B.8. – ENVIRONMENTAL FATE AND BEHAVIOUR

B.8.0. - Introduction

Flufenacet is an herbicide that was authorised for the use in the EU by its inclusion into the Annex I of the Council Directive 91/414/EEC (Commission Directive 2003/84/EC of 25 September 2003) in 2003 as entry No. 65 (at the time of inclusion as a new active substance). That authorisation entered into force from 1st January 2004 and was due to expire on the 31st December 2013. When the Directive 91/414/EEC was repealed by Council Regulation 1107/2009 of 21st October 2009, the authorisation of Flufenacet in the EU was granted by its listing, as entry No. 65, in the Part A of the Annex to the Commission Implementing Regulation (EC) 540/2011, expiring on 31st December 2013. That authorisation period was further extended to 31st October 2016 by means of the Commission Regulation (EC) No. 823/2012 of 14th September 2012.

The evaluation was based on the Draft Assessment Report prepared by the Rapporteur Member State – France, in August 1997, and Addenda to it on the basis of the documentation submitted by the Applicant – Bayer CropSciences, identified in course of the evaluation as a sole Applicant for Flufenacet. In support of the inclusion of Flufenacet into the Annex I of the Council Directive 91/414/EEC a Review Report for the active substance Flufenacet was issued (Flufenacet 7469/VI/98-final, 3 July 2003), summarising the results of the evaluation and providing the EU-agreed List of the EndPoints for this active substance.

For the purpose of the current evaluation, aimed on the renewal of the approval of Flufenacet in the EU, the Applicant provided a Dossier consisting of, in section B.8. – Environmental Fate and Behaviour, old studies, already evaluated for the previous approval for use of Flufenacet in the EU, and new studies, updating the dataset for Flufenacet in the following areas:

- Degradation in soil examined in laboratory (25 studies);
- Degradation in soil examined under field conditions (1 study);
- Soil sorption and mobility in soil of Flufenacet and its metabolites (11 studies);
- Fate and behaviour of Flufenacet the aquatic environment (7 studies);
- Fate and behaviour of Flufenacet and its degradation products in air – no new studies submitted;
- Monitoring data for Flufenacet and its degradation products (3 reports);
- Modelling exposure assessment (6 study reports).

All submitted studies, old and new, will be evaluated according to the current valid test guidelines and summarised below, under the relevant points of this Renewal Assessment Report, with exception of those considered not valid and/or being superseded by the newly submitted studies. In such cases, the studies will be cited in the Renewal Assessment Report, but not summarised. Instead, for each of them the extended rationale for its non-inclusion into the Assessment Report will be provided.

For all studies submitted for the first evaluation of Flufenacet, considered then valid and summarised in either Draft Assessment Report or Addenda to it, unless in course of the current evaluation they were found not valid, new summaries are provided to meet the current requirements.

For the first inclusion of Flufenacet into the Annex I the Applicant proposed the representative GAP comprising following uses:

- in Maize (Corn) to suppress annual grass weeds, pre-emergence, once per season in application rate 480 – 600 g/ha, in Northern and Southern European Countries;
- in Soybean and Sunflower, to suppress annual grass weeds, pre-emergence, once per season in application rate 480 – 600 g/ha, in Southern European Countries;
- in Winter Cereals (wheat, barley, rye and triticale), to suppress annual grass weeds, early post-emergence in autumn (at 2nd leaf stage of grass weeds), once per season in application rate 120 – 240 g/ha, in Northern and Southern European Countries.

The representative formulation was FOE 5043 WG 60, containing 60% of Flufenacet.

For the present evaluation the Applicant proposed the revised representative GAP, limiting the intended uses to those aimed on suppression of the annual weeds in cereals, pre-emergence and early post emergence (range of BBCH 00-22) in autumn and at early spring.

It shall be noted that, unlike for the previous assessment, the Applicant proposed the representative formulation codenamed DFF+FFA SC 600, containing 400 g/L Flufenacet and 200 g/L Diflufenican. The proposed trade names are Herold SC (to be used in both North- and South European countries), Fosburi (to be used only in NE climatic zone) and Forebird (to be used in SE climatic zone). This representative formulation was already evaluated for the purpose of the authorisation of Diflufenican in the EU (RMS – UK).

That new representative GAP, used in the evaluation in the area of environmental fate and behaviour, including the environmental exposure assessment, is presented below in the table B.8.0_CA-1. For clarity

reasons the application rates for the second active substance of the EU-representative formulation – diflufenican, were not reported in this table.

Table B.8.0_CA-1: The proposed updated representative GAP for Flufenacet.

Region	Crop	Product name	Data on application						
			Type of application	Number of Applic.	Interval between applications	Application time		Application rate - flufenacet [g/ha]	Spray volume [L/ha]
						Period	Crop's growth stage (BBCH)		
North EU	Cereals (winter wheat, winter barley, winter rye)	Herold SC (400 g/L flufenacet + 200 g/L diflufenican)	Foliar spraying	1	Not applicable – single application	Early post-emergence, Autumn only;	10-13	240	200 – 400
South EU	Cereals (wheat, winter barley)	Fosburi (400 g/L flufenacet + 200 g/L diflufenican)	Foliar spraying	1	Not applicable – single application	Early post-emergence	11-13	240	80 – 400
North EU	Cereals (winter wheat, winter barley, winter rye)	Forebird (400 g/L flufenacet + 200 g/L diflufenican)	Foliar spraying	1	Not applicable – single application	Pre-emergence and early post-emergence	00-22	120	200 – 400
South EU	Cereals (wheat, barley)	Herold SC (400 g/L flufenacet + 200 g/L diflufenican)	Foliar spraying	1	Not applicable – single application	Early post-emergence	11-13	160	200 – 400

Fulfilling the data requirement set in the Article 8 point 5 of the Regulation (EC) 1107/2009, the Applicant submitted the report presenting the results of the search of the scientific peer-reviewed open literature. This report, covering the results of the search performed for all sections, was submitted by the Applicant as a separate part of the Dossier – Document MCA, Section 9: Literature data. In this section of the Report it is summarised and evaluated under the point B.8.6. – Open literature review. All publications that were found relevant for the present assessment were summarised under the relevant points of the Report.

