pesticides): NDMA and halogenated DBPs formation.”; Water Research, 2011, **45**, 3164 – 3174;
- Krasner S. W., Mitch W. A., McCurry D. L., Hanigan D., Westerhoff P., “Formation, precursors, control and occurrence of nitrosoamines in drinking water: a review.”; Water Research, 2013, **47**, 4433 – 4450;

- Anon.: “Report on Carcinogens, Thirteen Edition; *N*-Nitrosamines: 15 Listing.”; NIH National Toxicology Program, Department of Health and Human Services; document available on-line on: <http://ntp.niehs.nih.gov/go/roc13>

Analysis of these documents showed that theoretically the group may be a precursor of nitrosamines containing aromatic group as one of functional groups. However, no similar structure could be found listed in the NIH-NIEHS report listing 15 priority nitrosamines. Also no analogues could be found in other publications. In publication by Le Roux et al (2011) a formation of NDMA from a similar structure – diuron, was examined. It was indicated that the presence of the carbonyl group – C=O in the immediate vicinity of both amino groups – terminal and linked to the dichlorophenyl ring significantly limited the formation of nitrosamines. Additionally, the reaction occurred for rather terminal group than that in the aliphatic chain. Finally, the “middle” amino-group was a secondary amine.

It shall be also indicated that in case of Flufenacet and all its degradation products containing the group of concern – FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone and FOE Methylsulfide, the group of concern, due to its surrounding, is in fact an amido- group, therefore less prone to form nitrosamines.

As a result, RMS is of the opinion that in spite of containing three N-atoms, and one of them in configuration of ternary amino- group, Flufenacet may not be considered as a would-be precursor of nitrosamines.

As a next step the effectiveness of the removal of Flufenacet from raw water treated to produce the drinking water was evaluated on the basis of the available scientific literature.

One of the key publications on which that assessment was based was the DEFRA report “Understanding the changes in pesticide usage to inform water company risk assessment”, issued in 2013 as a final report of the DEFRA Project WT1264 (reference: anon., “*Final Report of Project WT1246- Understanding changes in pesticide usage to inform water company risk assessment.*”, DEFRA 2013, available: <http://dwi.defra.gov.uk/research/completed-research/2000todate.htm>.)

The aims of that project were following:

- to characterize the current, for the period of the study, usage of Plant Protection products in England and Wales and observed recent trends in that area;
- to characterize the regulatory changes in that area, their potential impact and its time frame;
- developments of the scenarios estimating the impact characterised in the point above;
- estimation, on the basis of known properties and use patterns, the likelihood of the presence of the given Plant Protection Product (active substance) in substrate for drinking water abstraction (ground water or surface water) in concentration above the regulatory trigger value – 0.1 µg/L;
- assessment of the would-be effectiveness of the removal of the substances identified at the above step, from the processed raw water in the commonly used drinking water abstraction procedures.

Flufenacet was identified as one of active substances that were newly introduced within the period of 20 years preceeding the issuing of that report. The use of which rapidly increased. It was declared to be introduced in the UK – England and Wales (as the report specifically refers to these parts of the United Kingdom) in 2002 as a replacement for isoproturon to control black-grass in cereals. Its annual use reported in the document was 99 tonnes in 2006, 150 tonnes in 2008 and 244 tonnes in 2010, showing a general increase in use.

More detailed examination showed that in the year 2010, in case of cereals, the total area treated with flufenacet was 1236000 ha, the total amount used was 231000 kg and the application rate 0.187 kg/ha. Similar analysis performed for the use on maize showed that for 2010 the total area treated with that compound was 25082 ha, the total amount used in maize was 7818 kg and the application rate 0.312 kg/ha.

In the table presenting the potential impact on sources of drinking water Flufenacet was estimated to pose medium risk related to leaching, low risk related to runoff and high risk related to the drainflow. In that assessment the ADI = 0.005 mg/kg BW was also reported.

In the part of the report characterizing the regulatory changes in the pesticide use pattern Flufenacet is indicated as being one of the alternative compounds, together with diflufenican and prosulfocarb, for pendimethalin.

Characterising a risk posed to the water resources the authors once again indicated Flufenacet as a compound being the alternative for Pendimethalin – the active substance included into the group of high risk, Group 2 because of failing PBT criteria, and for Flumioxazin – the active substance included into the same group because of failing R2 criteria.

The next step – estimation of the would-be risk posed to the resources of drinking water, was performed using the numerical modelling, by calculating the PEC values. In case of the surface waters the calculations were performed using a modified ADAS implementation of SWAT model. In case of similar calculations for groundwater compartment the adapted MACRO model was used.

The classification of risk was based on the comparison of the obtained values with the so called “drinking water prescribed concentration or value (PVC) – 0.1 µg/L. The following four classes were identified:

- at risk – **AR**, with calculated PEC > 5 µg/L;
- possibly at risk – **PAR**, for 5 µg/L > PEC > 0.1 µg/L;
- possibly not at risk – **PNAR**, for 0.1 µg/L > PEC > 0.002 µg/L, and
- not at risk – **NAR**, with PEC < 0.002 µg/L.

Flufenacet was evaluated under the Scenario 4 for both surface water and ground water.

The assumptions used in calculations were following:

- for the **Baseline approach** the total weight of flufenacet applied was 299.4 tonnes, total area treated was 1233000 ha and the application rate was 0.24 kg/ha;
- for the **Scenario 4 approach** the total weight of flufenacet applied was 409.7 tonnes, total area treated was 1693000 ha and the application rate was 0.24 kg/ha;
- the differences between the two approaches were following: change in total weight applied (Scenario 4: Baseline) 36.9, change in total area treated (Scenario 4: Baseline) 37.3%, the application rate did not change;
- the characterised risk related to: leaching was **medium**, runoff was **low**, drainflow was **high**.

In case of the estimation of the surface water drinking water protected areas the results obtained for **Baseline** approach was following:

- 1.0% of such areas were classified as **AR**,
- 78.7% of such areas were classified as **PAR**,
- 19.1% of such areas were classified as **PNAR**,
- 1.2% of such areas were classified as **NAR**.

When **Scenario 4** approach these values looked as follows:

- 0.0% of the surface water drinking water protected areas were classified as **AR**;
- 85.7% of the surface water drinking water protected areas were classified as **PAR**;
- 13.2% of the surface water drinking water protected areas were classified as **PNAR**;
- 1.1% of the surface water drinking water protected areas were classified as **NAR**;

When referred to the individual Water Company Areas (WAC) the results of the estimation for Flufenacet looks as follows:

- for **Anglian WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 1.0%, as **PAR** accounted for 10.8%, as **PNAR** accounted for 0.0% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 11.8% for **PAR**, 0.0% for **PNAR** and 0.0% for **NAR**;
- for **Northumbrian WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 3.4%, as **PNAR** accounted for 1.6% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 3.5% for **PAR**, 1.5% for **PNAR** and 0.0% for **NAR**;
- for **Severn Trent WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 19.2%, as **PNAR** accounted for 0.6% and as **NAR** accounted for 0.2%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 19.7% for **PAR**, 0.1% for **PNAR** and 0.2% for **NAR**;
- for **South West WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 2.3%, as **PNAR** accounted for 1.0% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 2.8% for **PAR**, 0.5% for **PNAR** and 0.0% for **NAR**;
- for **Southern WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 5.2%, as **PNAR** accounted for 0.0% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 5.2% for **PAR**, 0.0% for **PNAR** and 0.0% for **NAR**;
- for **Thames WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 22.6%, as **PNAR** accounted for 0.0% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 22.65% for **PAR**, 0.0% for **PNAR** and 0.0% for **NAR**;
- for **UU WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 0.5%, as **PNAR** accounted for 4.2% and as **NAR** accounted for 0.4%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 2.6% for **PAR**, 2.1% for **PNAR** and 0.4% for **NAR**;
- for **Wales WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 3.6%, as **PNAR** accounted for 10.6% and as **NAR** accounted for 0.6%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 6.4% for **PAR**, 7.8% for **PNAR** and 0.5% for **NAR**;
- for **Wessex WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 4.6%, as **PNAR** accounted for 0.0% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 4.6% for **PAR**, 0.0% for **PNAR** and 0.0% for **NAR**;
- for **Yorkshire WAC** and assessment with **Baseline** approach the surface water drinking water protected areas classified as: **AR** accounted for 0.0%, as **PAR** accounted for 6.5%, as **PNAR** accounted for 1.1% and as **NAR** accounted for 0.0%; for the assessment with **Scenario 4** approach these numbers were: 0.0% for **AR**, 6.5% for **PAR**, 1.1% for **PNAR** and 0.0% for **NAR**;

In case of the estimation of the groundwater source protected zones the results obtained for **Baseline** approach was following:

- 0.0% of such areas were classified as **AR**,
- 0.0% of such areas were classified as **PAR**,
- 61.3% of such areas were classified as **PNAR**,
- 38.7% (19.0 in number) of such areas were classified as **NAR**.

When **Scenario 4 approach** these values looked as follows:

- 0.0% of the Groundwater source protected areas were classified as **AR**;
- 0.0% of the Groundwater source protected areas were classified as **PAR**;
- 60.6% of the Groundwater source protected areas were classified as **PNAR**;
- 39.2% of the Groundwater source protected areas were classified as **NAR**;

The results of the model estimation may indicate that while for the drinking water abstracted from the groundwater resources in the UK Flufenacet may pose no serious threat, it may become a compound of concern when in case of drinking water abstracted from the surface water resources.

As a next step of the assessment, the effectiveness of various methods of removal of micropollutants from drinking water were assessed. Initially, the assessment covered the following methods:

- adsorption on Granular Activated Carbon (GAC),
- adsorption on Powdered Activated Carbon (PAC),
- removal by ozone/GAC adsorption,
- removal by UV irradiation,
- removal by advanced oxidation,
- removal by nanofiltration/reverse osmosis.

All these methods were characterised and performance of one of them – adsorption on GAC, was characterised and evaluated for its performance in a more detailed way being relatively commonly used.

In case of Flufenacet it was stated that there was no known experimental data on the effectiveness of the removal of that compound from water. Therefore the whole assessment was based on the comparative analysis using Metazachlor as a reference compound. Metazachlor was selected because it belonged to the same family of anilide herbicides and displayed some structural similarities to Flufenacet. It was demonstrated to be very well removed by GAC. The comparison resulted in stating that Flufenacet displayed, in addition to higher molecular weight (363.33 g/mol vs. 277.75 g/mol for Metazachlor), lower solubility in water (56 mg/L vs. 450 mg/L) and higher affinity to organic substances expressed in terms of log K_{OW} (3.2 vs. 2.49). That, according to the authors of the report suggested that Flufenacet as well would be very well removed from treated water by GAC.

That conclusion was presented at the end of the summarized report, with suggestion however that the performance of GAC in the removal of the plant protection products subjected to the examination should be conformed experimentally.

Another identified by the RMS publication providing, this time based on the experimental data, the information on the removal efficiency of Flufenacet from raw water during its processing for drinking water was following:

Verstraeten I. M., Thurman E. M., Lindsey M. E., Lee E. C., Smith R. D., “Changes in concentrations of triazine and acetamide herbicides by bank filtration, ozonation and chlorination in a public water supply.”, *Journal of Hydrology*, 2002, **266**, 190 – 208

The aim of that study was to examine the changes in the concentration of several triazine and acetamide herbicides in the processed substrate at various stages of production of drinking water in drinking water abstraction plants. The analysed compounds were: atrazine and its degradation products, cyanazine and its degradation products, propazine, simazine, alachlor and its degradation products, acetochlor and its degradation products, metolachlor and its degradation products, dimethenamid and flufenacet.

The test facility was municipal drinking water treatment plant of the City of Lincoln, Nebraska, USA, abstracting water from the Platte River and groundwater wells.

The analytical period covered three years – from June 1997 to 1999. The analysed water samples were: raw riverine water, water samples from the collector wells, effluent after the bank filtration, post-ozonation effluent, post-chlorination and filtration effluent, treated drinking water (final product) and groundwater. The samples were taken during the study period in months April – June of each year, indicated as a typical period of the

spring runoff. That period was selected because then the concentrations of herbicides in the river significantly impacted the quality of surface water, groundwater and drinking water.

Characterising the test facility the authors of the publication stated that it contained a well field consisting of 38 wells, of which two were horizontal, collector wells with daily capacity of 25 m³ each, and remaining 36 were vertical wells with a daily capacity of up to 1 m³ each. The filling of the wells were layers of alluvial sand, gravel, silt and clay, having a total thickness of 27 m.

The riverine water was transported to them by means of bank filtration over the distance of 25 metres, with a mean estimated residence time of 6 days. The bank-filtered water was transported from collector wells to the treatment plant for subsequent treatment within 20-60 minutes. The subsequent stages of water treatment were: ozonation, filtration, chlorination, fluoridation, ammonization and residence in reservoir.

Characterising the plant the authors of the paper stated that it had a capacity of 190 m³/day and that more than 90% of treated water was a riverine water.

The concentrations of Flufenacet as a compound of interest at each step of the treatment process were determined only in 1999. The reason for that was not given, but as the paper bears the reference to the earlier publication, presenting the analysis of the concentrations of various pesticides in water from municipal collector wells, it may be assumed that Flufenacet in significant amounts was started to be detected from that year onwards (N.b. that may be confirmed by the results presented in the reports of USDA, summarized in the chapter dealing with the results of the monitoring studies, showing that Flufenacet started to be extensively used on the Great Plains about that period, with its peak occurring around the year 2002).

The analytical method used for the identification and quantitation of Flufenacet was that developed within the USDA by Kish et al. (2000), and it consisted of GC/MS analysis preceded by SPE. The LOQ for that method was 0.05 µg/L – a half of the regulatory drinking water limit set for the individual active substances of the plant protection products.

The concentrations of Flufenacet determined at each stage of the examination of treated water were:

- 0.19 µg/L for raw riverine water;
- 0.07 µg/L for the bank-filtered water,
- 0.07 – 0.08 µg/L for water collected from the collector wells,
- 0.05 µg/L for the post-ozonation effluent,
- < 0.05 µg/L for the post-chlorination and filtration effluent,
- 0.05 µg/L for the final product – treated drinking water.

The concentrations of Flufenacet in groundwater were not measured. The results indicate that Flufenacet was efficiently removed from the treated water during filtration, its concentration being reduced by 58%. However, there is no information about its degradation products, such as FOE Oxalate, FOE Sulfonic acid or FOE Thiadone, which may be formed during the bank filtration as a result of the degradation of Flufenacet. At the same time, in the paper, which examined also the fate of the analogues of FOE Oxalate and FOE Sulfonic acid – OXA and ESA degradation products of other acetamide plant protection products, namely of Alachlor, Acetochlor and Metolachlor, it was stated that not only these compounds may be partly removed during filtration, in amounts up to ~40% but efficiently removed, with 79%-effectiveness, during ozonation stage. It was stated that the process results in formation of alcohols, carbonyls, carboxylic acids (by cleavage of the double bonds), opening of aromatic rings and removal or oxidation of alkyl groups. Similar processes, with regard to the mechanisms and overall effectiveness, may take place also for the relevant degradation products of Flufenacet reaching that stage of water treatment.

The good insight into the possible efficiency of the removal of Flufenacet and its degradation products at later stages of treatment during the process of drinking water abstraction provides the following paper:

Sakkas V. A., Calza P., Vlachou A. D., Medana C., Minero C., Albanis T., “Photocatalytic transformation of flufenacet over TiO₂ aqueous suspension: Identification of intermediates and the mechanisms involved.”, *Applied Catalysis B: Environmental*, 2011, **110**, 238 – 250;

The paper provides the detailed characterisation of the mechanisms involved in photooxidation of Flufenacet in water carried out over the TiO₂ as a catalyst.

The aim of the experiment was to assess the efficiency of the removal of Flufenacet from the processed drinking water through its photochemical degradation in presence of TiO₂ as a catalyst. That was done by the means of:

- a) optimization of the process through the examination of the simultaneous effect of varying concentrations of TiO₂ and H₂O₂, and changes in pH on the efficiency of degradation;

- b) determination of transformation pathways through identification of the transformation products;
- c) examination of temporal evolution of final products of mineralization;
- d) assessment of the changes in the toxicity of treated water in function of the exposure to the reacting agents, by carrying out the luminescence bioassays using *Vibrio fischeri*

The test compound was “cold” (not radiolabelled) Flufenacet, having a chemical purity of >99%, supplied by Riedel-de H  en company. Other reagents used in the study were: analytical-grade pure 30% H₂O₂ – the oxidising agent, and TiO₂ powder (Degussa P25) used as photocatalyst.

The experiment aimed on the determination of the kinetics of degradation of Flufenacet – efficiency of the process, was carried out at combination of the following initial conditions:

- pH of the aqueous solution was 4.5, 7.0 or 9.5, with single samples having pH = 2.8 or pH = 11.2;
- concentration of the photocatalyst – TiO₂ in the solution was 250 mg/L, 500 mg/L or 750 mg/L, with single samples containing 80 mg/L or 920 mg/L of TiO₂;
- concentration of H₂O₂ in solution (in moles/L) was 0.013M, 0.026M or 0.039 M, with with single samples having concentration of H₂O₂ 0.004M or 0.048M;
- the volume of the solution was 50 mL, the concentration of the test compound in it was not specified, but it may be assumed that, to limit the number of variables it had to be constant (possibly 15 mg/L as in the second experiment);
- after introduction of the photocatalyst – TiO₂, the test solutions were pre-equilibrated in the darkness for 60 minutes before being irradiated (that was done to reach the adsorption equilibrium on the surface of semiconductor);
- irradiation was performed using Sunset CPS+ apparatus equipped with 1500-W xenon lamp and set of filters cutting off the radiation wavelengths $\lambda < 290$ nm, the temperature of irradiated samples was maintained at the level $T < 20^{\circ}\text{C}$;
- the estimation of the efficiency of the process of degradation of Flufenacet was performed in samples taken after 30 minutes of irradiation;
- liquid samples, before being analysed were filtered through 0.45 μm PVDF Millipore membrane filters to remove the suspended TiO₂.

To determine the mechanisms of photocatalytical degradation of Flufenacet in water and its kinetics second experiment was performed. Its major features were following:

- volume of the samples: 5 mL;
- concentration of the test item – Flufenacet: 15 mg/L;
- concentration of the photocatalyst – TiO₂: 200 mg/L;
- the experiment was performed in air-saturated conditions;
- the irradiation was carried out using a lamp having energy emission intensity of 40W/m² and maximum emission at $\lambda = 360$ nm;
- The temperature during irradiation reached $T = 38 \pm 2^{\circ}\text{C}$.

Samples for the content of Flufenacet and identification and quantitation of its transformation products were analysed using the following analytical methods:

- HPLC-MS – the primary identification method for the phototransformation products of Flufenacet;
- HPLC with the UV detection;
- Ion chromatography – method used for quantitation of some terminal products of photocatalytic degradation of Flufenacet, such as fluoride, sulphate, nitrite and nitrate ions;
- TOC analysis;

The toxicity of the samples, obtained at different time points in the experiment aimed on the elucidation of the transformation pathways of Flufenacet during its photooxidative decomposition, was examined using Microtox Model 500 Toxicity analyser. It was based on the determination of the ability of the given sample to inhibit the natural bioluminescence of the marine bacterium *Vibrio fischeri*.

In the preliminary experiments, lasting 2 hours, it was demonstrated that Flufenacet was not prone to either hydrolysis or direct photolysis and it was negligibly adsorbed onto TiO₂. As a result it was stated that these processes will have no influence on the results of the whole experiment.

The efficiency of the process was optimised using the determined % disappearance of Flufenacet from samples after 30-minutes lasting irradiation. The results are presented below in the table B.8.2.6._CA-1. They indicate generally high efficiency of the process, with the level of degradation $\geq 70\%$ of the initial amount of Flufenacet within relatively short exposure time. The efficiency of the process depended on all three variables, although not to the same extent. It was noticed that the increase of the concentration of H₂O₂ would have an

inhibitory effect. Also initial pH of the solution was demonstrated to have a substantial effect, related also to the catalyst properties. The process reached its optimum at $\text{pH} \approx 7$, which is estimated to be natural pH of the riverine water. Finally, it was demonstrated that the efficiency of the removal increased with the increasing concentration of TiO_2 , reaching the optimum at 500 mg/L, to stabilise or even decrease afterwards.

These results created the basis for further examination of the process for its kinetic performance and transformation patterns – the optimised conditions for that experiment have been presented above.

Table B.8.2.6._CA-1 The results of the experiment aimed on the optimisation of the process of photocatalytical degradation of Flufenacet over TiO_2 .

Experiment No	Experimental conditions			Degradation of Flufenacet [%]	
	Concentration of H_2O_2 [mole/L]	Concentration of TiO_2 [mg/L]	pH	predicted	observed
1	0.013	250	4.5	93.39	94.53
2	0.013	750	4.5	94.89	95.30
3	0.013	250	9.5	89.07	94.40
4	0.013	750	9.5	98.41	97.00
5	0.039	250	4.5	87.78	90.55
6	0.039	750	4.5	91.97	92.10
7	0.039	250	9.5	70.75	71.70
8	0.039	750	9.5	82.78	83.03
9	0.026	500	7.0	88.93	88.76

11	0.026	80	7.0	73.94	70.92
12	0.026	960	7.0	85.31	86.43
13	0.026	500	2.8	100.88	98.96
14	0.026	500	11.2	89.52	89.53
15	0.004	500	7.0	100.04	99.83
16	0.048	500	7.0	82.20	80.50

The examination of the transformation pattern showed that three possible mechanism are involved. First of them is an initial hydroxylation of either in fluorophenyl ring, isopropyl group or of the C atom standing next to the bridging O in the alkyl group. Second postulated mechanism is defluorination of the fluorophenyl ring and third N-delakylation of the molecule. These processes resulted in formation of 32 intermediate compounds (TP). The authors stated that the decomposition of Flufenacet was very quick, with $t_{1/2} = 5$ minutes. The compound totally disappeared from the solution within 60 minutes of irradiation and almost all of its identified TP within two hours from the initiation of the process. It was also stated that the proposed tentative reaction pathway displayed similarities to that determined in the environment, with the cleavage of the bridging C-O bond within the N-alkyl chain observed. Thiadiazole moiety was subjected to the ring cleavage, while N-alkylic chain and phenyl moiety were involved in hydroxylation and demethylation.

The analysis of the toxicity of the solution showed that at least some of TPs formed within the first 60 minutes of the process displayed higher toxicity than the active substance – while the initial inhibition of the luminescence of *Vibrio fischeri*, attributed to Flufenacet, was 32% and decreased slightly within first 5 minutes of the experiment, it significantly increased afterwards to reach the maximum 66%-level around its 30th minute. It decreased afterwards, first slowly (55% inhibition around 45th minute since the beginning of irradiation), to reach the level comparable to that obtained for the active substance at minute 60th and then dropping to the level of 5% around 120th minute of the whole experiment. That may indicate that by that time all toxic byproducts would be effectively eliminated from the treated substrate (treated water). However, although Flufenacet and its toxic phototransformation products disappeared within 120 minutes of the process, during that time only 60% mineralisation with regard to organic carbon and 40% mineralisation with regard to organic nitrogen was observed. It was estimated that to obtain the complete mineralisation of organic carbon, the required residence time would be 24 hours. After that period only 65% of N present in the molecule was recovered, what was attributed to the loss of it related to its partial photoconversion to N_2 . Of the recovered 65% of N, 25% was in form of ammonium ions and 40% as nitrite/nitrate.

Only 25% of Fluorine was recovered, but that in turn was attributed to the fact that the process of the transformation of $-\text{CF}_3$ was not sufficiently covered.

In conclusion the authors stated that the method has a great potential with regard to the removal of Flufenacet from water abstracted for drinking water, as a low-cost, environmental friendly and sustainable treatment technology.

Nowadays this, still considered novel, method of removal of micropollutants from treated drinking water is one of well-known and commonly applied method within the set of methods known under the common name “advanced oxidation process” or AOP. Its general characteristic may be found in many publications, such as:

Manoj A. Lazar, Shaji Varghese, Santosh S. Nair “Photocatalytic Water Treatment by Titanium Dioxide: Recent Updates.”, *Catalyst*, 2012, **2**, 572 – 601.

The already performed analysis for Flufenacet showed that also its degradation products should be efficiently removed from treated water during drinking water abstraction procedures. RMS however decided to further conform that using the available literature data.

The data on the removal efficiency of FOE Oxalate and FOE Thiadone from the substrate treated to obtain drinking water were found in the following publication:

Sinclair C., van Beinum W., Adams C., Bevan R., Levy L., Parsons S., Goslan E., Baumann G., “A Desk Study on Pesticide Metabolites, Degradation and Reaction Products to Inform the Inspectorate’s Position on Monitoring Requirements. Final Report for Drinking Water Inspectorate.”; The Food and Environment Research Agency (FERA), Sand Hutton, York, UK, FERA Project S3VB, DEFRA Project WT1221, DWI Project 70/2/232, February 2010, report available on-line on DEFRA web-site.

The study had following aims:

- to review and collate the available information on the degradation and transformation products of the Plant Protection Products used in the UK at the time of issuing of the Report;
- to identify the degradation and transformation products that may exhibit pesticidal activity and/or additional toxicological concerns;
- for the degradation products identified at previous step to estimate the likely concentrations in drinking water;
- to estimate, for the degradation products of concern, the would-be risk to human health;
- to estimate the likelihood and the extent of their reaction with ozone and/or chlorine during water treatment and the possibility of the formation of toxic compounds;
- to prepare the recommendations with regard to the updating of the relevant guidances in force at the period of the issuing of the report.

The review and collation of the available information on the degradation and transformation products, further called metabolites of the Plant Protection Products (further called active substances) in use in the UK at time of the performance of the research, resulted in the identification of 523 soil metabolites, originating from 185 active substances. For 485 of them (92.7% of the initial number) it was possible to identify 2-dimensional structural representation – their structural formulas. These data were next used to estimate the mammalian toxicity of the so pre-selected compounds using two modelling tools – DEREK and TOPKAT. The knowledge of the structural formulas of the metabolites of concern was also used to estimate their potential pesticidal activity in relation to their precursor – parent pesticides, through examination of the presence of toxicophores.

That complex analysis resulted in selection of 53 compounds for further investigation. Among them were two major soil degradation products of Flufenacet – FOE Oxalate and FOE Thiadone.

The next step of the examination was the estimation of the likely concentrations of the selected 53 degradation products in substrate and final product of drinking water abstraction processes.

That examination was carried out using three existing surface water abstraction catchments in England, two selected because of being identified as high-risk catchment for pesticide contamination, while the third one because of the availability of the data from monitoring of metabolites of atrazine. The identity of these catchments for the purpose of the study was not revealed, instead they were referred to in the study, and characterised, as Catchments A, B and C.

It was stated that the major migration route of the degradation products from the treated fields to the to the surface water bodies was a discharge from a drainage system. It was also assumed that, due to the shorter pathway, the concentrations in surface water following drainage would be higher than those in groundwater. As a result, the first step of the estimation was the calculation of the predicted concentrations in the drainflow, using the methodology adapted from the study undertaken on behalf of Pesticide Safety Directorate, into the controlling factors for pesticide losses via drainflow.

The whole estimation of the likely concentrations of the compounds of concern in drinking water consisted of the following three steps:

- 1) estimation of the concentrations in drainage water;

- 2) estimations of the concentrations in the downstream surface water
- 3) estimations of concentrations in finished drinking water.

In case of the third step, the performance of the treatment processes in removal of each investigated compound from treated water was evaluated. The processes taken into consideration were:

- coagulation;
- removal by activated carbon, granular (GAC) or powdered (PAC),
- ozonation,
- chlorination.

The estimation was performed for two types of treatment procedure:

- **conventional treatment**, comprising (in order of appearance) coagulation-flocculation, removal by PAC, chlorination; filtration was not included as it was not expected to result in any further removal;
- **advanced treatment**, comprising (in order of appearance) coagulation-flocculation, ozonation, removal by PAC and chlorination.

The estimation of the performance of each process was based on the examination of the known substance properties. For coagulation-flocculation/filtration it was based on the examination of how the given molecule is charged. The key parameter used in the estimation of the efficiency of removal by PAC was the log K_{OW} estimated or measured for the given molecule at pH = 7. In case of ozonation and chlorination QSPR (quantitative structure-property relationship) models were used and the molecules were converted from 2-D (planar) to 3-D (spatial) representation. The calculations were performed using the equations developed by Lei and Snyder.

The so estimated levels of removal of FOE Oxalate and FOE Thiadone are presented below in the table B.8.2.6._CA-2.

Table B.8.2.6._CA-2: The estimated levels of removal of FOE Oxalate and FOE Thiadone during drinking water treatment.

Removed compound	Conventional treatment - % removed in:				Advanced treatment - % removed in				
	Coagulation	PAC	Chlorination	Total	Coagulation	Ozonation	PAC	Chlorination	Total
FOE Oxalate	25	50	53.1	82.4	25	59	50	53.1	92.8
FOE Thiadone	0	50	6.5	53.3	0	50	50	6.5	76.6

It shall be indicated however that both FOE Oxalate and FOE Thiadone were classified, as a result of further examination, as “**Metabolites with unknown detoxification due to the lack of information on reactive sites or toxic moieties**”.

The determination of risk to human health, based on the calculation of the worst-case intake of metabolites from drinking water for each catchment, returned the results which, for FOE Oxalate and FOE Thiadone, are provided below in table B.8.2.6._CA-3. The conservative estimate assumed no removal of the compounds of concern from drinking water (consumption of raw water), while the refined estimate took into account the level of their removal during conventional and advanced treatments. The results were provided individually for each analysed catchment.

Table B.8.2.6._CA-3: The results of the estimation of the worst-case intake of FOE Oxalate and FOE Thiadone presented in the report.

Catchment	Compound	Estimated worst-case intake – percentage of ADI for:			
		Adult		Toddler	
		Conservative estimate	Refined estimate	Conservative estimate	Refined estimate
Catchment A	FOE Oxalate	0.09 – 0.21	<0.01	0.29 – 0.81	<0.01
	FOE Thiadone	0.08 – 0.17	<0.01	0.37 – 0.75	<0.01
Catchment B	FOE Oxalate	0.17 – 0.41	<0.01	0.176 – 1.86	<0.01
	FOE Thiadone	0.16 – 0.32	0.01	0.73 – 1.46	<0.01
Catchment C	FOE Oxalate	<0.01 – 0.01	<0.01	0.01 – 0.04	<0.01
	FOE Thiadone	<0.01 – 0.01	<0.01	0.01 – 0.03	<0.01

Both compounds were considered, as a result of the estimation presented in the table above, to be of no concern, because predicted for them daily total intake from drinking water was <10% ADI.

The analysis was performed only for these two degradation products. Neither FOE Sulfonic acid, formed in amounts comparable to those determined for FOE Oxalate and displaying similar to it mobility in soil but higher persistence, nor FOE Methylsulfone, another important soil degradation product of Flufenacet having a structure similar to that of FOE Oxalate, were taken into account. It shall be noted however that, because of the structural similarities the three metabolites display, the efficiency of their removal in either conventional or advanced treatment may be on the comparable level. Similar conclusion can be drawn also regarding FOE Methylsulfide.

Selected degradation/transformation products of Flufenacet – FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfone, FOE Thioglycolate sulfoxide and FOE Thiadone, have calculated risk indexes that may be used in creation of prioritisation schemes for drinking water supplies. These were provided in the supplementary data (available on-line) to the following publication:

Sinclair C. J., Boxall A. B. A., Parsons S. A., Thomas M. R., “Prioritization of Pesticide Environmental Transformation Products in Drinking Water Supplies.”, *Environmental Science and Technology*, 2006, **40** (23), 7283 – 7289;

The paper presented prioritization approach for identifying the most important, from the point of view of consumers risk, degradation/transformation products of pesticides. That approach was developed as a result of the workshop organized in Prague, Czech Republic, on the 5th of June 2004. To prioritise the transformation products their risk index should be calculated.

The proposed calculation methodology consisted of the following stage:

- **Stage 1:** calculation of the exposure index **E** for the given transformation product, comprising the following factors: index **A** characterising the amount of the given metabolite released into the environmental compartment of concern, index **F** that characterises the mobility of the given compound in the environment and index **P** that characterises its persistence in the environment (soil and water compartments); to calculate that index the following final equation is recommended to be used: $E = A \cdot F \cdot P$
- **Stage 2:** determination of the toxicological effects – the factor declared to be most useful here, for drinking water, was **ADI** – Acceptable Daily Intake.
- **Stage 3:** at that stage is performed risk characterisation and ranking; the analysis performed at two previous stages and obtained factors are used to calculate a risk index – **RI**, using the following equation: $RI = E/ADI$; it was stated that the higher was the RI value, the greater was the potential risk posed by the given metabolite to drinking water supplies within the defined system.

Characterising the approach the authors indicated that in many instances not all data required for determination of **E** factor (these are: maximum formation fraction for the given compound within the compartment of interest – *f*, *K_d*, *DT₅₀ SOIL* and *DT₅₀ WATER*) are available and, in case of their lack these shall be replaced by their default counterparts. Based on the data availability the degradation products were divided into five general data classes:

- A, with no default values required,
- B, with 1 default value required,
- C, with 2 default values required,
- D, with 3 default values required,
- E, with 4 default values required.

Class B was additionally divided into three subgroups:

- B_f in which a default for formation is used;
- B_m in which the default for mobility is required;
- B_p in which the default for persistence is used.

Two examples were provided to illustrate such approach – the priority list for the UK and priority list for California.

All ranked degradation products of Flufenacet were included into the background information used to create the priority list for the UK.

FOE Sulfonic acid and FOE Oxalate were included into class D with regard to the availability of the data for them, while FOE Methylsulfone, FOE Thiadone and FOE Thioglycolate sulfoxide to class E.

The risk index values calculated for them were:

- for FOE Sulfonic acid RI = 0.31247;
- for FOE Oxalate RI = 0.21737;
- for FOE Methylsulfone RI = 0.13586;
- for FOE Thioglycolate sulfone RI = 0.13586;
- for FOE Thiadone RI = 0.13586

RMS also briefly examined the available literature in search of the data informing about the would be impact of the residues of Flufenacet – the active substance or/and its identified major degradation products on wastewater treatment procedures.

Two such publications were identified.

First of them:

Hollender J., Zimmermann S. G., Koepke S., Krauss M., McArdell C. S., Ort C., Singer H., von Gunten U., Siegrist H., „Elimination of Organic Micropollutants in a Municipal Wastewater Treatment Plant Upgraded with a Full-Scale Post-Ozonation Followed by Sand Filtration.”, *Environmental Science and Technology*, 2009, **43** (20), 7862 – 7869.

examined the efficiency of additional step in wastewater treatment – post-ozonation (ozonation after biological purification of wastewater) followed by sand filtration, in elimination of some persistent organic micropollutants. The examination was performed on existing and fully operational Municipal Wastewater Treatment Plant located in Switzerland (WWTP Wüeri in Regensdorf, Switzerland), characterised as receiving typical Swiss municipal wastewater. The aim was to examine the efficiency of the elimination of some 220 organic micropollutants from the secondary effluent (after biological stage of wastewater treatment process), among them Flufenacet and its two degradation products – FOE Sulfonic acid and FOE Oxalate, listed in supplementary material as compounds of the targeted screening of the secondary effluent and ozonation effluent. For these compounds the Limit of Quantification (LOQ) was set to 15 ng/L for Flufenacet (not reported in the paper, but determined when contacting one of the authors), 13 ng/L for FOE Sulfonic acid and 23 ng/L for FOE Oxalate. These compounds were however not listed as those detected in any examined effluent, so it may be assumed that if present in the wastewater stream incoming to the WWPT, they were efficiently removed at earlier stages. That cannot be confirmed, as the paper provides no information with regard to the content of these compounds in raw wastewater or in the effluent entering the biological treatment step. At the same time it shall be indicated that such situation is probable in light of the results of the monitoring of the residues of Flufenacet in surface water bodies of five Swiss catchments, presented in the paper summarised in this Renewal Assessment Report in the document Vol. 3_CA – B.8. under the point B.8.5 (paper by [Moschet et al.; 2014]).

Another publication:

Dealtry S., Holmsgaard P. N., Dunon V., Jechalke S., Ding G-C. Krögerrecklenfort E., Heuer H., Hansen L. H., Springael D., Zühlke S., Sørensen S., Smalla K., „Shifts in abundance and Diversity of Mobile Genetic Elements after the Introduction of Diverse Pesticides into an On-Farm Biopurification System over the Course of a Year.”, *Applied and Environmental Microbiology*, 2014, **80** (13), 4012 – 4020.

presented the results of the performance of the typical on-farm Biopurification system (BPS) in controlling the environmental pollution caused by release of water containing Plant Protection Products. That was done by the means of examining the concentrations of various active substances of PPPs in BPS and their changes during the year, as well as diversity and abundance of microorganisms carrying MGEs – mobile genetic elements harboring genes involved in degradation of xenobiotic compounds. One of such group of MGEs were IncP-1 plasmids.

The examination was performed on a BPS in Kortrijk, Belgium, containing a biomix composed of coco chips, straw, manure and field soil, filtering wastewater containing different plant protection products from spillage and collected during cleaning the spraying equipment. Flufenacet was one of the compounds that was detected in wastewater reaching the BPS and then detected there. Although its amounts reaching the installation were not reported in the paper, it provided the results of its quantification in the BPS's filling material during the experiment: in March, when it was measured in concentration 150 ng/g, July – 5062 ng/g and September – 4804 ng/g. Other active substances detected in BPS were Azoxystrobin (23 – 38 ng/g), Bentazone (46060 – 55795 ng/g), Diflufenican (671 – 1647 ng/g), Duiro (80 – 111 ng/g), Epoxiconazole (612 – 936 ng/g), Ethofumesate (91 – 119 ng/g), Fenpropimorph (< 4 – 6 ng/g), Fluroxypyr (90 – 1251 ng/g), Metamitron (39 – 63 ng/g), Metribuzine (141 – 2065 ng/g), Propiconazole (46 – 168 ng/g), S-metolachlor (2958 – 11806 ng/g), Tebuconazole (796 – 941 ng/g) and Terbutylazine (694 – 8579 ng/g). The concentration profile of these compounds was positively correlated with the increase in abundance of bacteria carrying the IncP-1β plasmids, indicating their important role in degradation of Plant Protection Products. Also was observed high diversity of

different IncP-1 groups in BPS bacterial communities, similar to that observed in sewage sludge. That may indicate that Flufenacet present in mixture with other active substances and in relatively high amounts would probably not have a significant impact on the performance of wastewater treatment processes in such installations.

Conclusions:

On the basis of the presented above evaluation it can be stated that neither Flufenacet nor any of its identified major degradation products are expected to pose any serious threat or have any significant impact on the water treatment processes aimed on the abstraction of drinking water or purification of wastewater.

B.8.3 - Fate and behaviour in air

As the first step in the assessment of the fate and behaviour of Flufenacet in the air compartment RMS analysed the basic data on the volatility potential of that active compound and its major degradation products in order to identify the substances of concern for the atmosphere. The basic data on the volatility potential of Flufenacet and its major degradation products are presented below in the table B.8.3._CA-1. The data were taken from the section B.2 (AS) for Flufenacet, unless it was clearly stated that they were derived from other sources.

Table B.8.3._CA-1: The key physico-chemical properties of Flufenacet and its major degradation products relevant for the determination of the fate and behaviour in the atmosphere.

Parameter	Compound ¹⁾							
	FOE 5043	FOE Oxalate	FOE S. A.	FOE Methylsulfone	FOE Methylsulfide	FOE Thiadone	FOE TFESA	TFA ²⁾

Footnotes to the table:

- 1) The following code-names were used to denominate the substances: FOE 5043 for Flufenacet, FOE S. A. for FOE Sulfonic acid, FOE TFESA for FOE Trifluoroethanesulfonic acid and TFA for Trifluoroacetic acid;
- 2) **In aqueous solution TFA, being a very strong acid with $\text{pK}_a = 1.6$, is fully dissociated, therefore the values are provided for trifluoroacetate and the test substance used to determine them was TFA-Na salt;**
- 3) In section B.2 it was stated that Flufenacet isomerised by evaporation forming a mixture containing 10% of Flufenacet and 90% of its *N*-isomer; as a result, the value is that characteristic for *N*-isomer of Flufenacet;
- 4) The value determined at pH = 4;
- 5) The values determined for *N*-isomer of Flufenacet, using the solubility values determined for that compound;
- 6) The measured value not provided; instead the Applicant presented the value determined theoretically, using QSAR method, and for $T = 25^\circ\text{C}$; RMS subsequently converted that value to presented here value for $T = 20^\circ\text{C}$ using appropriate Van't Hoff equation (presented in the "Manual for FOCUS TOXSWA version 2.2.1", Alterra Report No. 586, Wageningen, 2006);
- 7) The value determined in unbuffered solution and representative for the whole environmentally relevant pH range, since it was experimentally demonstrated that water solubility of FOE S. A. is not pH-dependent;
- 8) Value not available;
- 9) The value determined in pH = 7 buffer solution, but considered representative for the whole environmentally relevant pH range, since it was experimentally demonstrated that water solubility of FOE Methylsulfone is not pH-dependent;
- 10) The theoretical value determined by the RMS using QSAR methods – it was calculated using Modified Grain method for $T = 25^\circ\text{C}$; for more details please refer to the data presented in the table B.8.8-a.3_CA-4 under the point B.8.8.-A.3 – Appendix 3, of this Renewal Assessment Report;
- 11) The value determined in pH = 6.1 buffer solution, but considered representative for the whole environmentally relevant pH range, since it was experimentally demonstrated that water solubility of FOE Methylsulfide is not pH-dependent;
- 12) The theoretical value determined by the RMS using QSAR methods – it was calculated using Modified Grain method for $T = 25^\circ\text{C}$; for more details please refer to the data presented in the table B.8.8-a.3_CA-4 under the point B.8.8.-A.3 – Appendix 3, of this Renewal Assessment Report;
- 13) The value determined at pH = 5.77;
- 14) The value determined at pH < 5.

The further analysis was carried out using the vapour pressure classification presented in the Guidance document "Pesticides in Air: Considerations for Exposure Assessment" – Report of the FOCUS Working Group on Pesticides in Air (FOCUS; 2008)]. That document provides the proposal for the classification of the given substance with regard to its volatility on the basis of its vapour pressure – table 2.7-1. The table is reproduced below on figure B.8.3.-CA-1.

Table 2.7-1: Vapour pressure classifications

Volatility of compounds	Vapour Pressure in Pa		
	Seiber, Woodrow, 1983 Unsworth <i>et al.</i> , 1999	Koerdel <i>et al.</i> , 1999	EPPO
Volatile	$> 10^{-1}$	$> 10^{-3}$	Soil : $> 10^{-1}$ Plants : 10^{-3}
Medium volatile	between 10^{-1} and 10^{-5}	between 5×10^{-3} and 10^{-6}	Soil : between 10^{-1} and 10^{-3} Plants : between 10^{-3} and 10^{-5}
Low or non volatile	$< 10^{-3}$	$< 10^{-6}$	Soil : $< 10^{-3}$ Plants : $< 10^{-5}$

Figure B.8.3._CA-1: The classification of the volatility of the compounds on the basis of their vapour pressure – the table copied from the FOCUS report “Pesticides in Air: Considerations for Exposure Assessment”.

According to that Guidance document the trigger values indicating the need to establish whether the substance has the potential to reach the air are:

- $V_p \geq 10^{-4}$ Pa at $T = 20^\circ\text{C}$ for volatilisation from soil, and
- $V_p \geq 10^{-5}$ Pa at $T = 20^\circ\text{C}$ for volatilisation from plants.

Using these criteria RMS identified the following compounds as those of potential concern:

- Flufenacet, being medium volatile according to the classification presented above on figure B.8.3._CA-1 and having a potential to reach air via volatilisation from plants;
- FOE Methylsulfone, being medium volatile according to the classification presented above on figure B.8.3._CA-1 and having a potential to reach air via volatilisation from soil and plants;
- FOE Methylsulfide, being medium volatile according to the classification presented above on figure B.8.3._CA-1 and having a potential to reach air via volatilisation from soil and plants; it shall be indicated however that for that compound the assessment is based on theoretically determined values;
- FOE Thiadone, being volatile according to the classification presented above on figure B.8.3._CA-1 and having a potential to reach air via volatilisation from soil and plants.

RMS also decided to take into consideration TFA. Although the experimental values presented in the table B.8.3._CA-1 do not indicate that it is a compound of concern, they were derived for trifluoroacetate. The examination of the available open-source data showed that the non-dissociated acid displayed high volatility potential resulting from its high vapour pressure – 11 kPa at $T = 20^\circ\text{C}$ (source: Pubchem – open chemistry database, url: <https://pubchem.ncbi.nlm.nih.gov>). For that reason RMS decided to evaluate its fate and behaviour in the atmosphere as well. **At the same time it shall be indicated that the $pK_a = 1.6$ value determined for TFA in aqueous solutions clearly indicate that when formed from Flufenacet either in soil or surface water compartments the compound, being entirely dissociated would display very limited volatility and hence risk to atmosphere, unless the environment becomes very acidic. Therefore the whole assessment for that compound is presented mainly for completeness.**

The whole evaluation is presented below, under the relevant data points.