The findings of the evaluation performed for the previous, first authorisation of Flufenacet in the EU are presented below (in form of a short summary based of the available documentation – DAR for Flufenacet, Addenda to it and the Review Report for this compound, containing the EU-agreed List of Endpoints).

Flufenacet was found to be rapidly degraded in aerobic soil with DT₅₀ ranging from 15 to 64 days at standard conditions (T = 20-21°C, and either 40% MWHC or 75% of 1/3 bar soil moisture). The initial degradation occurred by cleavage of the C-O α-bond, resulting in formation of Thiadone (M9), which was quickly mineralised. In case of the phenyl moiety of the molecule, it was postulated that it underwent conjugation to glutathione or cysteine (forming the transient degradation product M23) or transformation to either FOE chloroacetanilide (M8) in equilibrium with M23 or FOE Alcohol (M3). The degradation product M3 was postulated to be formed either directly from Flufenacet (primary degradation product) or as secondary metabolite from M23. It was further transformed to either terminal transformation products (CO₂, NER) or to FOE Oxalate (M1), which degraded to terminal transformation products (CO₂, NER). Several degradation products were postulated to be formed from the transient metabolite M23: FOE Methylsulfoxide (M6) subsequently transformed into FOE Methylsulfone (M7), FOE Thioglycolate Sulfoxide (M4) and FOE Sulfonic Acid (M2). All they ultimately degraded to the terminal transformation products (CO₂, NER). It shall be noted that of all the metabolites listed only M23 was not found in any of the studies examining the route of degradation of Flufenacet in aerobic soils.

Of the degradation products listed above, two – FOE Sulfonic acid (M2), formed in soil in amounts up to 26.3% AR and FOE Oxalate (M1), detected in test soils in amounts up to 15.6% AR, were classified as major. In case of all remaining degradation products it was stated that they were minor, not being detected in any test soil in amounts above 5% AR.

The mineralisation level was up to 20.8% AR in case of fluorophenyl-radiolabelled compound and 31.9% for thiadiazole-radiolabelled compound. Non-extractable residues (NER) were formed in amounts up to 56.2% AR (for the fluorophenyl-radiolabelled compound), still increasing at the end of incubation period. The level of NER detected for the thiadiazole-radiolabelled compound was much lower, not surpassing 7% AR during the study.

Of the two major degradation products, FOE Sulfonic acid (M2) was demonstrated to be persistent in soil, with LoEP-reported DT_{50} in range of 189-270 days, while FOE oxalate (M1) was shown to be moderately persistent in soil, with DT_{50} values ranging from 5 days to 130 days (values reported in LoEP).

Degradation of Flufenacet in soil under anaerobic conditions was not examined on the basis that for the proposed then application pattern the compound was not expected to be exposed to anaerobic conditions.

The examination of the photolysis on the soil surface led to the conclusion that Flufenacet was photolytically stable in soil, with less than 10% of the compound transformed by the end of irradiation period.

Additionally degradation of Flufenacet in soil was examined in field dissipation studies, performed on several locations in Europe – in Germany (6 trials), Northern France (4 trials), Southern France (4 trials) and Italy (2 trials). The trials were performed on either bare or cropped soil. In those experiments Flufenacet demonstrated persistence similar to that determined in the laboratory, with DT_{50} = 38-43 days for autumn applications and DT_{50} = 15-53 days for spring applications onto bare soil and DT_{50} = 13-16 days for early spring applications and DT_{50} = 16-48 days for spring applications onto cropped soil systems. These results were not subjected to further normalisation.

In the LoEP it was declared that none of the degradation products identified in laboratory studies was detected in the field trials in amounts >LOD. In the DAR however it was stated that two of them – FOE Oxalate (M1) and FOE Sulfonic acid (M2) were sporadically detected in amounts >LOD (0.01 mg/kg), but the information provided there is not fully clear.

Additionally, in relation to the field dissipation studies, soil stability of Flufenacet and its degradation products in soil was examined, showing that Flufenacet and its three relevant degradation products – FOE Alcohol (M3), FOE Oxalate (M1) and FOE Sulfonic acid (M2) were considered to be stable in soil stored under frozen conditions for at least two years.

Neither soil residue nor soil accumulation studies were performed. They were indicated as not necessary, because the trigger values had not been exceeded.

The adsorption of Flufenacet in soil was examined in seven soils, resulting in K_{foc} = 113 – 696 mL/g and $1/n$ = 0.84 – 0.98 (values taken from the EU-agreed LoEP, including soils having OC < 0.23%). On that basis Flufenacet was classified as being moderately mobile in soil.

The soil sorption of metabolites of Flufenacet was examined in four soils. The data were collected for five metabolites – FOE Methyl sulfoxide (M5), FOE Sulfonic acid (M2), FOE Oxalate (M1), FOE Alcohol (M3) and Thiadone (M9). The obtained results were following:

- for FOE Methyl sulfoxide (M5): K_{OC} = 46 – 463 mL/g (values taken from the DAR);
- for FOE Sulfonic acid (M2): K_{OC} = 10 (6 – 19) mL/g and $1/n$ = 0.86 – 1.18 (values taken from the EU-agreed LoEP);
- for FOE Oxalate (M1): K_{OC} = 11 (7 – 23) mL/g and $1/n$ = 0.82 – 1.42 (values taken from the EU-agreed LoEP);
- for FOE Alcohol (M3): K_{OC} = 84 – 314 mL/g (values taken from the DAR);
- for Thiadone (M9): K_{OC} = 29 – 58 mL/g (values taken from the DAR).