B.8.3.1. – Route and rate of degradation in air

In order to address this data requirement the Applicant submitted two study reports, also evaluated for the purpose of the previous authorisation of Flufenacet in the EU, examining the fate and behaviour of Flufenacet in the air compartment. They are summarised below as *Study 1* and *Study 2*.

It was also stated that three degradation products of Flufenacet – FOE Methylsulfone, FOE Methylsulfide and FOE Thiadone would require further assessment, being either semi-volatile or volatile compounds and therefore posing a potential threat to the atmosphere. Additionally RMS decided to include into the assessment another degradation product of Flufenacet – TFA, also displaying high volatility when not dissociated. For that reason RMS calculated their atmospheric half-lives using AOPWin modelling tool. The calculations are summarised under this point, individually for each compound, as *Studies 3 - 6*. In case of TFA the further assessment is based on the literature data.

Study 1:

Report: Hellpointner E., (1995): “Determination of the Volatilisation Behavior of FOE 5043 (60WG) in a Field Trial.”; Bayer AG, Crop Protection-Development, Institute for Metabolism Research and Residue Analysis, D-51368 Leverkusen, Germany (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, MO 64120, USA; Bayer Report No. 107281 (PF-4091); 12 September 1995; study reference number M-002237-01-2.

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 163-3, Field Volatility;
- BBA Guidelines for Testing of Plant Protection Products in Registration Procedure, Part IV, 6-1 (July 1990) entitled “Determination of the volatilization and the fate of plant protectants in the air”.

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.7.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. Evaluated for the purpose of the present assessment it was found acceptable and is summarised below.

Summary:

The aim of the study was to determine the level of volatilisation of Flufenacet from the soil surface under the field conditions. The experiment was performed in accordance with the BBA Test Guideline IV, 6-1 using one test soil, in three separate trials.

In order to carry out as complete as possible quantitative analysis, including the determination of the non-volatile degradation products as well as the residues of the active substance being bound to soil and/or plant matrices, the experiment was performed with the radiolabelled compound, having a specific activity of 65 kBq/mg (1.756 $\mu\text{Ci}/\text{mg}$) and radiochemical purity of > 99% (determined by HPLC and TLC). The compound was uniformly labelled in fluorophenyl ring. Its structural formula, together with the radiolabelling position indicated by an asterisk, is presented below on figure B.8.3.1._CA-1.

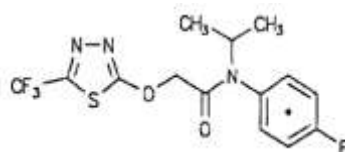

Figure B.8.3.1._CA-1: The structural formula of the test compound – [Phenyl-U-¹⁴C] Flufenacet, with radiolabelling positions is indicated by an asterisk;
(copied from the study report).

In the experiment it was used as a formulated product – FOE 5043 60 WP, prepared according to the recipe for the formulation FOE 5043 60 WG (for purpose of the present experiment the preparation of the formulation was terminated before the last stage – preparation of the wettable granules – WG). The content of the active substance in that formulation was 60% or 600 g/kg.

Due to the fact that when the experiment was carried out it was not permitted to use the radioactive isotopes in field trials (for reasons of radiation protection and health physics), each trial was performed in a plant container arrangement, presented below on figure B.8.3.1._CA-2.

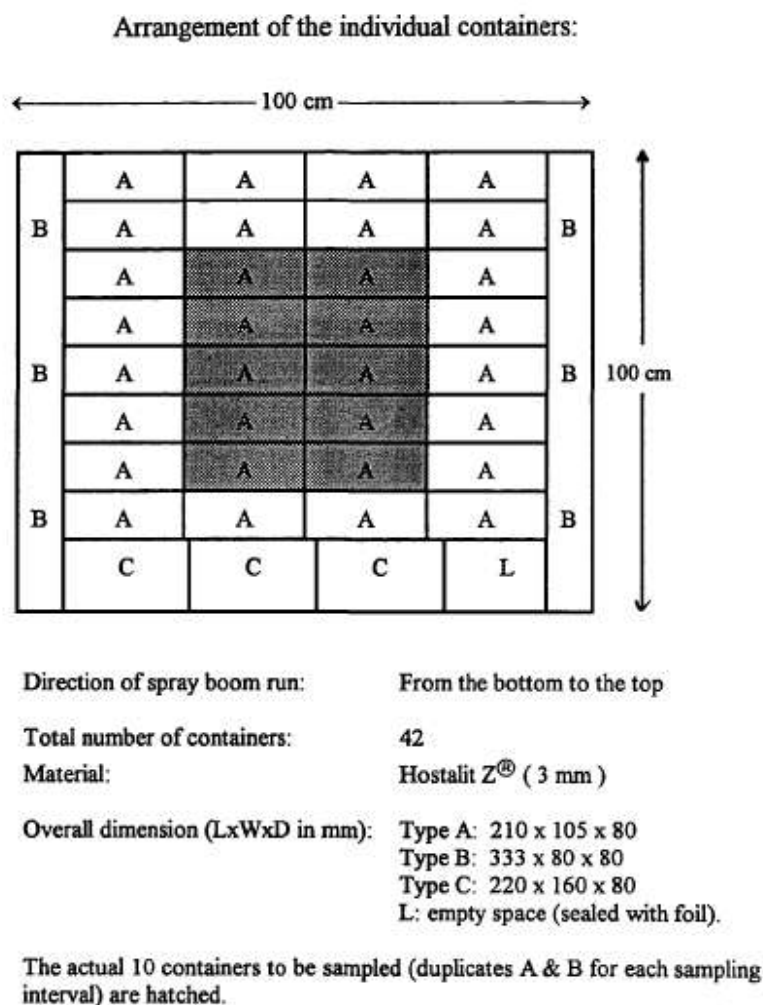

Figure B.8.3.1._CA-2: The scheme of the container arrangement used in the experiment; for explanations please refer to the text below (the scheme copied from the study report).

The whole setup consisted of 42 PVC vessels, of which 10 central, marked A and shaded gray on the scheme above, made the sampling area. They were surrounded by other 32 vessels simulating a close field situation to minimise the marginal effect. The vessels were fixed on a pallet and the whole set surrounded with a steel collar before being transferred to the test site.

Each vessel was filled with the test soil characterised below in the table B.8.3.1._CA-1.

Table B.8.3.1._CA-1: The characteristic of the test soil used in the experiment.

Parameter	Soil:
Soil origin	<i>Langenfeld, Rheinland, Germany</i>
Soil type USDA (as reported in the study)	Loamy sand
Soil type USDA (calculated by RMS)	US Loamy sand
Particle size distribution	Sand [%]
	77.3
	Silt [%]
	17.5
	Clay [%]
	5.2

The test formulation was applied to the bare surface of the test soil as a spray liquid, using automated application device consisting of a mobile steel frame with a vertically adjustable platform containing the arrangement of the spray nozzles attached to it. The spray boom contained 3 nozzles, each 50-cm apart from the others. During application it was moved at the constant speed 6 km/h, covering the spraying distance of 100 cm plus 10-cm distances for acceleration and stopping (120 cm in total). The spray liquid, prepared by dissolving the appropriate amount of the test formulation in 200 mL of the Milli-Q water, was administered from a tank, in which it was constantly mixed using magnetic stirrer, at a constant rate, using pressurised air. The amount of the application solution in the tank of the application device was 150 mL.

The application rate was calculated using the following assumptions:

- the formulation was intended to be used as a pre-emergence herbicide in maize;
- the application rate was in range 375 – 750 g Flufenacet/ha, depending on the soil characteristic, and OC content in particular.

Using the soil characteristic presented below in the table B.8.3.1._CA-1 it was determined to be 600 g Flufenacet/ha, corresponding to 1000 g formulation/ha, administered as a spray liquid at rate 340 L/ha.

The test compound was applied to the bare soil surface, being in a stage “shortly after seedbed preparation”, three times during the experiment: on 25th May 1994 at 10:00 am CET – 1st trial, on 26th May 1994 at 10:40 am CET – 2nd trial, and on 30th May 1994 at 10:00 am CET – 3rd trial. The characterisation of the spray liquid used in each trial is presented in the table B.8.3.1._CA-2.

Table B.8.3.1._CA-2: The characteristic of the application solution used in each trial.

Trial No.	Application time	Preparation of the spray liquid		Characteristic of the spray liquid		
		Amount of WP formulation [mg]	Amount of Milli-Q water [mL]	Activity [kBq/mL]	Concentration of Flufenacet [mg/mL]	Content of Flufenacet in solution [mg]
1	25/05/1994/10:00	592.3	200	111.98	1.723	344.60
2	26/05/1994/10:40	588.1	200	110.10	1.694	338.80
3	30/05/1994/10:00	459.3	150	118.74	1.827	274.05

The pallets containing the treated vessels were placed on the trial site immediately after treatment and exposed to the field conditions for up to 24 hours..

Each trial lasted for 24 hours after application of the test compound. At pre-designated time points – shortly after application (0-hours sample), 1 hour, 3 hours, 6 hours and 24 hours after application two containers from the sampling area (see figure B.8.3.1._CA-2) were removed from the set and immediately processed. That was done in the following way: the top 2-3 cm layer of soil was collected using a spoon and extracted with two 300-mL portions of MeOH. The extracts were combined, filtered through paper filters and analysed for radioactivity

content and nature. The surfaces of the rims of containers were cleaned with soft wipe paper, extracted then with MeOH. The extracts were analysed for radioactivity content by LSC.

The soil samples after extraction were analysed for radioactivity content. For that purpose the whole samples were air-dried, homogenised by grinding them and their subsamples combusted. The $^{14}\text{CO}_2$ formed during combustion was absorbed in Oxysolv C 400.

In a similar way were processed the residues contained on the paper filters and those used to clean the rims of the test vessels.

The whole processing procedure was performed immediately after sampling of the test vessels in order to minimise volatilisation effects during sampling and processing.

All samples were analysed for the radioactivity content by LSC, using Rackbeta 1219 Spectral, LS6000LL or LS6500 liquid scintillation counter.

Additionally organic extracts were analysed by TLC. The analysis was performed on silica gel 60 F₂₅₄, 20 x 20 cm., 0.25-mm thick TLC plates. The plates were developed in $\text{CHCl}_3/\text{CH}_3\text{COOC}_2\text{H}_5$ 3:1 solvent system. The detection was carried out using Bio-Imaging Analyser BAS 2000.

Additionally the HPLC method was used to check the radiochemical purity of the active substance in the formulation as well as its purity and content in the application solution.

During the whole experiment for each trial the weather data were continuously monitored. That was done within the 3 metres from the container arrangement at the soil level and at the level of 2 metres above the ground. The parameters recorded at the soil level (~0.5 m. above the ground) were:

- air temperature;
- air humidity;
- wind velocity (~1m. apart from the containers).

The parameters recorded at the level of 2 m. above the ground were:

- prevailing wind direction;
- wind velocity;
- duration of sunshine;
- intensity of sunshine.

Additional weather data were obtained either from the weather station located at the trial site (precipitation) or from the weather bulletins presented by local media (Kölner-Stadtanzeiger).

Results and their discussion:

The key results of the determination of the weather conditions during each trial are presented below in the table B.8.3.1_CA-3. The detailed results of that determination, recorded for each trial, are presented in a graphical form on figures B.8.3.1_CA-3 – B.8.3.1_CA-5.

Table B.8.3.1_CA-3: The weather conditions recorded for each trial.

Weather parameter		Results obtained for the trial (trial number / duration period):		
		No. 1/ 25 – 26. 05. 1994	No.2/ 26 – 27. 05. 1994	No 3/ 30 – 31. 05. 1994
Sunshine	Duration [h]	0 ¹⁾	0 ¹⁾	10.67
	Energy [kJ/cm ³]	0 ²⁾	0 ²⁾	25.513
Precipitation [mm]		6.2 ³⁾	0.0 ³⁾	0.03)

	Mean	0.7	0.8	0.5

Footnotes to the table:

- 1) During that period, according to the weather data provide in the study report the sky on the area where the experiment was performed was partly or totally clouded;
- 2) The value was lower than the detection limit of the sensor;
- 3) In the study report it was stated that to protect the containers from the rainfall during the night or when the rain was forecasted a stainless steel roof was installed 1 metre above the soil surface.

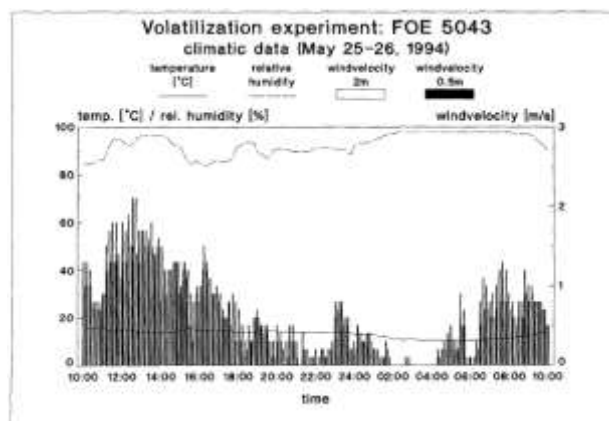

Figure B.8.3.1_CA-3: The detailed weather conditions – temperature, relative humidity and the windspeed, recorded for the trial No. 1 (copied from the study report).

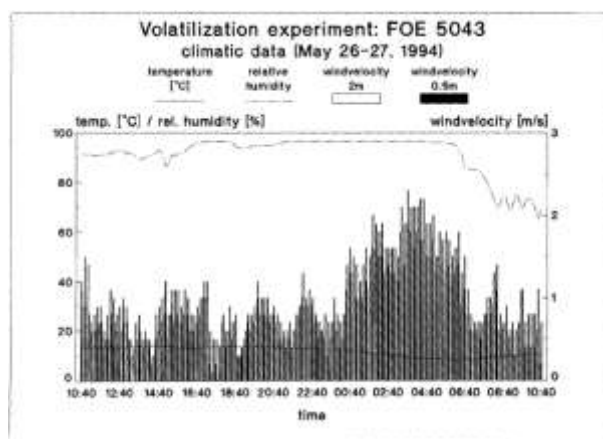

Figure B.8.3.1_CA-4: The detailed weather conditions – temperature, relative humidity and the windspeed, recorded for the trial No. 2 (copied from the study report).

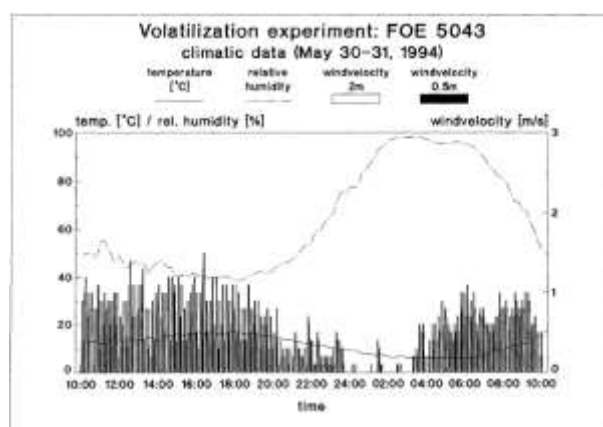

Figure B.8.3.1_CA-5: The detailed weather conditions – temperature, relative humidity and the windspeed, recorded for the trial No. 3 (copied from the study report).

The data concerning the application rates used in each trial are presented below in the table B.8.3.1._CA-4. The values are the averages of the two replicates.

Table B.8.3.1._CA-4: The data on the application rate of the test compound for each trial.

Trial No.	Radioactivity in application solution [kBq/mL]	Data on application			Radioactivity recovered immediately after application (0 hours after application)		
		Volume of the application solution sprayed [mL/m ²]	Amount of the test compound applied		from soil in [% AR]	from rims of the test vessels in [% AR]	Total radioactivity recovered in [% AR]
			in [mg/m ²]	in [g/ha]			
1	112.0	31.8	54.8	548	92.7	7.3	100.0
2	110.1	34.8	59.0	590	94.3	5.7	100.0
3	118.7	37.1	67.7	677	92.7	7.3	100.0
Mean	113.6	34.6	60.5	605	93.2	6.8	100.0

The results showed relatively good reproducibility of the application in all three trials, with $\geq 93\%$ of the applied radioactivity reaching the soil surface.

The results of the quantification of radioactivity in each trial in function of time are presented below in the table B.8.3.1._CA-5. The results are the mean of the two replicates. The radioactivity characterised in the table as “not recovered” was attributed to be lost due to the volatilisation. That term was applied also to the part of radioactivity bound to the soil particles and removed with them from the sampling area as a result of the wind erosion.

Table B.8.3.1._CA-5: The distribution of the radioactivity in the test systems during each trial as a function of time.

Trial No.	Radioactivity in the test system		The exposure time under field conditions				
			0 hours	1 hour	3 hours	6 hours	24 hours
1	Recovered [%AR]	in soil, extracted	72.10	64.46	67.60	63.73	60.40
		in soil, as NER fraction	26.91	19.06	16.97	23.58	26.30

		in soil, as NER fraction	26.81	25.25	28.41	33.77	33.88
		remainder	1.03	0.74	0.66	0.57	0.53
		Total recovered	100.00	92.09	94.09	92.55	92.10
	Not recovered (lost) [%AR]		0.00	7.91	5.92	7.45	7.90
Mean	Recovered [%AR]	in soil, extracted	69.65	63.06	61.14	54.77	53.53
		in soil, as NER fraction	29.34	24.57	23.03	28.70	29.26
		remainder	1.01	0.86	0.87	0.73	0.53
		Total recovered	100.00	88.49	85.04	84.20	83.52
	Not recovered (lost) [%AR]		0.00	11.51	14.96	15.80	16.48

The results showed that, depending on the trial, 70.83 – 92.10% AR, remained in the test system after 24 hours. The amount of radioactivity lost from the system after 24 hours was in range 7.90 – 29.17% AR, being highest – 29.17% AR, in the trial No. 2 and lowest – 7.90 % AR, in the trial No. 3. On average the amount of radioactivity recovered from soil, as extractable residues and the remainder fraction, was 83.52% AR while the amount lost from the test system after 24 hours due to volatilisation was 16.48% AR.

The results obtained in the trials No. 1. and No. 3 were considered by the Applicant to be similar, with the volatilisation on the level of 12.38% of the applied dose after 24 hours in the trial No. 1 and 7.90% of the applied dose in the trial No. 3. In case of the trial No. 3, the level of volatilisation was significantly higher – 29.17% of the applied dose after 24 hours. That phenomenon cannot however be explained by unfavourable weather

conditions, what indicated the Applicant. According to the Applicant, the analysis of the kinetics of volatilisation showed that it was the fastest during the 1st hour after application and after that time it slowed down. RMS however noticed that in case of the trial No. 2 the significant losses due to volatilisation occurred not within the 1st hour of the experiment, but within its first three hours, after what the process slowed down.

It shall be also indicated that while in case of the trials No. 2 and No. 3 a clear trend was observed – substantial initial volatilisation after first 1-3 hours and after that period the amount of radioactivity lost from the system remained on relatively stable level, in case of the trial No. 1 significant fluctuations were observed – the amount of radioactivity not recovered in samples taken 1 and 3 hours after treatment were higher than the levels of lost radioactivity recorded at later time points. The Applicant did not provide a satisfactory explanation of that phenomenon.

The radioactivity recovered from the test vessels was predominantly in the extractable fraction, although its significant portion – 16.97 – 26.91% AR in case of trial No. 1, 23.71 – 34.30% AR in case of the trial No. 2 and 25.25 – 33.88% AR in case of the trial No. 3, formed a non-extractable fraction. The level of that NER fraction in each trial was relatively stable throughout the whole exposure period. The explanation of that phenomenon was not provided, but in RMS's opinion that may be related to the extraction procedure, very mild one, which was not developed with aim to do the proper profiling of Flufenacet and its degradation and/or transformation products in the test soil.

It cannot be also excluded, because only the top 2 – 3-cm layer of the soil in each sampled vessel was analysed, that the losses may partly be attributed to the migration below that layer, although that process does not seem to be very significant, taking into account the study duration and the fact that the container arrangements were protected from the precipitation.

The further qualitative examination of the radioactivity extracted from soil, performed by means of TLC, showed that it consisted predominantly, if not solely, of Flufenacet. The exemplary TLC chromatograms, conforming that statement, are presented below on figure B.8.3.1._CA-6.

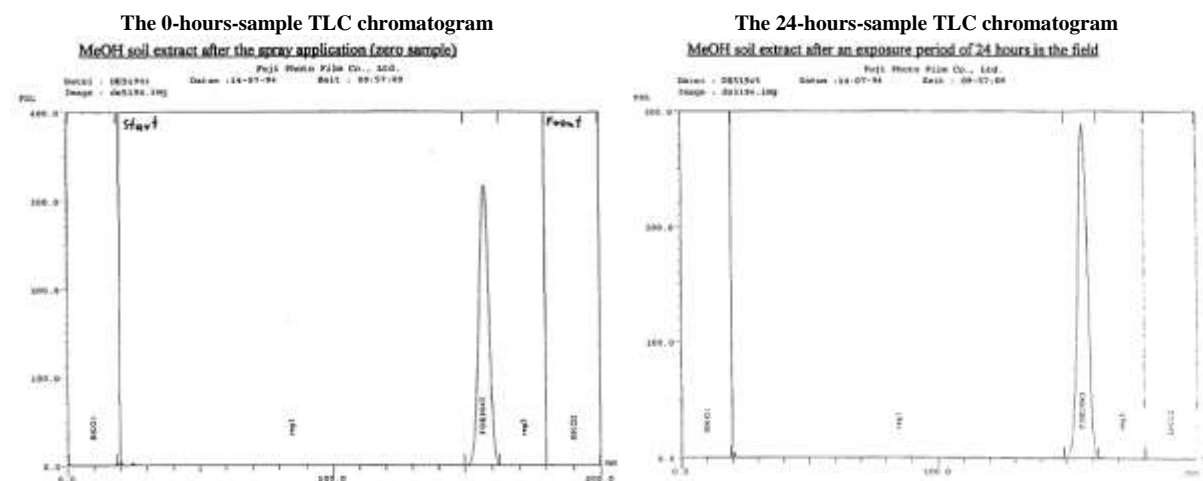

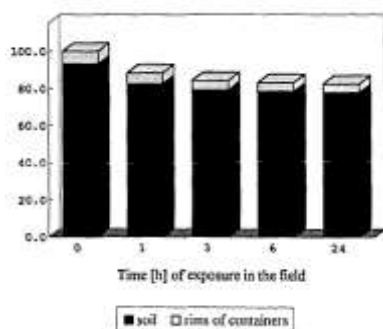

Figure B.8.3.1._CA-6: The graphical results of the qualitative examination of the soil extracts – the exemplary TLC chromatograms (copied from the study report).

The graphical analysis of the averaged results obtained in the study – the mean results of the three trials, are presented below on figure B.8.3.1._CA-7. The left-hand graph shows the recovery levels of radioactivity from soil and rims of containers in function of time and the right-hand graph the trend line for the total radioactivity recovery in the function of time. When reversed, that line would represent the trend line for volatilisation from soil.

The recoveries of radioactivity from the test vessels in function of time

The trend line showing the trend in change of the recovery level over the period of 24 hours

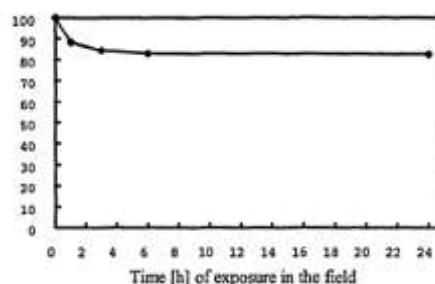

Figure B.8.3.1._CA-7: The graphical results of the experiment (copied from the study report).

Conclusions of the study:

The results of the experiment showed that the level of volatilisation of the residues of Flufenacet (active substance and its degradation products) from the bare soil surface within 24 hours after application of that compound would be on average 16.5% of the applied dose, ranging from ~8% to ~29% of the applied amount. The process was demonstrated to be most intensive within first one to three hours after application. After that time volatilisation was low or even negligible.

On that basis it was stated that volatilisation of Flufenacet would be low and therefore the compound is expected to pose a low to negligible threat to the atmosphere, as well as is not expected to cause a secondary pollution due to the wet or dry deposition from air.

Study 2:

Report: Hellpointner E., (1995): "Calculation of the Chemical Lifetime of Thiaflumide (FOE 5043) I the Troposphere."; Bayer AG, Crop Protection-Development, Institute for Metabolism Research and Residue Analysis, D-51368 Leverkusen, Germany; Report No. PF-4069 (HPO-123); 07 July 1995; study reference number M-002236-01-1.

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for Testing of Plant Protection Products in Registration Procedure, Part IV, 6-1 (July 1990) entitled "Determination of the volatilization and the fate of plant protectants in the air".

GLP: No, not required – model calculations;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.7.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. Evaluated for the purpose of the present assessment it was found acceptable and is summarised below.

Summary:

The aim of the study was to determine the half-life of Flufenacet in air when subjected to the reaction of photochemical degradation in presence of the $\bullet\text{OH}$ radicals. The assessment was performed using the calculation procedure developed by Atkinson. The calculations were carried out using AOPWin ver. 1.55a tool. They were performed for 12-hours long day and assuming the concentration of the $\bullet\text{OH}$ radicals equal to $1.5 \text{ E}6$ [radicals/ cm^3]. The results of the calculations – the report generated by the modelling tool, are presented below on figure B.8.3.1._CA-8. On their basis it was stated that the calculated by AOPWin overall rate constant was $27.2547 \text{ E-12} [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}]$. The calculated on that basis for Flufenacet in air, assuming 12-hours

lasting day and the concentration of the •OH radicals of $1.5 \text{ E}6 \text{ [radicals/cm}^3\text{]}$, $t_{1/2} = 4.7 \text{ hours}$, what corresponded to the chemical lifetime of Flufenacet in air $\text{DT}_{50} = 6.8 \text{ hours}$. On that basis it may be stated that Flufenacet will not be persistent in air, with $\text{DT}_{50} < 2 \text{ days}$.

Figure B.8.3.1._CA-8: The report of the calculations generated by the modelling tool – AOPWin ver. 1.55a (copied from the study report).

Conclusions of the study:

The model assessment of the persistence of Flufenacet in air showed that the compound would be short-living in that compartment, with the half-life, calculated assuming 12-hours lasting day and the concentration of the •OH radicals of $1.5 \text{ E}6 \text{ [radicals/cm}^3\text{]}$, $t_{1/2} = 4.7 \text{ hours}$, what corresponded to the chemical lifetime of Flufenacet in air $\text{DT}_{50} = 6.8 \text{ hours}$. That value is significantly shorter than the $\text{DT}_{50} = 2 \text{ days}$, what indicates that Flufenacet, even in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It would also not be prone to medium- or long-range transport in that compartment and therefore it would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

The next four summaries present the results of the determination of the persistence in air of the four major degradation products of Flufenacet identified, on the basis of the analysis of their physico-chemical properties, as semivolatile or volatile and for that reason posing a potential threat to the air compartment – FOE Methylsulfone (semi-volatile compound), FOE Methylsulfide (semi-volatile compound) FOE Thiadone (volatile compound and Trifluoroacetic acid (TFA) – highly volatile compound when not dissociated (that is based on the reported in the literature for that compound $V_p = 0.1446 \text{ atm}$. corresponding to $V_p = 14651.595 \text{ Pa}$). The results of that

assessment, performed using the approach developed by Atkinson, are presented individually for each compound in *Studies 3 – 6*.

Study 3:

Report: RMS (2016): “The determination of the persistence in air of FOE Methylsulfone – the major soil degradation product of Flufenacet, using Atkinson’s method and EPISuite modelling tool”; RMS’s internal report;

Guidelines: not applicable.

GLP: No, not applicable (modelling exercise);

RMS comments: not applicable

Summary:

The aim of the study was to determine the half-life of FOE Methylsulfone – the major soil degradation product of Flufenacet, in air when subjected to the reaction of photochemical degradation in presence of the •OH radicals. The assessment was performed using the calculation procedure developed by Atkinson and the AOPWin ver. 1.92, a part of EPISuite 4.1 modelling tool.

The estimation was performed for the following SMILES code created for FOE Methylsulfone:

c1c(F)ccc(N(C(C)(C))C(=O)CS(=O)(=O)C)c1

The calculations were performed for 12-hours long day and assuming the concentration of the •OH radicals equal to 1.5 E6 [radicals/cm³]. The results of the calculations – the report generated by the modelling tool, are presented below on figure B.8.3.1._CA-9.

Figure B.8.3.1._CA-9: The report of the calculations generated by the modelling tool – AOPWin ver. 1.92.

On their basis it was stated that the calculated by AOPWin overall rate constant was 19.0043 E-12 [cm³ • molecule⁻¹ • s⁻¹]. The calculated on that basis for FOE Methylsulfone in air, assuming

12-hours lasting day and the concentration of the $\bullet\text{OH}$ radicals of $1.5 \text{ E6} [\text{radicals}/\text{cm}^3]$, $t_{1/2} = \mathbf{6.754 \text{ hours}}$, what corresponded to the chemical lifetime of Flufenacet in air $\mathbf{DT_{50} = 0.563 \text{ days}}$. On that basis it may be stated that FOE Methylsulfone will not be persistent in air, with $\text{DT}_{50} < 2 \text{ days}$.

Conclusions of the study:

The model assessment of the persistence of FOE Methylsulfone in air showed that the compound would be short-living in that compartment, with the half-life, calculated assuming 12-hours lasting day and the concentration of the $\bullet\text{OH}$ radicals of $1.5 \text{ E6} [\text{radicals}/\text{cm}^3]$, $t_{1/2} = \mathbf{6.754 \text{ hours}}$, what corresponded to the chemical lifetime of FOE Methylsulfone in air $\mathbf{DT_{50} = 0.563 \text{ days}}$. That value is significantly shorter than the $\text{DT}_{50} = 2 \text{ days}$, what indicates that FOE Methylsulfone, even in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It would also not be prone to medium- or long-range transport in that compartment and therefore it would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

Study 4:

Report: RMS (2016): “The determination of the persistence in air of FOE Methylsulfide – the major aquatic degradation product of Flufenacet, using Atkinson’s method and EPISuite modelling tool”; RMS’s internal report;

Guidelines: not applicable.

GLP: No, not applicable (modelling exercise);

RMS comments: not applicable

Summary:

The aim of the study was to determine the half-life of FOE Methylsulfide – the major aquatic degradation product of Flufenacet, in air when subjected to the reaction of photochemical degradation in presence of the $\bullet\text{OH}$ radicals. The assessment was performed using the calculation procedure developed by Atkinson and the AOPWin ver. 1.92, a part of EPISuite 4.1 modelling tool.

The estimation was performed for the following SMILES code created for FOE Methylsulfide:

The calculations were performed for 12-hours long day and assuming the concentration of the $\bullet\text{OH}$ radicals equal to $1.5 \text{ E6} [\text{radicals}/\text{cm}^3]$. The results of the calculations – the report generated by the modelling tool, are presented below on figure B.8.3.1._CA-10.

On their basis it was stated that the calculated by AOPWin overall rate constant was $\mathbf{20.7043 \text{ E-12} [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}]}$. The calculated on that basis for FOE Methylsulfide in air, assuming 12-hours lasting day and the concentration of the $\bullet\text{OH}$ radicals of $1.5 \text{ E6} [\text{radicals}/\text{cm}^3]$, $t_{1/2} = \mathbf{6.199 \text{ hours}}$, what corresponded to the chemical lifetime of FOE Methylsulfide in air $\mathbf{DT_{50} = 0.517 \text{ days}}$. On that basis it may be stated that FOE Methylsulfide will not be persistent in air, with $\text{DT}_{50} < 2 \text{ days}$.

Figure B.8.3.1._CA-10: The report of the calculations generated by the modelling tool – AOPWin ver. 1.92.

Conclusions of the study:

The model assessment of the persistence of FOE Methylsulfide in air showed that the compound would be short-living in that compartment, with the half-life, calculated assuming 12-hours lasting day and the concentration of the •OH radicals of 1.5 E6 [radicals/cm³], $t_{1/2}$ = **6.199 hours**, what corresponded to the chemical lifetime of FOE Methylsulfide in air **DT₅₀ = 0.517 days**. That value is significantly shorter than the DT₅₀ = 2 days, what indicates that FOE Methylsulfide, even in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It would also not be prone to medium- or long-range transport in that compartment and therefore it would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

Study 5:

Report: RMS (2016): “The determination of the persistence in air of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet, using Atkinson’s method and EPISuite modelling tool”; RMS’s internal report;

Guidelines: not applicable.

GLP: No, not applicable (modelling exercise);

RMS comments: not applicable

Summary:

The aim of the study was to determine the half-life of FOE Thiadone – the major soil and aquatic degradation product of Flufenacet, in air when subjected to the reaction of photochemical degradation in presence of the •OH

radicals. The assessment was performed using the calculation procedure developed by Atkinson and the AOPWin ver. 1.92, a part of EPISuite 4.1 modelling tool.

The estimation was performed for the following SMILES codes created for FOE Thiadone:

The calculations were performed for 12-hours long day and assuming the concentration of the •OH radicals equal to 1.5 E6 [radicals/cm³]. The results of the calculations – the report generated by the modelling tool, are presented below on figure B.8.3.1._CA-11.

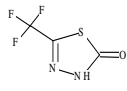

<p>Simulated compound: FOE Thiadone</p>	<p>Structural formula:</p> 
<p>Obtained results:</p> <p>SMILES : <chem>O=C1NN=C(C(F)(F)(F))S1</chem> CHEM : MOL FOR: C3 H1 F3 N2 O1 S1 MOL WT : 170.11</p> <p>----- SUMMARY (AOP v1.92): HYDROXYL RADICALS (25 deg C) -----</p> <p>Hydrogen Abstraction = 0.0000 E-12 cm3/molecule-sec Reaction with N, S and -OH = 0.0000 E-12 cm3/molecule-sec Addition to Triple Bonds = 0.0000 E-12 cm3/molecule-sec Addition to Olefinic Bonds = 0.0000 E-12 cm3/molecule-sec Addition to Aromatic Rings = 0.0000 E-12 cm3/molecule-sec Addition to Fused Rings = 0.0000 E-12 cm3/molecule-sec</p> <p>OVERALL OH Rate Constant = 0.000000 E-12 cm3/molecule-sec HALF-LIFE = -----</p> <p>----- SUMMARY (AOP v1.91): OZONE REACTION (25 deg C) -----</p> <p>***** NO OZONE REACTION ESTIMATION ***** (ONLY Olefins and Acetylenes are Estimated)</p> <p>Experimental Database: NO Structure Matches</p>	

Figure B.8.3.1._CA-11: The report of the calculations generated by the modelling tool – AOPWin ver. 1.92.

For that structure AOPWin modelling tool was not able to calculate the overall rate constant for reaction with hydroxyl radicals, hence the half-life of FOE Thiadone in air. That may indicate that FOE Thiadone when reaching the air compartment will not undergo the photochemical oxidative degradation in air.

Additional estimation was performed for a very similar structure, with the relocated double bond. That estimation was performed for the following SMILES code, representing FOE Thiadone:

The calculations were performed for 12-hours long day and assuming the concentration of the •OH radicals equal to 1.5 E6 [radicals/cm³]. The results of the calculations – the report generated by the modelling tool, are presented below on figure B.8.3.1._CA-12.

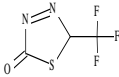

Simulated compound: FOE Thiadone	Structural formula: 
<p>Obtained results:</p> <p>SMILES : C1(C(F)(F)(F))SC(=O)N=N1 CHEM : MOL FOR: C3 H1 F3 N2 O1 S1 MOL WT : 170.11 ----- SUMMARY (AOP v1.92): HYDROXYL RADICALS (25 deg C) ----- **Hydrogen Abstraction = 0.3614 E-12 cm³/molecule-sec Reaction with N, S and -OH = 0.0000 E-12 cm³/molecule-sec Addition to Triple Bonds = 0.0000 E-12 cm³/molecule-sec Addition to Olefinic Bonds = 0.0000 E-12 cm³/molecule-sec Addition to Aromatic Rings = 0.0000 E-12 cm³/molecule-sec Addition to Fused Rings = 0.0000 E-12 cm³/molecule-sec OVERALL OH Rate Constant = 0.3614 E-12 cm³/molecule-sec HALF-LIFE = 29.594 Days (12-hr day; 1.5E6 OH/cm³) ** Designates Estimation(s) Using ASSUMED Value(s) ----- SUMMARY (AOP v1.91): OZONE REACTION (25 deg C) ----- ***** NO OZONE REACTION ESTIMATION ***** (ONLY Olefins and Acetylenes are Estimated)</p> <p>Experimental Database: NO Structure Matches</p>	

Figure B.8.3.1._CA-12: The report of the calculations generated by the modelling tool – AOPWin ver. 1.92.

On their basis it was stated that the calculated by AOPWin overall rate constant was **0.3614 E-12 [cm³ • molecule⁻¹ • s⁻¹]**. The calculated on that basis for FOE Thiadone in air, assuming 12-hours lasting day and the concentration of the •OH radicals of 1.5 E6 [radicals/cm³], **DT₅₀ = 29.594 days**. On that basis it may be stated that FOE Thiadone will be persistent in air, with DT₅₀ > 2 days.

Conclusions of the study:

The model assessment of the persistence of FOE Thiadone in air showed that the compound would be very persistent in air. For the structural formula exactly matching that of FOE Thiadone the results indicated that no reaction with •OH radicals occurred. For the structure that was slightly altered by comparison to that of FOE Thiadone – the double bond was repositioned from C=N to N=N, that reaction was demonstrated to be very slow with the half-life, calculated assuming 12-hours lasting day and the concentration of the •OH radicals of 1.5 E6 [radicals/cm³], **DT₅₀ = 29.594 days**. That value is significantly longer than the DT₅₀ = 2 days. The results therefore indicate that FOE Thiadone in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It would be prone to medium- or long-range transport in that compartment and therefore it may pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

Study 6:

Report: RMS (2016): “The determination of the persistence in air of TFA (Trifluoroacetic acid) – the major secondary soil degradation product of Flufenacet, using Atkinson’s method and EPISuite modelling tool”; RMS’s internal report;

Guidelines: not applicable.

GLP: No, not applicable (modelling exercise);

RMS comments: not applicable

Summary:

The aim of the study was to determine the half-life of Trifluoroacetic acid (TFA) – the major soil degradation product of Flufenacet, in air when subjected to the reaction of photochemical degradation in presence of the •OH radicals. The assessment was performed using the calculation procedure developed by Atkinson and the AOPWin ver. 1.92, a part of EPISuite 4.1 modelling tool.

The estimation was performed for the following SMILES code created for TFA:

The calculations were performed for 12-hours long day and assuming the concentration of the •OH radicals equal to 1.5 E6 [radicals/cm³]. The results of the calculations – the report generated by the modelling tool, are presented below on figure B.8.3.1._CA-13.

On their basis it was stated that the calculated by AOPWin overall rate constant was **0.5200 E-12 [cm³ • molecule⁻¹ • s⁻¹]**. The calculated on that basis for TFA in air, assuming 12-hours lasting day and the concentration of the •OH radicals of 1.5 E6 [radicals/cm³], **DT₅₀ = 20.569 days**. On that basis it may be stated that TFA will be persistent in air, with DT₅₀ > 2 days.

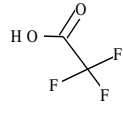

<p>Simulated compound: TFA</p>	<p>Structural formula:</p> 
<p>Obtained results:</p> <p>SMILES : OC(=O)C(F)(F)F CHEM : Trifluoroacetic acid MOL FOR: C2 H1 F3 O2 MOL WT : 114.02</p> <p>----- SUMMARY (AOP v1.92): HYDROXYL RADICALS (25 deg C) -----</p> <p>Hydrogen Abstraction = 0.0000 E-12 cm3/molecule-sec Reaction with N, S and -OH = 0.5200 E-12 cm3/molecule-sec Addition to Triple Bonds = 0.0000 E-12 cm3/molecule-sec Addition to Olefinic Bonds = 0.0000 E-12 cm3/molecule-sec Addition to Aromatic Rings = 0.0000 E-12 cm3/molecule-sec Addition to Fused Rings = 0.0000 E-12 cm3/molecule-sec</p> <p>OVERALL OH Rate Constant = 0.5200 E-12 cm3/molecule-sec HALF-LIFE = 20.569 Days (12-hr day; 1.5E6 OH/cm3)</p> <p>----- SUMMARY (AOP v1.91): OZONE REACTION (25 deg C) -----</p> <p>***** NO OZONE REACTION ESTIMATION ***** (ONLY Olefins and Acetylenes are Estimated)</p> <p>Experimental Database Structure Match: Chem Name : Trifluoroacetic acid CAS Number: 000599-00-8 Exper OH rate constant : 0.12 E-12 cm3/molecule-sec Exper OH Reference: CARR,S ET AL. Figure B.8.3.1._CA-13: The report of the calculations generated by the modelling tool – AOPWin ver. 1.92.

The additional calculations were also performed for the dissociated form of TFA – Trifluoroacetate in form of its sodium salt, using the same assumptions and the same modelling tool. The results of those calculations are presented below on figure B.8.3.1._CA-14. It shall be indicated that for that compound the modelling tool was not able to calculate the overall rate constant for the reaction with the •OH radicals and hence the half-life values for that compound.

Figure B.8.3.1._CA-14: The report of the calculations generated by the modelling tool – AOPWin ver. 1.92.

The results presented above for the acetate clearly indicate that that compound will not undergo degradative any reaction with the •OH radicals, so it would not degrade in the air compartment. It shall be indicated however that trifluoroacetate, unlike its not dissociated counterpart, displays very low vapour pressure so it is not volatile.

Conclusions of the study:

The model assessment of the persistence of TFA in air showed that the compound would be persistent in air, with the half-life, calculated assuming 12-hours lasting day and the concentration of the •OH radicals of 1.5 E6 [radicals/cm³], **DT₅₀ = 20.569 days**. That value is significantly longer than the DT₅₀ = 2 days, what indicates that TFA in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It may also be prone to medium- or long-range transport in that compartment and therefore it may pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

The results of the estimation of the persistence in air of the degradation products of Flufenacet that may pose a threat to the atmosphere due to their volatility (being either semivolatile compounds – FOE Methylsulfide and FOE Methylsulfone, or volatile compounds – FOE Thiadone and Trifluoroacetic acid, according to the values of their saturated vapour pressure) showed that neither FOE Methylsulfide nor FOE Methylsulfone, in case they migrate to the atmosphere in substantial amounts, would pose any threat to that compartment due to their low persistence in air.

In case of FOE Thiadone and TFA their high volatility, combined with the determined high persistence in air indicated that the further determination of their fate and behaviour in that environmental compartment was necessary.

In case of FOE Thiadone the Applicant did not submit any data to address that issue. Also the literature search performed by the RMS has not resulted in identification of any papers dealing with the problem.

It shall however be indicated that FOE Thiadone was observed in soil in amounts not surpassing 10%. It was also demonstrated to be quickly degraded in that compartment. Additionally the results of the studies aimed on the examination of soil photolysis of FOE Thiadone showed that the compound would be mineralised to much greater extent that it would evaporate from soil surface (in irradiated samples within 14 days of the experiment only ~5% of the radioactivity applied was recovered as VOC fraction, in the dark control samples that amount was only ~2.5%). Also in the experiments with radiolabelled FOE Thiadone aimed on the determination of its persistence in aerobic soil under laboratory conditions the levels of radioactivity recovered as VOC fraction was low: 2 – 4%AR at the study's end (10 – 14 days after the experiment was initiated) with no more than 5% of the initial amount of FOE Thiadone remaining in soil. **That may indicate, assuming that the VOC fraction is entirely FOE Thiadone, that despite its high vapour pressure the compound would not migrate to atmosphere from soil in amounts that may pose any substantial threat to that compartment. Also not relevant may be considered the volatilisation from plants as the route of exposure, because that compound would probably not be formed as a transformation product of Flufenacet on plant surfaces.**

The only potential route of exposure of air is volatilisation from SW bodies, where FOE Thiadone was demonstrated to be formed as a major degradation product, but at present there is no clear methodology to assess that issue.

In case of TFA the Applicant as well did not submit any relevant data. **However in the documentation submitted for the evaluation it was stated several times that the TFA formed as a degradation product of Flufenacet will be present as Trifluoroacetate – the dissociated form displaying very low volatility potential and as such not posing any substantial risk to the atmosphere. RMS agrees with that statement.**

The literature search performed by the RMS resulted in identification of several scientific papers addressing the issue of behaviour of TFA in the atmosphere, four of which dealt specifically with persistence, transformation mechanisms and mechanisms of elimination of TFA in/from air.

They are summarised below.