Of the compounds listed above only FOE Oxalate and FOE Sulfonic acid were characterised as expected to have a potential to leach into deeper soil layers in significant amounts.

Column leaching studies were not performed, considered to be covered by the results of batch sorption studies.

The results of the aged residue column leaching study indicated that Flufenacet and its three metabolites found in the study – FOE Oxalate (M1), FOE Sulfonic acid (M2) and FOE Thioglycolate sulfoxide (M4), might leach to deeper soil layers, but only Flufenacet, FOE Oxalate (M1) and FOE Sulfonic acid (M2) were expected to appear there in significant amounts.

Additionally, the mobility of Flufenacet and its degradation products in soil was examined in two lysimeter studies. As a result of these studies it was concluded that even under worst-case conditions it was not expected that the active substance would leach to the groundwater in amounts posing an unacceptable threat to that environmental compartment (in concentrations ≥ 0.1 µg/L). Similar conclusion was drawn for the two degradation products detected – FOE Oxalate (M1) and FOE Thioglycolate sulfoxide (M4). In case of another metabolite of Flufenacet – FOE Sulfonic acid (M2), it was stated that that compound may be found in soil layers below 1.2 m, or in groundwater, in amounts > 0.1 µg/L. That compound however was demonstrated to be neither toxicologically nor ecotoxicologically relevant.

The examination of the fate and behaviour of Flufenacet in water showed that the compound was hydrolytically and photolytically stable in that environment. The proper study on ready biodegradability of Flufenacet was not performed, but on the basis of the results of water/sediment studies it was stated that the compound was not readily biodegradable.

The examination of the fate and degradability of Flufenacet in water/sediment systems showed that its degradation pattern in aquatic systems was very similar to that elucidated in aerobic soil. Although it was

determined that a significant portion of radioactivity was translocated to the sediment phase, it was not clearly indicated whether it was related to the parent compound or to its degradation products.

The results presented in the DAR seemed to indicate that Flufenacet was predominantly present in water phase throughout the whole study and the migration to sediment was not a significant dissipation route – the maximum amount of the compound found in sediment phase was 34.2% (on DAT 30). The kinetic endpoints were determined for the whole system and water phase and were as follows (all values taken from the EU-agreed LoEP):

- in water phase: $DT_{50} = 46.3 - 61.7$ days, $DT_{90} = 154 - 205$ days (fluorophenyl label only);
- in the whole system, for fluorophenyl label $DT_{50} = 76.4 - 84.6$ days, $DT_{90} = 254 - 281$ days, while for thiadiazole label $DT_{50} = 20 - 31$ days, $DT_{90} = 67 - 104$ days.

Of the degradation products detected only FOE Methylsulfide (M5), for the test systems treated with phenyl-radiolabelled compound, and Thiadone (M9), for the test systems treated with thiadiazole-radiolabelled compound, were classified as major degradation products.

The exposure assessment performed for the soil compartment resulted in calculation of the following initial PEC_{SOIL} values:

- for application in maize, soybean and sunflower at 600 g a. s./ha **ini** $PEC_{SOIL} = 0.8$ mg/kg;
- for application in cereals at 240 g a. s./ha **ini** $PEC_{SOIL} = 0.32$ mg/kg.

The calculations for any of the identified degradation products were not performed, nor was assessed their accumulation potential.

The model exposure assessment of the Groundwater compartment was performed twice, first using PELMO 2.01 model (“Borstel” soil scenario and Hamburg weather scenario), then using FOCUS PELMO 2.2.2.

The results of both modellings indicated no risk posed to GW compartment by Flufenacet – the calculated $PEC_{GW} < 0.1$ µg/L. Also safe uses were demonstrated for FOE Oxalate (M1), although in case of calculations performed using FOCUS PELMO 2.2.2. model for use in cereals and maize the $PEC_{GW} > 0.1$ µg/L were obtained, the highest value being that of 0.64 µg/L in Jokioinen scenario for use in cereals. In case however of FOE Sulfonic acid (M2) all calculated PEC_{GW} values were higher than the trigger value of 0.1 µg/L, peaking at 16.63 µg/L in Hamburg scenario for the use in maize. That was in good agreement with conclusions on the risk posed by that compound to the GW compartment, drawn from the lysimeter studies.

The SW exposure assessment was performed for Flufenacet and its metabolite FOE Sulfonic acid (M2), assuming the spray drift as a sole migration route of Flufenacet to SW water bodies and its 10%-conversion there to FOE Sulfonic acid (M2). The calculations were performed for static SW water bodies, considered to be representative also for slow-moving SW bodies.

The determination of the fate and behaviour of Flufenacet in air was based on the examination of its vapour pressure and Henry’s law constant. These values were following:

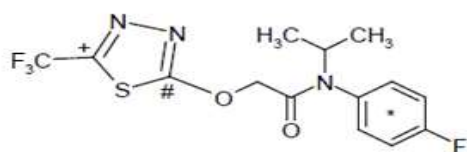

- vapour pressure (N-isomer) $V_p = 9E-5$ [Pa] ($T = 20^{\circ}C$);
- Henry’s law constant $H = 9E-4$ [$Pa \cdot m^3 \cdot mol^{-1}$] ($T = 20^{\circ}C$).

On the basis of these values it was stated that that no significant volatilization of Flufenacet is expected to occur. That was conformed by the results of the experiment on volatilization of the compound from soil, showing that within 24 hours up to 29% of the applied compound lost from the soil surface due to volatilization. The volatilization from plant surfaces was not examined.

For the process of photooxidative degradation in air the calculated (using Atkinson’s method) $DT_{50} = 4.7$ h, indicating that the compound was short-living in the atmosphere.

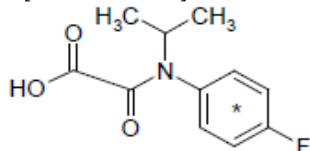

On the basis of the above results it was stated that the risk posed by Flufenacet to the atmosphere was minimal and the PEC_{AIR} values were not calculated.

In this assessment the environmental fate and behaviour of the active substance – Flufenacet, was examined using a compound radiolabelled in either phenyl ring (one radiolabelling position) or in thiadiazole moiety (two different radiolabelling positions), as shown on figure B.8.0._CA-1. The radiolabelled compounds were used also in examination of the fate and behaviour in the environment of the degradation products of Flufenacet. All radiolabelled structures used to examine the environmental fate and behaviour of Flufenacet, either as test compounds or as reference standards, are presented below on Fig. B.8.0._CA-1.

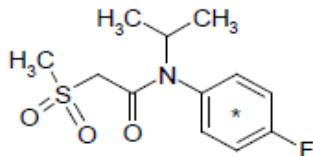

Flufenacet radiolabelled in phenyl and thiadiazole moieties;

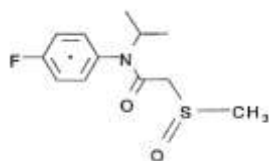

- * denotes [phenyl-UL-¹⁴C] radiolabelling position,
- # denotes [thiadiazole-2-¹⁴C] radiolabelling position;
- + denotes [thiadiazole-5-¹⁴C] radiolabelling position;

Figure B.8.0_CA-1: Radiolabelled forms of Flufenacet and its metabolites used in environmental fate and behaviour studies (all structures copied from the documentation provided by the Applicant).

In the documentation submitted by the Applicant following code names and alternative names for Flufenacet were used: fluthiamid, fluthiamide and FOE 5043.

B.8.1. – Fate and Behaviour in Soil

In order to adequately evaluate the studies examining the fate and behaviour of Flufenacet in soil it has become necessary to determine the application rate expressed in mass units (mg/kg) that may be subsequently used as a reference value. The analysis of the proposed EU-representative application pattern for Flufenacet (please refer to the table B.8.0._CA-1) enabled the identification of the critical use with regard to the soil exposure – 240 g Flufenacet/ha. Assuming uniform application to the top 5 cm soil layer, soil bulk density $d = 1.5 \text{ g/cm}^3$ and crop interception $CI = 0\%$ (application to bare soil), the application rate expressed in mass units (mg/kg) is **A = 0.32 mg/kg**. This value will be used as a reference in determining the validity of the studies examining fate and behaviour of flufenacet in soil.

B.8.1.1. – Route and rate of degradation in soil

Under this point are summarised the studies examining the route and rate of degradation of Flufenacet in soil under various conditions, both in the laboratory and in the field. The dossier submitted by the Applicant contained both old studies, already evaluated for the previous authorisation of Flufenacet in the EU, and the new/newly submitted (further referred to as “new”) studies, submitted specifically for the purpose of the renewal of the authorisation.

RMS – Poland, having examined the Assessment Report for Flufenacet and Addenda to it, prepared by the then-RMS France, decided to provide in this Report the summaries of all the studies submitted by the Applicant (old and new) and found acceptable. In case of the old studies RMS decided to evaluate them against the new Guidelines, but, unless it is stated that they significantly deviate from the current acceptability standards, do not change the conclusions with regard to their acceptability drawn by the former RMS – France. The old studies were summarised according to the current standards, the same as applied to the new ones.

B.8.1.1.1. – Route of degradation in soil

The route of degradation in soil was examined under aerobic and anaerobic conditions. Also was examined the relevance of the photolysis on the soil surface as the mechanism of degradation of Flufenacet in that compartment. The studies evaluated under this point provided the data for subsequent kinetic analysis, presented under the point B.8.1.1.2. In case the study report summarised under this point contained also the results of the kinetic analysis of the data, unless it was found as not meeting the current requirements, the reference to the relevant data point was made, under which that analysis was presented.

B.8.1.1.1.1. – Aerobic degradation

To address the issue of the route of degradation of Flufenacet in soil under aerobic conditions the Applicant submitted five study reports. Three of them had been evaluated for the first authorisation of this compound in the EU and summarised in the DAR prepared by the then-RMS – France. In order to maintain the consistency with the former evaluation RMS-Poland, decided to evaluate and provide the summaries of these three studies in the same order as they appeared in the former DAR. Additionally the analysis of that document revealed that to one of the studies – by Pangilinan and Smith [1994] – study Report No. MR106408, there was a supplementary study. In the previous Assessment Report both studies were summarised together. However, for the purpose of this Renewal Assessment Report RMS decided to provide for them two separate summaries.

Finally, the extensive search for open literature data enabled to identify two publications relevant in the area of the elucidation of the route of degradation of Flufenacet in aerobic soils. These publications are:

- Bloomberg A. M., Shadrick B. A., Arthur E. L., Clay V. E., “*Outdoor soil metabolism of [Phenyl- $U\text{-}^{14}\text{C}$] Flufenacet on California Soils.*”; ACS Symposium Series, 2002, vol. **813** – “Pesticide Environmental Fate” (chapter 12), 167 – 182 (book chapter);
- Lam C. K., McKinney M. K., Clay V. E., “*Evaluation of Laboratory and Field Extraction Methods: Extraction of [Phenyl- $U\text{-}^{14}\text{C}$] Flufenacet from Aged Soils.*”; ACS Symposium Series, 2002, vol. **813** – “Pesticide Environmental Fate” (chapter 11), 153 – 166 (book chapter);

Their summaries will be provided after those of the study reports submitted by the Applicant.