The persistence of TFA in atmosphere, by theoretical estimation of its transformation rate constant in reaction with the hydroxyl radicals, was examined in the following study by [Oeberg; 2005]:

Oeberg. T. "A QSAR for the hydroxyl radical reaction rate constant: validation, domain of application, and prediction."; Atmospheric Environment 2005, **39** (12), 2189 – 2200.

In this paper was presented the methodology of determining the theoretical rate constants for the reaction of 743 chemical compounds characterised by names, chemical structures (SMILES codes) and physical properties in the PhysPropDatabase, found among ~25000 listed there. The compounds were selected on the basis of the experimentally determined rate constants for the reaction with the •OH radicals at temperature range 295 – 300 K (corresponds to T = 22 – 27°C). They were used to calibrate and validate developed empirical QSAR model.

The approach was alternative to that developed by Atkinson and used by AOPWin software developed by US EPA, the limitations of which were briefly characterised.

As a next step the set of following molecular descriptors was generated:

- Constitutional descriptors,
- Topological descriptors,
- Walk and path counts,
- Connectivity indices,
- Information indices,
- 2D autocorrelations,
- Edge adjacency indices,
- BCUT descriptors,
- Topological charge indices,

- Eigenvalue-centered fragments,
- Functional group counts,
- Atom-centered fragments.

Most of them were taken from the available literature data.

The correct interpretation of the SMILES codes was validated by comparison of the molecular weights calculated and reported in the data bases.

The analysis of the data and modelling were carried out using ANOVA method (analysis of variance) partial least squares regression method (PLSR). The approach was fully characterised in the paper. The model was fully validated and compared with other approaches used in that area.

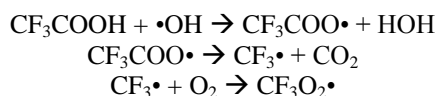

Finally, the list of 152 compounds that are high production volume chemicals (HPVC) with the rate constants of their reaction with the $\bullet\text{OH}$ radicals – k_{OH} and the half-lives in the troposphere. One of the compounds on that list was TFA for which $k_{\text{OH}} = 5.4 \text{ E-14 } [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}]$ and the half-life 148 days. That value was determined using, most probably, the concentration of the $\bullet\text{OH}$ radicals of $1.0 \text{ E6 } [\text{molecule}/\text{cm}^3]$, but the length of the day was not provided. It shall be indicated that although that value may be considered only supplementary in the current assessment, it confirms the fact that TFA is persistent in the air compartment.

The kinetic of the reaction of TFA with the $\bullet\text{OH}$ radicals was experimentally examined and the results of that examination presented in the following publication:

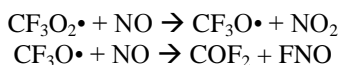

Hurley M. D., Sulbaek Andersen, M. P., Wallington T. J., Ellis D. A., Martin J. W., Mabury S. A., *“Atmospheric Chemistry of Perfluorinated Carboxylic Acids: Reaction with OH Radicals and Atmospheric Lifetimes.”*; Journal of Physical Chemistry, A, 2004, **108** (4), 615 – 620.

The general aim of that study was to determine the kinetics of the reaction of a series of perfluorinated aliphatic carboxylic acids, having a general formula $(\text{F}_3\text{C})_n\text{COOH}$ and containing 1 – 4 $-\text{CF}_3$ groups in the molecule, with the $\bullet\text{OH}$ radicals in 700 Torr and at $T = 296 \pm 2 \text{ K}$ ($\sim 23^\circ\text{C}$). These compounds is an emerging group of pollutants requiring thorough examination for their sources in the atmosphere as well as transformation pathways they are following in that compartment.

In case of TFA the $\bullet\text{OH}$ -initiated transformation is expected to proceed via the following steps:

The next step was the two-step reaction with the NO molecules leading to the formation of COF_2 and FNO molecules as final transformation products of the photooxidative degradation of TFA. The reactions involved in that process were following:

It was stated that the reaction of $\text{CF}_3\text{O}_2\bullet$ with NO may follow different pattern, which is shown below:

That process however was demonstrated to be a side-reaction, in which only 1.67% of the available $\text{CF}_3\text{O}_2\bullet$ radicals are involved.

The experimental rate constant of the photooxidative degradation of TFA initiated by the $\bullet\text{OH}$ radicals was determined as a relative value, using two reference compounds – C_2H_2 and C_2H_4 .

The initial concentration of CF_3COOH was in range 8-363 mTorr, those of the reference compounds – C_2H_2 and C_2H_4 , 2-10 mTorr, of CH_3ONO and NO (the compounds involved in the atmosphere in process of generating of the $\bullet\text{OH}$ radicals in presence of UV radiation) – 100-232 mTorr and 10-25 mTorr respectively. The reactions were examined in 700 mTorr of air diluent.

It was stated that the factor limiting the rate of photooxidative degradation of TFA, as well as other perfluorinated aliphatic carboxylic acid was their dimerisation, the reaction which is shown below on figure B.8.3.1._CA-14.

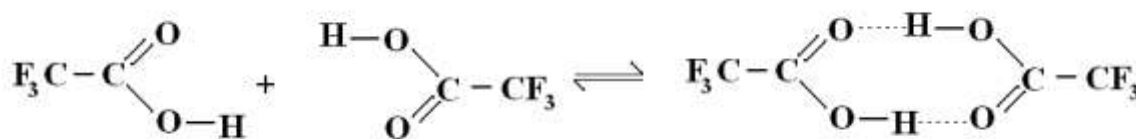

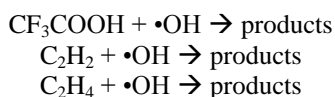

Figure B.8.3.1_CA-15: The reaction of the dimerisation of TFA (after [Hurley *et. al.*; 2004]).

In case of TFA the vapour-phase dimerisation constant was determined to be $K_d = 0.32 \pm 0.03$ [Torr⁻¹] at $T = 298\text{K}$ (corresponding to $\sim 25^\circ\text{C}$). The value was shown to be in good agreement with the results of other studies in the same area.

The rate constant for the reaction of CF_3COOH with the $\bullet\text{OH}$ radicals was determined as relative value to that for the analogous reactions for C_2H_2 and C_2H_4 , assuming the following reactions:

The so determined rate constants were:

$$\begin{aligned}k &= (8.70 \pm 1.44) \text{ E-14 } [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}], \text{ when relative to the reaction for } \text{C}_2\text{H}_2, \\ k &= (1.00 \pm 0.11) \text{ E-13 } [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}], \text{ when relative to the reaction for } \text{C}_2\text{H}_4,\end{aligned}$$

When averaged rate constant for the reaction of CF_3COOH with the $\bullet\text{OH}$ radicals was:

$$k = (9.35 \pm 2.08) \text{ E-14 } [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}]$$

The authors of the publication noted that the determined value was in quite good agreement with results of the other studies. It was also stated that the fact of dimerisation of TFA may not be a factor strongly limiting the reaction – it was suggested that the dimer may be reactive to some degree.

The estimated in that study atmospheric half-life of TFA was approx. 230 days. It was determined using the known atmospheric half-life of CH_3CCl_3 equal to 5.99 years and its rate constant for reaction with $\bullet\text{OH}$ radicals $k = 1.00 \text{ E-14 } [\text{cm}^3 \cdot \text{molecule}^{-1} \cdot \text{s}^{-1}]$.

It was stated that that value was not very sensitive for temperature change, therefore the value determined for $T = 296 \text{ K}$ is also representative for $T = 272 \text{ K}$ – the temperature optimal for such scaling analysis.

The value of atmospheric half-life were indicated to be a global average due to the fact that the concentrations of $\bullet\text{OH}$ radicals vary significantly depending on the location and season.

Finally, the calculated half-life was compared with the rate constants of other processes leading to the removal of TFA from the atmosphere.

In case of TFA, its removal from the atmosphere was estimated to occur at the similar rate as that determined for HNO , with the half-life for the wet deposition equal to 9 days and that for dry deposition of 10-30 days. That makes the reaction of TFA with $\bullet\text{OH}$ radicals of minor importance as the process of the loss of that compound from the air compartment.

The problem of the partition of TFA into water as a mechanism of its removal from the atmosphere was examined in several publications. Probably one of the earliest, basic studies, to which the references were made in numerous publication, including that summarised above, was the following paper:

Bowden D. J., Clegg S. L., Brimblecombe P. “*The Henry’s law constant of Trifluoroacetic acid and its partitioning into liquid water in the atmosphere.*”; *Chemosphere*, 1996, **32** (2), 405 – 420.

The aim of that study was to experimentally determine the Henry’s law constant for Trifluoroacetic acid and on that basis examine the implications for the partitioning of that compound and its removal from the atmosphere.

In the paper the degradation of HCFCs, such as CHCl_2CF_3 , CHClFCF_3 and CH_2FCF_3 , is indicated as one of the main sources of TFA in the air compartment. Additionally other potential sources of that compound, such as degradation of CF_3CHBrCl via CF_3COCl as intermediate, were also named.

The determination of the Henry's law constant for TFA was a multi-stage procedure. Its first step was the determination of the dissociation constant K_a for that compound at $T = 298.15 \text{ K}$ on the basis of the available data. By averaging the results of the several previous studies the authors of the summarised publication derived the $\text{p}K_a = 0.47 \pm 0.1 [\text{mol}/\text{dm}^3]$.

As a next step the equilibrium partial pressure of TFA – $p\text{CF}_3\text{COOH}$ over aqueous solution, in which the known amount of that compound was dissolved, was determined. That was done using the following method:

TFA was removed from above the solution with known concentration of that compound dissolved using the stream of N_2 . The compound present in the gas stream was absorbed in 10 cm^3 of 1.0 M KCl_{aq} solution (unbuffered), the pH of which was then determined. The change of pH of the solution was recorded and related to the amount of TFA in the gas stream.

In order to overcome a problem of strong dissociation of TFA, resulting from its low $\text{p}K_a$ value, strong acid – HBr , was added to the solution to suppress the dissociation of CF_3COOH in it. The amounts of that compound used in the experiment were in range $0.25 - 6.0 \text{ mol/kg}$.

Finally, as a reference, the partial pressures of pure HCl , compound of well known Henry's law constant, over its aqueous solutions were measured.

The measurements of the partial vapour pressure of CF_3COOH over its aqueous solution were performed at three different temperatures: $T = 5^\circ\text{C}$, $T = 25^\circ\text{C}$ and $T = 35^\circ\text{C}$, using three initial concentrations of that compound dissolved – $m\text{CF}_3\text{COOH}_{(\text{T})}$: 0.05 mol/kg (used only for the experiments at $T = 25^\circ\text{C}$ and $T = 35^\circ\text{C}$), 0.15 mol/kg and 0.25 mol/kg .

These values were subsequently used to determine the thermodynamic Henry's law constant – K_H , defined by the following equation:

$$K_H = m\text{CF}_3\text{COOH} \cdot \gamma\text{CF}_3\text{COOH} / f\text{CF}_3\text{COOH}$$

where:

K_H is thermodynamic Henry's law constant,

$m\text{CF}_3\text{COOH}$ is molality of undissociated TFA

$\gamma\text{CF}_3\text{COOH}$ is activity coefficient of undissociated TFA

$f\text{CF}_3\text{COOH}$ is fugacity of TFA, being the equivalent of its partial vapour pressure

When transformed to take into account the total amount of the CF_3COOH dissolved – $m\text{CF}_3\text{COOH}_{(\text{T})}$, the equation takes the following form:

$$p\text{CF}_3\text{COOH} = m\text{CF}_3\text{COOH} \cdot \gamma\text{CF}_3\text{COOH} / [(1 + K_a/m\text{H}^+) \cdot K_H]$$

where:

$p\text{CF}_3\text{COOH}$ is partial vapour pressure of TFA,

$m\text{CF}_3\text{COOH}_{(\text{T})}$ is the total amount of TFA dissolved,

$\gamma\text{CF}_3\text{COOH}$ is activity coefficient of TFA,

K_H is thermodynamic Henry's law constant,

K_a is dissociation constant of TFA.

That equation was used to calculate the K_H value at $T = 298.15 \text{ K}$. Additionally the change of the enthalpy – $\Delta_r H^0$, at the same temperature was calculated. The results are presented below:

$$K_H = 8.95 \text{ E}3 \pm 0.1 \text{ E}3 [\text{mol/kg} \cdot \text{atm}]$$

$$\Delta_r H^0 = -77.6 \pm 0.42 [\text{kJ/mol}]$$

Analysing the obtained results and their implications for the fate and behaviour of TFA in the air compartment the authors made the following statements:

- the Henry's law constant for TFA was similar to the values obtained for CH_3COOH and HCOOH , but its lower dissociation constant results in greater solubility in water; as a result TFA will entirely partition to cloud and fog water, where the liquid water content is $0.05 - 1 \text{ g/m}^3$, and the pH, of which is low;
- more complex would be the situation in case of the atmospheric aerosols displaying the water content of $1\text{E}-5 - 1\text{E}-4 \text{ g/m}^3$; there the partition would depend on the composition of aerosol and the temperature;

- as a result the removal of TFA from atmosphere was expected to occur primarily by means of wet deposition and to much lesser extent by dry deposition.

The problem was also examined, and the results of that examination presented in the following publication:

Kutsuna S., Hori H., "Experimental determination of Henry's law constants of trifluoroacetic acid at 278-298 K."; Atmospheric Environment, 2008, **42** (7), 1399 – 1412.

The aim of the study was to determine the Henry's law constant for Trifluoroacetic acid and the temperature-dependence of that thermodynamical constant. The obtained results were compared with those obtained in the summarised above study by [Bowden *et al.*; 1996].

To do that the partial vapour pressures of TFA over the aqueous solutions having the initial content of that compound in range 0.008 – 0.35 mol/dm³, were determined at three different temperatures – 278.15 K (5°C), 288.15 K (15°C) and 298.15 K (25°C). Additionally the same parameter was determined in solutions containing 0.008 – 0.1 mol/dm³ of TFA and 0.1 – 0.4 mol/dm³ H₂SO₄ at the same temperature range.

The experiment was performed by passing the N₂ stream through the column filled with the aqueous solution of TFA or TFA + H₂SO₄ mixture. The gaseous TFA was captured in two traps filled with 20 mL of 0.1M NaOH. The concentration of TFA in traps, as trifluoroacetate ions, in those solutions, was determined by ion exclusion chromatography. It was subsequently used to calculate the partial vapour pressure values for TFA. The N₂ used to purge the volatilised TFA from the test system was administered at a rate 0.55- 0.57 dm³/min. The concentrations of the not dissociated TFA and trifluoroacetate ions remaining in the solutions were determined by means of IR analysis.

The determined values of the Henry's law constant – K_H , were following:

- at T = 278.15 K, $K_H = 15600 \pm 2800$ [mol/dm³ · atm];
- at T = 288.15 K, $K_H = 9300 \pm 1400$ [mol/dm³ · atm];
- at T = 298.15 K, $K_H = 5800 \pm 700$ [mol/dm³ · atm];

For the T = 298.15 K the corresponding solvation enthalpy for gas-to-water transfer, assuming $K_H = 5780 \pm 30$ [mol/dm³ · atm], was $\Delta H_{\text{sol}} = -34.2 \pm 0.2$ kJ/mol. It was calculated using the van't Hoff equation relating the K_H to the temperature.

It was noticed that the determined in this experiment K_H value for the $\text{pK}_a = 0.47$ was 0.65 of the value reported by [Bowden *et al.*; 1996], but equal to that determined in another study with lower $\text{pK}_a = 0.20$.

As a result it was stated that although the obtained K_H value was very similar to that obtained by [Bowden *et al.*; 1996], the results may indicate that the CF₃COOH may be transported from water at low pH to atmosphere with much less difficulty than previously estimated. Also noticed was low dependence of K_H value on temperature, but the fully satisfying explanation of that fact was not provided.

RMS conclusions:

The presented above results of the determination of the fate and behaviour of TFA in air, based on the literature studies, clearly demonstrate high persistence of that compound in the atmosphere with the DT₅₀ values for the process of photooxidative degradation initiated by the •OH radicals as high as 230 days. The only relevant mechanism of elimination of TFA from that compartment would therefore be, predominantly, wet deposition – with rain or fog with estimated DT₅₀ = approx. 9 days, and, to some extent also by dry deposition, with estimated DT₅₀ = 10-30 days. The identified products of photooxidative degradation of TFA in air initiated by the •OH radicals are COF₂ and FNO. It was also indicated that the dimerisation of TFA may be the factor limiting the rate of degradation of that compound in air in the process of photooxidative degradation initiated by the •OH radicals.

The determination of the Henry's law constant for TFA demonstrated that the compound displayed high affinity towards water, therefore atmospheric water, either in form of clouds or as fog, may be an effective sink for that compound. At the same time however it was postulated that the evaporation of TFA from water phase to air cannot be totally excluded and the process can occur more easily than previously expected.

Conclusions of the assessment:

The examination of the fate and behaviour of Flufenacet in air showed that that compound displayed some tendency for migration to the atmosphere, with the determined average level of volatilisation from soil surface equal to 16.5% of the applied dose (with range of 7.9 – 29.2%), but was not expected to be persistent in that compartment – the determined for the process of the photooxidative degradation initiated by the •OH radicals **DT₅₀ = 6.8 hours**. That value, being significantly shorter than the DT₅₀ = 2 days, indicates that Flufenacet, even in case of reaching the atmosphere in significant amounts, would not pose a serious threat to that compartment. It

would also not be prone to medium- or long-range transport in that compartment and therefore it would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

Of seven major soil, aquatic or soil and aquatic major degradation products of Flufenacet, four were identified as posing potential threat to the atmosphere, being volatile or semivolatile – FOE Methylsulfone, FOE Methylsulfide, FOE Thiadone and Trifluoroacetic acid – TFA. For them was performed the additional estimation of their persistence in air, by determining the DT_{50} values for the process of the photooxidative degradation initiated by the $\bullet OH$ radicals. The calculated for FOE Methylsulfide and FOE Methylsulfone DT_{50} values for that process were **0.517 days** and **0.563 days** respectively, what clearly indicates that even in case of reaching the atmosphere in significant amounts, these compounds would not pose a serious threat to that compartment. They would also not be prone to medium- or long-range transport in that compartment and therefore it would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

The model assessment of the persistence of FOE Thiadone in air showed that the compound would be very persistent in air. For the structural formula exactly matching that of FOE Thiadone the results indicated that no reaction with $\bullet OH$ radicals occurred. For the structure that was slightly altered by comparison to that of FOE Thiadone – the double bond was repositioned from $C=N$ to $N=N$, that reaction was demonstrated to be very slow with the half-life, calculated assuming 12-hours lasting day and the concentration of the $\bullet OH$ radicals of $1.5 E6$ [radicals/cm³], $DT_{50} = 29,594$ days. That value is significantly longer than the $DT_{50} = 2$ days. The results therefore indicate that FOE Thiadone, in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It would be prone to medium- or long-range transport in that compartment and therefore it may pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

For that compound RMS was not able to identify any literature data dealing with its the fate and behaviour in air. It shall however be indicated that FOE Thiadone was observed in soil in amounts not surpassing 10%. It was also demonstrated to be quickly degraded in that compartment. Additionally the results of the studies aimed on the examination of soil photolysis of FOE Thiadone showed that the compound would be mineralised to much greater extent that it would evaporate from soil surface (in irradiated samples within 14 days of the experiment only ~5% of the radioactivity applied was recovered as VOC fraction, in the dark control samples that amount was only ~2.5%). Also in the experiments with radiolabelled FOE Thiadone aimed on the determination of its persistence in aerobic soil under laboratory conditions the levels of radioactivity recovered as VOC fraction was low: 2 – 4%AR at the study's end (10 – 14 days after the experiment was initiated) with no more than 5% of the initial amount of FOE Thiadone remaining in soil. That may indicate, assuming that the VOC fraction is entirely FOE Thiadone, that despite its high vapour pressure the compound would not migrate to atmosphere from soil in amounts that may pose any threat to that compartment. Also not relevant may be considered the volatilisation from plants as the route of exposure, because that compound would probably not be formed as a transformation product of Flufenacet on plant surfaces.

The only potential route of exposure of air is volatilisation from SW bodies, where FOE Thiadone was demonstrated to be formed as a major degradation product, but at present there is no clear methodology to assess that issue.

The model assessment of the persistence of TFA in air showed that the compound would be persistent in air, with the half-life, calculated assuming 12-hours lasting day and the concentration of the $\bullet OH$ radicals of $1.5 E6$ [radicals/cm³], $DT_{50} = 20,569$ days. That value is significantly longer than the $DT_{50} = 2$ days, what indicates that TFA in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It may also be prone to medium- or long-range transport in that compartment and therefore it may pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

The Applicant did not submit any relevant data enabling the elucidation of the fate and behaviour of TFA in the air compartment. However in the documentation submitted for the evaluation it was stated several times that the TFA formed as a degradation product of Flufenacet will be present as Trifluoroacetate – the dissociated form displaying very low volatility potential and as such not posing any substantial risk to the atmosphere.

The literature search performed by the RMS resulted in identification of several scientific papers addressing the issue of behaviour of TFA in the atmosphere, four of which specifically dealt with persistence, transformation mechanisms and mechanisms of elimination of TFA in/from air. On their basis it was possible to state that TFA clearly demonstrated high persistence in the atmosphere with the DT_{50} values for the process of photooxidative degradation initiated by the $\bullet OH$ radicals as high as 230 days. The only relevant mechanism of elimination of TFA from that compartment would therefore be, predominantly, wet deposition – with rain or fog with estimated $DT_{50} = \sim 9$ days, and, to some extent also by dry deposition, with estimated $DT_{50} = 10-30$ days. The identified products of photooxidative degradation of TFA in air initiated by the $\bullet OH$ radicals are COF_2 and FNO. It was also indicate that the dimerisation of TFA may be the factor limiting the rate of degrdation of that compound in air in the process of photooxidative degradation initiated by the $\bullet OH$ radicals.

The determination of the Henry's law constant for TFA demonstrated that the compound displayed high affinity towards water, therefore atmospheric water, either in form of clouds or as fog, may be an effective sink for that compound. At the same time however it was postulated that the evaporation of TFA from water phase to air cannot be totally excluded and the process can occur more easily than previously expected.

B.8.3.2. – Transport via air

In the document MCA, Section 7 for Flufenacet, under the point 7.3.2. the Applicant indicated one study report as addressing the problem of volatilisation of Flufenacet from soil surface and hence its transport through air. That study is the study by [Hellpointner; 1995], already summarised in this Renewal Assessment Report under the previous data point – B.8.3.1., as *Study 1*. It showed that under the standard German conditions when applied to the bare soil as pre-emergent herbicide in maize (in late May) the volatilisation of Flufenacet from soil would not be substantial. The average level of volatilisation from soil, including the process of wind erosion of soil particles with the compound, or its transformation products, adsorbed onto them, within 24 hour following application was 16.5%, with range (for three trials) of 7.9 – 29.2%.

Flufenacet was demonstrated to be short living in air, with the DT_{50} = 4.7 hours in the process of photochemical oxidative degradation in air.

On that basis it can be stated that the compound will not be prone to the medium-and long-range transport. However, the level of volatilisation does not exclude that the short-range transport effect may be observed. To assess the problem RMS examined the available literature data. One publication, summarised below, was identified presenting the results of the examination of effects of the transport in air.

In the following paper:

Vogel J. R., Majewski M. S., Capel P. D., "*Pesticides in Rain in Four Agricultural Watersheds in the United States.*"; Journal of Environmental Quality, 2008, **37**, 1101 – 1115.

were presented the results of the determination of the content of 42 selected active substances of the plant protection product – 18 herbicides, 21 insecticides and 3 fungicides, as well as their 40 degradation products, in rainfall samples collected at four agricultural locations across the USA in years 2003 and 2004. The samples were collected during the crops growth season.

The samples were collected on single sampling locations in small, well defined, intensively agriculturally used watersheds in Maryland, Indiana, Nebraska and California, chosen to meet the criteria of the US National atmospheric Deposition Programme.

The full characteristic of the sampling locations as well as the criteria for selecting the compounds of interest were provided in the paper:

Capel P. D., McCarthy K. A., Barbash J. E., "*National, Holistic, Watershed-Scale Approach to Understand the Sources, Transport, and Fate of Agricultural Chemicals.*"; Journal of Environmental Quality, 2008, **37**, 983 – 993 (contains extended supplement available on-line on the journal editor's web-site).

which RMS decided not to summarise, but which was cross-referenced in the study summarised here.

On the basis of the data provided in the cross-referenced study by [Capel et al.; 2008] it was possible to identify the sampling locations as following:

- for California: lower Merced River basin with the Mustang Creek catchment as a sub-location where the sampling sites for precipitation were located;
- for Maryland: Morgan creek catchment;
- for Indiana: Sugar Creek catchment, including the Leary Weber Ditch Basin;
- for Nebraska: Maple River catchment.

The primary crops identified on each sampling location were following:

- for California: almond groves (45%), Vineyards (12%) and maize (16%);
- for Maryland: maize, soybean small grain crops (60%), pastures (13%), orchards and nurseries (1.5%);
- for Indiana: soybean (50%) and maize (50%);
- for Nebraska: soybean (50%) and maize (50%)

In case of locations in Maryland, Indiana and Nebraska rain samples were collected and analysed as weekly samples during the growth season – from April/May till the end of September. In case of location in California the precipitation samples were collected and analysed on the event basis, because of the infrequent rainfall on the area, from November until March.

The samples were collected during two consecutive years – 2003 and 2004.

In case of Flufenacet, for which the laboratory reporting limit was set to 0.02 µg/L, 52 samples were analysed for its content. The compound was not detected in any of the samples collected in 2003 and in 4% of those collected in 2004. The total percentage of detection for the period 2003 – 2004 was 4% of the collected samples.

The detailed results for each location showed that Flufenacet was detected only in samples collected in Nebraska. It was found in the 11% of the 18 samples subjected to the analysis for the content of that compound (2 in total) with the maximum concentration of 0.05 µg/L recorded on the 4th of May 2004. The median concentration reported in the study was <0.02 µg/L and the wet deposition, estimated on the basis of the obtained results, was 3.09 µg/m² with maximum occurring on the 4th May 2004.

In none of the other examined locations Flufenacet was reported to be found in rainwater samples. It has to be indicated, that other herbicides being the target compounds in that study were detected more frequently and in much higher amounts, although their estimated use pattern was comparable to that of Flufenacet.

These results may indicate that Flufenacet, even in case of reaching the air compartment will not be subjected to the medium-and long distance transport, but rather deposited locally, at the site of use. The aeric mean deposition determined in that study (for not précised application rates) was not significant, by comparison to e. g. that determined in the SW modelling exposure assessment at Step 3 for the use of that compound in Autumn on Winter cereals at application rate 240 g/ha – 0.05 – 0.46 mg/m².

Therefore it may be stated that even when reaching the air compartment in substantial amounts Flufenacet would not be transported in air far from the application sites and pose a significant threat to adjacent areas by wet or dry deposition.

Of the four degradation products identified as semi-volatile or volatile, therefore potentially causing a threat to the atmosphere – FOE Methylsulfide, FOE Methylsulfone, FOE Thiadone and TFA (Trifluoroacetic acid), two – FOE Methylsulfide and FOE Methylsulfone were demonstrated to be short-living in air, therefore not prone to transport via air. The remaining two – FOE Thiadone and TFA were demonstrated not only to be highly volatile, but also persistent in air, with DT₅₀ values for the process of photochemical oxidative degradation in air of 29.6 days and 20.6 days respectively. Therefore in case they reach air compartment in significant amounts their medium- and long-range transport in that compartment is very probable. As a result that issue should be further examined. The Applicant provided no data on the issue of the transport of FOE Thiadone and TFA in air.

In case of FOE Thiadone RMS was also not able to identify any literature data dealing with the transport of that compound in air. It shall however be indicated that FOE Thiadone was observed in soil in amounts not surpassing 10%. It was also demonstrated to be quickly degraded in that compartment. Additionally the results of the studies aimed on the examination of soil photolysis of FOE Thiadone showed that the compound would be mineralised to much greater extent than it would evaporate from soil surface (in irradiated samples within 14 days of the experiment only ~5% of the radioactivity applied was recovered as VOC fraction, in the dark control samples that amount was only ~2.5%). Also in the experiments with radiolabelled FOE Thiadone aimed on the determination of its persistence in aerobic soil under laboratory conditions the levels of radioactivity recovered as VOC fraction was low: 2 – 4%AR at the study's end (10 – 14 days after the experiment was initiated) with no more than 5% of the initial amount of FOE Thiadone remaining in soil. That may indicate, assuming that the VOC fraction is entirely FOE Thiadone, that despite its high vapour pressure the compound would not migrate to atmosphere from soil in amounts that may pose any threat to that compartment. Also not relevant may be considered the volatilisation from plants as the route of exposure, because that compound would probably not be formed as a transformation product of Flufenacet on plant surfaces.

The only potential route of exposure of air is volatilisation from SW bodies, where FOE Thiadone was demonstrated to be formed as a major degradation product, but at present there is no clear methodology to assess that issue.

As a result, on the basis of the weight of evidence it may be stated that the migration of FOE Thiadone to the air is not expected to be a significant process and therefore the transport of that compound via air, despite its high vapour pressure and significant persistence in that compartment air, would not be an issue of concern. It shall be also indicated that FOE Thiadone is very soluble in water, what may indicate that even reaching atmosphere it will partition to water phase and probably quickly removed from there with rain.

In case of TFA the literature data indicate that the presence of that compound is associated with the phototransformation of haloalkanes and emission from installations where it is used. The physicochemical properties of that acid, and in particular its low pK_a value (≤ 1.0) clearly indicate that when formed in soil or SW compartment it will be present there in form of Trifluoroacetate, which has very low vapour pressure and hence TFA formed in these compartments from Flufenacet would not contribute to the overall content of TFA in the atmosphere. That statement was confirmed by the open-source literature data (for more details please see the text further down this section).

The literature search performed by the RMS showed that there are numerous publications examining the sources of TFA in that compartment as well as its impact on the atmosphere. From that number RMS selected several exemplary papers addressing the problem. They are summarised below.

The following paper:

Solomon K. R., Tang X., Wilson S. R., “*Changes in tropospheric composition and air quality due to stratospheric ozone depletion and climate change.*”; Photochemical and Photobiological Sciences, 2007 **6** (3), 301 – 310.

presented the impact of the various man-made chemicals on the atmosphere and implications of that for human health and global climate. A large section of that paper is focused on the impact of perfluorinated substances on the air compartment in terms of ozone depletion and global warming.

It was stated that long- and short chain HCFCs (hydrochlorofluorocarbons) are unlikely to form short-chain perfluorinated carboxyl acids, such as TFA. However, other polyfluorinated hydrocarbons, such as halothane, isoflurane, HCFC123, HCFC-124, HFC-134a and HFC-143a were indicated to be transformed entirely to TFA. Therefore with increasing emissions of the listed above compounds to the atmosphere, the concentrations of TFA in that compartment are expected to increase as well. At the time of issuing the publication the amounts of TFA in rainwater were in range <0.5 – 350 ng/L, depending on location and distance of the sampling point from the emission sources of its precursors, or TFA itself.

According to the estimates presented in that paper the total conversion of HFCs (hydrofluorocarbons) and HCFCs to TFA in the atmosphere may result in production of 22,00,000 tonnes of TFA, for which the final sink are oceans and landlocked lakes.

It was stated that the predominant sources of TFA in fresh surface water are anthropogenic, with concentrations in flowing SW bodies reaching the max. level of 350 ng/L, but higher in some landlocked lakes – up to 40000 ng/L.

In oceans the concentrations of TFA are close or equal to 200 ng/L, but unlike in fresh water SW bodies the compound is considered to come partly from the natural sources.

The authors pointed out that even for the estimated amount of TFA produced in the atmosphere from HFCs and HCFCs the increase of its concentrations in oceans as the terminal sink would be small – 0.016 ng/L. Even the consideration of other potential anthropogenic sources of TFA, that increase was estimated to be negligible.

It was also stated that TFA displayed very low toxicity to aquatic organisms, therefore no additional environmental risk resulting from the observed loadings to fresh- and saltwater dwellers was expected to be observed.

In the publication :

Römpf A., Klemm O., Fricke W., Hartmut F., „*Haloacetates in Fog and Rain.*“; Environmental Science and Technology, 2001, **35** (7), 1294 – 1298.

were presented the results of the determination of concentrations of various haloacetates, including TFA, in fog and rain samples collected in Northeastern Bavaria with estimation of the possible sources of those compounds in atmospheric water.

The analysis of the possible sources of atmospheric TFA, based on the determination of frequency of its appearance in samples and its concentrations in comparison to the concentrations of other compounds, showed that the compound came from various anthropogenic sources. That was stated on the basis of the fact that TFA was detected in all examined samples at relatively constant level of 0.43 – 0.65 µg/L and were strongly correlated with the atmospheric concentrations of SO_4^{2-} and NO_3^- (99%), the ions known to be emitted, or formed from the precursors emitted, predominantly by power plants, industrial facilities and motor vehicles. The fog/rain concentration ratio of TFA was on average 6.6 with range 0.2 – 18.

The problem of formation of TFA in the air compartment from HCFCs in the atmosphere and the impact on that process on the environment, as well as the impact of the emissions to the atmosphere of the HCFCs, such as HFO-1234yf, on the environment was characterised in the following paper by Henne and co-workers:

Henne, S.; Shallcross, D. E.; Reimann, S.; Xiao, P.; Boulos, S.; Gerecke, A. C.; Brunner, D.; “*Environmental impacts of HFO-1234yf and other HFOs.*”; Moving Towards Sustainability, ASHRAE/NIST Refrigerants Conference, Gaithersburg, MD, United States, Oct. 29-30, 2012 (2012), 13/1-13/13.

It focused on the formation of TFA from HCFCs in air and implications of that process for the environment. Although the main compound of concern was HFO-1234yf also the fate of other HFOs in air and their contribution to the formation of TFA in atmosphere was examined. HFO-1234yf was indicated as a compound having the highest transformation potential to TFA – 100%. Additionally, due to its relatively short DT_{50} in comparison to some other HFOs having similar transformation potential to TFA, such as HFC-134 (weeks v/s

years), the depositions of TFA formed from HFO-1234yf were estimated to be more localized than those from other HFOs.

The paper also provided the concentrations of TFA in rainwater samples collected in Switzerland in 2011 in course of the air-pollution monitoring programme carried out in that country in comparison to the results obtained in the years preceeding that period in various European and non-European countries.

It contained also the model estimations of the concentrations of TFA in air and the levels of wet deposition resulting from the estimated emission levels of HFO-1234yf.

Finally, in the paper:

Jordan A., Frank H., *“Trifluoroacetate in the Environment. Evidence for Sources Other Than HFC/HCFs.”*; Environmental Science and Technology, 1999, **33** (4), 522 – 527.

in a comprehensive way are presented all sources of TFA in atmosphere and their contribution to the pollution of the environment with that compound. The authors indicated that the HFCs and HCFCs, such as HFC-134a, HCFC-123 or HCFC-124 may be considered as main sources of TFA in the atmosphere. However, the other potential sources are also listed. Among them are fluorinated inhalation anesthetics – halothane (CF₃CHClBr), desflurane (CF₃CHFOCHF₂) and isoflurane (CF₃CHClOCHF₂), the emissions of TFA from industrial processes, such as electrolytic aluminium production, production and use of perfluorinated polymers and the active substances of the plant protection products containing trifluoromethyl groups, with trifluralin given as an example of such compound. It was stated that although volatilisation of such compounds and their transformation in atmosphere is possible, not expected is the process of their degradation leading to the formation of TFA. Additionally it was stated that although TFA may be formed from such compounds in processes of their degradation in soil, that process is not conceivable to be the relevant source of atmospheric TFA. That statement may be extended also to Flufenacet.

Therefore on the basis of the presented above literature data it may be stated that TFA in atmosphere comes from sources other than the use of the plant protection products such as Flufenacet and that the importance of these sources in the global pollution by TFA is much greater. The results also show that at present TFA in the atmosphere does not pose a serious threat to that compartment, being neither ozone-depleting compound nor greenhouse gas, or to other environmental compartments, such as SW water bodies (fresh and saltwater ones) which it may enter through wet or, predominantly, dry deposition from the atmosphere, because of its experimentally demonstrated low toxicity, in dissociated form (acetate), to the living organisms.

B.8.3.3. – Local and global effects

In the document MCA, Section 7 for Flufenacet, under the point 7.3.3. the Applicant made the following statement to address this issue: *“Local and global effects of flufenacet were not considered since its half-life in air is ≤ 2 days.”*

The RMS considers that statement acceptable and no additional data with regard to Flufenacet to cover that issue were required.

Also for none of the major identified degradation products of Flufenacet such assessment was not necessary, as showed the analysis of the available data for them performed under the preceeding data points.

B.8.3.4. – Summary: fate and behaviour in air

As the first step in the assessment of the fate and behaviour of Flufenacet in the air compartment RMS analysed the basic data on the volatility potential of that active compound and its major degradation products in order to identify the substances of concern for the atmosphere. The basic data on the volatility potential of Flufenacet and its major degradation products are presented below in the table B.8.3.4._CA-1. The data were taken from the section B.2 (AS) for Flufenacet, unless it was clearly stated that they were derived from other sources.

Table B.8.3.4._CA-1: The key physico-chemical properties of Flufenacet and its major degradation products relevant for the determination of the fate and behaviour in the atmosphere.

Parameter		Compound ¹⁾							
		FOE 5043	FOE Oxalate	FOE S. A.	FOE Methylsulfone	FOE Methylsulfide	FOE Thiadone	FOE TFESA	TFA ²⁾

Footnotes to the table:

- 1) The following code-names were used to denominate the substances: FOE 5043 for Flufenacet, FOE S. A. for FOE Sulfonic acid, FOE TFESA for FOE Trifluoroethanesulfonic acid and TFA for Trifluoroacetic acid;
- 2) **In aqueous solution TFA, being a very strong acid with $pK_a = 1.6$, is fully dissociated, therefore the values are provided for trifluoroacetate and the test substance used to determine them was TFA-Na salt;**
- 3) In section B.2 it was stated that Flufenacet isomerised by evaporation forming a mixture containing 10% of Flufenacet and 90% of its *N*-isomer; as a result, the value is that characteristic for *N*-isomer of Flufenacet;
- 4) The value determined at pH = 4;
- 5) The values determined for *N*-isomer of Flufenacet, using the solubility values determined for that compound;
- 6) The measured value not provided; instead the Applicant presented the value determined theoretically, using QSAR method, and for $T = 25^\circ\text{C}$; RMS subsequently converted that value to presented here value for $T = 20^\circ\text{C}$ using appropriate Van't Hoff equation (presented in the "Manual for FOCUS TOXSWA version 2.2.1", Alterra Report No. 586, Wageningen, 2006);
- 7) The value determined in unbuffered solution and representative for the whole environmentally relevant pH range, since it was experimentally demonstrated that water solubility of FOE S. A. is not pH-dependent;
- 8) Value not available;
- 9) The value determined in pH = 7 buffer solution, but considered representative for the whole environmentally relevant pH range, since it was experimentally demonstrated that water solubility of FOE Methylsulfone is not pH-dependent;
- 10) The theoretical value determined by the RMS using QSAR methods – it was calculated using Modified Grain method for $T = 25^\circ\text{C}$; for more details please refer to the data presented in the table B.8.8-a.3._CA-4 under the point B.8.8.-A.3 – Appendix 3, of this Renewal Assessment Report;
- 11) The value determined in pH = 6.1 buffer solution, but considered representative for the whole environmentally relevant pH range, since it was experimentally demonstrated that water solubility of FOE Methylsulfide is not pH-dependent;
- 12) The theoretical value determined by the RMS using QSAR methods – it was calculated using Modified Grain method for $T = 25^\circ\text{C}$; for more details please refer to the data presented in the table B.8.8-a.3._CA-4 under the point B.8.8.-A.3 – Appendix 3, of this Renewal Assessment Report;
- 13) The value determined at pH = 5.77;
- 14) Value determined at pH < 5.

The further analysis was carried out using the vapour pressure classification presented in the Guidance document "Pesticides in Air: Considerations for Exposure Assessment" – Report of the FOCUS Working Group on Pesticides in Air ([FOCUS; 2008]).

According to that Guidance document the trigger values indicating the need to establish whether the substance has the potential to reach the air are:

- $V_p \geq 10^{-4}$ Pa at $T = 20^\circ\text{C}$ for volatilisation from soil, and
- $V_p \geq 10^{-5}$ Pa at $T = 20^\circ\text{C}$ for volatilisation from plants.

Using these criteria RMS identified the following compounds as those of potential concern:

- Flufenacet, being medium volatile according to the classification presented above and having a potential to reach air via volatilisation from plants;
- FOE Methylsulfone, being medium volatile according to the classification presented above and having a potential to reach air via volatilisation from soil and plants;
- FOE Methylsulfide, being medium volatile according to the classification presented above and having a potential to reach air via volatilisation from soil and plants; it shall be indicated however that for that compound the assessment is based on theoretically determined values;
- FOE Thiadone, being volatile according to the classification presented above and having a potential to reach air via volatilisation from soil and plants.

RMS also decided to take into consideration TFA. Although the experimental values presented in the table B.8.3.4._CA-1 does not indicate that it is a compound of concern, they were derived for trifluoroacetate. The examination of the available open-sources data showed that the non-dissociated acid displayed high volatility potential resulting from its high vapour pressure – 11 kPa at $T = 20^\circ\text{C}$ (source: Pubchem – open chemistry database, url: <https://pubchem.ncbi.nlm.nih.gov>). For that reason RMS decided to evaluate its fate and behaviour

in the atmosphere as well. **At the same time it shall be indicated that the $pK_a = 1.6$ value determined for TFA in aqueous solutions clearly indicate that when formed from Flufenacet either in soil or surface water compartments the compound, being entirely dissociated would display very limited volatility and hence risk to atmosphere, unless the environment becomes very acidic.**

The examination of the fate and behaviour of Flufenacet in air showed that that compound displayed some tendency for migration to the atmosphere, with the determined average level of volatilisation from soil surface equal to 16.5% of the applied dose (with range of 7.9 – 29.2%), but was not expected to be persistent in that compartment – the determined for the process of the photooxidative degradation initiated by the $\bullet OH$ radicals **$DT_{50} = 6.8$ hours**. That value, being significantly shorter than the $DT_{50} = 2$ days, indicates that Flufenacet, even in case of reaching the atmosphere in significant amounts, would not pose a serious threat to that compartment. It would also not be prone to medium- or long-range transport in that compartment and therefore it would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

That statement may be confirmed by the results of the monitoring study carried out in the USA by the employees of USGS and aimed on the examination of the content of Flufenacet in the rainfall. The monitoring was performed in years 2003 – 2004 on four representative locations, in the areas of intensive agricultural activity, in California, Indiana, Nebraska and Maryland. Flufenacet was found only in two of 52 samples examined, and only at one location – in Nebraska, where the main crops were maize and soybean, on which Flufenacet was routinely used. The maximum concentration detected in rain samples was 0.05 $\mu g/L$ and it occurred on the 4th May 2004, presumably shortly after Flufenacet was applied. The median concentration reported in the study was $<0.02 \mu g/L$ and the wet deposition, estimated on the basis of the obtained results, was 3.09 $\mu g/m^2$ with maximum occurring on the 4th May 2004.

In none of the other examined locations Flufenacet was reported to be found in rainwater samples. It has to be indicated, that other herbicides being the target compounds in that study were detected more frequently and in much higher amounts, although their estimated use pattern was comparable to that of Flufenacet.

These results may indicate that Flufenacet, even in case of reaching the air compartment, will not be subjected to the medium- and long distance transport, but rather deposited locally, at the site of use. The aeric mean deposition determined in that study (for not precised application rates) was not significant, by comparison to e. g. that determined in the SW modelling exposure assessment at Step 3 for the use of that compound in Autumn on Winter cereals at application rate 240 g/ha – 0.05 – 0.46 g/m^2 .

Of seven major soil, aquatic or soil and aquatic major degradation products of Flufenacet, four were identified as posing potential threat to the atmosphere, being volatile or semivolatile – FOE Methylsulfone, FOE Methylsulfide, FOE Thiadone and Trifluoroacetic acid – TFA. For them the additional estimation of their persistence in air, by determining the DT_{50} values for the process of the photooxidative degradation initiated by the $\bullet OH$ radicals, was performed. The calculated for FOE Methylsulfide and FOE Methylsulfone DT_{50} values for that process were **0.517 days** and **0.563 days** respectively, what clearly indicates that even in case of reaching the atmosphere in significant amounts, these compounds would not pose a serious threat to that compartment. They would also not be prone to medium- or long-range transport in that compartment and therefore would not pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

The model assessment of the persistence of FOE Thiadone in air showed that the compound would be very persistent in air. For the structural formula exactly matching that of FOE Thiadone the results indicated that no reaction with $\bullet OH$ radicals occurred. For the structure that was slightly altered by comparison to that of FOE Thiadone – the double bond was repositioned from $C=N$ to $N=N$, that reaction was demonstrated to be very slow with the half-life, calculated assuming 12-hours lasting day and the concentration of the $\bullet OH$ radicals of $1.5 E6 [radicals/cm^3]$, **$DT_{50} = 29.594$ days**. That value is significantly longer than the $DT_{50} = 2$ days. The results therefore indicate that FOE Thiadone in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It would be prone to medium- or long-range transport in that compartment and therefore it may pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

For that compound RMS was not able to identify any literature data dealing with its fate and behaviour in air. It shall however be indicated that FOE Thiadone was observed in soil in amounts not surpassing 10%. It was also demonstrated to be quickly degraded in that compartment. Additionally the results of the studies aimed on the examination of soil photolysis of FOE Thiadone showed that the compound would be mineralised to much greater extent than it would evaporate from soil surface (in irradiated samples within 14 days of the experiment only ~5% of the radioactivity applied was recovered as VOC fraction, in the dark control samples that amount was only ~2.5%). Also in the experiments with radiolabelled FOE Thiadone aimed on the determination of its persistence in aerobic soil under laboratory conditions the levels of radioactivity recovered as VOC fraction was

low: 2 – 4%AR at the study's end (10 – 14 days after the experiment was initiated) with no more than 5% of the initial amount of FOE Thiadone remaining in soil. That may indicate, assuming that the VOC fraction was entirely FOE Thiadone, that despite its high vapour pressure the compound would not migrate to atmosphere from soil in amounts that may pose any threat to that compartment. Also not relevant may be considered the volatilisation from plants as the route of exposure, because that compound would probably not be formed as a transformation product of Flufenacet on plant surfaces.

The only potential route of exposure of air is volatilisation from SW bodies, where FOE Thiadone was demonstrated to be formed as a major degradation product, but at present there is no clear methodology to assess that issue.

The model assessment of the persistence of TFA in air showed that the compound would be persistent in air, with the half-life, calculated assuming 12-hours lasting day and the concentration of the $\bullet\text{OH}$ radicals of $1.5 \text{ E6} [\text{radicals/cm}^3]$, **$\text{DT}_{50} = 20.569 \text{ days}$** . That value is significantly longer than the $\text{DT}_{50} = 2 \text{ days}$, what indicates that TFA in case of reaching the atmosphere in significant amounts, would pose a serious threat to that compartment. It may also be prone to medium- or long-range transport in that compartment and therefore it may pose a threat of secondary pollution resulting from the wet and dry deposition from the atmosphere.

The Applicant did not submit any relevant data enabling the elucidation of the fate and behaviour of TFA in air compartment. However in the documentation submitted for the evaluation it was stated several times that the TFA formed as a degradation product of Flufenacet will be present as Trifluoroacetate – the dissociated form displaying very low volatility potential and as such not posing any substantial risk to the atmosphere.

The literature search performed by the RMS resulted in identification of several scientific papers addressing the issue of behaviour of TFA in the atmosphere, four of which specifically with persistence, transformation mechanisms and mechanisms of elimination of TFA from air. On their basis it was possible to state that TFA clearly demonstrated high persistence in the atmosphere with the DT_{50} values for the process of photooxidative degradation initiated by the $\bullet\text{OH}$ radicals as high as 230 days. The only relevant mechanism of elimination of TFA from that compartment would therefore be, predominantly, wet deposition – with rain or fog with estimated $\text{DT}_{50} = \sim 9 \text{ days}$, and, to some extent also by dry deposition, with estimated $\text{DT}_{50} = 10\text{-}30 \text{ days}$. The identified products of photooxidative degradation of TFA in air initiated by the $\bullet\text{OH}$ radicals are COF_2 and FNO. It was also indicated that the dimerisation of TFA may be the factor limiting the rate of degradation of that compound in air in the process of photooxidative degradation initiated by the $\bullet\text{OH}$ radicals.

The determination of the Henry's law constant for TFA demonstrated that the compound displayed high affinity towards water, therefore atmospheric water, either in form of clouds or as for, may be an effective sink for that compound. At the same time however it was postulated that the evaporation of TFA from water phase to air cannot be totally excluded.

The examination of the available literature data showed that the presence of the TFA in the atmosphere was not expected to be related to the degradation in that environmental compartment of the active substances of the plant protection products containing in their molecules the CF_3 - functional groups, nor to the possible volatilisation from soil of TFA formed there as a result of degradation of such agrochemicals.

On the basis of the results obtained in the area of the examination of the fate and behaviour of Flufenacet and its major degradation products in air, as well as their transport via air it was stated that the further examination of the local and global effects related to their would be presence in air was not necessary.

The key results on the assessment of fate and behaviour of Flufenacet and its degradation products identified as possibly posing a risk to atmosphere are presented below in format recommended for the EU-agreed LoEP.

Fate and behaviour in air (Regulation (EU) N° 283/2013, Annex Part A, point 7.3.1)

Direct photolysis in air	<i>Not studied - no data requested</i>
Photochemical oxidative degradation in air	DT ₅₀ of <i>4.7</i> hours derived by the Atkinson model (version <i>1.55</i>). OH (<i>12 h</i>) concentration assumed = <i>1.5 E6</i>
Volatilisation	from plant surfaces (BBA guideline): <i>not examined</i> from soil surfaces (BBA guideline): <i>16.5% (7.9 – 29.2%) after 24 hours</i>
Metabolites	<p>Degradation products requiring assessment due to their medium/high volatilisation potential: FOE Methylsulfide, FOE Methylsulfone, FOE Thiadone, TFA</p> <p>Data for FOE Methylsulfide: Direct photolysis in air: <i>Not studied - no data requested</i> Photochemical oxidative degradation in air: DT₅₀ of <i>0.563 days</i> derived by the Atkinson model (version <i>1.92</i>). OH (<i>12 h</i>) concentration assumed = <i>1.5 E6</i> Volatilisation: - from soil surfaces (BBA guideline): <i>Not studied - no data requested, the compound is aquatic metabolite, not expected to be formed in soil;</i> - from plant surfaces (BBA guideline): <i>Not studied - no data requested, the compound is an aquatic metabolite, not expected to be formed on plant surfaces</i></p> <p>Data for FOE Methylsulfone: Direct photolysis in air: <i>Not studied - no data requested</i> Photochemical oxidative degradation in air: DT₅₀ of <i>0.517 days</i> derived by the Atkinson model (version <i>1.92</i>). OH (<i>12 h</i>) concentration assumed = <i>1.5 E6</i> Volatilisation: - from soil surfaces (BBA guideline): <i>not examined, not requested</i> - from plant surfaces (BBA guideline): <i>Not studied - no data requested, the compound is a soil metabolite, not expected to be formed on plant surfaces</i></p> <p>Data for FOE Thiadone: Direct photolysis in air: <i>Not studied - no data requested</i> Photochemical oxidative degradation in air: DT₅₀ derived by the Atkinson model (version <i>1.92</i>). OH (<i>12 h</i>) concentration assumed = <i>1.5 E6 not possible to be determined, therefore it may be assumed that the compound does not undergo the photochemical oxidative degradation in air</i> Volatilisation: - from soil surfaces (BBA guideline): <i>not examined, not requested – the compound being not persistent in soil is not expected to migrate from that compartment into the atmosphere in any significant amounts</i> - from plant surfaces (BBA guideline): <i>Not studied - no data requested, the compound is a soil and aquatic metabolite, not expected to be formed on plant surfaces</i></p> <p>Data for TFA: Direct photolysis in air: <i>Not studied - no data requested</i> Photochemical oxidative degradation in air: DT₅₀ <i>20.569 days</i> derived by the Atkinson model (version <i>1.92</i>). OH (<i>12 h</i>) concentration assumed = <i>1.5 E6</i>, Volatilisation: - from plant surfaces (BBA guideline): <i>not examined, not requested – in soil TFA will be present in dissociated form, what is a factor very strongly limiting its volatility and hence the would-be migration to the air compartment</i> - from plant surfaces (BBA guideline): <i>Not studied - no data requested, the compound is a soil metabolite, not expected to be formed on plant surfaces</i></p>

B.8.4 - Definition of the residue

For the purpose of the previous authorisation of Flufenacet in the EU the then-RMS – France presented in the Annex B.7 of the Assessment Report under the point B.7.9 – Definition of the residue, the following general residue definition for Flufenacet:

“In view of the findings in the different sections of this chapter, it can be concluded that FOE 5043 itself, as well as the metabolite FOE sulfonic acid (M2) have to be considered as relevant residue for quantification in soil and water. In soil only, FOE Oxalate (M1) has to be taken into consideration as additional relevant metabolite.

The relevant residue with regard to quantification in air is the active ingredient only. None of the environmental fate studies indicated volatile metabolites except CO₂.

That residue definition, in light of the findings of the current assessment, required updating. The updated residue definition for the risk assessment and monitoring purposes, proposed by the Applicant and then verified and corrected by the RMS, is presented below.

B.8.4.1 – Definition of the residue for risk assessment

In the document MCA-Section 7 for Flufenacet under the point 7.4.1. the Applicant proposed the following residue definition for the risk assessment:

Soil:

Flufenacet, FOE oxalate, FOE sulfonic acid, FOE methylsulfone, FOE-thiadone, FOE 5043-trifluoromethanesulfonic acid, trifluoroacetic acid;

Groundwater:

Flufenacet, FOE oxalate, FOE sulfonic acid, FOE methylsulfone, FOE-thiadone, FOE 5043-trifluoromethanesulfonic acid, trifluoroacetic acid (same as for soil compartment);

Surface water:

Flufenacet, FOE oxalate, FOE sulfonic acid, FOE methylsulfone, FOE methylsulfide, FOE-thiadone, FOE 5043-trifluoromethanesulfonic acid, trifluoroacetic acid;

Sediment:

Flufenacet;

Air:

Flufenacet;

Having verified the Applicant's proposal and on the basis of the information provided in this Report RMS proposes the following residue definition for the risk assessment:

Soil:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE Trifluoromethanesulfonic acid, Trifluoroacetic acid;

Justification: RMS with this confirms the Applicant's proposal. All listed degradation products are major soil degradation products.

Groundwater:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE Trifluoromethanesulfonic acid, Trifluoroacetic acid (same as for soil compartment); additional compounds that may require assessment (on the basis of the results of lysimeter studies) are FOE Alcohol and FOE TGS;

Justification: The proposed residue definition is the same as proposed by the Applicant and contains the degradation products classified as major soil metabolites and displaying high leaching potential (excluding FOE Thiadone). The reason for inclusion of FOE Alcohol and FOE TGS is that in the lysimeter studies despite being

minor soil degradates they were detected in leachates in quantifiable amounts. Therefore it cannot be excluded that under unfavourable conditions they would pose a risk to GW compartment.

Surface water:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfide, FOE Methylsulfone, FOE Thiadone, FOE Trifluoroethanesulfonic acid, Trifluoroacetic acid;

Justification: The proposed residue definition is the same as proposed by the Applicant and contains the degradation products classified as major soil, aquatic or soil and aquatic metabolites. At the same time it shall be indicated that in case of FOE Trifluoroethanesulfonic acid and TFA the assessment in the aquatic environment could not be finalised due to the fact that there was no water/sediment study with Flufenacet radiolabelled in position enabling adequately address the problem.

Sediment:

Flufenacet;

Justification: only Flufenacet was included into that residue definition because of the degradation products listed above in the definition for SW compartment none displayed any significant affinity to the sediment compartment – if detected there they were found in low amounts, not surpassing 5%.

Air:

Flufenacet, FOE Thiadone and Trifluoroacetic acid;

Justification: Flufenacet was included by default, although it shall be indicated that it does not pose a serious threat to the atmosphere; the reason for including FOE Thiadone and TFA is that they are volatile (although in case of TFA it was demonstrated that, being dissociated, that compound when formed from Flufenacet is not expected to migrate to air in any significant amounts) and persistent in air, so they may pose a serious threat to the atmosphere.

B.8.4.2. – Definition of the residue for monitoring

In the document MCA-Section 7 for Flufenacet under the point 7.4.2. the Applicant made the following statement with regard to the definition of the residue for monitoring:

“The proposed residue definition for monitoring is flufenacet only for all compartments since none of the major degradation products is of toxicological or ecotoxicological relevance.”

Having verified the Applicant’s proposal and on the basis of the information provided in this Report RMS proposes the following residue definition for the risk assessment:

Soil:

Flufenacet, FOE Sulfonic acid, FOE Methylsulfone, Trifluoroacetic acid;

Justification: all listed compounds, including Flufenacet, displayed some potential (in case of TFA significant) for accumulation in soil (conclusion based on the results of the calculations of PEC_{SOIL} values) ;

Groundwater:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Trifluoroethanesulfonic acid and Trifluoroacetic acid;

Justification: the parent compound was included by default. In case of the degradation products listed above the reason for their inclusion was that for the proposed EU-representative application pattern in the GW model exposure assessment they were demonstrated to leach to the groundwater recharge in amounts $> 0.1 \mu\text{g/L}$. In many cases the calculated $PEC_{GW} > 0.75 \mu\text{g/L}$ and in case of TFA the calculated $PEC_{GW} > 10 \mu\text{g/L}$. The high leaching potential of FOE Sulfonic acid was confirmed in regulatory lysimeter studies. Finally, it shall be indicated that FOE Oxalate and FOE Sulfonic acid were detected in Groundwater in some monitoring studies, the results of which were presented in the publications summarised under the point B.8.5.

Surface water:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfide, FOE Thiadone and Trifluoroacetic acid

Justification: the parent compound was included by default. In case two degradation products – FOE Methylsulfide and FOE Thiadone, they were included into the definition due the fact that they are major aquatic degradation products (additionally FOE Thiadone was identified as major soil degradation product) with not defined persistence in natural water. The reason for including FOE Oxalate and FOE Sulfonic acid was that they are major soil degradation products and potentially major aquatic degradation products (in the water/sediment

studies their formation potential was not fully assessed) with unknown persistence in water and highly mobile. Additionally in some monitoring studies, summarised below under the point B.8.5, they were detected in SW bodies in quite significant amounts, as was Flufenacet. The reason for including TFA is that it is very persistent and common pollutant. Additionally the problem of its formation from Flufenacet in SW compartment was not satisfactorily addressed.

Sediment:

Flufenacet;

Justification: the definition comprises the parent compound only, which was included by default, but also because the degradation in the SW bodies will comprise the migration from water phase to sediment (main dissipation process for Flufenacet in water), where it will undergo degradation. None of the degradation products listed for SW compartment were included due to the fact that they were either not detected in sediment or found in that compartment in very low amounts (<5% of the initial amount of Flufenacet).

Air:

Flufenacet, FOE Thiadone and Trifluoroacetic acid;

Justification: the parent compound was included by default. In case two degradation products – FOE Thiadone and TFA they were included because of their high volatility and persistence in air, what results in a high level of risk they pose to the atmosphere – the monitoring should exclude Flufenacet as a potential source of FOE Thiadone and, in particular TFA, in the air compartment.

Residue definition – a summary:

The Applicant presented the proposal for the residue definition in the document MCA-Section 7 for Flufenacet under the points 7.4.1. – definition of the residue for the risk assessment, and 7.4.2 – definition of the residue for monitoring. RMS, having verified that proposal, proposes the following residue definition, with its justification:

- **Definition of residue for the risk assessment:**

Soil:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE Trifluoroethanesulfonic acid, Trifluoroacetic acid;

Justification: RMS with this confirms the Applicant's proposal. All listed degradation products are major soil degradation products.

Groundwater:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE Trifluoroethanesulfonic acid, Trifluoroacetic acid (same as for soil compartment); additional compounds that may require assessment (on the basis of the results of lysimeter studies) are FOE Alcohol and FOE TGS;

Justification: The proposed residue definition is the same as proposed by the Applicant and contains the degradation products classified as major soil metabolites and displaying high leaching potential (excluding FOE Thiadone). The reason for inclusion of FOE Alcohol and FOE TGS is that in the lysimeter studies despite being minor soil degradates they were detected in leachates in quantifiable amounts. Therefore it cannot be excluded that under unfavourable conditions they would pose a risk to GW compartment.

Surface water:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfide, FOE Methylsulfone, FOE Thiadone, FOE Trifluoroethanesulfonic acid, Trifluoroacetic acid;

Justification: The proposed residue definition is the same as proposed by the Applicant and contains the degradation products classified as major soil, aquatic or soil and aquatic metabolites. At the same time it shall be indicated that in case of FOE Trifluoroethanesulfonic acid and TFA the assessment in the aquatic environment could not be finalised due to the fact that there was no water/sediment study with Flufenacet radiolabelled in position enabling adequately address the problem.

Sediment:

Flufenacet;

Justification: only Flufenacet was included into that residue definition because of the degradation products listed above in the definition for SW compartment none displayed any significant affinity to the sediment compartment – if detected there they were found in low amounts, not surpassing 5%.

Air:

Flufenacet, FOE Thiadone and Trifluoroacetic acid;

Justification: Flufenacet was included by default, although it shall be indicated that it does not pose a serious threat to the atmosphere; the reason for including FOE Thiadone and TFA is that they are volatile (although in case of TFA it was demonstrated that, being dissociated, that compound when formed from Flufenacet is not expected to migrate to air in any significant amounts) and persistent in air, so they may pose a serious threat to the atmosphere.

- **Definition of the residue for monitoring:**

Soil:

Flufenacet, FOE Sulfonic acid, FOE Methylsulfone, Trifluoroacetic acid;

Justification: all listed compounds, including Flufenacet, displayed some potential (in case of TFA significant) for accumulation in soil (conclusion based on the results of the calculations of PEC_{SOIL} values) ;

Groundwater:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Trifluorethanesulfonic acid and Trifluoroacetic acid;

Justification: the parent compound was included by default. In case of the degradation products listed above the reason for their inclusion was that for the proposed EU-representative application pattern in the GW model exposure assessment they were demonstrated to leach to the groundwater recharge in amounts $> 0.1 \mu\text{g/L}$. In many cases the calculated $PEC_{GW} > 0.75 \mu\text{g/L}$ and in case of TFA the calculated $PEC_{GW} > 10 \mu\text{g/L}$. The high leaching potential of FOE Sulfonic acid was confirmed in regulatory lysimeter studies. Finally, it shall be indicated that FOE Oxalate and FOE Sulfonic acid were detected in Groundwater in some monitoring studies, the results of which were presented in the publications summarised under the point B.8.5.

Surface water:

Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfide, FOE Thiadone and Trifluoroacetic acid

Justification: the parent compound was included by default. In case two degradation products – FOE Methylsulfide and FOE Thiadone, they were included into the definition due the fact that they are major aquatic degradation products (additionally FOE Thiadone was identified as major soil degradation product) with not defined persistence in natural water. The reason for including FOE Oxalate and FOE Sulfonic acid was that they are major soil degradation products and potentially major aquatic degradation products (in the water/sediment studies their formation potential was not fully assessed) with unknown persistence in water and highly mobile. Additionally in some monitoring studies, summarised below under the point B.8.5, they were detected in SW bodies in quite significant amounts, as was Flufenacet. The reason for including TFA is that it is very persistent and common pollutant. Additionally the problem of its formation from Flufenacet in SW compartment was not satisfactorily addressed.

Sediment:

Flufenacet;

Justification: the definition comprises the parent compound only, which was included by default, but also because the degradation in the SW bodies will comprise the migration from water phase to sediment (main dissipation process for Flufenacet in water), where it will undergo degradation. None of the degradation products listed for SW compartment were included due to the fact that they were either not detected in sediment or found in that compartment in very low amounts ($< 5\%$ of the initial amount of Flufenacet).

Air:

Flufenacet, FOE Thiadone and Trifluoroacetic acid;

Justification: the parent compound was included by default. In case two degradation products – FOE Thiadone and TFA they were included because of they high volatility and persistence in air, what results in a high level of risk they pose to the atmosphere– the monitoring should exclude Flufenacet as a potential source of FOE Thiadone and, in particular TFA, in the air compartment.

That residue definition is additionally presented below in format recommended for the EU-agreed LoEP.

Residues requiring further assessment (Regulation (EU) N° 283/2013, Annex Part A, point 7.4.1)

Environmental occurring residues requiring further assessment by other disciplines (toxicology and ecotoxicology) and or requiring consideration for groundwater exposure

Soil: Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE Trifluorethanesulfonic acid, Trifluoroacetic acid
 Surface water: Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfide, FOE Methylsulfone, FOE Thiadone, FOE Trifluorethanesulfonic acid, Trifluoroacetic acid
 Sediment: Flufenacet
 Ground water: Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone, FOE Trifluorethanesulfonic acid, Trifluoroacetic acid (same as for soil compartment)
 Air: Flufenacet, FOE Thiadone and Trifluoroacetic acid

Definition of the residue for monitoring (Regulation (EU) N° 283/2013, Annex Part A, point 7.4.2)

Definition proposed on the basis of the results of the evaluation of the environmental fate and behaviour
 Soil: Flufenacet, FOE Sulfonic acid, FOE Methylsulfone, Trifluoroacetic acid
 Surface water: Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfide, FOE Thiadone, Trifluoroacetic acid
 Sediment: Flufenacet
 Ground water: Flufenacet, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfone, FOE Trifluorethanesulfonic acid, Trifluoroacetic acid
 Air: Flufenacet, FOE Thiadone and Trifluoroacetic acid
 Additionally see section 5, Ecotoxicology

B.8.5 – Monitoring data concerning fate and behaviour of the active substance, metabolites, degradation and reaction products

The Applicant based the whole assessment in this area on the results of the three open-source publications, one for Flufenacet and two other for TFA. Justifying such approach the Applicant stated that although Flufenacet and its degradation products were often included into the monitoring programmes carried out by the competent authorities across Europe, the results were not made publicly available by means of presenting them in peer-reviewed literature. Therefore the Applicant decided to present only the results of the monitoring studies found during the performed literature search.

At the same time the Applicant stated that the detected concentrations of Flufenacet in surface water were always below the EU limit of 0.1 µg/L, set for drinking water and groundwater.

RMS evaluated the publications submitted by the Applicant for their relevance in the assessment of Flufenacet for the renewal of its authorisation in the EU. All three submitted publications were found relevant and will be summarised below, under the data point B.8.5.1.

The additional literature search resulted in identification of several other publications reporting the results of the monitoring studies aimed on the determination of the concentration of Flufenacet and its selected degradation products, mainly FOE Oxalate and FOE Sulfonic acid, in Groundwater and Surface water bodies. These studies were carried out in the USA and in Europe. Also the studies presenting the results of worldwide monitoring of TFA in various environmental compartments were identified as a result of that repeated literature search. All these results are presented below, under the data point B.8.5.1.

B.8.5.1 – Summary monitoring data

The literature search performed by the Applicant resulted in identification of one study presenting the results of the monitoring carried out for Flufenacet. RMS identified another twelve publications presenting the results of the monitoring projects or those containing the elements of monitoring, carried out in North America or Europe.

The monitoring data for the North America came predominantly from the United States and were presented in seven publications. In these publications were reported the results obtained by the researchers of the US Geological Survey monitoring the levels of various pesticides in groundwater, surface water and rain water samples collected in the decade of 1990s and in early 2000 years – until 2004 in the Midwestern states of the USA.

The methodology of the selection of the sampling areas was presented in the already cited in this report, under the point B.8.3.2., publication:

Capel P. D., McCarthy K. A., Barbash J. E., “*National, Holistic, Watershed-Scale Approach to Understand the Sources, Transport, and Fate of Agricultural Chemicals.*”; Journal of Environmental Quality, 2008, **37**, 983 – 993 (contains extended supplement available on-line on the journal editor’s web-site).

The research area covered by these studies were nine Midwestern states, the area of intensive agricultural production with maize, cereals and other arable crops being the main crops grown there.

The study period reported in these reports coincided with the highest estimated level of use of Flufenacet, presented in the following USGS report:

Baker N. T., Stone W. S., “*Estimated Annual Agricultural Pesticide Use for Counties of the Conterminous United States, 2008 – 12.*”; US Geological Survey Data Series 907, 2015.

According to the data presented in that report Flufenacet was used for the first time in 1998, in amounts close to 0.9 million US pounds (corresponding to ~408233 kg) to increase in the following years to the maximum level of ~1.5 million US pounds in 2004 (corresponding to 680389 kg. During the period 1999-2005, covered by the cited studies that level was in range 1.0 – 1.5 million US pounds (corresponding to the range 453592 – 680389 kg/year), with the aerial use rate in range 0.62 – >1.84 pound/mile², what corresponded to 0.108 – 0.322 kg/km² (assuming the conversion factors pound:kg 0.4535 and the ratio 1 mile²/1 km² 1:2.59). It shall be indicated that these values were related to the whole analysed area and not just treated fields, therefore they are different from

the label application rates. The main treated crop was maize, followed by soybean and cereals (all results are given for the E Pest-high estimates).

In two publications were presented the results of the determination of various pesticides and their degradation products in groundwater sampled in wells.

In 2001 Kolpin and co-workers examined the concentrations of 21 herbicides and their 24 degradation products in water of 86 municipal wells in Iowa. These wells were selected in 1992 within the Iowa Ground Water Monitoring programme (IGMW) and were representative for major types of aquifers of the area: alluvial (32), bedrock/karst (20), glacial drift (12) and bedrock/nonkarst (22) region. The research on the content of the residues of selected herbicides in water samples taken from them, carried out in 2001, was an extension of IGMW programme and followed the sample collection procedure developed within it. The samples were analysed for the content of the residues of herbicides using GC/MS and LC/MS techniques.

Flufenacet was among the substances selected for that study, as well as its two major degradation products: FOE Oxalate (in the study called flufenacet oxalinic acid) and FOE Sulfonic acid (in the study bearing the name Flufenacet ethanesulfonic acid). For all three compounds the reporting level (RL) was 0.05 µg/L. It was stated that neither Flufenacet nor its two metabolites of concern were detected in any examined samples in amounts > RL. The results of that examination were presented in the publication:

Kolpin D. W., Schnoebelen D. J., Thurman M. E., *“Degradates Provide Insight to Spatial and Temporal Trends of Herbicides in Ground Water.”*; Groundwater, 2004, **42** (4), 601 – 608.

In another publication:

Mills P. C., Kolpin D. W., Scribner E. A., Thurman E. M., *“Herbicides and degradates in shallow aquifers of Illinois: spatial and temporal trends.”*; JAWRA Journal of the American Water Resources Association, 2005, **41** (3), 537 – 547.

were presented the results of the similar research project performed in Illinois. The aim of that study was to determine the concentrations of selected herbicides and their degradates in 55 wells completed in unconsolidated aquifers (37 wells) and bedrock aquifers (18 wells), underlying grain producing regions in Illinois, in order to better understand the spatial and temporal occurrence of these compounds in Illinois groundwater. Samples were taken in October and November 2000 and analysed for the content of 16 herbicides and 13 their degradation products. Flufenacet, FOE Oxalate and FOE Sulfonic acid were among the analysed compounds. The reporting limit for them was 0.05 µg/L. It was stated that neither Flufenacet nor its degradation product of concern were detected in any water sample collected.

The results of the monitoring of Flufenacet and its selected degradation products in surface water were presented in four publications summarised below.

Rebich and co-workers examined the concentrations of selected herbicides in streams located in Mississippi River Basin. The research project, carried out from March 1999 to May 2001 was a part of the US Geological Survey (USGS) National Stream Quality Accounting Network (NASQAN). The results were presented in the following paper:

Rebich R. A., Coupe R. H., Thurman E. M., *“Herbicide concentrations in the Mississippi River Basin – the importance of chloroacetanilide herbicide degradates.”*; Science of the Total Environment, 2004, **321** (1-3), 189 – 199.

The analysed water samples were collected on four locations, which were four key junctures of the Mississippi River Basin:

- Mississippi River at Grafton, IL;
- Missouri River Herman, MO;
- Ohio River near Grand Chain, IL;
- Mississippi River at St. Francisville, LA.

The methods of sample collection and analysis were those developed and routinely used by the USGS. Flufenacet and its Oxalate- (OA) and Sulfonic acid- (ESA) degradates were among the chloroacetanilide herbicides and their degradates being analysed within the frame of that study. For them the method reporting level (MRL) was set to 0.05 µg/L. The levels of Flufenacet were determined in 39 samples, while those of OA and ESA in 38 samples collected during the study duration, all after September 2000. Flufenacet was detected in 3% of the analysed samples, in max. amount of 0.12 µg/L. Flufenacet OA and Flufenacet ESA were not detected in amounts > 0.05 µg/L (MRL) in any of the samples analysed for their content.

Another study aimed on the determination of the concentrations of acetamide herbicides – dimethenamid, Flufenacet and Metolachlor, as well as their OXA (Oxalate)- and SA (Sulfonic acid)- degradation products, in the SW water from the same catchment - Mississippi River Basin, was carried out by Zimmerman and co-workers in years 1999-2000. In this study samples were collected from one location – Mississippi river at Baton Rouge, LA, where the river bears 41% of water collected from the whole catchment. The drained area comprises major maize- and soybean-growing regions, where acetamide herbicides were commonly used. Water samples were collected in monthly intervals between March and December of each of the study years. In times considered to coincide with the spring flush of the herbicides they were collected more often.

The collected samples were subjected to SPE extraction and the analysed compounds, recovered after SPE, were analysed by GC-MS or HPLC-MS.

For Flufenacet and its degradates it was stated that during the experimental period they were not observed in any of the analysed samples in amounts $> 0.05 \mu\text{g/L}$ (method detection limit – MDL), with exception of two samples (6%) in which SA degradate of Flufenacet was observed in amounts above that level. That was postulated to be due to the fact that when the study was carried out Flufenacet was still a relatively new herbicide (n. b. same conclusions were drawn for dimethenamid, despite the fact that the frequency and levels of detection of that herbicide and its degradation products were higher).

The results of that study were presented in the following publication:

Zimmerman L. R., Schneider R. J., Thurman E. M., “*Analysis and Detection of the Herbicides Dimethenamid and Flufenacet and Their Sulfonic and Oxalinic Acid Degradates in Natural Degradates in Natural Water.*”; Journal of Agricultural and Food Chemistry, 2002, **50** (5), 1045 – 1052.

The concentrations of selected herbicides and their degradation products, as well as antibiotics, in 51 streams of nine Midwestern states of the USA – IOWA, Illinois, Indiana, Kansas, Minnesota, Missouri, Ohio and Wisconsin, were examined in 2002 Scribner and co-workers.

The results of that monitoring programme were presented in the following publication:

Scribner E. A., Battaglin W. A., Dieze J. E., Thurman E. M., “*Reconnaissance Data for Glyphosate, Other Selected Herbicides, Their Degradation Products, and Antibiotics in 51 Streams in Nine Mid-Western States 2002.*”; US Geological Survey Open-File Report 03-217, 2003. available online at the url: <http://ks.water.usgs.gov/pubs/reports/ofr.03-217.html>

Flufenacet was one of the acetamide herbicides listed among the analysed compounds, while the list of the degradates of the acetamide herbicides contained two of its degradation products – Oxalate (OXA) and Sulfonic acid (ESA). The reporting limit (LOQ) for all three of them was $0.05 \mu\text{g/L}$.

The sampling sites were selected on the basis of the ranking of 147 sampling sites used in 1989 to measure the concentrations of pesticides during the post-application period. The sites were divided into three categories, according to the total herbicide concentrations:

- having highest concentrations of herbicides; from that group 25 locations were randomly selected to be used in that study;
- having medium concentrations of herbicides; from that group 13 sites were randomly selected to be used in that study;
- with low concentration of pesticides; from that group 12 sites were selected.

From each site three samples were collected during the study period (in 2002): one in May-June, after the application of the pre-emergence herbicides (further called pre-emergence sample), another in June-July, when the post-emergence herbicides were applied (further called post-emergence samples) and the third in September – November, during or after harvest (further called harvest-season samples).

Samples were processed and analysed for the content of the test compounds using standardised USGS analytical methods.

The frequency of detection in case of Flufenacet and its degradation products was following:

- Flufenacet was detected in 11 of 51 pre-emergence samples, 9 of 52 post-emergence samples and 1 of 51 harvest season samples;
- FOE Oxalate was detected in 2 of 51 pre-emergence samples, 4 of 52 post-emergence samples and 3 of 51 harvest season samples;
- FOE Sulfonic acid was detected in 3 of 51 pre-emergence samples, 3 of 52 post emergence samples and 2 of 51 harvest season samples.

In pre-emergence samples the median concentration of Flufenacet was $<0.05 \mu\text{g/L}$, and the concentrations in those where it was detected (in samples from 11 of 51 monitored streams) were in range $0.06 - 0.93 \mu\text{g/L}$. It was measured in two streams in Iowa, one in Illinois, one in Kansas, one in Missouri, five streams in Nebraska,

where the concentrations were the highest and one in Ohio. It was not detected in any examined streams of Indiana, Minnesota and Wisconsin.

In post-emergence samples the median concentration of Flufenacet was $<0.05 \mu\text{g/L}$, and the concentrations in those where it was detected (in samples from 9 of 52 monitored streams) were in range $0.06 - 1.6 \mu\text{g/L}$. It was measured in four streams in Iowa, one in Illinois, one in Kansas and three in Nebraska, where the concentrations were the highest. It was not detected in any examined streams of Indiana, Minnesota, Missouri, Ohio and Wisconsin.

Finally, in harvest season samples the median concentration of Flufenacet was $<0.05 \mu\text{g/L}$, and the concentration in that, where it was detected - in sample from just one of the 51 monitored streams, was $0.13 \mu\text{g/L}$. It was measured in one stream in Illinois.

It is worth of indicating that the highest concentrations of Flufenacet in pre-emergence and post-emergence samples were recorded in Nebraska, the state in which that compound was detected in rain water by Vogel and co-workers (please refer to the point B.8.3.2.).

The frequency of detection and measured levels of FOE Oxalate and FOE Sulfonic acid were much lower. In pre-emergence samples the maximum measured concentration was $0.09 \mu\text{g/L}$ for both compounds, in post emergence ones it was $0.18 \mu\text{g/L}$ for FOE Oxalate and $0.13 \mu\text{g/L}$ for FOE Sulfonic acid, while for harvest season samples it was $0.13 \mu\text{g/L}$ for FOE Oxalate and $0.08 \mu\text{g/L}$ for FOE Sulfonic acid. The analysis of the results showed that when detected these two compound usually appeared in the same streams.

It shall be indicated that these results were also presented, in abridged form, in the following publication:

Battaglin W. A., Kolpin D. A., Scribner E. A., Kuivila K. M., Sandstrom M. W., "Glyphosate, other herbicides, and transformation products in Midwestern streams, 2002."; JAWRA Journal of the American Water Resources Association, 2005, **41** (2), 323 – 332.

Finally, the concentrations of Flufenacet in rainfall of the Midwestern states of the USA were examined by Vogel and co-workers. The results of that monitoring study were presented in the paper:

Vogel J. R., Majewski M. S., Capel P. D., "Pesticides in Rain in Four Agricultural Watersheds in the United States."; Journal of Environmental Quality, 2008, **37**, 1101 – 1115.

already summarised in this document under the data-point B.8.3.2. In that study Flufenacet was found only in two rain samples, both collected in Nebraska in early May 2004, in concentrations not surpassing $0.05 \mu\text{g/L}$.

The results of the monitoring of Flufenacet and its selected degradation products in Europe were presented in another seven publications, identified by either Applicant – 1 publication, or by RMS – six publications.

For the purpose of the present evaluation the Applicant submitted a paper presenting the results of the monitoring study examining the migration of the pesticides to surface water body in the agricultural catchment.

The publication submitted for the evaluation was:

Bishoff G., Pestmer W., Rodemann B.; "Entry of pesticides into surface waters – new results of Lamspringe run-off monitoring project 1999 – 2001."; Pesticide in Air, Plant, Soil and Water System, Proceedings of the Symposium Pesticide Chemistry, 12th, Piacenza, Italy, 2003, pp. 849 – 856.

The experiment was performed in Lamspringe catchment, located in Lower Saxony, Germany, the growing area for Winter cereals (winter wheat, winter barley), winter rape and sugar beet as the main crops. According to the characteristic provided in the paper the catchment had the area of approx. 110 ha, the fields on that area were managed with conservation tillage methods and the drainage system was set there transporting the surplus of precipitation water to the stream flowing across the catchment. The samples of the stream water were collected on the effluent side of the 100-ha area over almost three consecutive years – from October 1998 until May 2001 using automatic sampling device. The samples were collected as daily samples and then mixed to prepare weekly samples that were analysed. Additional samples were collected after each strong rain event. The weekly samples were filtered, processed by SPE extraction and the SPE extracts were subjected for GC/MS and LC/MS-MS analysis for the presence of 32 substances identified as used on the area. The monitored active substances of the plant protection products were: Azoxystrobin, Carbendazim, Carbetamid, Chloridazon, Cyprodinil, Diflufenican, Dimefuron, Epoxiconazole, Esfenvalerate, Ethofumesat, Fenpropidin, Fenpropimorph, Flufenacet, Isoproturon, Kresoxim-methyl, Lambda-cyhalothrin, Metazachlor, Metconazole, Phenmedipham, Propaquizafop, Propiconazole, Spiroxamine, Tebuconazole, Thiophanate-Methyl, Trinexapac-ethyl and Vinclozolin. During the experimental period – 1998 – 2001, Flufenacet was applied in two consecutive years – in 1999 and in 2000, twice during each of those years. It was not detected in any of the samples collected during the Period 1 – from

the 1st October 1998 to the 30th April 1999 and within the experimental Period 2 – from the 1st of May 1999 till the 31st December 2001, it was detected in three samples. The maximum level detected for that compound in any analysed sample was 0.07 µg/L. It shall be indicated that the LOQ value was set to 0.05 µg/L. The conclusions drawn from that study referred to the general concentrations of the pesticides detected in water samples, with no particular reference to Flufenacet.

Another publication presenting the results of the monitoring of Flufenacet in various water samples in Germany was, identified by the RMS, following paper:

Kowal S. Balsaa P., Werres F., Schmidt T. C., *“Fully automated standard addition method for the quantification of 29 polar pesticide metabolites in different water bodies using LC-MS/MS.”*; Analytical and Bioanalytical Chemistry, 2013, **405**, 6337 – 6351.

Although the main aim of the research presented in that paper was the development and validation of the novel, sensitive and high-precision analytical method enabling the routine quantitative analysis of the 29 polar degradation products of the active substances of the plant protection products, including FOE Oxalate and FOE Sulfonic acid, its performance was validated by analysing the concentrations of the test compounds in 200 natural water samples. The water samples used in validation were drinking water-, groundwater-, deep well water- surface water- and wastewater samples collected in Rhine and Ruhr region of North Rhine-Westphalia, Germany.

The developed method, standard addition method (SAM) for LC-MS/MS analysis, was demonstrated to be fully reliable, with recoveries of both Flufenacet degradation products in range 95 – 105%, LOD levels of 4 µg/L for FOE Oxalate and 8 µg/L for FOE Sulfonic acid and LOQ levels of 14 µg/L for FOE Oxalate and 29 µg/L for FOE Sulfonic acid.

As a part of the method's validation, 200 natural water samples were analysed – 6 of waste water, 14 of surface water, another 14 of deep well water, 156 of groundwater and 17 of drinking water. The results were presented in form of the bar graphs showing the range of the obtained concentrations. In case of all analysed samples of waste water, surface water, deep well water, and groundwater, the concentrations of both FOE Oxalate and FOE Sulfonic acid were well below 0.05 µg/L, usually in range of 0.00 – 0.25 µg/L. Only in case of drinking water samples the concentrations of FOE Sulfonic acid were above the level of 0.05 µg/L, but still below the threshold value of 0.1 µg/L.

It shall be indicated that in the paper little was said about the sampling procedure used to obtain those samples, including sampling period. For that reason the results may be considered only as indicative ones.

RMS identified four publications presenting the results of the determination of the concentrations of Flufenacet and its two degradation products – FOE Oxalate and FOE Sulfonic acid in SW water bodies in Switzerland.

Kern and co-workers carried out the research aimed on the comparison of the estimated using the numerical models concentrations of the selected active substances and their degradation products in the SW water bodies with the field data – the concentrations measured in surface water from existing catchment. Among the test substances were Flufenacet and its two degradation products – FOE Oxalate and FOE Sulfonic acid. The field data were collected from the river La Petite Glâne, located in western Switzerland (Canton Vaud), ~30 km long and having a catchment of 90 km², a tributary to the river La Broye, entering Lake Murten. The catchment of the river La Petite Glâne is an agriculture-dominated one with cereals (wheat, barley, maize), sugar beet, potatoes and rapeseed being the dominant crops. Water samples were taken from spring to autumn of 2008, mainly after intensive rainfall events – 20 samples. Additionally three samples were taken during the base flow to establish background concentrations. They were divided into three sets:

- application period samples, collected in May and June; nine such samples were analysed;
- post application periods samples, collected in July; eight such samples were analysed;
- harvesting period samples, collected between August and October; three such samples were analysed.

In case of the base-flow samples the concentrations of the test compounds were provided for two samples – that collected during the post-application period and that collected during the harvest period.

Additionally the concentrations of the test compounds in 22 groundwater samples from groundwater screening in the Swiss Plateau were determined.

Collected samples were processed by SPE extraction and analysed using LC-MS/MS method. The LOD and LOQ values for SW water samples were following:

- for Flufenacet LOD = 0.3 ng/L and LOQ = 1.0 ng/L;
- for FOE Oxalate LOD = 0.3 ng/L and LOQ = 1.0 ng/L;
- for FOE Sulfonic acid LOD = 0.3 ng/L and LOQ = 1.0 ng/L.

The results obtained in SW water samples for Flufenacet and its degradation products were following:

- **Flufenacet:** the median concentration in application period samples was 71 ng/L with range 26 – 350 ng/L, the median concentration in the post-application period samples was 8 ng/L with range 6 – 37 ng/L, the median concentration in harvesting period samples was 4 ng/L with range 3 – 4 ng/L;
- **FOE Oxalate:** the median concentration in application period samples was 3 ng/L with range 2 – 6 ng/L, the median concentration in the post-application period samples was 3 ng/L with range <1 – 6 ng/L, the median concentration in harvesting period samples was <1 ng/L with range <1 – 4 ng/L;
- **FOE Sulfonic acid:** the median concentration in application period samples was 4 ng/L with range 2 – 9 ng/L, the median concentration in the post-application period samples was 7 ng/L with range <1 – 25 ng/L, the median concentration in harvesting period samples was 8 ng/L with range 7 – 13 ng/L.

The concentrations of these compounds in the base-flow samples were following:

- in base-flow sample collected during the post-application period, the concentration of Flufenacet was 4 ng/L, that of FOE Oxalate <1 ng/L and that of FOE Sulfonic acid 8 ng/L;
- in base-flow sample collected during the harvesting period, the concentration of Flufenacet was 1 ng/L, that of FOE Oxalate <1 ng/L and that of FOE Sulfonic acid <1 ng/L.

In none of the analysed groundwater samples Flufenacet or its degradation products of interest were found.

The results of that study were presented in the following paper:

Kern S., Singer H., Hollender J., Schwarzenbach R. P., Fenner K., “*Assessing Exposure to Transformation Products of Soil-Applied Organic Contaminants in Surface Water: Comparison of Model Predictions and Field Data.*”; Environmental Science and Technology, 2011, **45** (7), 2833 – 2841 (with the supplement available on-line on the editor’s web-page).

Three other papers presented the results of the studies carried out by Moschet and co-workers.

That research team examined and then modelled the concentrations of selected organic micropollutants in a large river and lake catchment, using an international catchment of Lake Constance, located in the border area between Austria, Germany and Switzerland and collecting water from Alpine regions of these three countries, having a total catchment area of 11500 km². Its main tributary, also draining the lake, is Rhine river. Additionally the lake has 11 other tributary rivers.

Initially, to identify the organic micropollutants of concern samples of lake water were taken from four different spots and analysed by SPE-HPLC-Orbitrap method for the presence of 252 compounds – active substances of the plant protection products and their degradation products, pharmaceuticals and their transformation products, biocides and their transformation products, industrial chemicals cosmetics, food additives. These samples were collected in August 2008 and on the basis of the results obtained then the organic micropollutants for more detailed monitoring, performed from April till October of the year 2009 on twelve main tributaries of Lake Constance and on the lake itself.

The sampling points used in the preliminary monitoring in August 2008 were located in Bergenzer Bucht at the depth 0 and 50 metres, in the middle of the Upper Constance Lake at the depths 0, 10 and 230 metres, in Zellersee at the depths of 0 and 20 metres and in Rheinsee at the depths of 0 and 40 metres.

Flufenacet and its two degradates – FOE Oxalate (named Flufenacet OXA) and FOE Sulfonic acid (named Flufenacet-ESA) were listed among the compounds of concern during the preliminary monitoring study, with the LOD values 2 ng/L, 4 ng/L and 2 ng/L respectively.

The results of that preliminary monitoring, presented in the supplement SI 3 to the publication showed that neither Flufenacet nor its degradation products of concern were detected in the lake water sampled on these locations.

The results of that experiment were presented in the following publication:

Moschet C., Götz C., Longrée P., Hollender J., Singer H., “*Multi-Level Approach for the Integrated Assessment of Polar Organic Micropollutants in an International Lake Catchment: The Example of Lake Constance.*”; Environmental Science and Technology, 2013, **47** (13), 7028 – 7036 (with the supplement available on-line on the editor’s web-page).