Study 1:

Report: Kelley I., Wood S., McKinney M., (1995): “Degradation of [Phenyl-UL-¹⁴C]FOE 5043 in Three Soil Types.”; Bayer Corporation (formerly Miles Inc), Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120, USA; study No. F3042104; unpublished Bayer Report No. MR 106664; 31 August 1995; study reference number: M-002146-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Official Testing of Plant Protectants, Part IV, 4-1 (1986): Persistence, Transformation and Metabolism;
- US. EPA Guideline 162-1 Aerobic Soil Metabolism (supplemental);

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.1.1.1.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. The study was evaluated for its compliance with OECD Guideline 307 – Aerobic and Anaerobic Transformation in Soil. RMS stated that the study complied with the provisions of the reference Guideline, therefore it can be considered acceptable for the present assessment. It is summarised below in its part related to the route of degradation, while for the rate of degradation the information is placed under the point B.8.1.1.2.1.

Summary:

The aim of the study was to determine the route and rate of degradation of Flufenacet in soil under aerobic conditions. The experiment was performed on three European (German) soils. Their characteristic is given below in the table B.8.1.1.1.1._CA-1.

Table B.8.1.1.1.1._CA-1: The characteristic of soils used in the study.

Parameter			Soil		
			BBA 2.2	Laacherhof	Höfchen im Tal
Soil origin			Germany; EU	Germany; EU	Germany; EU
Soil type (in the DAR)			Loamy sand	Silt Loam	Silt Loam
Soil type (USDA; re-assessed)			Loamy sand	Silt Loam	Silt Loam
Particle size distribution	Sand [%]		86.2	36.9	3.6
	Silt [%]		7.7	51.1	80.8
	Clay [%]		6.1	12.0	15.6
pH value (in H ₂ O, CaCl ₂)			6.2	7.3	5.8
Organic carbon content (C _{org}) [%]			2.58	0.9	2.40
Cation Exchange Capacity – CEC [mEq/100g]			9.7	10.0	10.0
Maximum water holding capacity [%]			53.8	48.6	71.6
Soil biomass expressed in mg microbial C/kg soil	Control (no FOE 5043)	Initial (DAT 0)	350	227	490
		On DAT 56	226	270	587
		Final (DAT 120)	216	161	443
	Treated with FOE 5043	Initial (DAT 0)	315	279	520
		On DAT 56	275	256	706
		Final (DAT 120)	230	155	403
Soil biomass expressed as %OC	Control (no FOE 5043)	Initial (DAT 0)	1.3	2.52	2.04
		On DAT 56	0.88	3.0	2.45
		Final (DAT 120)	0.84	1.79	1.85
	Treated with FOE 5043	Initial (DAT 0)	1.22	3.1	2.17
		On DAT 56	1.07	2.84	2.94
		Final (DAT 120)	0.89	1.72	1.68

The test soils were selected according to BBA guidelines for examining the degradation of chemicals in soil. They were freshly collected from the agriculturally used land in Germany, from the top 15-cm layer, and sent to the test facility. There the containers were immediately opened and planted with alfalfa to maintain the biological viability of soils. The test soils were then kept for 27 days in the greenhouse, until the study began. At the beginning of the study the soils were air-dried and sieved through a 2-mm sieve.

Samples of each test soil were then taken for the textural analysis and the determination of soil properties. The soil microbial activity was controlled throughout the study by determining microbial biomass at three intervals

during the incubation period: at its beginning – on DAT 0, on DAT 56 and at its end – on DAT 120, using the method of Anderson and Domsch (method presented by Parkinson and Smith in “*Microbial Biomass*” in Page A. L (ed.), **1982**, *Methods of Soil Analysis, Part 2*; Soil Science of America Inc., Madison, pp.824-826

Also before the experiment began the soil water content at 40% MWHC was determined. This was done using soil samples that were oven-dried overnight and then passed through a 2-mm sieve. The 50-grams portions of so prepared test soils were weighed into preweighed Buchner funnels equipped with GF/C filters. The funnels were placed in beakers filled with water up to the soil level. Then the soils were allowed to soak up water for 1 hour before being drained until dripping stopped. Then the funnels were reweighed and the maximum water holding capacity of each test soil determined by difference in weight. Next the amount of water necessary for obtaining 40% MWHC was calculated.

The test substance used in the experiment was the ^{14}C -FOE 5043 radiolabelled uniformly in phenyl ring, as shown below on figure B.8.1.1.1.1._CA-1

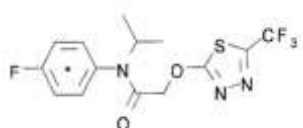

Figure B.8.1.1.1.1._CA-1: The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 66.5 mCi/mmol and the radiochemical purity of its application solution, determined by HPLC, was 96.3% (content of [^{14}C] FOE 5043).

The test substance was applied in form of the application solution containing nominally 20 ppm of the radiolabelled Flufenacet. It was prepared by adding 0.831- μL aliquot of [^{14}C] FOE 5043 solution (conc. 12.028 $\mu\text{g}/\mu\text{L}$), having the specific activity of 0.18 $\mu\text{Ci}/\mu\text{g}$, corresponding to 6.8 kBq/ μg) and 2 mL of acetonitrile (CH_3CN) to a previously sterilised 500 mL volumetric flask. Next the solution was brought to a volume with distilled water and analysed for the radiochemical concentration using LSC. The actual concentration of the test compound – Flufenacet, in so prepared solution was determined to be 19.1 $\mu\text{g}/\text{mL}$ (3.49 $\mu\text{Ci}/\text{mL}$, corresponding to 129.19 kBq/mL). The radiochemical purity of so prepared application solution was 96.3 % with relation to FOE 5043.