It shall be indicated that RMS identified another publication dealing with the transboundary transport of Flufenacet in surface water. That publication presented the results of the investigation of the concentrations of various active substances in the border areas of the Netherlands. Flufenacet was indicated as one of the compounds present in the amounts above the acceptability limits in the border zone between the Netherlands and Belgium and that between the Netherlands and Germany. However its presence was limited only to that zone and

not beyond, possibly also due to the fact that Flufenacet at period of preparation and issuing the publication was not authorised in the Netherlands. The exceedence index for that compound was of order 0.6 - 0.7 for the border zone with Belgium and of 0.3 – 0.4 for that with Germany. On that basis it was stated that the presence of Flufenacet in the SW bodies of the borderland with Belgium and Germany was due to long-distance transport of that compound with water, possibly also from more distant areas where the compound was commonly used, e.g. France. These results were presented in the following paper:

Van't Zelfde M., Tamis W. L., Vijver M. G., De Snoo G. R., *"The contribution of neighbouring countries to pesticide levels in Dutch surface waters."*; Communications In Agricultural and Applied Biological Sciences (Univ. Ghent), 2011, **76** (4), 867 – 877.

RMS however decided, signalling it, not to include that publication into the list of the relevant open-source publications due to the fact that it did not contain any measured concentrations of Flufenacet, just a reference to their source – the Dutch Atlas of Pesticides. For that reason its utility is, in RMS's opinion, limited. It may however be more relevant for zonal or MS registration.

Another study by Moschet and co-workers was aimed on the monitoring of Flufenacet and its two degradation products – FOE Oxalate and FOE Sulfonic acid, in Swiss riverine water. Its results were presented in the following two papers:

Moschet C., Wittmer I., Simovic J., Junghans M., Piazzoli A., Singer H., Stamm C., Leu C. Hollender J., *"How a Complete Pesticide Screening Changes the Assessment of Surface Water Quality."*; Environmental Science and Technology, 2014, **48** (10), 5423 – 5432 (with the supplement available on-line on the editor's web-page).

Moschet C., Vermeirsser E. L. M, Singer H., Stamm C., Hollender J., *"Evaluation of in-situ calibration of Chemcatcher passive samplers for 322 micropollutants in agricultural and urban affected rivers."*; Water Research, 2015, **71**, 306 – 317 (with the supplement available on-line on the editor's web-page).

The monitoring was carried out during the period between 19th March and 23rd July 2012 on five river catchments distributed over Swiss plateau:

- Fürtbach river catchment located in northern Switzerland, having the area of 38 km²,
- Limpach river catchment in central Switzerland, having the area of 73 km²,
- Mentue river catchment in south-western Switzerland, having the area of 105 km²,
- Salmsacher Aach river catchment in north-eastern Switzerland, having the area of 47 km²,
- Surb river catchment located north-westerly to the Fürtbach river catchment, having the area of 66 km².

The two dominant crops in all these catchments were cereals and maize.

The samples at each sampling site were collected in weekly intervals and in the analysing laboratory were mixed to obtain the two-weeks representative samples, nine from each catchment, processed by SPE and then analysed using appropriate chromatographic technique – LC-HRMS/MS. They were analysed for the presence of 289 active substances of the plant protection products and their 136 degradates. Among the analysed herbicides and its degradates were Flufenacet, with the LOQ = 3 ng/L, FOE Oxalate, with the LOQ = 7 ng/L, and FOE Sulfonic acid with the LOQ = 3 ng/L.

Flufenacet was detected in samples from all five rivers, with average detection frequency of 53% and the maximum concentration of 290 ng/L. In individual rivers those parameters looked as follows:

- in Fürtbach river it was detected in 56% of the analysed samples with maximum concentration of 80 ng/L;
- in Limpach river it was detected in 78% of the analysed samples with maximum concentration of 160 ng/L;
- in Mentue river it was detected in 67% of the analysed samples with maximum concentration of 35 ng/L;
- in Salmsacher Aach river it was detected in 11% of the analysed samples with maximum concentration of 31 ng/L;
- in Surb river it was detected in 56% of the analysed samples with maximum concentration of 290 ng/L.

FOE Sulfonic acid was detected in samples from all five rivers, with average detection frequency of 62% and the maximum concentration of 38 ng/L. In individual rivers those parameters looked as follows:

- in Fürtbach river it was detected in 44% of the analysed samples with maximum concentration of 14 ng/L;
- in Limpach river it was detected in 100% of the analysed samples with maximum concentration of 30 ng/L;
- in Mentue river it was detected in 89% of the analysed samples with maximum concentration of 38 ng/L;

- in Salmsacher Aach river it was detected in 44% of the analysed samples with maximum concentration of 7.9 ng/L;
- in Surb river it was detected in 33% of the analysed samples with maximum concentration of 17 ng/L.

FOE Oxalate was not detected in any of the analysed water samples.

Analysing both papers RMS noticed that, providing the results of the same study, they had different aim. The paper published in 2014 in the “Environmental Science and Technology” had the aim to demonstrate the advantages of the full scale monitoring in the exposure and risk assessment, while that presented in 2015 in “Water research” compared the performance of two different analytical methods used to determine broad range of organic micropollutants in water samples.

Additionally, eight publications, considered relevant, were identified presenting the results of the quantitation of Trifluoroacetic acid (TFA) in various environmental compartments. Two of them were submitted by the Applicant as a result of the performed open-literature search. Six other publications were found by the RMS during the repeated literature search. All they are presented below.

Marine environment, in particular oceans, were indicated in numerous publications as a terminal sink for the TFA reaching the environment. Therefore the concentrations of that compound in marine water was examined by several research teams. The results of two such studies were presented in the publications submitted by the Applicant.

Hartmut and co-workers presented the results of the determination of the concentrations of TFA in water sampled in Mid-Atlantic Ocean in January 1998 and in Southern Ocean in December 1998 and January 1999. The water samples were taken by specialised oceanographic ships from various depths. The Mid-Atlantic water samples were taken from the depths of 0 – 4150 metres. Those from Southern Ocean were taken down to the depth of 2000 metres. Additionally for samples taken in 1998 approx. 400-years-old mineral water from the source in Germany was used.

The content of TFA in all samples was determined, after their pre-processing, comprising derivatisation of the analysed compound, by GC-MS.

The concentrations of TFA in Mid-Atlantic water samples were at relatively constant level of 190 – 210 ng/L, with the mean value of 200 ng/L. Similar results were obtained for Southern Ocean water samples for both sampling periods: 185 – 210 ng/L in case of samples collected in December 1998 and 165 – 220 ng/L for samples collected in January 1999 with the mean value of 200 ng/L. The authors stated that the concentrations of TFA in analysed samples were not dependent on the depth from which the samples were taken.

That implied that although in the perfluorinated haloalkanes, such as CFCs, emitted to the atmosphere were indicated as a substantial source of TFA in the environment, in ocean water that compound was demonstrated to originate from not identified natural sources, significantly surpassing contribution from any man-made sources.

These results were presented in the following publication:

Frank H., Christoph E. H., Holm-Hansen O., Bullister J. L., “Trifluoroacetate in Ocean Waters.”; Environmental Science and Technology, 2002, **36** (1), 12 – 15.

The second paper, written by Scott and co-workers, presented the results of much broader examination of the concentrations of TFA in oceans. The water profile samples were collected at 22 sites located in Arctic, North Atlantic, South Atlantic and Pacific oceans. The sampling depth was, depending on the location of the sampling site, down to 5300 m. below the sea surface (b. s. s.).

The exact locations of the sampling sites and their maximum monitored depths were following:

- Canada Basin in Western Arctic – two sampling sites with the sampling depths 1500 metres b. s. s. and 3000 metres b. s. s.;
- Nares Strait in Eastern Arctic – three sampling sites with the sampling 365 metres b. s. s., 489 metres b. s. s. and 579 metres b. s. s.;
- North Atlantic in the vicinity of the US shores – two sampling sites with the sampling depths of 974 metres b. s. s. and 1000 metres b. s. s.;
- North Atlantic near North-African shores – one sampling point with the sampling depth of 3800 metres b. s. s.;
- South Atlantic along the African shores and in the Antarctic zone – three sampling sites with sampling depths of 3875 metres b.s. s., 5300 metres b. s. s. and 5053 metres b. s. s.;
- South Pacific in the vicinity of South American shores – two sampling sites, one of them near the deep-sea volcanic vent, with sampling depths of 3830 metres b. s. s. and 2500 metres b. s. s.;
- Eastern North Pacific along Asian coast – six sampling sites the sampling depths 175 metres b. s. s., 200 metres b. s. s., and 300 metres b. s. s (for four sampling locations);

- Western North Pacific along the North American (Canadian) coast – two sampling sites, both near the deep-sea volcanic vents, with sampling depths 2200 metres b. s. s. and 3986 metres b. s. s.;
- Mediterranean Sea near the volcanic vent – one sampling site with the sampling depth of 200 metres b. s. s.;

The measured concentrations of TFA at these sites were following:

- for Canada Basin in Western Arctic: 34 – 181 ng/L and 61 – 172 ng/L;
- Nares Strait in Eastern Arctic: 120 – 170 ng/L (two sites) and 8 – 125 ng/L;
- North Atlantic in the vicinity of the US shores: 17 – 150 ng/L and 28 – 190 ng/L;
- North Atlantic near North-African shores: 120 – 150 ng/L;
- South Atlantic along the African shore and in the Antarctic zone: 64 – 155 ng/L, 100 – 145 ng/L and 130 – 200 ng/L;
- South Pacific in the vicinity of South American shores: 1 – 150 ng/L and 1 – 90 ng/L;
- Eastern North Pacific along Asian coast: 1 – 25 ng/L, 1 – 30 ng/L, 1 – 68 ng/L, 1 – 80 ng/L, 1 – 20 ng/L and 2 – 50 ng/L;
- Western North Pacific along the North American (Canadian) coast: 3 – 140 ng/L and 2 – 230 ng/L;
- Mediterranean Sea near the volcanic vent: 0.5 – 50 ng/L.

In general terms, the concentrations recorded in the Atlantic Ocean and estimated in Indian Ocean displayed higher degree of consistency with the average concentration of 175 ng/L down to the depth of 10000 metres. The same value was obtained for the Pacific Ocean when the layer 4000 – 10000 metres below the sea level was considered. However, in case of the upper layers the higher variability in concentrations was estimated with the average concentration of 9 ng/L in the layer 0 – 200 metres b. s. s., 31 ng/L for the layers 200 – 1000 metres b. s. s. and 1000 – 2000 metres b. s. s., 7.1 ng/L for the layer 2000 – 3000 metres b. s. s. and 40 ng/L for the layer 3000 – 4000 metres b. s. s.

These results were presented in the paper:

Durham L., Fisk A., Kannan K., Macdonald R. W., Muir D. C. G., Scott B. F., Spencer C., Witter A., Yamashita N., *“Trifluoroacetate profiles in the Arctic, Atlantic, and Pacific Oceans.”*; Environmental Science and Technology, 2005, **39** (17), 6555 – 6560.

There are numerous publications reporting the results of the monitoring of TFA in the other than sea environmental compartments – freshwater bodies, soil and precipitation. RMS identified six such publications, which may be considered exemplary publications with regard to monitoring of TFA in the environment.

The already summarised under the data point B.8.3.2. publication by Henne and co-workers:

Henne, S.; Shallcross, D. E.; Reimann, S.; Xiao, P.; Boulous, S.; Gerecke, A. C.; Brunner, D.; *“Environmental impacts of HFO-1234yf and other HFOs.”*; Moving Towards Sustainability, ASHRAE/NIST Refrigerants Conference, Gaithersburg, MD, United States, Oct. 29-30, 2012 (2012), 13/1-13/13.,

provides the results of the determination of the concentrations of TFA in rain samples collected in Europe and outside that continent during the last decade of the 20th century and the first decade of the 21st Century, reported in other publications. In case of Europe those values were following:

- in samples collected in 1995 in urban regions of Germany the mean concentration of TFA in precipitation was 100 ng/L with range of 25 – 280 ng/L;
- in samples collected in urban and rural Germany in years 1995 and 1996 the mean concentration of TFA in precipitation was 110 ng/L, with range 10 – 410 ng/L;
- in samples collected in rural areas of Germany in years 1998 and 1999 the mean concentration of TFA in precipitation was ~100 ng/L, ranging from ~20 ng/L to ~580 ng/L;
- the analysis of precipitation samples collected in urban and rural areas of Switzerland in 1995 showed that the concentration of TFA in precipitation was in range 40 – 80 ng/L;
- the mean concentration of TFA in samples of precipitation collected in 1996 in remote areas of Ireland was 39 ng/L with range 2 – 92 ng/L;
- the analysis of the precipitation samples collected in 1996 in urban areas of Poland showed that the mean concentration of TFA in them was 318 ng/L with range of 26 – 1100 ng/L.

These results were used as a reference for the values obtained in the precipitation samples collected and analysed specifically for purpose of the research activity described in the summarised publication in 2011 at following three locations in Switzerland:

- Dübendorf, a sub-urban site in northern Switzerland;
- Magadino, a rural site in southern Switzerland,
- Rigi-Seebodenalp – an elevated rural site in the foothills of the northern Alps.

From each sampling site 33 precipitation samples were analysed for the content of TFA. The determined mean concentrations were 126 ng/L for the Dübendorf site, 315 ng/L for Magadino site and 198 ng/L for Rigi-Seebodenalp site.

The result of another, broader monitoring study aimed on the determination of the concentrations of TFA in various water samples in Switzerland were presented in the following publication:

Berg M., Müller S. R., Mühlemann J., Wiedmer A., Schwarzenbach R. P., „*Concentrations and Mass Fluxes of Chloroacetic acids and Trifluoroacetic acid in Rain and Natural Waters in Switzerland.*”; Environmental Science and Technology, 2000, **34** (13), 2675 – 2683;

The paper presented the results of the determination of the concentrations of various haloacetic acids, including TFA in water samples collected at various locations in Switzerland during the period of 1996 – 1997. The analysed matrices were: rain and snow – 73 samples, riverine water – 80 samples, midland lakes water – 20 samples, mountain lakes water – 8 samples, moor water – 3 samples, very old groundwater – 3 samples, all representing natural waters, as well as drinking water – 6 samples, swimming pools water – 4 samples, communal wastewater – 17 samples and industrial wastewater – 5 samples.

The determined levels of TFA in those samples were as follows:

- in rain-and snow-water samples the mean concentration of TFA was 151 ng/L and its range was <3 – 1550 ng/L;
- in riverine water samples the mean concentration of TFA was 87 ng/L and its range was 12 – 328 ng/L;
- in water sampled from midland lakes the mean concentration of TFA was 119 ng/L and its range was 37 – 204 ng/L;
- in water samples from mountain lakes the mean concentration of TFA was 141 ng/L and its range was 46 – 360 ng/L;
- in moor water samples the mean concentration of TFA was 107 ng/L and its range was 59 – 175 ng/L;
- in very old groundwater samples (having the average age of 15000 ± 1800 years) the mean concentration of TFA was <5;
- in drinking water samples the mean concentration of TFA was 71 ng/L and its range was 16 – 123 ng/L;
- in water samples from the swimming pools the mean concentration of TFA was 4800 ng/L and its range was 4100 – 5700 ng/L;
- in communal wastewater samples the mean concentration of TFA was 230 ng/L and its range was 90 – 600 ng/L;
- in industrial wastewater samples the mean concentration of TFA was 47300 ng/L and its range was <100 – 206000 ng/L.

Estimating the annual mass fluxes of TFA the authors stated that of the yearly influx of $240 \text{ g}/(\text{km}^2 \cdot \text{year})$, 96%, corresponding to $230 \text{ g}/(\text{km}^2 \cdot \text{year})$, came from wet deposition, while another 4% ($10 \text{ g}/(\text{km}^2 \cdot \text{year})$) from communal wastewater. That load in 62% ($150 \text{ g}/(\text{km}^2 \cdot \text{year})$) went to soil and groundwater recharge with no degradation observed and in 38% ($90 \text{ g}/(\text{km}^2 \cdot \text{year})$) was exported with riverine water.

As the conclusion of that research it was stated that although TFA was demonstrated to be not harmful to the aquatic ecosystems in concentrations up to 100 µg/L, its concentrations in the environment should be monitored because of risk posed to terrestrial and groundwater compartments.

Römpf and co-workers in their study, summarised already in this RAR under the point B.8.3.2., examined the concentrations of TFA in rain and fog samples collected at ecological research site in northeast Bavaria from 17 July 1998 to 24 March 1999. The median concentration of TFA in fog water samples – 85 in total, collected during the experimental period was 230 ng/L with range of 20 – 1900 ng/L. The concentrations of that compound in rain samples were relatively lower, with maximum of ~600 ng/L, but generally being <200 ng/L.

These results were presented in the publication:

Römpf A., Klemm O., Fricke W., Hartmut F., „*Haloacetates in Fog and Rain.*”; Environmental Science and Technology, 2001, **35** (7), 1294 – 1298.

The results of the monitoring of TFA in air and natural waters in Germany were also presented in another publication:

Jordan A., Frank H., „*Trifluoroacetate in the Environment. Evidence for Sources Other Than HFC/HCFCs.*”; Environmental Science and Technology, 1999, **33** (4), 522 – 527.

That publication was also summarised earlier in this Renewal Assessment Report, under the data point B.8.3.2.

TFA in that study was measured in three types of environmental matrices collected in Bayreuth from March 1995 to September 1996: air samples, rain water samples (collected at the university of Bayreuth's Botanical Garden and in the nearby forest) and river water collected in Bayreuth from Roter Main river.

The concentrations of TFA in air were in range of 0.01 – 0.125 ng/m³, with an average of 0.044 ng/m³. They were similar to those obtained for Zürich, Switzerland, in September 1995 and at Waldstein, Northern Bavaria, Germany, in June 1995.

In precipitation the level of TFA were in range 10 – 410 ng/L, with an average of 110 ng/L and in riverine water it ranged from 60 to 280 ng/L with the average concentration of 140 ng/L.

For comparative purposes may serve two publications presenting the concentrations of TFA in precipitation and fresh surface water bodies in North America.

Wujcik and co-workers examined the levels of TFA in precipitation and surface water in Nevada and California. The samples were collected in years 1996 and 1997 from three locations for precipitation and three SW catchments.

The samples of precipitation – rainfall, were collected at two sites in California – Rohnert Park and Selma, and one in Nevada - Reno. Also at two Californian sites were collected samples of fog. That type of samples were not collected in Nevada because of the lack of that phenomenon. Precipitation samples were collected from December 1996 to September 1997

For the monitoring of the concentrations of TFA in surface water three water systems were selected:

- Truckee river from its sources in Sierra Nevada Mountains range – a tributary stream to Lake Tahoe to the terminal endpoint in Pyramid Lake;
- Carson River from its sources in the high Sierra Nevada Mountains to its ending at Stillwater National Wildlife Refuge;
- Mono Lake with its tributaries.

Fogwater was collected in duplicate using two portable high-volume fog sampling units. Six fog samples were collected on the site at Rohnert Park and twenty one on Selma sampling site.

The rain samples were collected in duplicate in 500-mL amber bottles. The total volume of the sample collected during one event was 100 – 800 mL. 31 samples were collected on Rohnert Park site, 23 on Selma site and 6 on Reno site.

The samples of surface water were collected in duplicate by submersing 1000-mL amber-glass bottles in the sampled water body near its shore. In case of Truckee River system 34 samples were collected, of which 19 samples upstream of Reno, 8 downstream of Reno and 7 from Pyramid Lake. From the Carson River system 20 samples were collected, of which 6 upstream of Carson City, 8 downstream of Carson City and 6 in Stillwater National Wildlife Refuge. 12 samples were collected in Mono Lake system, of which 2 from Rush Creek and 10 from Mono Lake.

Samples were filtered under vacuum through a GF/F filter, then their pH and conductivity was measured.

Samples having a conductivity <500 µS were subjected to direct anion exchange extraction. The extracts were derivatised and analysed by GC-ECD method for the content of TFA.

Samples having a conductivity > 500 µS were processed by liquid-liquid extraction and the extracts were subjected to GC-ECD analysis for the content of TFA.

The LOQ of the analytical method was set to 36 ng/L for 400-mL sample.

The results of the quantification of TFA in precipitation – fog and rain, were following:

- for samples collected in Rohnert Park, California, the mean concentration of TFA in rain water was 46.6 ng/L with range of 25.1 – 158 ng/L (in nine samples concentrations of that compound were the method's <LOQ) and in fog water the mean concentration of TFA was 723 ng/L with range 86.6 – 809 ng/L;
- for samples collected in Selma, California, the mean concentration of TFA in rain water was 63.9 ng/L with range of 20.7 – 463 ng/L (in five samples concentrations of that compound were the method's <LOQ) and in fog water the mean concentration of TFA was 689 ng/L with range 101 – 1390 ng/L;
- for samples collected in Reno, Nevada, the mean concentration of TFA in rain water was 136 ng/L with range of 108 – 763 ng/L.

The results of the determination of TFA in surface water are presented below, individually for each analysed water system.

The concentrations of TFA in Truckee River system were following:

- upstream of Reno the mean concentration of TFA was 28.9 ng/L with range of 12.8 – 47.7 ng/L (in 17 of 19 analysed samples the concentrations were < LOQ of 36 ng/L, so in the publication that value was indicated as bearing the high level of uncertainty);
- downstream of Reno the mean concentration of TFA was 50.8 ng/L with range of 31.0 – 66.5 and the concentration <LOQ recorded in one analysed sample;
- in Pyramid Lake the mean concentration of TFA was 79 ng/L with range 77.1 – 95.1 ng/L.

The concentrations of TFA in Carson River system were following:

- upstream of Carson City the mean concentration of TFA was 45.3 ng/L with range 36.6 – 60.5 ng/L;
- downstream of Carson City the mean concentration of TFA was 84.2 ng/L with range 76.9 – 154 ng/L;
- in water samples from Stillwater National Wildlife Refuge the mean concentration of TFA was 432.5 ng/L with range 314 – 472 ng/L.

Finally, in Mono Lake system the concentrations of TFA were following:

- in Rush Creek the mean concentration of TFA was 51.0 ng/L with range 50.1 – 52.0 ng/L;
- in Mono Lake the mean concentration of TFA was 192 ng/L with range 186 – 227 ng/L.

Additionally the yearly inputs of TFA into the terminal lakes in Truckee River system – Pyramid Lake, and Mono Lake system – Mono Lake, were estimated using the obtained results. The estimation was performed for two scenarios – **Scenario 1** in which dry deposition into the terminal lake was determined from the results of the experiment carried out by Zehavi and Seiber on the open reservoir flux, and **Scenario 2**, in which dry deposition was based on the estimates provided by Grosjean.

The results of that estimation for the Mono Lake were following:

- for **Scenario 1** the total content of TFA in lake was 677 kg, yearly inputs: from streams – 8.4 kg, from wet deposition onto lake – 6.9 kg, from dry deposition – 146.2 kg, what yielded in the total yearly input of 161.5 kg and the estimated time to accumulate TFA to the level of observed concentrations: 4.2 years;
- for **Scenario 2** the total content of TFA in lake was 677 kg, yearly inputs: from streams – 8.4 kg, from wet deposition onto lake – 6.9 kg, from dry deposition – 79.4 kg, what yielded in the total yearly input of 94.7 kg and the estimated time to accumulate TFA to the level of observed concentrations: 7.2 years.

The results of that estimation for the Pyramid Lake were following:

- for **Scenario 1** the total content of TFA in lake was 2478 kg, yearly inputs: from streams – 24.0 kg, from wet deposition onto lake – 13.3 kg, from dry deposition – 365.8 kg, what yielded in the total yearly input of 403.1 kg and the estimated time to accumulate TFA to the level of observed concentrations: 6.2 years;
- for **Scenario 2** the total content of TFA in lake was 2478 kg, yearly inputs: from streams – 24.0 kg, from wet deposition onto lake – 13.3 kg, from dry deposition – 153.0 kg, what yielded in the total yearly input of 190.3 kg and the estimated time to accumulate TFA to the level of observed concentrations: 13 years.;

In the analysis of the obtained results the man-made sources – mainly HFCs and HCFCs generated locally in the urban areas and transported from more distant locations, like San Francisco Bay area, were indicated as a possible source of TFA in the atmosphere and hence in precipitation. Also the processes occurring in the atmosphere were indicated as possible factor driving the distribution of TFA between phases.

The monitoring of TFA in the systems of Truckee River and Carson River showed a substantial increase downstream of the urbanized areas of Reno and Carson City respectively. That may indicate the significant contribution of these areas as anthropogenic sources of TFA.

The results of the study were presented in the following publication:

Wujcik C., Cahill T. M., Seiber J. N., “*Determination of Trifluoroacetic Acid in 1996 – 1997 Precipitation and Surface Waters in California and Nevada.*”; Environmental Science and Technology, 1999, **33** (10), 1747 – 1751.

In Canada Scott and co-workers carried out in 1997 the research project aimed on the determination of the levels of TFA in precipitation and lake water. The precipitation samples were taken at seven different locations across Canada (from west to east of the country): Saturna Island in British Columbia, Snare Rapids in Northwest Territories, Ester on the borderline between Alberta and Saskatchewan, Island Lake in Manitoba, Algoma in Ontario, on the Great Lakes, Chapais in Quebec and Kejimikujik in New Brunswick. Additionally two sampling points for precipitation were set at the Laurentian Great Lakes – Burnt Island and Point Petre.

The samples of lake water were taken from four lakes associated with the sampling points for precipitation – Loon Lake in British Columbia, Great Slave Lake in the Northwest Territories, Lake Winnipeg in Manitoba and Lake Kejimikujik in New Brunswick, as well as from ten locations on the Laurentian Great Lakes.

Additionally were analysed the drinking water samples from the city of Hamilton, Ontario, and the samples of cold tap water from Burlington city.

The precipitation samples were collected and analysed as 24-hours samples in polyethylene bags. The samples of lake water were taken in triplicate form 1 metre below the surface using Go-flo bottles. In the laboratory the samples were processed and, after derivatisation, analysed for the content of selected haloacetic acids – TFA, MCA, DCA, TCA and MBA, using GC-MS. For TFA the LOD was set to 0.5 ng/L.

The results of the determination of TFA in precipitation samples were following:

- for the **Saturna Island** sampling site: the number of precipitation events recorded on site was 9, the average concentration of TFA in collected samples was 29 ng/L with range of <0.1 – 170 ng/L;
- for the **Snare Rapids** sampling site: the number of precipitation events recorded on site was 4 with the average concentrations of TFA in collected samples of <0.1 ng/L;
- for **Ester** sampling site: the number of precipitation events recorded on site was 6, the average concentration of TFA in collected samples was 85 ng/L with range of 38 – 160 ng/L;
- for **Island Lake** sampling site: the number of precipitation events recorded on site was 9, the average concentration of TFA in collected samples was 40 ng/L with range of <0.1 – 59 ng/L;
- for **Algoma** sampling site: the number of precipitation events recorded on site was 11, the average concentration of TFA in collected samples was 48 ng/L with range of 4 – 120 ng/L;
- for **Chapais** sampling site: the number of precipitation events recorded on site was 11, the average concentration of TFA in collected samples was 24 ng/L with range of <0.1 – 69 ng/L;
- for **Kejimikujik** sampling site: the number of precipitation events recorded on site was 11, the average concentration of TFA in collected samples was 43 ng/L with range of <0.1 – 130 ng/L;

In case of precipitation samples collected on two sites at the Laurentian Great Lakes, the fluxes of TFA were reported together with the level of precipitation recorded for the period, for which the flux was determined. In case of the sampling site Burnt Island the results were following:

- for the period 20. 10. – 17. 11. 1997 the amount of precipitation was 32 mm and the flux of TFA 2330 ng/m²;
- for the period 17. 11. – 15. 12. 1997 the amount of precipitation was 32 mm and the flux of TFA 1260 ng/m²;
- for the period 15. 12. 1997 – 12. 01. 1998 the amount of precipitation was 32 mm and the flux of TFA <3.8 ng/m².

The results obtained for the sampling site Piont Petre were as follows:

- for the period 21. 10. – 18. 11. 1997 the amount of precipitation was 80 mm and the flux of TFA 3260 ng/m²;
- for the period 18. 11. – 16. 12. 1997 the amount of precipitation was 26 mm and the flux of TFA 1550 ng/m²;
- for the period 16. 12. 1997 – 13. 01. 1998 the amount of precipitation was 88 mm and the flux of TFA 1950 ng/m²;

The analysis of the concentration of TFA in lake water from four Canadian regional lakes gave the following results:

- in Loon Lake the concentration of TFA was <0.5 ng/L;
- in Great Slave Lake the concentration of TFA was in range <0.5 – 10 ng/L;
- in Lake Winnipeg the concentrations of TFA were in range 100 – 360 ng/L;
- in Lake Kejimikujik the concentrations of tFA were in range 12 – 28 ng/L.

High concentrations of TFA in water samples from Winnipeg Lake, in comparison to other lakes, were explained by its location downstream from the possible urban sources, while the three remaining lakes were situated in isolated locations and were not subjected to industrial or urban activity.

The results of the determination of TFA in Laurentian Great Lakes were following:

- in samples from Lake Superior the concentrations of TFA were 0.5 ng/L and 2 ng/L;
- in samples from Lake Huron the concentrations of TFA were 100 ng/L and 110 ng/L;
- in samples from Georgian Bay the concentration of TFA was 74 ng/L;
- in samples from Lake Erie the concentrations of TFA were 130 ng/L and 140 ng/L;

- in samples from Lake Ontario the concentrations of TFA were 130 ng/L and 150 ng/L;
- in samples of drinking water from Hamilton city the concentration of TFA was 183 ng/L;
- in samples of drinking water from the city of Burlington the concentration of TFA was 120 ng/L.

Additionally in Lake Superior the seasonal variation in concentrations of haloacetic acids was examined. For that purpose the water samples from three different locations were taken and analysed at spring and in summer. For TFA the results were following:

- for sampling site located in the western bassin (site 1) the concentration of TFA at spring was 16 ng/L and in summer 2 ng/L;
- for sampling site located in mid lake (site 2) the concentration of TFA at spring was 18 ng/L and in summer 3 ng/L;
- for sampling site located in eastern bassin (site 3) the concentration of TFA at spring was 17 ng/L and in summer <0.5 ng/L.

In conclusions it was stated that the levels of TFA, when that compound was detected in analysed samples, were comparable to the results obtained for Europe and North America (in general). It was also indicated that the atmospheric transport and deposition may play a significant role in distribution of TFA in the environment of Canada, including the aquatic compartment. Finally, it was postulated that the urban centers as well as such activities like pyrolysis of perfluorinated plastics may be a substantial sources of the emission of TFA to the environment.

Monitoring data: short summary:

The Applicant addressing the problem of the monitoring of Flufenacet in the environment stated that there were numerous monitoring programmes carried out by the competent authorities, into which that compound and its transformation products were included. These data however were not available, so the Applicant was not able to identify and present them. For that reason the presentation of the monitoring data was limited to the available literature data. The Applicant was able to identify three papers presenting the results of the monitoring studies for Flufenacet and its degradation products. One of them was aimed on the determination of the several active substances of the plant protection products in the watercourse of the small agricultural catchment located in Germany, other two presented the results of the determination of TFA (Trifluoroacetic acid) – the most persistent degradate of Flufenacet, in Oceans which are considered to be the terminal environmental sink of TFA.

RMS performing the repeated literature search was able to identify several publications presenting their results of the monitoring studies in which Flufenacet and two its major degradates – FOE Oxalate and FOE Sulfonic acid were the target compounds.

The results may be divided into two groups, according to the geographical location of the monitoring studies. To none of them belong the results obtained in the monitoring studies carried out from 1999 until 2004 in USA and more specifically in Mid-Western States, the so-called corn-belt states, by USGS (US Geological Service) employees.

The extensive monitoring of groundwater sampled from 55 wells in Indiana in 2000 showed that neither Flufenacet, nor its degradates FOE Oxalate and FOE Sulfonic acid were detected in analysed samples. The limit of detection in that study was set to 0.05 µg/L. Also neither Flufenacet nor its degradates – FOE Oxalate and FOE Sulfonic acid were found in groundwater analysed in a similar monitoring project carried out in Iowa in 2001, in which samples from 86 municipal wells were analysed for the content of several active substances of the plant protection products and their degradates.

The analysis of the concentrations of Flufenacet and its degradation products – FOE Oxalate and FOE Sulfonic acid in the Mississippi River basin showed that these compounds, if detected, were present sporadically and in low concentrations. In the study carried out in the year 2000 and aimed on the determination of the levels of selected chloroacetanilide plant protection products and their degradates in surface water bodies of the Mississippi River catchment, Flufenacet was detected in 3% of 39 analysed samples in maximum amount of 0.12 µg/L, while FOE Oxalate and FOE Sulfonic acid were not detected at all in 38 samples analysed for their presence. Samples were taken at for key junctures of the Mississippi River Basin. In another monitoring study on Mississippi River catchment with one sampling point set at Baton Rouge, LA, and carried out at the same period (1999 – 2000), neither Flufenacet nor FOE Oxalate were detected in any analysed samples, while FOE Sulfonic acid was detected in amounts > 0.05 µg/L in two of them (6% of analysed samples).

Finally, in 2002 within the big monitoring programme, the concentrations of Flufenacet, FOE Oxalate and FOE Sulfonic acid were monitored, alongside other herbicides, their degradates and pharmaceuticals, in 51

streams selected as representative for nine Mid-Western states of the USA. Samples were collected at spring during pre-emergence period (May – June), in summer during post-emergence period (June – July) and during the harvest period in autumn (September – November). Flufenacet was detected in 11 of 51 pre-emergence samples with the max amount 0.93 µg/L, 9 of 52 post-emergence samples with max amount 1.6 µg/L and only one of 51 harvest-period samples. It was found more frequently in samples taken from Nebraskan streams, while not detected at all during the whole experimental period in those from Indiana, Minnesota and Wisconsin.

The frequency of detection of FOE Oxalate and FOE Sulfonic acid was much lower – the compounds were found during each sampling period in max. 4 samples of analysed 51/52. Their maximum concentrations were up to 0.09 µg/L in pre-emergence samples, up to 0.18 µg/L in post-emergence samples and up to 0.13 µg/L in harvest samples.

Finally in the study in which the concentrations of Flufenacet were monitored in precipitation water in four agricultural catchments across the USA that compound was detected only in two samples taken in Nebraska in May.

For all those monitoring studies the method detection limit MDL, corresponding to LOQ, was 0.05 µg/L.

In case of Europe the quantitative results of the monitoring of the residues of Flufenacet in water samples were available for two countries – Germany and Switzerland. Additionally the qualitative results were available for the Netherlands.

The results of the monitoring study performed for the small rural catchment of Lamspringe in Lower Saxony, Germany, in years 1998 – 2000 showed that Flufenacet, applied to the fields in the research area in 1999 and 2000 was detected in stream water samples collected only in the year 2000. It was detected in three samples, in maximum amount 0.07 µg/L, slightly above the LOQ = 0.05 µg/L set for the analytical method used in the study.

In another study, in order to validate the developed novel analytical method for determination of polar degradates of organic micropollutants in water samples, including FOE Oxalate and FOE Sulfonic acid, 200 samples of natural water were analysed, of which six of waste water, fourteen of surface water, another fourteen of deep well water, 156 of groundwater and seventeen of drinking water. All samples were collected in Rhine and Rhur regions of the North Rhine-Westphalia, Germany. In case of all analysed samples of waste water, surface water, deep well water, and groundwater the concentrations of both FOE Oxalate and FOE Sulfonic acid were well below 0.05 µg/L, usually in range of 0.00 – 0.25 µg/L. Only in case of drinking water samples the concentrations of FOE Sulfonic acid were above the level of 0.05 µg/L, but still below the threshold value of 0.1 µg/L.

In case of Switzerland the results of monitoring were available for the catchment of the river La Petite Glâne, located in western Switzerland in the canton Vaud, for the Lake Constance – the example of the interboundary landlocked catchment collecting surface water from three countries, and five small- to medium in size river catchments located across Switzerland, displaying at least partly agricultural character. All results are quite recent, being collected in the first and second decades of the 21st century, between the years 2008 and 2012.

The monitoring of the surface water samples collected in the catchment of the river La Petite Glâne, carried out from May to October of the 2008 with aim of determination of selected active substances of the plant protection products and their degradates in the water collected after rainfall events from the stream passing through the catchment, showed that the highest concentrations of Flufenacet in analysed water were recorded at spring, during application period of that compound. The median concentration was 0.071 µg/L with range 0.026 – 350 µg/L. Much lower were concentrations recorded after the rainfall events in summer and at autumn – the median values were 0.008 µg/L and 0.004 µg/L respectively. In case of the two monitored degradation products – FOE Oxalate and FOE Sulfonic acid their levels in stream water samples collected after the rainfall events were generally much lower, in case of FOE Oxalate not surpassing 0.003 µg/L and for FOE Sulfonic acid 0.008 µg/L. It was noticed that while in case of FOE Oxalate the highest concentrations were recorded for the application period of Flufenacet – at spring, in case of FOE Sulfonic acid the highest levels were recorded in autumn, what may reflect the temporal formation patterns and persistence of these compounds in soil.

The levels of those three compounds in the base-flow samples – collected in periods between the occurrence of the rainfall events were very low, not surpassing 0.01 µg/L. Additionally the samples of groundwater collected in and around the catchment were analysed for the content of the compounds of concern. It was stated that in none of the analysed samples Flufenacet, FOE Oxalate or FOE Sulfonic acid were detected. The detection (LOD) and quantification (LOQ) limits for those compounds were set, for the purpose of that study, as follows:

- for Flufenacet LOD = 0.3 ng/L and LOQ = 1.0 ng/L;
- for FOE Oxalate LOD = 0.3 ng/L and LOQ = 1.0 ng/L;
- for FOE Sulfonic acid LOD = 0.3 ng/L and LOQ = 1.0 ng/L.

In another study, aimed on the determination of the levels of several organic micropollutants in the surface water collected from five river catchments located across Switzerland – Fürtbach river, Limpach river, Mentue river, Salmsacher river and Surb river, the results obtained for Flufenacet, FOE Sulfonic acid and FOE Oxalate were following:

Flufenacet was detected in samples from all five rivers, with average detection frequency of 53% and the maximum concentration of 290 ng/L. In individual rivers those parameters looked as follows:

- in Fürtbach river it was detected in 56% of the analysed samples with maximum concentration of 80 ng/L;
- in Limpach river it was detected in 78% of the analysed samples with maximum concentration of 160 ng/L;
- in Mentue river it was detected in 67% of the analysed samples with maximum concentration of 35 ng/L;
- in Salmsacher Aach river it was detected in 11% of the analysed samples with maximum concentration of 31 ng/L;
- in Surb river it was detected in 56% of the analysed samples with maximum concentration of 290 ng/L.

FOE Sulfonic acid was detected in samples from all five rivers, with average detection frequency of 62% and the maximum concentration of 38 ng/L. In individual rivers those parameters looked as follows:

- in Fürtbach river it was detected in 44% of the analysed samples with maximum concentration of 14 ng/L;
- in Limpach river it was detected in 100% of the analysed samples with maximum concentration of 30 ng/L;
- in Mentue river it was detected in 89% of the analysed samples with maximum concentration of 38 ng/L;
- in Salmsacher Aach river it was detected in 44% of the analysed samples with maximum concentration of 7.9 ng/L;
- in Surb river it was detected in 33% of the analysed samples with maximum concentration of 17 ng/L.

FOE Oxalate was not detected in any of the analysed water samples.

The quantitation limits for these compounds were following: for Flufenacet LOQ = 3 ng/L, for FOE Oxalate LOQ = 7 ng/L and for FOE Sulfonic acid LOQ = 3 ng/L.

The analysis of the concentrations of Flufenacet, FOE Oxalate and FOE Sulfonic acid in water samples from lake Constance was carried out as a preliminary part of the study aimed on the determination of the concentrations of selected micropollutants in that water body and in its tributaries. In none of the analysed samples, collected from four locations on the lake Constance the compounds of concern were detected.

In another study reporting results of the monitoring of Flufenacet in the borderline surface water bodies in the Netherlands it was stated that Flufenacet was detected in the borderland zones, but not hinterland. On that basis, as Flufenacet was not a compound authorised to be used in the Netherlands, but having such authorisation in the neighbouring countries – Belgium and Germany, it was stated that it may be prone to transboundary transport in surface water. However, the estimations provided in that study were rather qualitative than quantitative.

On the basis of the obtained monitoring results derived from the open-source literature data it may be stated that neither Flufenacet nor its two degradates – FOE Oxalate and FOE Sulfonic acid are expected to be present in natural water samples in amounts significantly surpassing the level of 0.1 µg/L – the drinking water limit.

Of the other degradation products of Flufenacet identified as major the monitoring data are available only for Trifluoroacetic acid – TFA, the compound considered to be common organic pollutant of the environment coming, originating from various sources.

As TFA is considered to be the organic pollutant found primarily in atmosphere as a result of the photooxidative transformation of several halogenated compounds, such as HCFs and HFCFs and is removed from there by means of wet and dry deposition, several studies were carried out with aim of the determination of the concentrations of trifluoroacetate in the atmospheric water – rain- and fog water. The concentrations of TFA determined in rain water are in general lower than those measured in fog water, usually not surpassing 500 ng/L on average. They strongly depend on the character of region, where they were collected, being higher in urbanised and industrial regions. The levels of TFA in fog samples were sometimes of the order of magnitude higher than those in water samples collected at the same sampling sites.

In the open-source literature oceans are indicated as the terminal environmental sink of the TFA with the surface water bodies, such as rivers, being the intermediate collectors. Also landlocked lakes were indicated as a possible sink for TFA.

In the global ocean the level of TFA was estimated to be, on the basis of the available results of the monitoring studies, ~200 ng/L and quite stable. The levels of TFA determined in fresh surface water bodies were similar, but it was indicated that in some landlocked lakes they may be higher. For example the results of the determination of the concentrations of TFA in Canadian lakes carried out in the year 1997 showed that the concentrations of TFA in those SW bodies were in range of <0.5 ng/L – 360 ng/L, being highest in lakes located in the highly urbanised and industrialised areas with high level of antropopression.

It shall be indicated that in all available publication presenting the results of the monitoring studies for TFA the man-made sources were indicated as a primary sources of that compound in inland environment. However, it was also indicated that in case of the oceans, and possibly also some inland ecosystems there may be some, still not identified natural sources contributing to the overall concentrations of TFA in the geosphere.

B.8.6 – Open literature review

Complying with the data requirement set in the Article 8 point 5 of the Regulation (EC) 1107/2009, the Applicant submitted the following report presenting the results of the search of the scientific peer-reviewed open literature, according to EFSA Guidance Document “Submission of scientific peer-reviewed open literature for approval of pesticide active substances under Regulation (EC) No 1107/2009 [EFSA Journal; **2011**; 9(2); 2092]:

Study 1:

Report: Derpmann J., Teubner. L.; **2014**: “Summary of the literature data for Flufenacet”; Bayer CropScience; Document MCA: Section 9 Literature Data Flufenacet (unpublished document No. M-482180-01-1); issuing date: 2014. 03. 18;

Guidelines: EFSA Guidance Document “Submission of scientific peer-reviewed open literature for approval of pesticide active substances under Regulation (EC) No 1107/2009 [EFSA Journal; **2011**; 9(2); 2092]

GLP: no, not required

RMS comments: The literature search was performed in line with the recommendations of the EFSA Guideline, therefore, from the formal point of view, it can be considered acceptable. However, the Thorough examination of the report showed that the correctness of the detailed assessment cannot be fully verified, as for the rejected papers only their citation data (authors, titles and data on periodicals in which they were published) were provided. As a results RMS performed additional literature search, the results of which are presented below the summary of the report provided by the Applicant.

Summary:

The aim was to carry out the literature search in a comprehensive and transparent way, in order to fulfil the data requirement set, as mandatory for the AIR 3 compounds (such as flufenacet), by, at the time of submission, Regulation (EU) No 844/2012, subsequently repealed by the Regulation (EC) 283/2013, but in which this requirement was maintained.

It was performed in line with the EFSA Guidance document on the “Submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) No 1107/2009” published in EFSA Journal; **2011**; 9(2); 2092 (further referred to as EFSA Guidance document on literature search).

Presenting the adopted search strategy the Applicant stated that the evaluation was based on the examination of the abstracts of all references identified as potentially relevant. Patents were not considered in the literature search, because they are not included into the definition of “scientific peer-reviewed open literature”.

The literature search covered the period of thirteen years predating the submission - from the 1st January 2000 to the 13th November 2013.

Several data bases were used by the Applicant to perform the search. Their list is provided below, on figure B.8.6_CA-1 (table reproduced from the report submitted by the Applicant).

Table 1: List of data bases for the literature search flufenacet and date of last database update

Database Name	Trifluoroacetic acid (C10)	Flufenacet and metabolites (except C10)
Agricola	2013-10-22	2013-11-05

Figure B.8.6_CA-1: List of data bases used by the Applicant in literature search for Flufenacet (reproduced from the Applicant’s report).