Additionally a second application solution, containing solely non-radiolabelled Flufenacet was prepared by dissolving 10 mg of the test compound with sterile distilled water in 500-mL volumetric flask. In order to facilitate solubilisation of the test compound 2 mL of CH_3CN were added to the volumetric flask prior to its filling in to the calibration mark with distilled water. That solution was used to treat the control samples used in determination of soil biomass.

The experiment was performed using the glass biometer flasks, presented below on figure B.8.1.1.1.1._CA-2. They consisted of 250-mL Erlenmeyer flasks with wide-diameter glass tube adapters, sealed with traps for volatile compounds. The traps consisted of a glass adapter containing of ~1g plug of glass wool soaked with 2% mineral oil in hexane to absorb possible VOC and soda lime layer (~10 g.) to capture formed $^{14}\text{CO}_2$, capped with a layer of glass wool (separator) above which further ~4-grams. layer of soda lime was placed to prevent soda-lime sorbent from being saturated with atmospheric CO_2 . On the top 4-grams layer of glass wool was placed. The side-arm inlet tube, sealed with a rubber septum was set to enable the adjustment of soil moisture by adding the necessary amounts of distilled water during the study.

Each test vessel contained the equivalent of 100 grams d. w. test soil, with soil moisture adjusted to ~40% MWHC by addition of the appropriate amount of the distilled water. That level was maintained throughout of the incubation period, lasting up to 120 days.

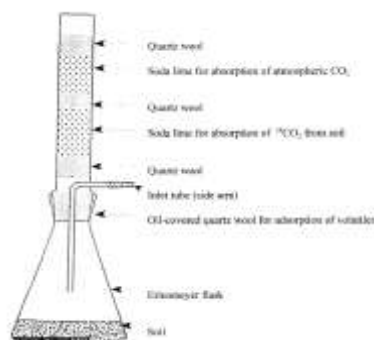

Figure B.8.1.1.1._CA-2: The biometer flask used in the experiment (scheme copied from the study report).

The test compound was applied onto the test soils in form of the application solution described above, having the nominal concentration of 20 mg/L, and actual concentration of 19.1 mg/L.

The test substance was applied at two different application rates: 750 g a. s./ha (0.67 lb a. s./acre) in case of two test soils and 1500 g a. s./ha (1.34 lb a. s./acre) in case of one soil. The appropriate volumes of the application solution were evenly distributed over the soil surface. The details of the application of Flufenacet to the test soils are presented below in the table B.8.1.1.1._CA-2.

Table B.8.1.1.1._CA-2: The characteristics of the treatment of test soils with Flufenacet.

Test soil	Target application rate [g/a. s./ha]	Volume of application solution [mL]	Concentration of the test compound in treated soil	
			Concentration [ppm]	Assumptions made
BBA 2.2 (Loamy sand)	750	5	1	soil depth: 5 cm soil density: 1.5 g/cm ³
Laacherhof (Silt loam)	750	5	1	soil depth: 5 cm soil density: 1.5 g/cm ³
Höfchen im Tal (Silt loam)	1500	10	2	soil depth: 5 cm soil density: 1.5 g/cm ³

After treatment the appropriate amounts of distilled water were sprinkled onto each test soil to establish a soil moisture of ~40% MWHC. The amounts of water used for each test soil were:

- 1.92 mL for BBA 2.2 soil;
- 1.43 mL for Laacherhof soil;
- 0.97 mL for Höfchen im Tal soil.

Controls were treated with the solution of non-radiolabelled Flufenacet in such amount to obtain its concentration of 1 ppm. As it was in case of treated soils the controls were then brought to ~40% MWHC by adding the appropriate amount of distilled water.

After treatment the Erlenmayer incubation flask were sealed with traps for volatile compounds, weighed and covered with aluminium foil to exclude light.

So prepared incubation systems were placed in a walk-in, temperature controlled environmental chamber and incubated in the darkness at $T = 20 \pm 1^{\circ}\text{C}$ for up to 120 days. The temperature in the incubation chamber was recorded continuously with circular charts changed every 7th day. Treated samples were removed for the analysis at DAT (Days After Treatment) 0, 7, 14, 28, 56, 70, 100 and 120. Control samples were removed for analysis at DAT 0, 56 and 120. For each time point duplicate samples were prepared. The adjustment of soil moisture was performed in 2-weeks intervals by weighing the incubation flasks and, when necessary, introducing the appropriate amounts of distilled water through the side-arm inlet tube.

At the designated time points duplicate test flask for each soil were removed from the incubation chamber and for 15 minutes purged gently with N₂ in order to flush the produced CO₂ and VOCs into the traps.

Next soils from each test vessel were analysed. That was done by extracting the entire soil samples in multistep extraction procedure.

In case of DAT 0 samples it consisted of two following steps:

- Step 1: extraction with water – twice 150 mL, lasting for two hours (stir extraction at room temperature), to determine the residues immediately available for plants or leaching to groundwater. The extracts were combined, their volume recorded and triplicate aliquots analysed by LSC.

- Step 2: organic extraction with two 150-mL portions of 0.01N HCl in CH₃CN (stir extraction). So obtained organic extracts were combined, their volumes recorded and 100-μL or 500-μL aliquots analysed by LSC. The remaining organic extracts were then evaporated under reduced pressure, redissolved in small amounts of MeOH and analysed by using HPLC.

For all samples collected at later time points, with exception of those collected at DAT 100 and DAT 120, three-step extraction procedure was used, consisting of:

- Step 1: extraction with water – twice 150 mL, lasting for two hours (stir extraction at room temperature), to determine the residues immediately available for plants or leaching to groundwater. The extracts were combined, their volume recorded and triplicate aliquots analysed by LSC.
- Step 2: organic extraction with two 150-mL portions of 0.01N HCl in CH₃CN (stir extraction). So obtained organic extracts were combined, their volumes recorded and 100-μL or 500-μL aliquots analysed by LSC. The remaining organic extracts were then evaporated under reduced pressure, redissolved in small amounts of MeOH and analysed by using HPLC (that extract will be further called “**organic extract 1**”).
- Step 3: additional harsher organic extraction with two 100-mL portions of CH₃CN: 0.1N HCl_{aq} 1:1 v/v solution (stir extraction). The obtained extracts were treated in the same manner as described above for Step-2 organic extracts. That step was introduced because it was stated that with time the amount of bound residues increased significantly. (That extract will be further called “**organic extract 2**”).

Finally for soils collected at DAT 100 and DAT 120 Step 2 was omitted and the extraction procedure consisted again of only two, following steps:

- Step 1: extraction with water – twice 150 mL, lasting for two hours (stir extraction at room temperature), to determine the residues immediately available for plants or leaching to groundwater. The extracts were combined, their volume recorded and triplicate aliquots analysed by LSC.
- Step2 (formerly Step 3): harsher organic extraction with two 100-mL portions of CH₃CN: 0.1N HCl_{aq} 1:1 v/v solution (stir extraction). The obtained extracts were treated in the same manner as described above for Step-2 organic extracts. That step was introduced because it was stated that with time the amount of bound residues increased significantly. (That extract will be further called “**organic extract 2**”).

Additionally, DAT 120 samples were further extracted for the additional RA using following extraction methods:

- Soxhlet extraction with 0.1N HCl_{aq}:CH₃CN solution;
- Soxhlet extraction with CH₃COOC₂H₅ (ethyl acetate);
- Soxhlet extraction with CH₂Cl₂ (methylene chloride)
- Soxhlet extraction with CH₃OH;
- Stir heating extraction with 1N HCl_{aq};
- Stir extraction with 1N NaOH.

The extracted soils were subsequently analysed for NER fraction. To do that each soil sample was allowed to air-dry overnight, after what it was ground to the fine powder, weighed, and its triplicate aliquots analysed for radioactivity content after combustion by LSC.

Traps for volatile compounds, recovered from test vessels were dissected into soda lime trap and mineral oil coated glasswool plug sections.

The filling of each soda lime trap section was ground, weighed, oxidised and analysed by LSC. In the same way were analysed unexposed soda lime traps and spiked soda lime traps.

Mineral oil coated glasswool plugs were extracted with ~100 mL CH₃COOC₂H₅ in 30-min. sonication. The volumes of extract were recorded and triplicate 500-μL or 1000-μL aliquots analysed by LSC. Unexposed plugs were used as blanks. As the levels of radioactivity recovered from plugs were low, samples from later intervals were combined, 10 μL of C₁₀H₂₁OH added to minimise losses during processing and combined samples were evaporated at Rotovap. The oily residue was redissolved in 1.5 mL CH₃CN and 250-μL aliquots of so prepared solution analysed by HPLC.

The extracts from DAT 0 samples were used to verify the stability of the test compound during sample treatment. Additionally the stability of the test compound in the application solution was tested.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a Packard Tri-Carb Model 4640 counter equipped with automatic external standardisation.

Liquid samples were radioassayed after addition of 15-20 mL of Ultima Gold solution to 100 – 1000 μ L aliquots, depending on sample. The minimum sensitivity of LSC analysis for those samples was 0.00018 ppm, and when expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 70 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 35 cpm.

Solid samples were oxidised using Packard Model 306 sample oxidizer, generated $^{14}\text{CO}_2$ trapped on 6 mL Carbo-sorb E and 15 mL Perma Fluor E. The minimum sensitivity of LSC analysis for those samples was 0.00091 ppm, and when expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 70 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 35 cpm.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- TLC – conformatory method for identification of degradation products;
- LC-MS - identification and quantitation method for parent compound and its degradation products.

The RP-HPLC analysis was performed in a gradient mode. The system, consisted of Hewlett Packard 1090 chromatograph equipped Spherisorb 3 μ ODS2 (7 cm * 10 mm) chromatographic column and two detectors – UV absorbance flow detector, set at 254 nm, and Raytest Ramona radioactivity detector. It worked in the following gradient regime:

- Mobile phase A: Water + 0.4% CH_3COOH ,
- Mobile phase B: CH_3CN + 0.4% CH_3COOH ,
- Gradient mode: linear from 0% B at 0 min to 100% B at 60 min.

The flow rate in the system was set to 1 mL/min.

The TLC method – conformatory for identification of metabolites, used pre-coated 0.25-mm thick silica gel plates with fluorescent indicator. Plates were developed in $\text{CHCl}_3/\text{CH}_3\text{COOC}_2\text{H}_5$ 3:1 solution and further separation was performed on the same plate using a solvent system $\text{CH}_3\text{CN}/(\text{CH}_3)_2\text{CHOH}/\text{CH}_3\text{COOH}/\text{H}_2\text{O}$ (20:3:2:1 v/v). Radioactive bands were detected by exposing the plates to X-Ray film.

The LC-MS analysis was performed using Varian 5400 HPLC equipped with a C18 (5- μ) Novapak column (15 cm * 3.9 mm) working in a gradient mode, and Finnigan MAT 90 MS detector. The parameters of gradient were following:

- Mobile phase A: Water + 0.1% CH_3COOH ,
- Mobile phase B: CH_3OH ,
- Gradient mode: linear from 0% B at 0 min to 100% B at 30 min.