It was indicated that as a preferred provider was selected STN – a scientific information platform hosted by CAS, division of the American Chemical Society.

The search was performed using the following key pieces of information: IUPAC name, CAS name/number, common names, codes and abbreviations, molecular structure, molecular formula, molar mass and other available names and/or codes.

The example of search input parameters is given below (for flufenacet) on figure B.8.6_CA-2.

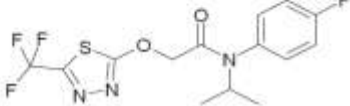

i) Flufenacet	
IUPAC name:	N-(4-fluorophenyl)-N-isopropyl-2-([5-(trifluoromethyl)-1,3,4-thiadiazol-2-yl]oxy)acetamide
CAS number:	142459-56-3
STN Query	(142459-56-3 OR FLUFENACET OR FLUTHIAMID OR FLUTHIAMIDE OR THIAFLUAMIDE OR FOE 504) OR (DRAGO OR DRADO OR CADOU OR TIARA OR FIREBRID OR FOEBURI OR HEROLD OR ANTILOPE(W)(RTM OR R OR TM)) AND PY>1999 NOT PDT
Molecular structure:	

Figure B.8.6_CA-2: The example of search input parameters used by the Applicant in the literature search for Flufenacet (reproduced from the Applicant's report).

The search was performed for Flufenacet and its following degradation products: **FOE oxalate (M1)** – code C01, **FOE sulfonic acid (M2)** – code C02, **FOE-Thiadone (M9)** – code C03, **FOE Methylsulfone (M7)** – code C04, **FOE Thioglycolate sulfoxide** – code C05, **3-((2-((4-fluorophenyl)(isopropyl)amino)-2-oxoethyl)sulfinyl)-2-hydroxypropanoic acid** – code C06, **FOE-conjugate with cysteine** – code C07, **FOE trifluoroethane sulfonic acid** – code C08, **FOE Methylsulfide (M5)** – code C09 and **Trifluoroacetic acid (TFA, M45)** – code C10.

In case of Flufenacet and its degradation products bearing the codes C01 – C09 no keyword filter was used. Such filter was however used in case of TFA, for which 53 chains of refining key words (L2 – L54), encompassing all areas of evaluation, were used. They were all listed by the Applicant in the Appendix II to the study report. In case of environmental fate and behaviour at least 11 chains of refining key words (L44 – L54 in the Appendix II) may be considered as directly or indirectly related to the search in that area.

The whole search and evaluation procedure followed the conceptual scheme presented below on the figure B.8.6_CA-3.

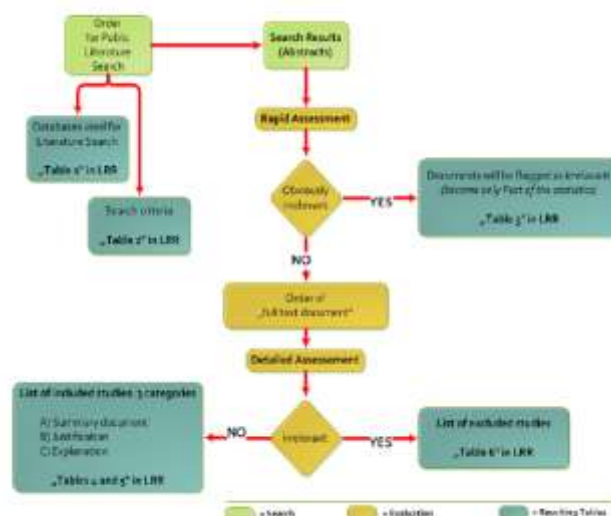

Figure B.8.6_CA-3: The conceptual scheme of search and evaluation procedure used in the literature search for Flufenacet (reproduced from the Applicant's report).

Initially 3489 publications were found, of which 369 were those for flufenacet and 3120 for its degradation products. Of that number 3089 were for TFA (including salts). No publications were found for either FOE Methylsulfide (M5) or FOE Trifluoroethane sulfonic acid. Of the remaining 31, 11 publications were found for FOE oxalate (M1) and the same number for FOE sulfonic acid (M2), 4 for FOE-Thiadone (M9) and 2 for FOE Methylsulfone (M7). In case of the remaining four degradation products, for each of them 1 potentially relevant publication was found.

Evaluation of the search results was performed according to the rules set by the *EFSA Guidance document on literature search*.

At the “Rapid assessment” stage the following topics were used in assessment of the relevance of publications (considered as the exclusion criteria):

- Efficacy;
- Analytical method development;
- New ways of synthesis;
- Studies on a molecular level, which cannot be related to risk assessment (RA);
- Non-EU monitoring studies;
- Publications in non-EU language without English abstract;
- Abstract refers to a conference contribution and does not contain data, full text not available;
- Not relevant due to missing information: Studies with target organisms.

Using these criteria the Applicant excluded from the further assessment as not relevant 278 of 369 publications found for Flufenacet, 3036 of 3089 of those found for TFA, 8 of 11 found for FOE Oxalate, 7 of 11 found for FOE sulfonic acid, 2 of 4 found for FOE-Thiadone and all found for four remaining degradation products. The remaining 153 publications – 91 for Flufenacet and 62 for its degradation products (including 53 for TFA) underwent the detailed assessment based on the examination of their full text versions.

The assessment criteria, considered as the non-relevance criteria, adopted at that stage were following:

- Target substance not a test item;
- Conversion into units useful for RA not possible;
- Study design/test system not sufficiently described;
- Study design/test system not adequate;
- Study design/test system not relevant to EU data requirements;
- Test system not relevant to representative uses/GAPs;
- Test method does not cover the right targets;
- Test material deviates from composition of BCS active ingredient/product;
- Findings not related to a certain test system;
- No endpoint can be derived;
- Observations are not attributable (i.e. ecotox) to a specific substance;
- Effects are caused by non-relevant route of exposure;
- Observations cannot be transferred into an endpoint;
- The information is already available in other peer-reviewed articles.

As a result of that detailed assessment of 91 of the publications for flufenacet qualified for the second stage, 89 were rejected and two considered as relevant or of unclear relevance. Of 153 publication for degradation products evaluated at the “Detailed assessment” step only seven were found relevant or of unclear relevance, all of them were the publications for TFA. In total 9 publications were found relevant or of unclear relevance and included into the dossier, as inform the results of the publication selection process presented in the Table 3 of the Applicant’s report.

The results of the detailed assessment were presented in three separate tables, in line with the recommendations given in the *EFSA Guidance document on literature search*. Tables 4 and 5 contain the relevant publications included into the dossier after the detailed assessment of full-text documents for relevance, ordered by data requirement (Table 4) and by authors (Table 5). These Tables contain 7 publications each.

In Table 6 were listed all remaining publications evaluated at the “Detailed assessment” step, but found not relevant. The table contains 137 positions arranged in alphabetical order with regard to their first authors. For each of the listed publication their full citation data were provided together with a short rationale for their non-relevance.

RMS noticed two discrepancies between the results presented in the Table 3 (general results of the assessment) and those given in Tables 4-6.

Of the 9 publications declared as relevant or potentially relevant, two were not included in the final list, one for the active substance and another for the degradation product TFA. The Applicant did not explain the reason for that difference in number of relevant publications.

It was also stated that the Table 6 lists only 137 publications, while their number should be higher – 144. This difference may however be explained by the fact that, as declared the Applicant, double entries, resulting from the separated search performed for the compounds, were removed from the Table 6.

Below are presented the results of the detailed assessment of the publications found during the literature search. They are given in tabularised form. First table – B.8.6_CA-1, provides the list of publications considered not relevant by the Applicant. RMS decided to maintain the format of the table proposed by the Applicant. At the same time the publications listed in that table were limited by the RMS to those, the title of which indicated that they were related to the assessment of the environmental fate and behaviour of flufenacet, according to the data requirements set by the Regulation (EC) 283/2013. It shall be noted that the provided list, consisting of 41 entries, may not be complete, or may contain the publications not fully relevant to this area of assessment, as Applicant compiling that list provided nor full neither texts nor even the summaries of rejected publications. That fact also significantly complicated the RMS's task of verification of the appropriateness of the justifications provided by the Applicant, what resulted in repeated literature search performed by the RMS, described below that summary.

Table B.8.6_CA-1: Results of the “Detailed assessment” stage of the literature search – publications not included into the dossier on the basis of their non-relevance (table reproduced from the Applicant's report, modified by the RMS).

Author(s)	Year	Title	Source	Reason(s) for not including publication in dossier
Barron, Leon; Paull, Brett [Reprint Author]	2004	Determination of haloacetic acids in drinking water using suppressed micro-bore ion chromatography with solid phase extraction.	Analytica Chimica Acta, (September 27 2004) Vol. 522, No. 2, pp. 153-161. print. ISSN: 0003-2670 (ISSN print).	Findings not related to a certain test system
Bazooobandi, M.; Yaduraju, N. T.; Kulshrestha, G.	2000	Analysis of flufenacet in soil, wheat grain and straw by gas chromatography	Journal of Chromatography, A (2000), 886(1+2), 319-322	The article does not contain information related to the substance of concern, as flufenacet was not detected in any of the investigated water samples and is therefore assessed as irrelevant.
Brimblecombe P (Reprint) Lifongo L L; Bowden D J	2004	Photodegradation of haloacetic acids in water	CHEMOSPHERE, (APR 2004) Vol. 55, No. 3, pp. 467-476. ISSN: 0045-6535.	The article does not contain information related to the substance of concern

Studio in colonna della percolazione di alcuni diserbanti residuali del mais.	Giornate Fitopatologiche 2006, Riccione (RN), 27-29 marzo 2006. Atti, volume primo (2006) , pp. 591-598.	The test design used does not fulfill the requirements of current test guidelines. Furthermore, the test was performed with a formulation and hence, the results are not useable for RA of ai
Chen, Baiyang; Lee, Wontae; Westerhoff, Paul K.; Krasner, Stuart W.; Herckes, Pierre	2010	Solar photolysis kinetics of disinfection byproducts	Water Research (2010), 44(11), 3401-3409	The article does not contain information related to the substance of concern
Chiaia-Hernandez, Aurea C.; Krauss, Martin; Hollender, Juliane	2013	Screening of Lake Sediments for Emerging Contaminants by Liquid Chromatography Atmospheric Pressure Photoionization and Electrospray Ionization Coupled to High Resolution Mass Spectrometry	Environmental Science and Technology (2013), 47(2), 976-986;	The article does not contain information related to the substance of concern, as flufenacet was not detected in any of the investigated sediment samples.

Author(s)	Year	Title	Source	Reason(s) for not including publication in dossier
Conte, E.; Rossi, E.; Spera, G.; Pompei, V.; Carfi, F.; Spadoni, A. R.; Rosati, M.; Montereali, M. R.; Donnarumma, L.; Perconti, W.	2003	Presence of plant protection products in three agricultural areas of Regione Lazio	Communications in Agricultural and Applied Biological Sciences (2003), 68(4b), 865-874	The observations made are based upon unknown exposure. Flufenacet was only found in soil of agricultural fields and not in water or air. However, it is not known at all if FFA was used since the agricultural uses were not reported.
Deon, Jessica C.; Hurley, Michael D.; Wallington, Timothy J.; Mabury, Scott A.	2006	Atmospheric Chemistry of N-methyl Perfluorobutane Sulfonamidoethanol, C ₄ F ₉ SO ₂ N(CH ₃)CH ₂ CH ₂ OH: Kinetics and Mechanism of Reaction with OH	Environmental Science and Technology (2006), 40(6), 1862-1868	The article does not contain information related to the substance of concern
Finizio, A.; Villa, S.; Vighi, M.	2005	Predicting pesticide mixtures load in surface waters from a given crop.	Agric., Ecosyst. Environ., Volume 111, Issue 1-4, Page 111-118, Publication Year 2005	The article does not contain information related to the substance of concern
Godejohann, Markus; Berset, Jean-Daniel; Muff, Daniel.	2011	Non-targeted analysis of wastewater treatment plant effluents by high performance liquid chromatography-time slice-solid phase extraction-nuclear magnetic resonance/time-of-flight-mass spectrometry.	J. Chromatogr., A, Volume 1218, Issue 51, Page 9202-9209, Publication Year 2011	The investigation does not report results in values reflecting agreed determinants for the hazard or exposure characterization or risk assessment under Reg. EC No 1107/2009. Flufenacet not in the supplementary list of analysed compounds
Gupta, Suman; Gajbhiye, Vijay T.	2002	Effect of concentration, moisture and soil type on the dissipation of flufenacet from soil	Chemosphere (2002), 47(9), 901-906	The article descr. 4 tests in total. Only 1 was conducted in style of current guidelines. Its results are in line with known results, not influencing the RA. The other tests were performed at extreme conditions & are therefore not reliable & not usable for RA
Hamilton, M. C.; Woudneh, M.; Grace, R.	2007	Analysis of current use pesticides in environmental and wastewater samples by high resolution GC with high resolution mass spectrometric detection.	Organohalogen Compd., Volume 69, Page 600/1-600/4, Publication Year 2007	The article does not contain information related to the substance of concern, as flufenacet was not detected in any of the investigated water samples and is therefore assessed as irrelevant.
Henne, S.; Shallcross, D. E.; Reimann, S.; Xiao, P.; Boulos, S.; Gerecke, A. C.; Brunner, D.	2012	Environmental impacts of HFO-1234yf and other HFOs	Moving Towards Sustainability, ASHRAE/NIST Refrigerants Conference, Gaithersburg, MD, United States, Oct. 29-30, 2012 (2012), 13/1-13/13.	The observation made is based upon a route of exposure that cannot be considered representative for the intended use of the substance of concern
Henne, Stephan [Reprint Author]; Shallcross, Dudley E.; Reimann, Stefan; Xiao, Ping; Brunner, Dominik; Odoherly, Simon; Buchmann, Brigitte	2012	Future Emissions and Atmospheric Fate of HFC-1234yf from Mobile Air Conditioners in Europe.	Environmental Science and Technology, (FEB 7 2012) Vol. 46, No. 3, pp. 1650-1658.	The observation made is based upon a route of exposure that cannot be considered representative for the intended use of the substance of concern

Xiang W (Reprint) Xiang J; Zhang J G; Wu F; Tang J H	2005	Geochemical transformation of trichloroacetic acid to chloroform in fresh waters - The results based upon laboratory experiments	WATER AIR AND SOIL POLLUTION, (NOV 2005) Vol. 168, No. 1-4, pp. 289-312. ISSN: 0049-6979.	The article does not contain information related to the substance of concern
Young, Cora J.; Hurley, Michael D.; Wallington, Timothy J.; Mabury, Scott A.	2009	Atmospheric chemistry of CF ₃ CF ₂ H and CF ₃ CF ₂ CF ₂ CF ₂ H: Kinetics and products of gas-phase reactions with Cl atoms and OH radicals, infrared spectra, and formation of perfluorocarboxylic acids	Chemical Physics Letters (2009), 473(4-6), 251-256	The article reports on chemical synthesis or development of methods for measurements of the chemical without its application to natural samples

In the second table – B.8.6_CA-2, are given the publications considered relevant by the Applicant after the detailed assessment and included into the documentation submitted for evaluation. As it was in case of the excluded publications, RMS presented only those publications that may be considered as addressing the issues related to the assessment of the environmental fate and behaviour according to the data requirements set by the Regulation (EC) 283/2013.

Table B.8.6_CA-2: Results of the “Detailed assessment” stage of the literature search – publications found relevant by the Applicant and included into the dossier (table reproduced from the Applicant’s report, modified by the RMS).

KCA - SANCO Data Point	KCP - SANCO Data Point	Author(s)	Year	Title	Source	Justification for classification of the publication
KCA 7.5. Monitoring data	KCP 9.2. Fate and behaviour in water and sediment	Bischoff, G.; Rodemann, B.; Pestemer, W.	2003	Entry of pesticides into surface waters - new results of the Lamspringe run-off monitoring project 1999-2001	Pesticide in Air, Plant, Soil and Water System, Proceedings of the Symposium Pesticide Chemistry, 12th, Piacenza, Italy, June 4-6, 2003 (2003), 849-856.	b) The literature describe findings of FFA in surface water from 1999-2001
KCA 7.5. Monitoring data		Frank, Hartmut; Christoph, Eugen H.; Holm-Hansen, Osmund; Bullister, John L.	2002	Trifluoroacetate in Ocean Waters	Environmental Science and Technology (2002), 36(1), 12-15.	b) Provides monitoring information in surface water (ocean), thus no change of endpoints.
KCA 7.5. Monitoring data		Scott B F; Macdonald R W; Kannan K; Fisk A; Witter A; Yamashita N; Durham L; Spencer C; Muir D C G	2005	Trifluoroacetate profiles in the Arctic, Atlantic, and Pacific Oceans.	Environmental Science and Technology, (2005 Sep 1) Vol. 39, No. 17, pp. 6555-6560.	b) Provides monitoring information in surface water (oceans); Contains information of anthropogenic and natural sources of TFA.

In light of the doubts related to the results of detailed assessment performed by the Applicant – Bayer CropSciences, RMS decided to repeat the literature search for Flufenacet, using the search criteria similar to those applied by the Applicant. The only difference was that the search was not limited to the last thirteen years predating the application (i. e. covering the period 2000 – 2013), but was broader, what enabled to find earlier or later publications, not found by the BCS. The repeated literature search for the degradation product TFA (trifluoroacetic acid) was not performed, because the information from the Applicant's report indicated that it may be considered thorough and exhaustive.

In case of the literature search for Flufenacet performed by RMS the following available literature data bases were used:

- Science Direct On Site – data base for Elsevier's publications (full texts) on ICM UW server;
- Science Direct On Line – data base for Elsevier's publications (full texts, including books and book chapters) on the editor's server;
- Springer – data base for Springer's publications (full texts) on ICM UW server;
- Springer link – data base for Springer's publication (full texts including books and book chapters) on the editor's server;
- Wiley – data base for Willey's publications (full texts) on the editor's server;
- ACS – data base for ACS publications (full texts) on the editor's server;
- EBSCOhost Web – search platform for grouping several more specialized scientific literature providers (e.g. Environment Complete, Academic Search Complete, Agricola, Medline), providing abstracts with the possible access to full texts;
- Environment Complete – search platform providing abstracts;
- SCOPUS – search platform providing abstracts with the possible access to full texts;
- Web of Science – data base for literature search, providing abstracts, on ICM UW server;
- Web of Science (Thomson Reuters) – search platform, providing abstracts, on the server of Thomson Reuters (service provider);
- Environmental Impact – data base for literature search, providing abstracts;

In case of EBSCOhost Web platform, the following data bases were selected for search:

- Environment Complete,
- Academic Search Complete,
- Agricola,
- Green File,
- Health source,
- Library, Information Science& Technology Abstracts,
- Masterfile Premium,
- Medline.

At the first step, the returned results – publications with its abstracts, were analysed for their potential relevance in the assessment of environmental fate and behaviour of Flufenacet and/or its degradation products. The results of the search at first step are summarised below.

The preliminary results of the search were following:

- **Science Direct On Site** returned 102 records, of which 16 were identified as potentially relevant and selected for further verification (further called **Science Direct on ICM UW**);
- **Science Direct On Line** returned 134 records, of which 17 were identified as potentially relevant and selected for further verification (further called **Science Direct – Elsevier**);
- **Springer data base on ICM UW server** returned same search results as Science Direct On Site, as Science Direct On Site is a common search engine for Elsevier and Springer; for that reason they are not presented here (further called **Springer on ICM UW**);
- **Springer link** returned 63 records, of which 13 were identified as potentially relevant and selected for further verification (further called **Springer link**);
- **Wiley data base** returned 90 records, of which 14 were identified as potentially relevant and selected for further verification (further called **Wiley**);
- **ACS data base** returned 49 records, of which 15 were identified as potentially relevant and selected for further verification (further called **ACS**);
- **EBSCOhost Web platform** returned initially 137 records, of which 78 were displayed after removal of the duplicates, and of which 15 were identified as potentially relevant and selected for further verification (further called **EBSCOhost**);
- **SCOPUS data base** returned 75 records, of which 15 were identified as potentially relevant and selected for further verification (further called **SCOPUS**);

- the data base **Web of Science – Thomson Reuters** returned 77 records, of which 19 were identified as potentially relevant and selected for further verification (further called **Web of Science**);
- the data base **Web of Science at ICM UW server** returned the same search results as cited above Web of Science – Thomson Reuters data base, so results obtained for this search engine were not further considered;
- **Environmental Impact** data base returned 67 records, of which 24 were identified as potentially relevant and selected for further verification (further called **Environmental Impact**);
- **Environment Complete** – data base consulted independently of EBSCOhost data base, it returned 41 records, of which 11 were identified as potentially relevant and selected for further verification (further called **Environment Complete**).

Additionally several smaller data bases were searched. These were:

- **Taylor and Francis Journals On-Line** – data base that returned 22 records, of which 1 was found relevant, but was also found elsewhere (further called **Taylor and Francis**);
- **Oxford Journals** webpage – the data base that returned 1 record, considered potentially relevant (further called **Oxford Journals**);
- **ASM (American Society for Microbiology)** webpage – the data base returned 2 records, considered potentially relevant (further called **ASM Journals**);
- **Journal of Environmental Quality** journal home page – returned 4 records, considered potentially relevant (further called **JEQ**);
- **Nature** journal webpage – no records meeting search criteria were returned;
- **Science** journal webpage – no records meeting search criteria were returned;
- **Freshwater Science** journal homepage – no records meeting search criteria were returned;
- **Lake and Reservoir Management** journal homepage – no records meeting search criteria were returned.

As a next step the results obtained from different data bases were compared and combined to identify the records that were repetitiously returned by them. The results are provided, in alphabetical order for the authors, in the table B.8.6_CA-3 below. The results were also compared to those identified by the Applicant as potentially relevant and selected for Step 2- detailed, assessment.

Table B.8.6_CA-3: The results of the literature search performed by the RMS – publications identified as potentially relevant in the area of environmental assessment and directed for the further assessment.

At that stage all publications potentially relevant in the area of the assessment of the impact on environment were considered without differentiation between those related to the assessment of fate and behaviour in the environment and those dealing with ecotoxicity of Flufenacet.

As a next stage RMS checked the availability of the full texts of the publications identified as potentially relevant in the area of the influence of Flufenacet on the Environment, including those found by the Applicant and listed in the table B.8.6_CA-2. In case of difficulties with gaining the access to the full texts the Applicant was asked for providing them (mainly if these were at his disposal) and/or the requests for the copies were sent to the corresponding authors.

Next the available full texts were checked for their relevance. At that stage the publications dealing mainly with ecotoxicological aspects of the influence of Flufenacet on environment were identified and checked for their relevance in the area of the assessment of environmental fate and behaviour, mainly with regard to the information on the determined concentrations in examined habitats (monitoring issues) or transformation patterns.

RMS decided, unlike the Applicant, not to reject the monitoring data coming from the USA and Canada. The justification for that is that although such results are not fully relevant to the situation in the EU, because of the well developed monitoring strategies they may be considered as supplementary and providing a sound insight of behaviour of Flufenacet in the environment and the risk it may pose to the various environmental compartments.

It shall be noted that the detailed assessment enabled the identification of several publications not previously found as potentially relevant, which were subsequently verified for their relevance for the assessment of flufenacet. These publications are listed below in the table B.8.6_CA-4.

Table B.8.6_CA-4: The list of publications found as a cross-reference resulting from the detailed examination of the potentially relevant publications.

No	Publication data	With cross-reference to the publication:
1	anon., "Final Report of Project WT1246- Understanding changes in pesticide usage to inform water company risk assessment.", DEFRA 2013, available: http://dwi.defra.gov.uk/research/completed-research/2000today.htm	No direct cross-reference – publication found as an additional when DEFRA site was scanned for additional potentially relevant publications
2	Baker N. T., Stone W. S., "Estimated Annual Agricultural Pesticide Use for Counties of the Conterminous United States, 2008 – 12.", US Geological Survey Data Series 907, 2015. available:	No direct cross-reference – publication found as an additional when USGS site was scanned for additional potentially relevant publications.

The results of the detailed examination of the relevance of the publications found is provided below in two tables. The first of them – table B.8.6_CA-5, lists the publications that were found not relevant by the RMS in course of the repeated literature search. For each publication non-included the rationale for its rejection is given, together with information, where reliable, whether RMS’s conclusions were similar to those drawn by the Applicant. The publications in that table, except those identified as potentially relevant and subsequently verified with regard to that, are presented in alphabetical order for their first author.

In the second table – B.8.6_CA-6 are listed the publications that RMS found relevant and included into the assessment. In that table the order of publications follows the SANCO data point in the assessment, for which they are considered relevant.

Table B.8.6_CA-5: Results of the “Detailed assessment” stage of the literature search performed by the RMS – publications not included into the RAR on the basis of their non-relevance.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
1	Barriuso E., Benoit P., Dubus I. G., “ <i>Formation of Pesticide Nonextractable (Bound) Residues in Soil: Magnitude, Controlling Factors and Reversibility.</i> ”; Environmental Science and Technology, 2008, 42 (6), 1845 – 1854.	Paper initially considered relevant as a supplementary study, helpful in concluding on the nature of NER fraction formed during transformation of Flufenacet in aerobic soil. However, careful examination of the publication showed that it contained very general conclusions, based rather on the results obtained for other active substances. Although the numerical results for Flufenacet with regard to the amount of bound residues formed from it were provided, these were taken from the EU registration report, therefore it was stated that the paper contained no new/adverse data for Flufenacet in this area. As a result, RMS changed the initial decision with regard to the relevance of the publication for the assessment of Flufenacet. The paper, as well as the supporting information, is available on request.	Not applicable – the paper not identified by the Applicant as potentially relevant.
2	Barron L., Brett P., “ <i>Determination of haloacetic acids in drinking water using suppressed micro-bore ion chromatography with soil phase extraction</i> ”; Analytica Chimica Acta 2004, 522, 153 – 161	Paper focuses mainly on the development and validation of the analytical method. Although it provides levels of TFA in drinking water as a final product of water abstraction plants, the source of that compound is different that considered in the assessment of flufenacet – TFA is a by product of the process of fluorination of treated water.	No , Applicant stated that findings were not related to a certain test system.
3	Bazoobandi M., Yaduraju N. T., Kulshrestha G., “ <i>Analysis of flufenacet in soil, wheat grain and straw by gas chromatography.</i> ”; Journal of Chromatography A, 2000, 886 (1-2), 319 – 322.	Paper focuses mainly on the development and validation of the analytical method that was not used by the Applicant. Also the paper provides no information on the results obtained with that method for natural not spiked samples	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern in the natural samples.
4	Bishop C. A., Ashpole S. L., Edwards M. A., van Aggelen G., Elliot J. E., “ <i>Hatching success and pesticide exposure in amphibians living in agricultural habitats of the South Okanagan Valley, British Columbia, Canada (2004 – 2006).</i> ”; Environmental Toxicology and Chemistry, 2010, 29 (7), 1593 – 1603.	Flufenacet was listed among the compounds of concern, with given LOD of 1.1 ng/L, but the concentrations measured in environment were not reported. Additionally, the SW exposure was determined in the ponds located in orchards, so not relevant for the proposed EU use pattern, and the application regime for flufenacet was not reported, so the paper is of little relevance for monitoring purposes. The relevance for the assessment in the area of ecotoxicology to be confirmed by the expert performing the evaluation.	Not applicable – the paper not identified by the Applicant as potentially relevant.
5	Boithias L., Sauvage S., Srinivasan R., Leccia O., Sánchez-Pérez J.-M., “ <i>Application date as a controlling factor of pesticide transfers to surface water during runoff events.</i> ”; Catena, 2014, 119 , 97 – 103.	Study did not contain any referenced to the compounds of interest – flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
6	Cedergreen N., Streiberg J. C., "The toxicity of herbicides to non-target aquatic plants and algae: assessment of predicted factors and hazard."; Pest Management Science, 2005, 61 (12), 1152 – 1160.	Paper contains no data related to the environmental fate and behaviour of Flufenacet. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	No , The justification for non-inclusion into the Dossier concerns the evaluation in the area of ecotoxicology with no reference to the assessment in the area of e-fate.
7	Chen B., Lee W., Westerhoff P. K., Krasner S. W., Herckes, P., "Solar photolysis kinetics of disinfection byproducts."; Water Research, 2010, 44 (11), 3401 – 3409.	Paper bears no reference to any compound of concern in the evaluation, in particular to TFA.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
8	Chiaia-Hernandez A. C., Krauss M., Hollender J., "Screening of Lake Sediments for Emerging Contaminants by Liquid Chromatography Atmospheric Pressure Photoionization and Electrospray Ionization Coupled to High Resolution Mass Spectrometry."; Environmental Science and Technology, 2013, 47 (2), 976 – 986.	Paper mainly focused on the developed analytical method. Flufenacet listed among the compounds of potential interest, but subsequently not listed among those screened for in the natural samples taken from the lake Greifensee.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern in the natural (sediment) samples.
9	Chowdhury A., Pradhan S., Saha M., Sanyal N., "Impact of pesticides on soil microbiological parameters and possible bioremediation strategies."; Indian Journal of Microbiology, 2008, 48 (1), 114 – 127.	Paper provides a reference to Flufenacet, but focuses on the general evaluation of the impact of pesticides on soil microflora, with emphasis on other pesticides, for instance 2,4-D.	Not applicable – the paper not identified by the Applicant as potentially relevant.
10	Conte, E., Rossi, E., Spera, G., Pompei, V., Carfi, F., Spadoni, A. R., Rosati, M., Montereali, M. R., Donnarumma, L., Perconti, W., "Presence of plant protection products in three agricultural areas of Regione Lazio."; Communications in Agricultural and Applied Biological Sciences, 2003, 68 (4b), 865-874	Study refers to the concentrations of Flufenacet in soils and water on examined areas, but does it in a general and rather qualitative than quantitative way. Additionally no history of the use of Flufenacet on the examined areas is provided.	Yes , Applicant gave the same rationale.
11	Cross P., Edwards-Jones G., "Variation in pesticide hazard from arable crop production in Great Britain from 1992 to 2008: an extended time-series analysis."; Crop Protection, 2011, 30 (12), 1579 – 1585.	Study did not contain any reference to the compounds of interest – flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.
12	D'Eon (Appl. Deon) J. C., Hurley M. D., Wallington, T. J., Mabury S. A., "Atmospheric Chemistry of N-methyl Perfluorobutane Sulfonamidoethanol, C ₄ F ₉ SO ₂ N(CH ₃)CH ₂ CH ₂ OH: Kinetics and Mechanism of Reaction with OH."; Environmental Science and Technology, 2006, 40 (6), 1862 – 1868.	TFA was identified as a terminal product within a transformation scheme, with no further assessment of its fate and behaviour in the environment	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
13	De Schamphelleire M., Sopanoghe P., Brusselman E., Sonck S., <i>"Risk assessment of pesticide spray drift damage in Belgium."</i> ; Crop Protection, 2007, 26 (4), 602 – 611.	Flufenacet was not an active substance examined in detail. The spray drift-related risk for use of flufenacet was examined for its application on potatoes – crop not listed in the EU-representative use pattern.	Not applicable – the paper not identified by the Applicant as potentially relevant.
14	Delcour I., Spanoghe P., Uyttendaele M., <i>"Literature review: Impact of climate change on pesticide use."</i> ; Food Research International, 2015, 68 (complete), 7 – 15.	Paper presents in general the factors influencing the use pattern of plant protection products and changes in it, but with no reference to any specific PPP.	Not applicable – the paper not identified by the Applicant as potentially relevant.
15	Devos Y., Cougnon M., Vergucht S., Bulcke R., Haesaert G., Steurbaut W., Reheul D., <i>"Environmental impact of herbicide regimes used with genetically modified herbicide-resistant maize."</i> ; Transgenic Research, 2008, 17 (6), 1059 – 1077.	The publication does not contain any information on the environmental fate and behaviour of Flufenacet. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Not applicable – the paper not identified by the Applicant as potentially relevant.
16	Dolan T., Parsons D. J., Howsam P., Whelan M. J., Varga L., <i>"Identifying Adaptation Options and Constraints: The role of Agronomist Knowledge in Catchment Management Strategy."</i> , Water Resources Management, 2014, 28 (2), 511 – 526.	Study did not contain any referenced to the compounds of interest – flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.
17	Fay E., Flynn J., Lundehehn J. R., Chapman P. J., Mason R. D., <i>"The Joint Evaluation Procedure for Active Substances contained in Plant Protection Products within the European Community – 10 Years of the ECCO-Project."</i> ; Journal für Verbraucherschutz und Lebensmittelsicherheit, 2007, 2 (1), 61 – 77.	Paper characterizes the activities of ECCO Project during the period of its functioning. It provides a reference to Flufenacet, but very general and not in the area of its environmental fate and behaviour.	Not applicable – the paper not identified by the Applicant as potentially relevant.
18	Finizio A., Villa S., Vighi M., <i>"Predicting pesticide mixtures load in surface waters from a given crop."</i> ; Agriculture, Ecosystems and Environment, 2005, 111 (1-4), 111 – 118	Paper presents the results of the assessment of risk to the freshwater organisms resulting from the use of the mixtures various pesticides in maize. The assessment was based on the determination of the PEC values and their use in the determination of the risk factors for algae, aquatic invertebrates represented by Daphnia spp. and fish. Flufenacet was one of the compounds of concern and the PEC values for it were determined, however their utility, and hence the paper as such, for the current assessment was low, because the modelling approach was different from that currently used in the EU for regulatory purposes.	No – the Applicant stated that the paper did not contain any reference to the substance of concern – Flufenacet.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
19	Fohrer N., Dietrich A., Kolychalov O., Ulrich U., "Assessment of the Environmental Fate of the Herbicides Flufenacet and Metazachlor with the SWAT Model."; Journal of Environmental Quality, 2014, 43 (1), 75 – 85.	The publication presents the results of the model estimation of the concentrations of Flufenacet in water of a small river. The calculations were performed for an existing, well characterised catchment located within the EU – Kielstau watershed, and it was validated against the experimental data obtained for that catchment, however these data were not presented. Instead were briefly characterised the results of the modelling exposure assessment obtained using the modelling tool alternative to that used in the regulatory process in the EU – SWAT model. For that reason, after careful examination of the publication, RMS decided to classify it as not relevant.	Not applicable – the paper not identified by the Applicant as potentially relevant.
20	Forest K., Rayne S., "Congener-specific organic carbon-normalized soil and sediment-water partitioning coefficients for the C1 through C8 perfluoroalkyl carboxylic and sulfonic acids."; Journal of Environmental Science and Health, Part A: Toxic/Hazardous Substances and Environmental Engineering, 2009, 44 (13), 1374 – 1387.	Paper provides the values for TFA, but these are determined using QSAR, so of limited utility for regulatory purposes, unless no corresponding measurable values are provided.	Yes, Applicant also indicated the problem of the similar nature.
21	Fujiwara T., O'Hagan D., "Successful fluorine-containing herbicide agrochemicals."; Journal of Fluorine Chemistry, 2014, 167 (complete), 16 – 29.	Publication presents the mechanism of synthesis of various fluorinated active substances of the Plant Protection Products. Authors indicated that the described mechanisms may not be those used by the industry. Publication bears no reference to the environmental fate and behaviour of Flufenacet.	Not applicable – the paper not identified by the Applicant as potentially relevant.
22	Gajbhiye V. T., Gupta S., Agnihotri N. P., "Gas liquid chromatographic method of analysis for a herbicide flufenacet (FOE 5043)."; Pesticide Research Journal, 2000, 12 (1), 41 – 47.	Paper focuses mainly on the development and validation of the analytical method that was not used by the Applicant. Also the paper provides no information on the results obtained with that method for natural not spiked samples	Yes, Applicant also indicated that the paper did not contain the information related to the substance of concern in the natural samples.
23	Gassman P. W., Sadeghi A. M., Srinivasan R., "Applications of the SWAT Model Special Section: Overview and Insights."; Journal of Environmental Quality, 2014, 43 , 1 – 8.	The paper presents the concept and applicability of the novel modelling tool – SWAT. It was initially selected as a supplementary study, supporting selected the assessment presented in the literature study by [Fohrer et al., 2014], also finally not included in the assessment.	Not applicable – the paper not identified by the Applicant as potentially relevant.
24	Gilliom R. J., Barbash J. E., Crawford C. G., Hamilton P. A., Martin J. D., Nakagi N., Nowell L. H., Scott J. C., Stackelberg P. E., Thelin G. P., Wolock D. M., "Quality of Our Nation's Waters. Pesticides in the Nation's Streams and Ground Water, 1992 – 2001."; USGS Circular 1291, 2006, US Geological Survey 2007 (revised version 15 February 2007).	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
25	Godejohann M., Berset. J.-D., Muff D., "Non-targeted analysis of wastewater treatment plant effluents by high performance liquid chromatography-time slice-solid phase extraction-nuclear magnetic resonance/time-of-flight-mass spectrometry."; Journal of Chromatography, A, 2011, 1218 (51), 9202 – 9209.	Paper focuses on the development and validation of the analytical procedure for determining the micropollutants in WWTP effluents. Although Flufenacet was one of the target compounds, as indicate the data presented in the supplement, and it was found in the effluents, the data, because of their qualitative rather than quantitative nature are difficult in interpretation.	Yes , Applicant also indicated the problem of the similar nature.
26	Greulich K. Alder L., "Fast multiresidue screening of 300 pesticides in water for human consumption by LC-MS/MS."; Analytical and Bioanalytical Chemistry, 2008, 391 (1), 183 – 197.	The publication focused totally on the development and validation of the analytical method for determination of the active substances of plant protection products in water samples. Although flufenacet was one of the test compounds, the publication was considered not valid, as it provided no results of the examination of natural, not spiked, samples.	Not applicable – the paper not identified by the Applicant as potentially relevant.
27	Guy M., Singh M., Mineau P., "Using field data to assess the effects of pesticides on crustacean in freshwater aquatic ecosystems and verifying the level of protection provided by water quality guidelines."; Integrated Environmental Assessment and Management, 2011, 7 (3 – special issue: Challenges Posed by Radiation and Radionuclide releases to the Environment), 426 – 436.	The publication does not contain any information on the environmental fate and behaviour of Flufenacet. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Not applicable – the paper not identified by the Applicant as potentially relevant.
28	Hanson M. L., Sibley P. K., Mabury S. A., Muir D. C., Solomon K. R., "Chlorodifluoroacetic acid fate and toxicity to the macrophytes Lemna gibba, Myriophyllum spicatum and Myriophyllum sibiricum in aquatic microcosm."; Environmental Toxicology and Chemistry, 2001, 20 , 2758 – 2767.	The publication does not contain any information on the environmental fate and behaviour of Flufenacet. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Not applicable – the paper not identified by the Applicant as potentially relevant.
29	Hanson M. L., Solomon K. R., "New technique for estimating thresholds of toxicity in ecological risk assessment."; Environmental Science and Technology, 2002, 36 (15), 3257 – 3264.	Publication focuses on the determination of the risk for aquatic plants with no reference to the concentrations measured in the environment. Additionally, the test substance was MCA and not TFA – the compound of concern. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
30	Hanson M., Sibley P. K., Ellis D. A., Fineberg N. A., Mabury S. A., Salomon K. R., Muir D. C., "Trichloroacetic acid fate and toxicity to the macrophytes Myriophyllum spicatum and Myriophyllum sibiricum under field conditions."; Aquatic Toxicology, 2002, 56 , 241 – 255;	The publication not relevant because it deals with TCA, not TFA – compound of concern being the metabolite of Flufenacet. However it provided a cross-reference to two other papers dealing with fate and behaviour of TFA in water, which were in turn checked for their relevance in the assessment. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
31	Hanson M., Sibley P. K., Ellis D. A., Mabury S. A., Muir D. G. C., Salomon K. R., "Evaluation of monochloroacetic acid (MCA) degradation and toxicity to Lemna gibba, Myriophyllum spicatum and Myriophyllum sibiricum in aquatic microcosm."; Aquatic Toxicology, 2002, 56 , 241 – 255;	The publication not relevant because it deals with MCA, not TFA – compound of concern being the metabolite of Flufenacet. However it provided a cross-reference to other papers dealing with fate and behaviour of TFA in water, which were in turn checked for their relevance in the assessment. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
32	Hanson M. L., Sibley P. K., Mabury S. A., Muir D. C. G., Solomon K. R., "Field level evaluation and risk assessment of the toxicity of dichloroacetic acid to the aquatic macrophytes Lemna gibba, Myriophyllum spicatum, and Myriophyllum sibiricum."; Ecotoxicology and Environmental Safety, 2003, 55 (1), 46 – 63.	The publication not relevant because it deals with DCA, not TFA – compound of concern being the metabolite of Flufenacet. However it provided a cross-reference to other papers dealing with behaviour of TFA in water nad its ecotoxicity. The relevance for the assessment in the area of ecotoxicology to be conformed by the expert performing the evaluation.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
33	Harris K. A. Dangerfield N., Woudneh M., Brown T., Verrin S., Ross P. S., "Partitioning of current-use and legacy pesticides in salmon habitat in British Columbia, Canada."; Environmental Toxicology and Chemistry, 2008, 27 (11), 2253 – 2262.	The impact of 80 active substances was examined. Flufenacet was among 19 active substances considered under the general name "others", not included into the top 10 active substances for which the detailed assessment was performed. The reason for that was not clear, as the LOD was not reported. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	No , Applicant also indicated that the paper did not contain the information related to the substance of concern.
34	Henne S., Shallcross D. E., Reimann S., Xiao P., Brunner D., O' Doherty S., Buchmann B., "Future Emissions and Atmospheric Fate of HFC-1234yf from Mobile Air Conditioners in Europe."; Environmental Science and Technology, 2012, 46 (3), 1650 – 1658.	The publication presents the estimated levels of concentration of TFA in air over Europe and its deposition with precipitation. The estimations were performed for the estimated levels of emission of various HFCs and HCFCs to the atmosphere, therefore its utility is limited. Additionally, these results, together with the measured amounts of TFA in different environmental compartments, were presented in another publication by the same research team.	Yes , Applicant also indicated the problem of the similar nature.
35	Hillocks R. J., "Farming with fewer pesticides: EU pesticide review and resulting challenges for UK agriculture."; Crop Protection, 2012, 31 (1), 85 – 93.	The publication contains a reference to flufenacet only with regard to its current and future use, but does not deal with any environmental issue related to it.	Not applicable – the paper not identified by the Applicant as potentially relevant.
36	Hurley M. D., Wallington T. J., Sulbaek Andersen M. P., Ellis D. A., Martin J. W., Mabury S. A., "Atmospheric Chemistry of Fluorinated Alcohols: Reaction with Cl Atoms and OH Radicals and Atmospheric Lifetimes."; Journal of Physical Chemistry, A, 2004, 108 (11), 1973 – 1979.	Paper deals with perfluorinated alcohols and no reference in it was made to TFA – the compound of concern in the assessment for Flufenacet.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
37	Jähniq S. C., Kuemmerlen M., Kiesel J., Domisch S. Cai Q., Schmalz B., Fohrer N., <i>"Modelling of riverine ecosystems by integrating models: conceptual approach, a case study and research agenda."</i> ; Journal of Biogeography, 2012, 39 (12), 2253 – 2263.	The publication presents the results of the model estimation of the concentrations of Flufenacet in water of a small river. The calculations were performed for an existing, well characterised catchment located within the EU – Kielstau watershed. It presents the results of the modelling obtained using the modelling tool alternative to that used in the regulatory process in the EU – SWAT model. It was selected as a supplementary data supporting the assessment presented in the literature study by [Fohrer et al., 2014], also finally not included in the assessment.	Not applicable – the paper not identified by the Applicant as potentially relevant.
38	Kannan K., Ridal J., Sturges J., <i>"Pesticides in the Great Lakes."</i> ; The Handbook of Environmental Chemistry, Volume 5N – Persistent Organic Pollutants in the Great Lakes, 2006, 151 – 199 (book chapter).	Publication contains the reference to Flufenacet and its major degradates, but none of the compounds of concern was a subject of more extensive examination.	Not applicable – the paper not identified by the Applicant as potentially relevant.
39	Katagi T., <i>"Behaviour of Pesticides in Water-Sediment systems."</i> ; Reviews in Environmental Contamination and Toxicology, 2006, 187 , 133 – 251 (book chapter)	Publication provides the detailed information on the transformation of Flufenacet in water/sediment system, but these data are taken from the Assessment Report prepared for the first authorisation of that compound in the EU.	Not applicable – the paper not identified by the Applicant as potentially relevant.
40	Klaus J., Zehe E., Elsner M., Palm J. Schneider D., Schröder B., Steinbeiss S., van Schaik L., West S., <i>"Controls of event-based pesticide leaching in natural soil: a systematic study based on replicated field scale irrigation experiments."</i> ; Journal of Hydrology, 2014, 512 (complete), 528 – 539.	The usefulness of the publication for the regulatory purposes was limited, even though Flufenacet was one of the test compounds, as it mainly focused on the factors influencing the movement of the test compounds through the soil profile to the drainage system on the test field. It could only be used as conformatory for the SW modelling, conforming the relevance of drainage as migration route of Flufenacet to Sw bodies.	Not applicable – the paper not identified by the Applicant as potentially relevant
41	Kolpin D., Battaglin W. A., Conn K. E., Furlong E. T., Glassmeyer S. T., Kalkhoff S. J., Meyer M. T., Schnoebelen D. J., <i>"Occurrence of Transformation Products in the Environment."</i> ; Handbook of Environmental Chemistry Volume 2P – Transformation Products of Synthetic Chemicals in the Environment, 2009, 83 – 100 (book chapter).	Publication as such is of the limited relevance, but it provides several cross-references to other relevant publications.	Not applicable – the paper not identified by the Applicant as potentially relevant.
42	Kuster M., López de Alda M., Barceló D., <i>"Liquid chromatography-tandem mass spectrometric analysis and regulatory issues of polar pesticides in natural and treated waters."</i> ; Journal of Chromatography A, 2009, 1216 (3), 520 – 529.	The publication focused totally on the development and validation of the analytical method for determination of the active substances of plant protection products in water samples. The substances of concern were those registered in the EU up to 2008, so flufenacet was included. However, it provided no results of the examination of natural, not spiked, samples.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
43	Lechelt-Kunze C., Meissner R. C., Drewes M., Tietjen, K., <i>"Flufenacet herbicide treatment phenocopies the fiddlehead mutant in Arabidopsis thaliana."</i> ; Pest Management Science, 2003, 59 (8), 847 – 856.	Paper contains no data related to the environmental fate and behaviour of Flufenacet. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	No , The justification for non-inclusion into the Dossier concerns the evaluation in the area of ecotoxicology with no reference to the assessment in the area of e-fate.
44	Lifongo L. L.; Bowden D. J., Brimblecombe. P., <i>"Photodegradation of haloacetic acids in water."</i> ; Chemosphere, 2004, 55 (3), 467 – 476.	Paper bears no reference to any compound if concern in the evaluation, in particular to TFA.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
45	Loos M., Krauss M., Fenner K., <i>"Pesticide Nonextractable Residue Formation in Soil: Insights from Inverse Modeling of Degradation Time Series."</i> ; Environmental Science and Technology, 2012, 46 (18), 9830 – 9837.	Paper provides information with regard to the mechanisms of formation of NER in soil for several compound, but flufenacet was not among them.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
46	Mabury, Scott A.; <i>"Redefining persistence - Fluorinated pollutants in the environment"</i> ; Proceedings of the Biennial International Conference on Monitoring and Measurement of the Environment, 4th, Toronto, ON, Canada, May 27-30, 2002 (2002), 35-40.	Paper informs in a very general way about the mechanisms of the formation of TFA that reaches the environment, but with no reference to the active substances of the Plant Protection Products as its potential source.	Yes , Applicant also indicated that the paper did not contain the information related to the evaluated route of exposure.
47	Machefer G., <i>"Alternatives to isoproturon-based products for the control of grasses and broad-leaved weeds in cereals."</i> (<i>"Alternative Lösungen zu Isoproturon-haltigen Produkten bei der Ungras- und Unkrautbekämpfung in Getreide."</i>); Zeitschrift für Pflanzenkrankheiten und Pflanzenschutz, 2000, Sonderh. 17 , 501 – 508.	Paper deals with the determination of the efficacy of the Plant Protection Products that could be considered the replacements for isoproturon-based herbicides. Flufenacet was one of the examined active substances, used in combination with diflufenican. Paper provides no reference to the environmental fate and behaviour of Flufenacet.	Yes, partly ; Applicant stated that the article reported "effects on organisms considered as such target organisms".
48	Martin J. W., Franklin J., Hanson M. L., Solomon K. R., Mabury S. A., Ellis D. A., Scott B. F., Muir D. G. C., <i>"Detection of Chlorodifluoroacetic Acid in Precipitation: A Possible Product of Fluorocarbon Degradation."</i> ; Environmental Science and Technology, 2000, 34 , 274 – 281.	Paper provided information on the behaviour of TFA in natural water and its sources in the atmosphere, but these were rather references to other publications. Instead it focused mainly on other haloacetic acid – chlorodifluoroacetic acid. As a result, RMS, after thorough examination of the publication decided that it was not relevant for the present assessment.	Not applicable – the paper not identified by the Applicant as potentially relevant. By RMS it was identified as potentially relevant by means of cross-reference.
49	Meffe R., de Bustamante I., <i>"Emerging organic contaminants in surface water and groundwater: A first overview of the situation in Italy."</i> ; Science of the Total Environment, 2014, 481 (complete), 280 – 295.	Paper informs that monitoring concerned 137 active substances, of which 79 were herbicides, but Flufenacet was not listed among them.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
50	Milan M., Ferrero A., Letey M., DePalo F., Vidotto F., "Effect of buffer strips and soil texture on runoff losses of flufenacet and isoxaflutole from maize fields."; Journal of Environmental Science and Health, Part B – Pesticides, Food Contaminants & Agricultural Wastes, 2013, 48 (12), 1021 – 1033.	The paper was aimed on the examination of the efficiency of vegetated buffer stripes of variable size and the way of preparation of the seedbed on in reducing runoff from maize fields. Some key parameters, enabling the appropriate interpretation of the results, such as exact application rates and timing, were missing.	Yes , the justification for rejection provided by the Applicant was similar.
51	Müller M., Mentel M., van Hellemond J. J., Henze K., Woehle A. G. M., Martin W. F., "Biochemistry and Evolution of Anaerobic energy Metabolism in Eukaryotes."; Microbiology and Molecular Biology Reviews, 2012, 76 (2), 444 – 495.	Publication contains no reference to either Flufenacet or any of its transformation products. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.
52	Nilsson, E. J. K.; Nielsen, O. J.; Johnson, M. S.; Hurley, M. D.; Wallington, T. J., "Atmospheric chemistry of cis-CF ₃ CH=CHF: Kinetics of reactions with OH radicals and O ₃ and products of OH radical initiated oxidation."; Chemical Physics Letters, 2009, 473 (4-6), 233 – 237.	Paper bears no reference to any compound of concern in the evaluation, in particular to TFA.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
53	Osteen C. D., Fernandez-Cornejo J., "Economic and Policy issues of U.S. agricultural pesticide use trends."; Pest Management Science, 2013, 69 (9), 1001 – 1025.	Although publication contains few references to Flufenacet, they are not in the area of its environmental fate and behaviour, because that was not the aim of the paper.	Not applicable – the paper not identified by the Applicant as potentially relevant.
54	Paci F., Bartolini D., Rapparini G., "Residual effects of various herbicides on wheat after vegetables." ("Effetti residui di diversi erbicidi su frumento dopo orticole."); Informatore agrario, 2002, 58 (32), 71 – 74.	Paper focuses on the determination of the phytotoxicity of the residues of Plant Protection Products in soil on the succeeding crops. Flufenacet was one of the tested active substances, but it was used as a part of the mix formulation, consisting of Flufenacet and Metribuzin or Flufenacet, Metribuzin and Pendimethalin – the combination not being the subject of the current evaluation. Additionally, no data were provided for the tested mix formulations	Not applicable – the paper not identified by the Applicant as potentially relevant.
55	Paris P., Citro L., Di Carlo E., Maschio G., Pace E., Ursino S., "Rapporto nazionale pesticidi nelle acque, dati 2009 – 2010."; ISPRA Rapporti 175/2013, ISPRA Roma, Italy, 2013.	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.
56	Paris P., Biscceglie S., Maschio G., Pacer E., Parisi Pressice D., Ursino S., "Rapporto nazionale pesticidi nelle acque, dati 2011 – 2012."; ISPRA Rapporti 208/2014, ISPRA Roma, Italy, 2014.	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
57	Park H., Vecitis C. D., Cheng J., Choi W., Mader B. T., Hoffmann M. R., "Reductive Defluorination of Aqueous Perfluorinated Alkyl Surfactants: Effects of Ionic Headgroup and Chain Length."; Journal of Physical Chemistry, A, 2009, 113 (4), 690 – 696.	Contains no reference to the compound of concern – TFA.	No , the provided rationale stressed on the lack of the values relevant in light of the Regulation EC 1107/2009.
58	Parker D. C., Simmons F. W., Wax L. M., "Fall and Early Preplant Application Timing Effects on Persistence and Efficacy of Acetamide Herbicides."; Weed Technology, 2005, 19 (1), 6 – 13.	The paper presented the results of the efficacy testing for several active substances applied in autumn, including Flufenacet. The compound was applied as a combined formulation containing also metribuzin. Although the persistence of the test compounds in soil was examined, by measuring their concentrations at different time points after application, that was not done for Flufenacet. As a result, it was stated that the publication did not contain any information related to the environmental fate and behaviour of Flufenacet.	Not applicable – the paper not identified by the Applicant as potentially relevant.
59	Perreau F., Einhorn J., "Determination of frequently detected herbicides in water by solid-phase microextraction and gas chromatography coupled to ion-trap tandem mass spectrometry."; Analytical and Bioanalytical Chemistry, 2006, 386 (5), 1449 – 1456.	The publication focused totally on the development and validation of the analytical method for determination of the active substances of plant protection products in water samples. Although flufenacet was one of the test compounds, the publication was considered not valid, as it provided no results of the examination of natural, not spiked, samples.	Yes , Applicant also indicated that the publication also focused on the characterisation of the newly developed analytical method.
60	Pfannerstill M., Guse B., Fohrer N., "A multi-storage groundwater concept for the SWAT model to emphasize nonlinear groundwater dynamics in lowland catchments."; Hydrological Processes, 2014, 28 (12), 5599 – 5612.	Paper was focused on the performance of SWAT model with no reference to any specific compound.	Not applicable – the paper not identified by the Applicant as potentially relevant.
61	Postigo C., Barceló D., "Synthetic organic compounds and their transformation products in groundwater: Occurrence, fate and migration."; Science of the Total Environment, 2015, 503 – 504 (complete), 32 – 47.	Publication provides the concentrations of the two degradation products of Flufenacet – M2 and FOE OXA, in GW compartment, but with no additional information. There is however a reference to the source study, which was consulted for its relevance.	Not applicable – the paper not identified by the Applicant as potentially relevant.
62	Renner R., "A tale of two fish."; Environmental Science and Technology, 2008, 42 (18), 6784 – 6785.	Paper not relevant as it bears no reference to Flufenacet or any of its degradation products. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern
63	Roberti R., Badiali F., Pisi A., Veronesi A., Pancaldi D., Cesari A., "Sensitivity of <i>Clonostachys rosea</i> and <i>Trichoderma</i> spp. As potential biocontrol agents to pesticides."; Journal of Phytopathology, 2006, 154 (2), 100 – 109.	Paper contains no data related to the environmental fate and behaviour of Flufenacet. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	No , The justification for non-inclusion into the Dossier concerns the evaluation in the area of ecotoxicology with no reference to the assessment in the area of e-fate.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
64	Robles-Molina J., Lara-Ortega F. J., Gilbert-López B., García-Reyes J. F., Molina-Díaz A., "Multi-residue method for the determination of over 400 npriority and emerging pollutants in water and wastewater by solid-phase extraction and liquid chromatography-time-of-flight mass spectrometry."; Journal of Chromatography A, 2014, 1350 , 30 – 43.	The publication focused totally on the development and validation of the analytical method for determination of the active substances of plant protection products in water samples. Although flufenacet was one of the test compounds, the publication was considered not valid, as it provided no results of the examination of natural, not spiked, samples.	Not applicable – the paper not identified by the Applicant as potentially relevant.
65	Ryberg K. R., Vecchia A. V., Martin J. D., Gilliom R. J., "Trends in Pesticide Concentrations in Urban Streams in the United States, 1992 – 2008."; US Geological Survey Scientific Investigations Report 2010-5139, 2010.	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.
66	Ryberg K. R., Vecchia A. V., Gilliom R. J., Martin J. D., "Pesticide Trends in Major Rivers of the United States, 1992 – 2010."; US Geological Survey Scientific Investigations Report 2014-5135, 2014.	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.
67	Schulte-Oehlmann U., Oehlmann J., Keil F., "Before the Curtain Falls: Endocrine-active Pesticides – a German Contamination Legacy."; Reviews of Environmental Contamination and Toxicology, 2011, 213 , 137 – 159 (book chapter).	Paper provides very limited relevant information for Flufenacet in the area of its environmental fate and behaviour – it was only stated that, being one of the compounds of concern of Germany with regard to its relevance for water pollution control, it was detected in Surface Water, but displayed no endocrine disruption activity.	Not applicable – the paper not identified by the Applicant as potentially relevant.
68	Scott B. F., Spencer C., Martin J. W., Barra R., Bootsma H. A., Jones K. C., Johnston A. E., Muir D. C. G., "Comparison of Haloacetic Acids in the Environment of the Northern and Southern Hemispheres."; Environmental Science and Technology, 2005, 39 (22), 8664 – 8670.	The publication provided the data on the distribution of various haloacetic acids, including TFA in selected environmental matrices of selected countries. One of them was the UK. However, the potential sources of TFA in examined environmental matrices were not identified. For the paper it is also not fully clear what soils (agriculturally used or others) were examined, what limits the publication's utility	Yes , Applicant gave the similar rationale.
69	Scott C., Pandey G., Hartley C. J., Jackson C. J., Cheesman M. J., Taylor M. C., Pandey R., Khurena J. L., Teese M., Coppin Weir K. M., Jain R. K. Lal R., Russel R. J., Oakeshott J. G., "The enzymatic basis for pesticide bioremediation."; Indian Journal of Microbiology, 2008, 48 , 65 – 79.	Publication provides the information on the mode of action of several enzymes and classes of enzymes catalysing the transformation of the active substances of Plant Protection Products, but it contains no specific reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
70	Simončič A., Sušin J., Baša-Česnik H., Bolta Š. V., Gregorčič A., Vrščaj B., "The investigation of agricultural soil pollution in groundwater protection areas of Ljubljana Municipality by plant protection products from 2005 to 2010." („Spremljanje onesnaženosti kmetijskih zemljišč no vodovarstvenih območjih v Mestni občini Ljubljana med leti 2005 in 2010."); Zbornik Predavanj Referatov, 10, Slovenskega Posvetovanja o Varstvu Rastlin, Podčetrtek, Slovenia, 1.-2. Marec 2011, 2011, 157 – 163.	Flufenacet was one of the examined compounds, but no results were presented for it or any other individual compound under examination	Not applicable – the paper not identified by the Applicant as potentially relevant.
71	Singh K. P., Gupta S., Basat N., Mohan N., "QSTR Modelling for Qualitative and Quantitative Toxicity Predictions of Diverse Chemical Pesticides in Honey Bee for Regulatory Purposes."; Chemical Research in Toxicology, 2014, 27 (9), 1504 – 1515.	Study not relevant as it bears no reference to the assessment in the area of environmental fate and behaviour. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.
72	Steckel L. E., Simmons W. F., Sprague C. L., "Soil Factor Effects on Tolerance of Two Corn (<i>Zea mays</i>) Hybrids to Isoxaflutole Plus Flufenacet."; Weed Technology, 2003, 17 (3), 599 – 604,	Paper presented the results of the examination of the phytotoxicity of Flufenacet to maize, also in relation to some soil properties. However the experiment was performed not for Flufenacet alone, but for its combined formulation – with isoxaflutole. Publication contained no reference to the environmental fate and behaviour of Flufenacet.	Not applicable – the paper not identified by the Applicant as potentially relevant.
73	Stone W. W., Gilliom R. J., Martin J. Q., "An Overview Comparing Results from Two Decades of Monitoring for Pesticides in the Nation's Streams and Rivers, 1992 – 2001 and 2002 – 2011."; US Geological Survey Scientific Investigation Report 2014-5154, 2014.	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.
74	Stuart M., Lapworth D., Crane E., Hart A., "Review of risk from potential emerging contaminants in UK groundwater."; Science of the Total Environment, 2012, 416 (complete), 1 – 21.	Paper contains no data related to the environmental fate and behaviour of Flufenacet. It provides however the cross-reference to other publications that were checked for their relevance.	Not applicable – the paper not identified by the Applicant as potentially relevant.
75	Tallevi G., Rapparini G., "New ideas emerging from COLUMA '98" ("Le novità emerse al COLUMA '98."); Informatore Fitopatologico, 1999, 49 (7/8), 32 – 39;	Paper contains reference to Flufenacet as newly developed herbicide to be used in cereals, maize, soya and some other crops, but no data related to the environmental fate and behaviour of Flufenacet.	Not applicable – the paper not identified by the Applicant as potentially relevant.
76	Toccalino P. L., Gilliom R. J., Lindsey B. D., Rupert M. D., "Pesticides in Groundwater of the United States: Decadal –Scale Changes, 1993 – 2011."; Groundwater, 2014, 52 (Focus Issue), 112 – 125.	Paper does not contain any reference to Flufenacet or any of its degradation products.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
77	Truong L., Reif D. M., St Mary L., Geier M. C., Truong H. D., Tanguay R. L., "Multidimensional In Vivo Hazard Assessment using Zebra Fish."; Toxicological Sciences, 2014, 137 (1), 212 – 233.	Paper contains no data related to the environmental fate and behaviour of Flufenacet. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.
78	Tsai W.-T., "Environmental hazards and health risk of common liquid perfluoro-n-alkanes, potent greenhouse gases."; Environment International, 2009, 35 (2), 418 – 424	Study is not relevant as it deals mainly with perfluoro-n-alkanes and not their carboxylic acids. Although they are considered as potential precursors of TFA and other perfluorinated carboxylic acids in the atmosphere little is said about the impact of the latter on the environment. Additionally no numerical data are given on the global emissions of perfluoroalkanes into atmosphere and their turnover rates to carboxylic acids.	Yes , Applicant indicated that observations were made for exposure route not representative for the intended use of the compound of concern.
79	Tsai W.-T., "Environmental property modeling of perfluorodecalin and its implications for environmental fate and hazards"; Aerosol and Air Quality Research, 2011, 11 (7), 903 - 907;	Compound of concern is perfluorodecalin – fluoroinated alkane with C ₁₀ chain. The compound is considered to be a potential precursor of TFA – compound of concern in the atmosphere, but its contribution to formation of TFA is estimated to be minimal , as expected concentrations in air are <0.1 ppt.	Yes , Applicant indicated that observations were made for exposure route not representative for the intended use of the compound of concern.
80	Tucci S., Vacula R., Krajcovic J., Proksch P., Martin W., "Variability of Wax Ester Fermentation in Natural and Bleached Euglena gracilis Strains in Response to Oxygen and the Elongase Inhibitor Flufenacet."; Journal of Eukaryotic Microbiology, 2010, 57 (1), 63 – 69.	The paper contains no information related to the fate and behaviour of Flufenacet in the environment. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.
81	Ulrich U., Schulz F., Hugenschmidt C., Fohrer N., "Comparing measurements of herbicides lossess on three different scales." ("Vergleichende Messungen zu Herbizidaustragen auf drei unterschiedlichen Größenskalen."); Hydrologie und Wasserbewirtschaftung, 2012, 56 (4), 215 – 228.	The paper should be considered as relevant, in the area of monitoring, for the purpose of the current assessment. It shall however be indicated that only its abstract and the headings of tables and figures are in english, while the body text is in German. That was the limiting factor with regard to the possibility of verifying its relevance for the assessment. For that reason, although it provides relevant results, RMS decided not to include it into the list of the relevant publications.	Not applicable – the paper not identified by the Applicant as potentially relevant.
82	Ulrich U., Zeiger M., Fohrer N., "Soil structure and herbicide transport on soil surfaces during intermittent artificial rainfall."; Zeitschrift fur Geomorphologie, 2013, 57 Supplement 1, 135 – 155.	The paper examines the run-off of Flufenacet on a laboratory scale – the design of the study is not realistic, therefore of limited utility for the regulatory purpose.	Yes , the reasons for the non-relevance of the paper given by the Applicant were the same.
83	Ulrich U., Dietrich A., Fohrer N., "Herbicide transport via surface runoff during intermittent artificial rainfall: A laboratory plot scale study."; Catena, 2013, 101 (complete), 38 – 49.	The paper examines the run-off of Flufenacet on a laboratory scale – the design of the study is not realistic, therefore of limited utility for the regulatory purpose.	Yes , the reasons for the non-relevance of the paper given by the Applicant were the same.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
84	Unterreiner G. A., Kehew A. E., <i>"Spatial and temporal distribution of herbicides and herbicide degradates in a shallow glacial drift aquifer/surface water system, south-central Michigan."</i> ; Groundwater Monitoring & Remediation, 2005, 25 (2), 87 – 95.	Paper contains the reference to Flufenacet and its degradation products, but without providing any measurable values for them, because they were not target compounds in that particular study.	Not applicable – the paper not identified by the Applicant as potentially relevant.
85	Van't Zelfde M., Tamis W. L., Vijver M. G., De Snoo G. R., <i>"The contribution of neighbouring countries to pesticide levels in Dutch surface waters."</i> ; Communications In Agricultural and Applied Biological Sciences (Univ. Ghent), 2011, 76 (4), 867 – 877.;	Paper reported the results of the extensive monitoring study performed in the Netherlands and focused on the transboundary pollution of SW bodies in that country with pesticides. Flufenacet is one of the compounds indicated as causing problems. However the whole assessment is rather qualitative than quantitative, with no concentrations reported. For that reason it is of the limited utility for the assessment and RMS decided not to include it into the list of relevant publications.	Not applicable – the paper not identified by the Applicant as potentially relevant.
86	Vasilakoglou I. B., Eleftherohorinos I. G., <i>"Persistence, efficacy and selectivity of amide herbicides in corn."</i> ; Weed Technology, 2003, 17 (2), 381 – 388.	Paper focused mainly on examining phytotoxicity of Flufenacet to maize. There are references to the persistence of that compound in soil under field conditions, but they are presented in rather qualitative than quantitative way.	Not applicable – the paper not identified by the Applicant as potentially relevant.
87	Vasilakoglou I. B., Eleftherohorinos I. G., Dhima K. B., <i>"Activity, adsorption and mobility of three acetanilide and two new amide herbicides."</i> ; Weed Research, 2001, 41 (6), 535 – 546.	Paper provides the data on the soil sorption of Flufenacet, however due to the several identified deficiencies, mainly related to the analytical protocol, cannot be considered as providing reliable estimates of the adsorption parameters for Flufenacet. For that reason, after thorough examination, it was not included into the list of reliable scientific papers to be used in the assessment.	Yes , the Applicant also indicated that the deficiencies of the experimental protocol excluded the paper from the list of publications that may be used in the assessment.
88	Verro R., Finizio A., Otto S., Vighi S., <i>"Predicting Pesticide Environmental Risk in Intensive Agricultural Areas. I: Screening Level Risk Assessment of Individual Chemicals in Surface Waters."</i> ; Environmental Science and Technology, 2009, 43 (2), 522 – 529.	The paper provides a very general evaluation, although for a specific catchment. Flufenacet was one of the compounds of concern, but the paper contains no specific data related to it. The paper provides the numerical values, but obtained by means of modelling using the approach alternative to that currently used in the EU for regulatory purposes.	Not applicable – the paper not identified by the Applicant as potentially relevant.
89	Verro R., Finizio A., Otto S., Vighi S., <i>"Predicting Pesticide Environmental Risk in Intensive Agricultural Areas. II: Screening Level Risk Assessment of Complex Mixtures in Surface Waters."</i> ; Environmental Science and Technology, 2009, 43 (2), 530 – 537.	Paper deals with toxicity and the risk posed to aquatic environment by the mixtures of the active substances. From that point of view its relevance for the assessment in the area of environmental fate and behaviour, although Flufenacet is listed among the examined compounds, is very limited. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be confirmed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
90	von der Ohe P. C., Dulio V., Slobodnik J., De Deckere E., Kühne R., Ebert R.-U., Ginebreda A., De Cooman W., Schüürmann G., Brack W., "A new risk assessment approach for the prioritization of 500 classical and emerging organic microcontaminants as potential river basin specific pollutants under the European Water Framework Directive."; Science of the Total Environment, 2011, 409 (11), 2064 – 2077.	The paper contains the reference to Flufenacet, but of a very limited utility for the regulatory process.	Not applicable – the paper not identified by the Applicant as potentially relevant.
91	Wheeler J. R., Maynard S. K., Crane M., "An evaluation of fish early life stage tests for predicting reproductive and longer-term toxicity from plant protection product active substances."; Environmental Toxicology and Chemistry, 2014, 33 (8), 1874 – 1878.	Paper does not contain any reference to the environmental fate and behaviour of flufenacet or its degradation products. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.
92	Whiteside M., Mineau P., Morrison C., Knopper L. D., "Comparison of a score-based approach with risk-based ranking in-use agricultural pesticides in Canada to aquatic receptors."; Integrated Environmental Assessment and Management, 2008, 4 (2), 215 – 236.	Paper provides the data on categorisation of active substances on the basis of their exposure-to effect factor. Flufenacet is among the substances of concern, but with no clear reference to its environmental fate and behaviour. The paper focuses more on the ecotoxicological aspects of the problem. Its relevance, or lack of it, to the assessment in the area of ecotoxicology to be conformed by the expert performing evaluation in that area.	Not applicable – the paper not identified by the Applicant as potentially relevant.
93	Włodarczyk M., Wybieralski J., Praczyk T., "Influence of dose of flufenacet on its degradation on light soil." ("Wpływ wielkości dawki flufenacetu na jego trwałość w glebie lekkiej."); Progress in Plant Protection, 2007, 47 (3), 306 – 309.	Paper displays several deficiencies in analytical protocol and there are inconsistencies in the conclusions drawn.	Not applicable – the paper not identified by the Applicant as potentially relevant.
94	Włodarczyk M., Wybieralski J., Praczyk T., "Influence of adjuvants on flufenacet degradation in light soil in field condition." ("Wpływ adiuwantów na trwałość flufenacetu w glebie lekkiej w warunkach polowych."); Progress in Plant Protection, 2008, 48 (4), 1271 – 1275.	Paper displays several deficiencies in analytical protocol and there are inconsistencies in the conclusions drawn. Additionally the main focus is on the examination of the influence of adjuvant on the persistence of Flufenacet in soil under field conditions.	Not applicable – the paper not identified by the Applicant as potentially relevant.
95	Włodarczyk, M.; Wybieralski, J.; „Adsorption kinetics of atrazine and flufenacet and their water/soil partition coefficients <i>K_d</i> and <i>KOC</i> ”; Ekologia i Technika (2006), 14(1), 16-22	Paper displays several deficiencies in analytical protocol. It seems not to comply with the provisions of OECD 106 Guideline, mainly because the test compound – Flufenacet was applied as a formulated product containing another active substance – atrazine, what might have corrupted the results.	Yes , the Applicant also indicated that the deficiencies of the experimental protocol excluded the paper from the list of publications that may be used in the assessment.

No	Publication data	Reason(s) for considering the publication not relevant for the assessment	RMS' and Applicant's conclusions similar Yes/No
96	Włodarczyk M., "Influence of adjuvant Adpros 850 SL on adsorption of flufenacet on soils with different organic carbon content." ("Wpływ adiuwantu Adpros 850 SL na adsorpcję flufenacetu na glebach o różnej zawartości węgla organicznego."); Progress in Plant Protection, 2009, 49 (3), 1456 – 1460.	Paper displays several deficiencies in analytical protocol. It seems not to comply with the provisions of OECD 106 Guideline, mainly because the test compound – Flufenacet was applied as a formulated product, probably containing also another active substance – atrazine. Additionally, its main goal was to examine the influence of adjuvant on the adsorption of Flufenacet onto soil.	Yes , the Applicant also indicated that the deficiencies of the experimental protocol excluded the paper from the list of publications that may be used in the assessment.
97	Woudnech M. B., Ou Z., Sekela M., Tuominen T., Gledhik M., "Pesticide Multiresidues in Waters of the Lower Fraser Valley, British Columbia, Canada. Part I. Surface Water."; Journal of Environmental Quality, 2009, 38 , 940 – 947.	Flufenacet was among the compounds selected for determination, with reporting limits (LOD?) of 0.86 ng/L, but no measurable values were provided. As the use pattern on the examined area was not given, it cannot be stated what was the reason for the non-detection of Flufenacet in natural water samples.	Not applicable – the paper not identified by the Applicant as potentially relevant.
98	Xiang W., Xiang J., Zhang J. G., Wu F., Tang J. H., "Geochemical transformation of trichloroacetic acid to chloroform in fresh waters - The results based upon laboratory experiments."; Water, Air and Soil Pollution, 2005, 168 (1-4), 289 – 312.	Paper deals with reductive transformation of TCA to chloroform, so it does not concern the compound of interest – TFA.	Yes , Applicant also indicated that the paper did not contain the information related to the substance of concern.
99	Young C. J., Hurley M. D., Wallington T. J., Mabury S. A., "Atmospheric chemistry of CF ₃ CF ₂ H and CF ₃ CF ₂ CF ₂ H: Kinetics and products of gas-phase reactions with Cl atoms and OH radicals, infrared spectra, and formation of perfluorocarboxylic acids."; Chemical Physics Letters, 2009, 473 (4-6), 251 – 256.	Study does not contain any reference to the substances of concern, in particular TFA.	No , Applicant in his rationale pointed out that the paper reported chemical synthesis or the development of measurement methods with no application to natural samples.

Table B.8.6_CA-6: Results of the "Detailed assessment" stage of the literature search performed by the RMS – publications found relevant and included into the RAR.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
1	KCA B.8.1.1.1.1.	Bloomberg A. M., Shadrick B. A., Arthur E. L., Clay V. E., "Outdoor soil metabolism of [Phenyl-U- ¹⁴ C] Flufenacet on California Soils."; ACS Symposium Series, 2002, vol. 813 – "Pesticide Environmental Fate" (chapter 12), 167 – 182 (book chapter); published (print) 2009.	Study presents the results of the examination of the degradation of Flufenacet in two soils under field, semi-controlled conditions – in open vessels placed outdoors and treated with radiolabelled Flufenacet. Status of the study: because the study enabled the identification and quantitation of the degradation products of Flufenacet, it should be considered as relevant and used to derive regulatory endpoints.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
2	KCA B.8.1.1.1.1.1.	Lam C. K., McKinney M. K., Clay V. E., “ <i>Evaluation of Laboratory and Field Extraction Methods: Extraction of [Phenyl-¹⁴C] Flufenacet from Aged Soils.</i> ”; ACS Symposium Series, 2002, vol. 813 – “Pesticide Environmental Fate” (chapter 11), 153 – 166 (book chapter); published (print) 2009.	The study presents the performance parameters of two analytical procedures, one of which was used in the studies submitted by the Applicant. For that reason it can be used to conform the validity of the studies. Additionally it provides the information on the amounts of two major degradation products formed. Status of the study: supplementary, not to be used to derive regulatory endpoints.
3	KCA B.8.1.1.2.1.1. KCA B.8.1.2. KCA B.8.1.3.1.	Gupta S., Gajbhiye V. T., Agnihotri N. P., “ <i>Adsorption-Desorption, Persistence, and Leaching Behaviour of Flufenacet in Alluvial Soil of India.</i> ”; Bulletin of Environmental Contamination and Toxicology, 2001, 66 (1), 9 – 16.	Study provides numerical results of the determination of persistence, adsorption parameters and leaching in soil column for one soil. The test soil is a non-EU soil, what somehow limits the utility of the study, nevertheless it provides the data that can be considered supplementary to the Applicant’s ones. Status of the study: supplementary, not to be used to derive regulatory endpoints.
4	KCA B.8.1.1.2.1.1.	Gupta S., Gajbhiye V. J., “ <i>Effect of concentration, moisture and soil type on the dissipation of flufenacet from soil.</i> ”; Chemosphere, 2002, 47 (9), 901 – 906.	Study provides numerical results of the determination of persistence in three different soils and influence of different parameters on the process. The test soils were non-EU soils, what somehow limits the utility of the study, nevertheless it provides the data that can be considered supplementary to the Applicant’s ones. Status of the study: supplementary, not to be used to derive regulatory endpoints.
5	KCA B.8.1.1.2.2.	Rouchaud J., Neus O., Cools K., Bulcke R., “ <i>Flufenacet Soil Persistence and Mobility in Corn and Wheat Crops.</i> ”; Bulletin of Environmental Contamination and Toxicology, 1999, 63 (4), 406 – 466.	Study provides the numerical results of the examination of the dissipation Flufenacet in soil in field conditions. The test system was well characterised. Status of the study: supplementary, not to be used to derive regulatory endpoints.
6	KCA B.8.1.1.2.2.; KCA B.8.1.2.	Rouchaud J., Neus O., Cools K., Bulcke R., “ <i>Dissipation and mobility of the oxyacetamide flufenacet herbicide in corn and wheat crops.</i> ”; Mededelingen – Faculteit Landbouwkundige en Toegepaste Biologische Wetenschappen, Universiteit Gent, 1999, 64 (3b), 673 – 677.;	examination of the dissipation Flufenacet in soil in field conditions. The test system was well characterised. It provides also information on accumulation potential of Flufenacet in soil and the phytotoxicity of its residues for succeeding crops. Status of the study: supplementary, not to be used to derive regulatory endpoints.
7	KCA B.8.1.1.2.2.	Rouchaud J., Neus O., Eelen H., Bulcke R., “ <i>Persistence, Mobility, and Adsorption of the Herbicide Flufenacet in the Soil of Winter Wheat Crops.</i> ”; Bulletin of Environmental Contamination and Toxicology, 2001, 67 (4), 609 – 616.	Study provides the numerical results of the examination of the dissipation Flufenacet in soil in field conditions. The test system was well characterised. It provides a further insight into a test systems presented in the earlier study (Rouchaud et al; 1999). Status of the study: supplementary, not to be used to derive regulatory endpoints.
8	KCA B.8.1.2.	Gajbhiye V. T., Gupta S., “ <i>Adsorption-desorption behaviour of flufenacet in five different soils of India.</i> ”; Pest Management Science, 2001, 57 (7), 633 – 639.	Paper provides the numerical results of the examination of adsorption of flufenacet in five soils. Although the specific guidelines are not specified, study seemed to comply with OECD 106 Guideline, and the paper provides all data required in such cases. It shall however be pointed out that the test soils are non-EU soils, so the results are only supplementary ones. Status of the study: supplementary, not to be used to derive regulatory endpoints.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
9	KCA B.8.1.3.1.	Campagna G., Paci F., Fabbri A., Rapparini G., “ <i>Percolation of acetochlor, dimethenamid, flufenacet and s-metolachlor applied in columns.</i> ” (“ <i>Studio in colonna della percolazione di alcuni dieserbanti residuali del mais.</i> ”); Giornate Fitopatologiche 2006, Riccione (RN), 27-29 Marzo 2009 Atti, volume primo (University of Bologna) 2006, 591 - 598, (book chapter, conference paper)	Paper provides the numerical results of the examination of leaching behaviour of flufenacet in soil columns. Although the specific guidelines are not specified, study seemed to comply with OECD 312 Guideline, and the paper provides all data required in such cases. Status of the study: supplementary, not to be used to derive regulatory endpoints.
10	KCA B.8.2.1.1.	Rani Sunita, Kumari Beena., Kathpal T. S., “ <i>Effect of pH on the dissipation behaviour of flufenacet (FOE-5043) in water.</i> ”; Pesticide Research Journal, 2006, 18 (2), 201 – 204.	Paper provides the results of the examination of the aqueous hydrolysis of Flufenacet. The experimental protocol seems to comply with OECD 111 Guideline, although the measurements were performed at ambient temperature and it was not indicated whether the buffer solutions were sterile throughout the experiment. Status of the study: supplementary, not to be used to derive regulatory endpoints.
11	KCA B.8.2.2.4.; KCP B.8.4.	Ellis D. A., Hanson M. L., Sibley P. K., Shahid T., Fineberg N. a., Solomon K. R., Muir D. C. G., Mabury S. A., “ <i>The fate and persistence of trifluoroacetic and chloroacetic acids in pond water.</i> ”; Chemosphere, 2001, 42 , 309 – 318	Paper describes the fate and behaviour of TFA in natural water body – a pond. It may be considered a special case of water/sediment study. Status of the study: supplementary, not to be used to derive regulatory endpoints.
12	KCA B.8.2.6	anon., “ <i>Final Report of Project WT1246- Understanding changes in pesticide usage to inform water company risk assessment.</i> ”, DEFRA 2013,	The reports provides the estimates of the concentrations of Flufenacet and its degradation products in drinking water and substrate for its abstraction. It also provides estimates for the removal of Flufenacet during the substrate treatment for drinking water. Status of the study: major, enabling the addressing the issue of the impact on water treatment procedures.
13	KCA B.8.2.6	Sinclair C. J., van Beinum W., Adams C., Bevan R., Levy L., Parsons S., et al., “ <i>A desk study on pesticide metabolites, degradation and reaction products to inform the Inspectorate’s position on monitoring requirements.</i> ”; Final Report for Drinking Water Inspectorate, York: Food and Environment Research Agency (FERA), 2010.	The reports provides the estimates of the concentrations of Flufenacet and its degradation products in drinking water and substrate for its abstraction. It also provides estimates for the removal of the degradation products Flufenacet during the substrate treatment for drinking water as well as their potential toxicity. Status of the study: major, enabling the addressing the issue of the impact on water treatment procedures.
14	KCA B.8.2.6	Manoj A. Lazar, Shaji Varghese, Santhosh S. Nair, “ <i>Photocatalytic Water Treatment by Titanium Dioxide: Recent Updates.</i> ”; Catalysis, 2012, 2 , 572 – 601.	Provides a general overview of AOP process using TiO ₂ . Status of the study: supplementary, in the area of the impact on water treatment procedures.
15	KCA B.8.2.6	Sakkas V. A., Calza P., Vlachou A. D., Medana C., Minero C, Albanis T., “ <i>Photocatalytic transformation of flufenacet over TiO₂ aqueous suspensions: Identification of intermediates and the mechanisms involved.</i> ”; Applied Catalysis, B: Environmental; 2011, 110 (complete), 238 – 250;	The paper describes the transformation of flufenacet in water during the process of UV-induced Advanced Oxidation Process (AOP) with TiO ₂ as catalyst, which is now commonly used step in purification of water abstracted for drinking purposes and specifically for elimination of pesticides from the substrate. Status of the study: major, enabling the addressing the issue of the impact on water treatment procedures.
16	KCA B.8.2.6	Verstraeten I. M., Thurman E. M., Lindsey M. E., Lee E. C., “ <i>Changes in concentrations of triazine and acetamide herbicides by bank filtration, ozonation, and chlorination in a public water supply.</i> ”, Journal of Hydrology, 2002, 266 (3-4), 190 – 208.	Paper presents the efficiency of the removal of Flufenacet in the typical drinking water abstraction plant. All steps of treatment are covered. Status of the study: major, enabling the addressing the issue of the impact on water treatment procedures.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
17	KCA B.8.2.6	Dealtry S., Holmsgaard P. N., Dunon V., Jechalke S. Ding G.-C., Krögerrecklenfort E., Heuer H., Hansen L. H., Springael D., Zühlke S., Sørensen S. J., Smalla K., “ <i>Shifts in Abundance and Diversity of Mobile Genetic Elements after the Introduction of Diverse Pesticides into an On-Farm Biopurification System over a Course of a Year.</i> ”; Applied and Environmental Microbiology, 2014, 80 (13), 4012 – 4020.	Paper presents the performance of On-farm wastewater treatment plants in treasting wastewater containing the residues of plant protection products. Flufenacet was one of 7 major compounds of concern. The study, despite its limitations – it reports only the concentrations of flufenacet retained in BPS material without reporting its concentrations in water prior and after the treatment, it may be considered indicative with regard to the efficiency of the removal of Flufenacet by such installations. Status of the study: supplementary, in the area of the impact on water treatment procedures.
18	KCA B.8.2.6	Hollender J., Zimmermann S. G., Koepke S., Krauss M., McArdell C. S., Ort C., Singer H., von Gunten U., Siegrist H., “ <i>Elimination of Organic Micropollutants in a Municipal Wastewater Treatment Plant Upgraded with Full-Scale – Ozonation Followed by Sand Filtration.</i> ”; Environmental Science and Technology, 2009, 43 (20), 7862 – 7869;	Study examined the efficiency of the removal of 220 micropollutants present in secondary effluent of WWTP, by ozonation. Flufenacet and its OXA and ASA metabolites were listed among the compounds screened in secondary and post-ozonation effluents, but with no numerical results provided, most probably not detected in concentrations > 15 ng/L. There is no information about the initial concentrations of these compounds in treated wastewater. Status of the study: supplementary, in the area of the impact on water treatment procedures.
19	KCA B.8.2.6	Sinclair C. J., Boxall A. B. A., Parsons S. A., Thomas M. R., “ <i>Prioritization of Pesticide Environmental Transformation Products in Drinking Water Supplies.</i> ”; Environmental Science and Technology, 2006, 40 (23), 7283 – 7289.	Paper does not contain any specific reference to flufenacet or its degradation products, but it provides a clear methodology for assessing the importance of the degradation products for the processes of the abstraction of drinking water. From that point of view it may be considered useful with regard to the evaluation of the impact of the degradates of Flufenacet on weater treatment procedures. Status of the study: supplementary, in the area of the impact on water treatment procedures.
20	KCA B.8.3.1.	Hurley M. D., Sulbaek Andersen, M. P., Wallington T. J., Ellis D. A., Martin J. W., Mabury S. A., “ <i>Atmospheric Chemistry of Perfluorinated Carboxylic Acids: Reaction with OH Radicals and Atmospheric Lifetimes.</i> ”; Journal of Physical Chemistry, A, 2004, 108 (4), 615 – 620.	It provides the information relevant for elucidating the route and rate of degradation of TFA in the atmosphere. Status of the study: supplementary, not to be used to derive regulatory endpoints.
21	KCA B.8.3.1.	Oeberg, T. “ <i>A QSAR for the hydroxyl radical reaction rate constant: validation, domain of application, and prediction.</i> ”; Atmospheric Environment 2005, 39 (12), 2189 – 2200.	Paper provides the half life for TFA in atmosphere. Three calculations were in line with EU recommendations. Status of the study: supplementary, not to be used to derive regulatory endpoints.
22	KCA B.8.3.1.	Kutsuna S., Hori H., “ <i>Experimental determination of Henry's law constants of trifluoroacetic acid at 278-298 K.</i> ”; Atmospheric Environment, 2008, 42 (7), 1399 – 1412.	Paper provides the value of Henry's law constant for TFA and therefore addresses the issue of the would-be behaviour of the compound on the borderline between water and air, as well as possible implications for air pollution. Status of the study: supplementary, not to be used to derive regulatory endpoints.
23	KCA B.8.3.1.	Bowden D. J., Clegg S. L., Brimblecombe P. “ <i>The Henry's law constant of Trifluoroacetic acid and its partitioning into liquid water in the atmosphere.</i> ”; Chemosphere, 1996, 32 (2), 405 – 420;	Paper provides the value of Henry's law constant for TFA and therefore addresses the issue of the would-be behaviour of the compound on the borderline between water and air, as well as possible implications for air pollution. Status of the study: supplementary, not to be used to derive regulatory endpoints.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
24	KCA B.8.3.2.; KCA B.8.5.	Capel P. D., McCarthy K. A., Barbash J. E., “ <i>National, Holistic, Watershed-Scale Approach to Understand the Sources, Transport, and Fate of Agricultural Chemicals.</i> ”; Journal of Environmental Quality, 2008, 37 , 983 – 993.	Paper provides the characterisation of the methodological approach as well as characteristic of the sampling locations used in several other studies aimed on the monitoring of Flufenacet and its degradation products across the USA. It was identified by cross-reference in the study by [Vogel et al.; 2008], used in this assessment as the relevant study in the area of the examination of transport of Flufenacet in the atmosphere. For that reason, although it contains no data directly related to the monitoring of Flufenacet, this publication was included as relevant into the Renewal Assessment Report. Status of the study: supplementary, not to be used to derive regulatory endpoints.
25	KCA B.8.3.2.; KCA B.8.5.	Vogel J. R., Majewski M. S., Capel P. D., “ <i>Pesticides in Rain in Four Agricultural Watersheds in the United States.</i> ”; Journal of Environmental Quality, 2008, 37 , 1101 – 1115.	Paper provides the measured concentrations of Flufenacet in rain water samples. Status of the study: relevant in the area of determination of the behaviour of Flufenacet in the air and its secondary deposition, however not to be used to derive regulatory endpoints.
26	KCA B.8.3.2.; KCA B.8.5.	Henne, S.; Shallcross, D. E.; Reimann, S.; Xiao, P.; Boulos, S.; Gerecke, A. C.; Brunner, D.; “ <i>Environmental impacts of HFO-1234yf and other HFOs.</i> ”; Moving Towards Sustainability, ASHRAE/NIST Refrigerants Conference, Gaithersburg, MD, United States, Oct. 29-30, 2012 (2012), 13/1-13/13.	The paper presents potential sources of TFA in environment. As such it may be used to demonstrate the contribution of flufenacet as source of TFA in environment as marginal. Additionally it provides the numerical data on concentrations of TFA in rain water. Status of the study: supplementary and conformatory in the areas of the assessment of fate and behaviour in air and monitoring.
27	KCA B.8.3.2.; KCA B.8.5.	Jordan A., Frank H., “ <i>Trifluoroacetate in the Environment. Evidence for Sources Other Than HFC/HCFCs.</i> ”; Environmental Science and Technology, 1999, 33 (4), 522 – 527;	The paper presents potential sources of TFA in environment. As such it may be used to demonstrate the contribution of flufenacet as source of TFA in environment as marginal. Additionally it provides the numerical data on concentrations of TFA in rain water. Status of the study: supplementary and conformatory in the areas of the assessment of fate and behaviour in air and monitoring.
28	KCA B.8.3.2.	Wilson S. R., Solomon K. R., Tang X., „ <i>Changes in tropospheric composition and air quality due to stratospheric ozone depletion and climate change.</i> ”; Photochemical and Photobiological Sciences, 2007, 6 (3), 301 – 310.	Paper provides the information on the sources of TFA as well as its removal from that compartment via wet deposition, as well as background concentrations in water. Status of the study: fully relevant with regard to fate and behaviour of TFA in the atmosphere, however not to be used to derive regulatory endpoints.
29	KCA B.8.5.	Baker N. T., Stone W. S., “ <i>Estimated Annual Agricultural Pesticide Use for Counties of the Conterminous United States, 2008 – 12.</i> ”; US Geological Survey Data Series 907, 2015.	Paper provides the background information on the methodology for the preparation of maps of use on pesticides in the US, including Flufenacet. It is relevant as the background information for the studies presenting the results of the monitoring for Flufenacet residues in GW and SW compartments. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment.
30	KCA B.8.5.	Battaglin W. A., Kolpin D. A., Scribner E. A., Kuivila K. M., Sandstrom M. W., “ <i>Glyphosate, other herbicides, and transformation products in Midwestern streams, 2002.</i> ”; JAWRA Journal of the American Water Resources Association, 2005, 41 (2), 323 – 332.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in streams. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
31	KCA B.8.5.	Berg M., Müller S. R., Mühlemann J., Wiedmer A., Schwarzenbach R. P., „Concentrations and Mass Fluxes of Chloroacetic acids and Trifluoroacetic acid in Rain and Natural Waters in Switzerland.”; Environmental Science and Technology, 2000, 34 (13), 2675 – 2683;	Paper provides the data on the concentrations of TFA in precipitation and water samples collected in Switzerland. Status of the study: relevant in the area of monitoring of TFA in environment, however not to be used to derive regulatory endpoints.
32	KCA B.8.5.	Bishoff G., Pestmer W., Rodemann B.; “Entry of pesticides into surface waters – new results of Lamsprange run-off monitoring project 1999 – 2001.”; Pesticide in Air, Plant, Soil and Water System, Proceedings of the Symposium Pesticide Chemistry, 12 th , Piacenza, Italy, 2003, pp. 849 – 856.	Paper submitted by the Applicant, presents the results of the monitoring study carried out in an agricultural European catchment. Flufenacet was one of the compounds of concern. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.
33	KCA B.8.5.	Durham L., Fisk A., Kannan K., Macdonald R. W., Miur D. C. G., Scott B. F., Spencer C., Witter A., Yamashita N., “Trifluoroacetate profiles in the Arctic, Atlantic, and Pacific Oceans.”; Environmental Science and Technology, 2005, 39 (17), 6555 – 6560.	Paper submitted by the Applicant, provides the data on the concentrations of TFA in marine environment. Status of the study: relevant in the area of monitoring of TFA in environment, however not to be used to derive regulatory endpoints.
34	KCA B.8.5.	Frank H., Christoph E. H., Holm-Hansen O., Bullister J. L., “Trifluoroacetate in Ocean Waters.”; Environmental Science and Technology, 2002, 36 (1), 12 – 15.	Paper submitted by the Applicant, provides the data on the concentrations of TFA in marine environment. Status of the study: relevant in the area of monitoring of TFA in environment, however not to be used to derive regulatory endpoints.
35	KCA B.8.5.;	Kern S., Singer H., Hollender J., Schwarzenbach R. P., Fenner K., “Assessing Exposure to Transformation Products of Soil-Applied Organic Contaminants in Surface Water: Comparison of Model Predictions and Field Data.”; Environmental Science and Technology, 2011, 45 (7), 2833 – 2841.	Paper provides the results of measuring and modelling assessment of the concentrations of Flufenacet, FOE OXA and FOE ASA in SW and GW compartments. It is therefore relevant for monitoring, may be also considered as indicative and conformatory for performed FOCUS GW and FOCUS SW modelling exposure assessment. Status of the study: relevant in the area of monitoring of residues of Flufenacet in GW and SW compartments, however not to be used to derive regulatory endpoints.
36	KCA B.8.5	Kolpin D. W., Schnoebelen D. J., Thurman M. E., “Degradates Provide Insight to Spatial and Temporal Trends of Herbicides in Ground Water.”; Groundwater, 2004, 42 (4), 601 – 608.	Paper provides the concentrations of Flufenacet, FOE ASA and FOE OXA in 86 GW wells used as the source of drinking water, measured in 2001. Status of the study: relevant in the area of monitoring of residues of Flufenacet in GW compartment, however not to be used to derive regulatory endpoints.
37	KCA B.8.5.	Kowal S. Balsaa P., Werres F., Schmidt T. C., “Fully automated standard addition method for the quantification of 29 polar pesticide metabolites in different water bodies using LC-MS/MS.”; Analytical and Bioanalytical Chemistry, 2013, 405 , 6337 – 6351.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in natural water and wastewater samples collected in North Rine-Westphal land of Gernany (regions of Rhine and Ruhr rivers). Status of the study: relevant in the area of monitoring of residues of Flufenacet in GW and SW compartments.
38	KCA B.8.5.	Mills P. C., Kolpin D. W., Scribner E. A., Thurman E. M., “Herbicides and degradates in shallow aquifers of Illinois: spatial and temporal trends.”; JAWRA Journal of the American Water Resources Association, 2005, 41 (3), 537 – 547.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in natural water samples. Status of the study: relevant in the area of monitoring of residues of Flufenacet in GW and SW compartments, however not to be used to derive regulatory endpoints.

No	SANCO Data Point	Publication data	Reason(s) for inclusion into RAR and status
	KCA B.8.5.	Moschet C., Götz C., Longrée P., Hollender J., Singer H., “ <i>Multi-Level Approach for the Integrated Assessment of Polar Organic Micropollutants in an International Lake Catchment: The Example of Lake Constance.</i> ”; Environmental Science and Technology, 2013, 47 (13), 7028 – 7036.	Flufenacet, FOE OXA and FOE ASA were listed among the compounds searched for in lake water, but not detected there. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.
40	KCA B.8.5.	Moschet C., Wittmer I., Simovic J., Junghans M., Piazzoli A., Singer H., Stamm C., Leu C. Hollender J., “ <i>How a Complete Pesticide Screening Changes the Assessment of Surface Water Quality.</i> ”; Environmental Science and Technology, 2014, 48 (10), 5423 – 5432.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in rivers. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.
41	KCA B.8.5.	Moschet C., Vermeirsser E. L. M., Singer H., Stamm C., Hollender J., “ <i>Evaluation of in-situ calibration of Chemcatcher passive samplers for 322 micropollutants in agricultural and urban affected rivers.</i> ”; Water Research, 2015, 71 , 306 – 317.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in rivers. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.
42	KCA B.8.5.	Rebich R. A., Coupe R. H., Thurman E. M., “ <i>Herbicide concentrations in the Mississippi River Basin – the importance of chloroacetanilide herbicide degradates.</i> ”; Science of the Total Environment, 2004, 321 (1-3), 189 – 199.	Paper provides the measured concentrations of Flufenacet in riverine water. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.
43	KCA B.8.5.	Scott B. F., MacTavish D., Spencer C., Strachan W. M. J., Muir D. C., “ <i>Haloacetic Acids in Canadian Lake Waters and Precipitation.</i> ”; Environmental Science and Technology, 2000, 34 (20), 1266 – 4272.	Paper submitted by the Applicant, provides the data on the concentrations of TFA in fresh surface water bodies and precipitation in Canada. Status of the study: relevant in the area of monitoring of TFA in environment, however not to be used to derive regulatory endpoints.
44	KCA B.8.5.	Scribner E. A., Battaglin W. A., Diez J. E., Thurman E. M., “ <i>Reconnaissance Data for Glyphosate, Other Selected Herbicides, Their Degradation Products, and Antibiotics in 51 Streams in Nine Mid-Western States 2002.</i> ”; US Geological Survey Open-File Report 03-217, 2003.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in natural water samples. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartment, however not to be used to derive regulatory endpoints.
45	KCA B.8.5.	Wujcik C., Cahill T. M., Seiber J. N., “ <i>Determination of Trifluoroacetic Acid in 1996 – 1997 Precipitation and Surface Waters in California and Nevada.</i> ”; Environmental Science and Technology, 1999, 33 (10), 1747 – 1751.	Paper submitted by the Applicant, provides the data on the concentrations of TFA in fresh surface water bodies and precipitation in the USA. Status of the study: relevant in the area of monitoring of TFA in environment, however not to be used to derive regulatory endpoints.
46	KCA B.8.5.	Zimmerman L. R., Schneider R. J., Thurman E. M., “ <i>Analysis and Detection of the Herbicides Dimethenamid and Flufenacet and Their Sulfonic and Oxalinic Acid Degradates in Natural Degradates in Natural Water.</i> ”; Journal of Agricultural and Food Chemistry, 2002, 50 (5), 1045 – 1052.	Paper provides the measured concentrations of Flufenacet and its OXA and ASA degradation products in natural water samples. Status of the study: relevant in the area of monitoring of residues of Flufenacet in SW compartments, however not to be used to derive regulatory endpoints.

The publications listed in the table B.8.6_CA-6 are summarized under the relevant points of the Renewal Assessment Report, indicated in the second column of the table.

Additionally, for the purpose of the assessment of the impact of water treatment procedures (drinking water abstraction) were used the following publications, dealing with the problem of the toxic by-products formed during the processing of the raw water for the drinking water:

- Bond T., Tempelton M. R., Graham N. “Precursors of nitrogenous disinfection byproducts in drinking water – A Critical review and analysis.”; Journal of Hazardous Materials 2012, **235-236**, 1 – 16.
- Boorman G. A., Dellarco V., Dunnick J. K., Chapin R. E., Hunter S., Hauchman F., Gardner H., Cox M., Sills R. C., “Drinking Water Disinfection Byproducts: Review and Approach to Toxicity Evaluation.”; Environmental Health Perspectives, 1999, **107 Supplement 1**, 207 – 217;
- Richardson S. D., Postigo C., “Drinking Water Disinfection By-products” in Barcelo D. (ed.) “Emerging Organic Contaminants and Human Health”, “Handbook of Environmental Chemistry”, 2012, Springer Verlag, 93 – 138;
- Toxicological data sheet for TFA published on TOXNET – Toxicology Data Network, site of US NIH National Library of Medicine; available on-line at <http://toxnet.nlm.nih.gov/index.html> as a record CASRN: 76-05-1;
- Le Roux J., Gallard H., Croué J.-P., “Chloramination of nitrogenous contaminants (pharmaceuticals and pesticides): NDMA and halogenated DBPs formation.”; Water Research, 2011, **45**, 3164 – 3174;
- Krasner S. W., Mitch W. A., McCurry D. L., Hanigan D., Westerhoff P., “Formation, precursors, control and occurrence of nitrosoamines in drinking water: a review.”; Water Research, 2013, **47**, 4433 – 4450;
- Kim J., Clevenger T. E., “Prediction of *N*-nitrosodimethylamine (NDMA) formation as a disinfection by-product.”; Journal of Hazardous Materials, 20007, **145**, 270 – 276;
- Nawrocki J., Andrzejewski P., “Nitrosoamines and water.”; Journal of Hazardous Materials 2011, **189**, 1 – 18;
- Mitch W. A., Sedlak D. L., “Factors controlling nitrosamine formation during wastewater chlorination.”; Water Science and Technology: Water Supply, 2002, **2** (3), 191 – 198;
- Rostkowska K., Zwierz K., Róžański A., Moniuszko-Jakoniuk J., Roszczenko A., „Formation and Metabolism of *N*-Nitrosamines.”; Polish Journal of Environmental Studies, 1998, **7** (6), 321 – 325;
- Anon.: “Report on Carcinogens, Thirteen Edition; *N*-Nitrosamines: 15 Listing.”; NIH National Toxicology Program, Department of Health and Human Services; document available on-line on: <http://ntp.niehs.nih.gov/go/roc13>

These publications were identified independently of the literature search performed for Flufenacet by both the Applicant and the RMS, therefore were not listed in any of the tables above. However, they were used as the reference papers in the evaluation and for that reason RMS decided to list them here. These publications will be also listed under the point B.8.7 presenting the references relied upon, under the letter-subpoint *b) Open- source literature used in the evaluation.*

B. 8.7 – References relied on**Literature search:**

The Applicant carried out literature search, summarising its results in the document MCA section 9 as a following study report:

Derpmann J., Teubner. L.; **2014**: “*Summary of the literature data for Flufenacet*”; Bayer CropScience; Document MCA: Section 9 Literature Data Flufenacet (unpublished document No. M-482180-01-1); issuing date: 2014. 03. 18.

According to the Applicant it was performed in line with the recommendations given in the EFSA guidance document “Submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) No 1107/2009”, published in *EFSA Journal*, 2011, **9** (2), 2092.

RMS having verified the report stated that it complied with the Guidelines referred to, therefore from formal point of view it may be considered acceptable. The report is summarised above under the point B.8.6 – Open literature review.

The thorough examination of the Applicant’s report performed by the RMS showed, that at the initial stage 369 publications were found for flufenacet and 3120 for its metabolites, of which 3089 for trifluoroacetic acid (TFA). Of them for the detailed assessment were qualified 91 publications for flufenacet and 62 for its degradation products, 53 of which for TFA.

The detailed assessment resulted in identification of only nine publications relevant for the assessment - two for flufenacet and seven for TFA. No relevant open source publication relevant for the assessment was found for any of the remaining degradation products of flufenacet.

Examining the results presented in the report cited above RMS stated that:

- 1) Initial stage of the literature search – selection of the data bases, key words and phrases, time window and the rapid assessment of the results, was performed fully in line with the recommendations given in the EFSA Guidelines referred to above.
- 2) For the detailed assessment alongside the applied selection criteria, the full list of evaluated publications was provided in form of two tables – one presenting the publications identified as relevant, the second listing those found not relevant with rationale for their rejection. However, only for the publications considered relevant the Applicant provided information enabling their appropriate placing in the Assessment Report, as well as summaries and full texts. In case of rejected publications they were neither attributed to the relevant sections of the Report nor, at least, their summaries were provided, what would enable the verification of the correctness of Applicant’s selection.

In light of the doubts related to the results of detailed assessment performed by the Applicant – Bayer CropSciences, RMS repeated the literature search, using the search criteria similar to those applied by the Applicant. The only difference was that the search was not limited to the last thirteen years predating the application (i. e. covering the period 2000 – 2013), but was broader, what enabled to find earlier or later publications, not found by the BCS.

The results of the literature search performed by the RMS are presented under the point 9.6., under the summary of the report on the literature search submitted by the Applicant – Bayer CropSciences.

Additionally all peer-reviewed publications found relevant for the current evaluation, either by the Applicant or by the RMS as a result of the repeated literature search, are listed in the table placed under the letter “b” of this data point.

a) studies submitted by the Notifier:

b) Open- source literature used in the evaluation:

Annex point/ reference number	Author(s)	Year	Title of publication; Reference data (source's name, publication date)	Status of the publication	Submitted by:	Submitted – Original dossier (1 st inclusion) / Supplementary dossier (renewal of the inclusion)
KCA 7.1.1.1./07;	Bloomberg A. M., Shadrick B. A., Ellen A. L., Clay V. E.	2002	„Outdoor Soil Metabolism of [Phenyl-U- ¹⁴ C] Flufenacet on California Soils.”; published in: Phelps W. (ed.) “ ACS Symposium Series, vol. 813: Pesticide Environmental Fate ”, chapter 12, pp 167 – 182 ; American Chemical Society, Washington, DC, 2002, publication date March 1, 2002;	Study considered as relevant and used to derive regulatory endpoints, because it enabled the identification and quantitation of the degradation products of Flufenacet, in particular FOE alcohol as major metabolite.	Listed by RMS, submitted by Applicant on the request by RMS	Submitted in the supplementary dossier (renewal of the inclusion).
KCA 7.1.1.1./08;	Lam C. K., McKinney M. K., Clay V. E.,	2002	“Evaluation of Laboratory and Field Extraction Methods: Extraction of [Phenyl-U- ¹⁴ C] Flufenacet from Aged Soils.”; published in: Phelps W. (ed.) “ ACS Symposium Series, vol. 813: Pesticide Environmental Fate ”, chapter 11, pp 153 – 166 ; American Chemical Society, Washington, DC, 2002, publication date March 1, 2002;	Supplementary study, not to be used to derive regulatory endpoints.	Listed by both Applicant and RMS, submitted by Applicant on the request by RMS	Submitted in the supplementary dossier (renewal of the inclusion).
KCA 7.1.2.1.1./26; KCA 7.1.2.1.2; KCA 7.1.3.1.1/05; KCA 7.1.4.1./02	Gupta S., Gajbhiye V. T., Agnihotri N. P.	2001	“Adsorption-Desorption, Persistence, and Leaching Behaviour of Flufenacet in Alluvial Soil of India.”; published in: Bulletin of Environmental Contamination and Toxicology , 2001, 66 (1) , 9 – 16.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant, most probably because it was beyond the temporal limits set for the literature search (the paper was issued in 2001, a year before the Applicant's search began).
KCA 7.1.2.1.1./27; KCA 7.1.2.1.2;	Gupta S., Gajbhiye V. J.,	2002	“Effect of concentration, moisture and soil type on the dissipation of flufenacet from soil.”; Published in: Chemosphere , 2002, 47(9) , 901 – 906.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by both Applicant and RMS, submitted by Applicant on the request by RMS	Submitted in the supplementary dossier (renewal of the inclusion).

Annex point/ reference number	Author(s)	Year	Title of publication; Reference data (source's name, publication date)	Status of the publication	Submitted by:	Submitted – Original dossier (1 st inclusion) / Supplementary dossier (renewal of the inclusion)
KCA 7.1.2.2.1./08;	Rouchaud J., Neus O., Cools K., Bulcke R.	1999	“Dissipation and mobility of the oxyacetamide flufenacet herbicide in corn and wheat crops.”; Published in: Mededlingen – Faculteit Landbouwkundige en Toegepaste Biologische Wetenschappen, Universiteit Gent , 1999, 64 , (3b), 673 – 677.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant, most probably because it was beyond the temporal limits set for the literature search (the paper was issued in 1999, two years before the Applicant's search began).
KCA 7.1.2.2.1./09;	Rouchaud J., Neus O., Cools K., Bulcke R.	1999	“Flufenacet Soil Persistence and Mobility in Corn and Wheat Crops.”; Published in: The Bulletin of Environmental Contamination and Toxicology , 1999, 63 , 460 – 466.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant, most probably because it was beyond the temporal limits set for the literature search (the paper was issued in 1999, two years before the Applicant's search began).
KCA 7.1.2.2.1./10; KCA 7.1.3.1.1./07	Rouchaud J., Neus O., Eelen H., Bulcke R.	2001	“Persistence, Mobility and Adsorption of the Herbicide Flufenacet in the Soil of Winter Wheat Crops.”; Published in: “ The Bulletin of Environmental Contamination and Toxicology ”, 2001, 67 , 609 – 616.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by both Applicant and RMS, submitted by Applicant on the request by RMS	Submitted in the supplementary dossier (renewal of the inclusion).
KCA 7.1.3.1.1./06	Gajbhiye V. T., Gupta S.	2001	“Adsorption-desorption behaviour of flufenacet in five different soils of India.”; Published in: Pest Management Science , 2001, 57 , 633 – 639.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant, most probably because it was beyond the temporal limits set for the literature search (the paper was issued in 2001, a year before the Applicant's search began).
KCA 7.1.4.1./03	Campagna G. Paci F., Fabbi A., Rapparini G.,	2006	“Studio in colonna della percolazione di alcuni diserbanti residuali del mais.” (<i>title in English</i> : “Percolation of acetochlor, dimethenamid, flufenacet and s-metolachlor applied in columns.”); Published in: Giornate Fitopatologiche , 2006, I , 591 – 598;	Supplementary study, not to be used to derive regulatory endpoints.	Listed by both Applicant and RMS, submitted by Applicant on the request by RMS	Submitted in the supplementary dossier (renewal of the inclusion).
KCA 7.2.1.1./04	Sunita Rani, Beena Kumari, TS Kathpal,	2006	“Effect of pH on the Dissipation Behaviour of Flufenacet (FOE- 5043) in Water.”; Published in: Pesticide Research Journal , 2006, 18 (2), 201 – 204;	Supplementary study, not to be used to derive regulatory endpoints.	Listed by both Applicant and RMS, submitted by Applicant on the request by RMS	Submitted in the supplementary dossier (renewal of the inclusion).

Annex point/ reference number	Author(s)	Year	Title of publication; Reference data (source's name, publication date)	Status of the publication	Submitted by:	Submitted – Original dossier (1 st inclusion) / Supplementary dossier (renewal of the inclusion)

Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant.
KCA 7.5.;	Wujcik C., Cahill T. M., Seiber J. N.,	1999	“Determination of Trifluoroacetic Acid in 1996 – 1997 Precipitation and Surface Waters in California and Nevada.”; Published in: Environmental Science and Technology , 1999, 33 (10), 1747 – 1751.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant.
KCA 7.5.;	Zimmerman L. R., Schneider R. J., Thurman E. M.,	2002	“Analysis and Detection of the Herbicides Dimethenamid and Flufenacet and Their Sulfonic and Oxalinic Acid Degradates in Natural Degradates in Natural Water.”; Published in: Journal of Agricultural and Food Chemistry , 2002, 50 (5), 1045 – 1052.	Supplementary study, not to be used to derive regulatory endpoints.	Listed by RMS,	No - the Applicant has not identified the paper as a potentially relevant.

c) other documents relevant for the evaluation

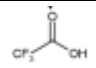

- Draft Assessment Report for Flufenacet prepared by the RMS – France in support for the inclusion of this compound into Annex I of the Council Directive 91/414/EEC and Addenda to it;
- Review Report for the active substance flufenacet – Flufenacet 7469/VI/98-final, 3 July 2003;

The specific Guidelines used in the evaluation are listed in the Volume 1, Level 3, point 3.4 – Appendices, Appendix 1 – Guidance documents used in this assessment.

B.8.8 - Appendices

B.8.8-A.1 – Appendix 1: List of evaluated compounds

Common name/ codename	Chemical (CAS or IUPAC) name	Structural formula	Molecular weight [g/mole]	Function	Occurrence
<i>Flufenacet (formerly fluthiamide)/ FOE5043</i>	N-(4-Fluorophenyl)-N-isopropyl-2-[[5-(trifluoromethyl)-1,3,4-thiadiazol-2-yl]oxy]acetamide		363.4	Active substance	Soil, water, sediment, air
<i>Flufenacet – N-Isomer</i>	N-(4-Fluorophenyl)-N-(1-methylethyl)-2-[2-oxo-5-(trifluoromethyl)-1,3,4-thiadiazol-3-yl]acetamide		363.4	Impurity of Flufenacet	Soil, water, sediment,
<i>FOE Alcohol</i>	N-(4-Fluorophenyl)-2-hydroxy-N-(1-methylethyl)acetamide		211.2	Metabolite of Flufenacet	Soil (major),
<i>FOE Oxalate</i>	[(4-Fluorophenyl) (1-methylethyl) amino] oxoacetic acid		225.2	Metabolite of Flufenacet	Soil (major),
<i>FOE Sulfoxide acid</i>	2-[(4-Fluorophenyl) (1-methylethyl) amino]-2-oxoethylsulfonic acid		275.3	Metabolite of Flufenacet	Soil (major),
<i>FOE Methylsulfoxide</i>	N-(4-Fluorophenyl)-N-(1-methylethyl)-2-(methylsulfinyl)acetamide		257.3	Metabolite of Flufenacet	Soil (major),
<i>FOE Methylsulfone</i>	N-(4-Fluorophenyl)-N-(1-methylethyl)-2-(methylsulfonyl)acetamide		273.3	Metabolite of Flufenacet	Soil (minor),
<i>FOE Methylsulfide</i>	N-(4-Fluorophenyl)-N-(1-methylethyl)-2-(methylthio)acetamide		241.0	Metabolite of Flufenacet	Water and sediment (major)
<i>FOE Thioglycolate sulfoxide</i>	4-Fluoro-N-methylethyl-aniline sulfenyldiacetic acid amide		315.4	Metabolite of Flufenacet	Soil (minor),
<i>FOE Thioglycolate</i>	4-Fluoro-N-methylethyl-aniline thiodiacetic acid amide		285.3	Metabolite of Flufenacet	Soil (minor),
<i>FOE Chloroacetanilide</i>	N-(4-Fluorophenyl)-2-chloro-N-(1-methylethyl)acetamide		229.7	Metabolite of Flufenacet	Soil (minor),
<i>FOE Thiadone</i>	5-(trifluoromethyl)-1,3,4-thiadiazol-2(3H)-one		170.1	Metabolite of Flufenacet	Soil (major),

Common name/ codename	Chemical (CAS or IUPAC) name	Structural formula	Molecular weight [g/mole]	Function	Occurrence
<i>FOE 5043- Trifluoroethane- sulfonic acid</i>	2,2,2-Trifluoroethane- Sulfonic acid		164.1	Metabolite of Flufenacet	Soil (major),
<i>Trifluoroacetic acid (TFA)</i>	Trifluoroacetic acid		114.02	Metabolite of Flufenacet	Soil (major),

B.8.8-A.2 – Appendix 2: Abbreviations and symbols used in the text:

<i>Symbol/term/ abbreviation</i>	<i>Meaning</i>
AR	Applied Radioactivity
a. s.	active substance
approx.	approximate/approximately
aver.	average
BBCH	BBCH scale or BBCH codes – a scale, and corresponding codes, used to describe phenologic growth phases for mono- and dicotyledonous plants (the abbreviation derived from the names of the organisations that developed the scale – B BA, B SA and C hemical Industry)
c	centi- ($\times 10^{-2}$), e. g. centimetre (cm, 10^{-2} metre)
°C	degree Celsius
C_{org}	Organic carbon content
CEC	Cation Exchange Capacity
Ci	Curie, the non-SI unit of the activity of radiation
CI	Confidence Interval; also Crop Interception factor
cfu	colony forming units – unit for counting microbial activity in the given matrix
d	days
DAT	Days After Treatment
DAF	Days After Flooding - a term used in soil anaerobic degradation study
DFOP	Double First Order in Parallel – one of the bi-phasic kinetic models within the 1 st order kinetics
dpm	decays per minute
DT₅₀	Period required for 50 percent degradation or dissipation
DT₉₀	Period required for 90 percent degradation or dissipation
E_h	Redox potential [mV]
EU	European Union
Eq (mEq)	Equivalent/milieuivalent – one of the alternative quantity unit
equiv.	equivalent (abbreviation commonly used in the summary of the lysimeter study)
FAO	Food and Agriculture Organisation of the UN
ff	kinetic formation fraction,
FOCUS	Forum for the Co-ordination of Pesticide Fate Models and their Use
FOMC	First Order Multi-Compartment – one of the bi-phasic kinetic models within the 1 st order kinetics
g	gram – the non-SI basic unit of weight (equal to 0.001 kg)
GAP	Good Agricultural Practice, here used to denominate the table containing the data on application of the given plant protection product/active substance (standard technical term)
Gy	Gray – the SI unit of absorbed dose
ha	hectare
HPLC	High Performance Liquid Chromatography
hr	hours
HS	Hockey Stick – one of the bi-phasic kinetic models within the 1 st order kinetics
k	degradation rate constant [days ⁻¹]
k	kilo ($\times 10^3$)
kg	kilogram – the basic SI unit of weight (1 kg = 1000 g)
L	Litre
LC	Liquid chromatography
LC/MS	Liquid chromatography with mass spectrometry detection
LC/MS/MS	Liquid chromatography with double mass spectrometry detection
LOD	Limit of Detection
LOQ	Limit of Quantitation
LSC	Liquid scintillation counting
m	metre
m	in front any unit milli- ($\times 10^{-3}$), milligram (10^{-3} gram)
mg	milligram
mL	millilitre
mm	millimetre
M	Molar
M₀	Initial concentration, expressed on the weight basis
min.	minute; also minimum or minimal
MS	Member State
MWHC	Maximum Water Holding Capacity
n	in front any unit nano- ($\times 10^{-9}$), e. g. nanogram (10^{-9} gram)
ng	nanogram
nm	nanometre
N	normal, an old way of expressing the concentration in liquids (used mainly for acids and bases), a

<i>Symbol/term/ abbreviation</i>	<i>Meaning</i>
	concentration of 1g equivalent/dm ³
NER	Non-Extractable residues
NP-	Normal Phase (for TLC analysis)
ode	oven dry equivalent
OECD	Organisation for Economic Co-operation and Development
Pa	Pascal – SI unit of pressure
PEC	Predicted Environmental Concentrations
pH	the acidity logarithmic scale
PNAP	<i>p</i> -nitroacetophenone
P_{ow}/K_{ow}	Octanol/water partition coefficient
PTFE	polytetrafluorethylene
pyr	pyridine
r	correlation coefficient
r²/R²	coefficient of determination
RMS	Rapporteur Member State
RP-	Reversed Phase (for TLC and HPLC analysis)
RP-HPLC	Reversed Phase High Performance Liquid Chromatography
RSD	relative standard deviation
s/sec.	second
S	(also) Siemens – the conductivity unit
SD/s	standard deviation
S_{aa}	Solubility in water
SFO	Single First Order kinetics – a kinetic model within the 1 st order kinetics
SPE	Solid phase extraction
T	temperature
TIC	Total Inorganic Carbon
TLC	Thin Layer Chromatography
TOC	Total Organic Carbon
TRR	Total Radioactive Residue
TWA	Time-Weighted Average (concentration)
UK	United Kingdom <i>of Great Britain and Northern Ireland</i> (specific technical term)
US	United States <i>of America</i> (specific technical term)
USDA	United States Department of Agronomy
UV	Ultraviolet radiation – the radiation within the wavelength range of 200-400 nm
UV-Vis	Ultraviolet – Visible radiation – the radiation within the wavelength range of 200-800 nm
Vis	Visible radiation – the radiation within the wavelength range of 400-800 nm
ver.	version
v/w	volume-to-weight ratio
V	Volt – the SI unit of electric potential
V_p	Vapour pressure [Pa]
WHC	Water Holding Capacity
γ–	Gamma, Greek letter, used here to denominate the gamma radiation
μ	in front of any unit - micro (x10 ⁻⁶), e.g. micrometer (μm), microgram (μg) or microlitre (μL)
λ	Lambda, Greek letter used here to denominate the wavelength

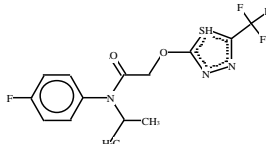

In this Appendix are presented the detailed results of QSAR calculations performed for FOE Alcohol and FOE Oxalate that had as aim to provide the data supporting the proposal to cover the exposure assessment for FOE Alcohol with that performed for FOE Oxalate. Additionally, in order to validate the results of calculations, the simulation for Flufenacet was performed. All calculations were made using EPI Suite[®] tool, developed by US EPA. Also are presented the results of the calculations performed for FOE Methylsulfide aimed on the determination of the input parameters – water solubility and adsorption coefficient, to be used in the SW model exposure assessment.

The results are presented in three separate tables, individually for each compound of concern.

Table B.8.8-A.3 CA-1: The detailed results of QSAR calculations for Flufenacet.

Note: * = asterisk designates: Chemical may not be soluble enough to measure this predicted effect. If the effect level exceeds the water solubility by 10X, typically no effects at saturation (NES) are reported.

Class Specific LogKow Cut-Offs

If the log Kow of the chemical is greater than the endpoint specific cut-offs presented below, then no effects at saturation are expected for those endpoints.

Amides :

Maximum LogKow: >8.5 (LC50)

Maximum LogKow: >8.0 (EC50,ChV)

Baseline Toxicity SAR Limitations:

Maximum LogKow: 5.0 (Fish 96-hr LC50; Daphnid LC50)

Maximum LogKow: 6.4 (Green Algae EC50)

Maximum LogKow: 8.0 (ChV)

A Probability Greater Than or Equal to 0.5 indicates --> Biodegrades Fast
A Probability Less Than 0.5 indicates --> Does NOT Biodegrade Fast

Ready Biodegradability Prediction: (YES or NO)

Criteria for the YES or NO prediction: If the Biowin3 (ultimate survey model) result is "weeks" or faster (i.e. "days", "days to weeks", or "weeks" AND the Biowin5 (MITI linear model) probability is ≥ 0.5 , then the prediction is YES (readily biodegradable). If this condition is not satisfied, the prediction is NO (not readily biodegradable). This method is based on application of Bayesian analysis to ready biodegradation data (see Help). Biowin5 and 6 also predict ready biodegradability, but for degradation in the OECD301C test only; using data from the Chemicals

Evaluation and Research Institute Japan (CERIJ) database.

MOL WT : 211.24

----- HYDROWIN v2.00 Results -----

Hydrolyzable Function detected: Amides

-C-C(=O)-N-C-

With the exception of a few halogenated acetamides, most amides hydrolyze to acids extremely slowly at 25 degC and pH7 with half-lives measured in centuries. Electronegative groups on carbon or nitrogen greatly accelerate base catalyzed hydrolysis, but alkyl groups on nitrogen retard both acid and base catalyzed processes. No neutral hydrolysis is evident (Mabey and Mill, 1978). Selected amides half-lives include:

Half-Live (in years at 25C, pH7)

Acetamide	3950
Chloroacetamide	1.46
Dichloroacetamide	0.73
Trichloroacetamide	0.23
N-Methylacetamide	38000

Additional experimental amide data are available in the HYDRO on-line User Guide (help file).

BCFBAF Program (v3.01) Results:

=====

SMILES : c1ccc(F)cc1C(C)(C)NC(=O)CO

CHEM :

MOL FOR: C11 H14 F1 N1 O2

MOL WT : 211.24

----- BCFBAF v3.01 -----

Summary Results:

Log BCF (regression-based estimate): 0.41 (BCF = 2.59 L/kg wet-wt)
 Biotransformation Half-Life (days) : 0.0726 (normalized to 10 g fish)
 Log BAF (Arnot-Gobas upper trophic): 0.52 (BAF = 3.31 L/kg wet-wt)

Log Kow (experimental): not available from database

Log Kow used by BCF estimates: 1.52

Equation Used to Make BCF estimate:

Log BCF = 0.6598 log Kow - 0.333 + Correction

Correction(s):	Value
Aromatic ring-CH-OH	-0.256

Estimated Log BCF = 0.413 (BCF = 2.589 L/kg wet-wt)

ECOSAR v1.11 Class-specific Estimations

 | Not Related to an Existing ECOSAR Class Definition |
 |
 | Estimates provided below use the Neutral Organics QSAR equations which |
 | represent baseline toxicity potential (minimum toxicity) assuming a simple |
 | non-polar narcosis model. Without empirical data on structurally similar |
 | chemicals, it is uncertain if this substance will present significantly |
 | higher toxicity above baseline estimates. |

ECOSAR Class	Organism	Predicted Duration	End Pt	mg/L (ppm)
Neutral Organics	: Fish	96-hr	LC50	2010.702

Neutral Organics	: Daphnid	48-hr	LC50	1026.323
Neutral Organics	: Green Algae	96-hr	EC50	492.154
Neutral Organics	: Fish		ChV	173.332
Neutral Organics	: Daphnid		ChV	74.410
Neutral Organics	: Green Algae		ChV	101.666
Neutral Organics	: Fish (SW)	96-hr	LC50	2513.900
Neutral Organics	: Mysid	96-hr	LC50	4081.939
Neutral Organics	: Fish (SW)		ChV	134.892
Neutral Organics	: Mysid (SW)		ChV	496.647
Neutral Organics	: Earthworm	14-day	LC50	515.761

Note: * = asterisk designates: Chemical may not be soluble enough to measure this predicted effect. If the effect level exceeds the water solubility by 10X, typically no effects at saturation (NES) are reported.

Class Specific LogKow Cut-Offs

If the log Kow of the chemical is greater than the endpoint specific cut-offs presented below, then no effects at saturation are expected for those endpoints.

Neutral Organics:

Maximum LogKow: 5.0 (Fish 96-hr LC50; Daphnid LC50, Mysid LC50)
 Maximum LogKow: 6.0 (Earthworm LC50)
 Maximum LogKow: 6.4 (Green Algae EC50)
 Maximum LogKow: 8.0 (ChV)

A Probability Greater Than or Equal to 0.5 indicates --> Biodegrades Fast
A Probability Less Than 0.5 indicates --> Does NOT Biodegrade Fast

Criteria for the YES or NO prediction: If the Biowin3 (ultimate survey model) result is "weeks" or faster (i.e. "days", "days to weeks", or "weeks" AND the Biowin5 (MITI linear model) probability is ≥ 0.5 , then the prediction is YES (readily biodegradable). If this condition is not satisfied, the prediction is NO (not readily biodegradable). This method is based on application of Bayesian analysis to ready biodegradation data (see Help). Biowin5 and 6 also predict ready biodegradability, but for degradation in the OECD301C test only; using data from the Chemicals Evaluation and Research Institute Japan (CERIJ) database.

HYDROWIN Program (v2.00) Results:

SMILES : c1ccc(F)cc1C(C)(C)NC(=O)C(=O)O

CHEM :

MOL FOR: C11 H12 F1 N1 O3

MOL WT : 225.22

----- HYDROWIN v2.00 Results -----

Currently, this program can NOT estimate a hydrolysis rate constant for
the type of chemical structure entered!!

ONLY Esters, Carbamates, Epoxides, Halomethanes (containing 1-3 halogens),
Specific Alkyl Halides & Phosphorus Esters can be estimated!!

When present, various hydrolyzable compound-types will be identified.
For more information, (Click OVERVIEW in Help or see the User's Guide)

***** CALCULATION NOT PERFORMED *****

BCFBAF Program (v3.01) Results:

SMILES : c1ccc(F)cc1C(C)(C)NC(=O)C(=O)O

CHEM :

MOL FOR: C11 H12 F1 N1 O3

MOL WT : 225.22

----- BCFBAF v3.01 -----

Summary Results:

Log BCF (regression-based estimate): 0.50 (BCF = 3.16 L/kg wet-wt)

Biotransformation Half-Life (days) : 0.109 (normalized to 10 g fish)

Log BAF (Arnot-Gobas upper trophic): 0.17 (BAF = 1.5 L/kg wet-wt)

Log Kow (experimental): not available from database

Log Kow used by BCF estimates: 0.85

Equation Used to Make BCF estimate:

Log BCF = 0.50 (Ionic; Log Kow dependent)

Estimated Log BCF = 0.500 (BCF = 3.162 L/kg wet-wt)

A Probability Greater Than or Equal to 0.5 indicates --> Biodegrades Fast

A Probability Less Than 0.5 indicates --> Does NOT Biodegrade Fast

Ready Biodegradability Prediction: (YES or NO)

Criteria for the YES or NO prediction: If the Biowin3 (ultimate survey model) result is "weeks" or faster (i.e. "days", "days to weeks", or "weeks" AND the Biowin5 (MITI linear model) probability is ≥ 0.5 , then the prediction is YES (readily biodegradable). If this condition is not satisfied, the prediction is NO (not readily biodegradable). This method is based on application of Bayesian analysis to ready biodegradation data (see Help). Biowin5 and 6 also predict ready biodegradability, but for degradation in the OECD301C test only; using data from the Chemicals Evaluation and Research Institute Japan (CERIJ) database.

BCFBAF Program (v3.01) Results:

=====

SMILES : c1c(F)ccc(N(C(C)(C))C(=O)CSC)c1

CHEM :

MOL FOR: C12 H16 F1 N1 O1 S1

MOL WT : 241.33

----- BCFBAF v3.01 -----

Summary Results:

Log BCF (regression-based estimate): 1.50 (BCF = 31.3 L/kg wet-wt)

Biotransformation Half-Life (days) : 0.383 (normalized to 10 g fish)

Log BAF (Arnot-Gobas upper trophic): 1.65 (BAF = 44.5 L/kg wet-wt)

Log Kow (experimental): not available from database

Log Kow used by BCF estimates: 2.77

Equation Used to Make BCF estimate:

Log BCF = 0.6598 log Kow - 0.333 + Correction

Correction(s): Value

No Applicable Correction Factors

Estimated Log BCF = 1.496 (BCF = 31.35 L/kg wet-wt)

=====

Whole Body Primary Biotransformation Rate Estimate for Fish:

=====

TYPE	NUM	LOG BIOTRANSFORMATION FRAGMENT DESCRIPTION	COEFF	VALUE
Frag	1	Amide [-C(=O)-N or -C(=S)-N]	-0.5952	-0.5952
Frag	1	Aromatic fluoride [-F]	0.0000	0.0000
Frag	1	Fluorine [-F]	0.2759	0.2759
Frag	4	Aromatic-H	0.2664	1.0655
Frag	3	Methyl [-CH3]	0.2451	0.7353
Frag	1	-CH2- [linear]	0.0242	0.0242
Frag	1	-CH- [linear]	-0.1912	-0.1912
Frag	1	Benzene	-0.4277	-0.4277
L Kow	*	Log Kow = 2.77 (KowWin estimate)	0.3073	0.8521
MolWt	*	Molecular Weight Parameter		-0.6188
Const	*	Equation Constant		-1.5371

RESULT	LOG Bio Half-Life (days)	-0.4171
RESULT	Bio Half-Life (days)	0.3827
NOTE	Bio Half-Life Normalized to 10 g fish at 15 deg C	

=====

Biotransformation Rate Constant:

kM (Rate Constant): 1.811 /day (10 gram fish)

kM (Rate Constant): 1.018 /day (100 gram fish)

kM (Rate Constant): 0.5727 /day (1 kg fish)

kM (Rate Constant): 0.3221 /day (10 kg fish)

Arnot-Gobas BCF & BAF Methods (including biotransformation rate estimates):

Estimated Log BCF (upper trophic) = 1.648 (BCF = 44.45 L/kg wet-wt)

Estimated Log BAF (upper trophic) = 1.648 (BAF = 44.45 L/kg wet-wt)

Estimated Log BCF (mid trophic) = 1.537 (BCF = 34.41 L/kg wet-wt)

Estimated Log BAF (mid trophic) = 1.537 (BAF = 34.41 L/kg wet-wt)

Estimated Log BCF (lower trophic) = 1.495 (BCF = 31.27 L/kg wet-wt)

Estimated Log BAF (lower trophic) = 1.496 (BAF = 31.3 L/kg wet-wt)

Arnot-Gobas BCF & BAF Methods (assuming a biotransformation rate of zero):

Estimated Log BCF (upper trophic) = 1.807 (BCF = 64.1 L/kg wet-wt)

Estimated Log BAF (upper trophic) = 1.843 (BAF = 69.65 L/kg wet-wt)

Volatilization From Water

=====

Chemical Name:

Molecular Weight : 241.33 g/mole
 Water Solubility : -----
 Vapor Pressure : -----
 Henry's Law Constant: 2.77E-009 atm-m³/mole (estimated by Bond SAR Method)

	RIVER	LAKE
	-----	-----
Water Depth (meters):	1	1
Wind Velocity (m/sec):	5	0.5
Current Velocity (m/sec):	1	0.05
HALF-LIFE (hours) :	3.284E+005	3.582E+006
HALF-LIFE (days) :	1.368E+004	1.493E+005
HALF-LIFE (years) :	37.46	408.6

STP Fugacity Model: Predicted Fate in a Wastewater Treatment Facility

=====

(using 10000 hr Bio P,A,S)

PROPERTIES OF:

Molecular weight (g/mol)	241.33
Aqueous solubility (mg/l)	0
Vapour pressure (Pa)	0
(atm)	0
(mm Hg)	0
Henry's law constant (Atm-m ³ /mol)	2.77E-009
Air-water partition coefficient	1.13285E-007
Octanol-water partition coefficient (Kow)	588.844
Log Kow	2.77
Biomass to water partition coefficient	118.569
Temperature [deg C]	25
Biodeg rate constants (h ⁻¹), half life in biomass (h) and in 2000 mg/L MLSS (h):	
-Primary tank	0.00 1916.82 10000.00
-Aeration tank	0.00 1916.82 10000.00
-Settling tank	0.00 1916.82 10000.00

STP Overall Chemical Mass Balance:

	g/h	mol/h	percent
Influent	1.00E+001	4.1E-002	100.00