The flow rate in the system was set to 1 mL/min.

The parameters of MS detector were following:

- source temperature: 250 $^\circ\text{C}$,
- aerosol temperature: 210 $^\circ\text{C}$,
- vaporiser temperature gradient : 170 $^\circ$ at 100% H_2O to 148 $^\circ\text{C}$ at 100% CH_3OH ,
- scans collected at: 150-600 amu at rate 10 sec/dec,
- 0.2 M ammonium acetate added post column at rate of 0.5 mL/min.

The identification of Flufenacet and its degradation products in HPLC and TLC analysis was performed by means of comparison of the R_t (HPLC) and R_f (TLC) factors in examined extracts with those of the standards. The R_t and R_f values for each of the analysed compounds in HPLC and TLC analysis are given in the table B.8.1.1.1.1._CA-3 below.

Table B.8.1.1.1._CA-3: Chromatographic (HPLC and TLC) identification of Flufenacet and its degradation products in the study.

Compound	Compound's identity	Identification with:	
		HPLC – R_t [min]	TLC – R_f
Parent	Flufenacet	44.7	0.93
Metabolite 1	FOE Sulfonic acid	16.4	0.52
Metabolite 2	FOE Oxalate	18.4	0.38
Metabolite 3	FOE Thioglycolate sulfoxide	25.7	0.30
Metabolite 4	FOE Methylsulfoxide	30.3	0.62
Metabolite 5	FOE Methylsulfone	33.8	0.84
Metabolite 6	FOE Amine acetate	37.5	0.81
Metabolite 7	FOE Methylsulfide	40.6	0.62
Metabolite 8	FOE Alcohol	37.6	0.74

The identification of Flufenacet and its degradation products in LC/MS analysis was performed by comparison of mass spectra of each chromatographic peak with those obtained for the standards, for which base signals and protonated molecular ion signals were identified. These are presented below in the table B.8.1.1.1.1_CA-4. It shall be noted that of all compounds listed in the table B.8.1.1.1.1_CA-3 above, the identification with LC/MS was performed for the parent compound and the metabolites either present in amounts > 10% AR in combined aqueous and organic extracts, or those <10% AR in combined aqueous and organic extracts, but not exhibiting a decreasing trend towards the end of the study.

Table B.8.1.1.1.1_CA-4: LC/MS identification of Flufenacet and its degradation products in the study.

Compound	Representative signals used in identification	
	Position – m/z	Description
Flufenacet	364	Protonated molecular ion $[M+H]^+$ = base peak
	381	Ammonia adduct $[M + NH_4]^+$
FOE sulfonic acid	274	Base Peak $[M - H]^-$ = molecular ion
FOE oxalate	226	Protonated molecular ion $[M+H]^+$
	243	Base peak (Ammonia adduct $[M + NH_4]^+$)
FOE methylsulfone	274	Protonated molecular ion $[M+H]^+$
	291	Base peak (Ammonia adduct $[M + NH_4]^+$)

Results and their discussion:

The stability tests performed using DAT 0 samples demonstrated that Flufenacet was stable during application and routine extraction procedure. In case however of extraction with 1N NaOH the compound was undergoing the decomposition, what complicated the interpretation of the results obtained during the additional analysis of the NER fraction (bound residues).

It was also shown that in the application solution the compound was stable for the period of at least 9 months, when the solution was stored in refrigerator at 4°C.

The analysis of the soil biomass showed that in all three soils it was > 1% OC at the beginning of the study and although decreasing towards it end it was still above that level in two of them – Laacherhof (1.72-1.79% OC) and Höfchen im Tal (1.68-1.85% OC). In case of BBA 2.2 soil on DAT 120 (end of the incubation period) it dropped below the level of 1% OC – to 0.84-0.89% OC.

In all three soils the microbial biomass decreased towards the end of the study – by 27.0% (control treated with Flufenacet) – 38.3% (untreated control) in case of BBA 2.2 soil, 29.1% (untreated control) – 44.4% (control treated with Flufenacet) in case of Laacherhof soil and by 9.59% (untreated control) – 22.5% (control treated with Flufenacet) in case of for Höfchen im Tal soil. It shall be pointed out however, that while in BBA 2.2 soil that decline was steady, in case of the two remaining soils the amount of biomass was higher at DAT 56 than that at DAT 0.

In the study report it was stated that the decline of soil microbial biomass was attributed rather to the storage of the samples and test conditions, while the addition of the test compound had little effect on that phenomenon.

The recovery of the applied radioactivity in all three experimental soils was generally good, in line with the recommendations of the relevant Guidelines. For the individual soils it looked as follows:

- for BBA 2.2 soil: 91.3 – 106.0% AR (average 98.3% AR);
- for Laacherhof soil: 92.4 – 100.5% AR (average 95.9% AR);
- for Höfchen im Tal soil: 91.3 – 100.4% AR (average 97.7% AR).

The level of mineralization gradually increased throughout the study, to reach at its end (DAT 120) 14.2% AR in BBA 2.2 soil, 23.8% AR in Laacherhof soil and 12.0% AR in Höfchen im Tal soil (determined as $^{14}CO_2$ captured in volatile compounds trap). Also the NER fraction increased with time to reach at the end of the study – DAT 120, the levels of 42.3% AR in BBA 2.2 soil, 37.1% AR in Laacherhof soil and 58.0% AR in Höfchen im Tal soil.

The amount of AR present as combined extractable fraction decreased with time all three soils, to reach at the end of the study (DAT 120) the level of 37.4% AR in BBA 2.2 soil, 31.5% AR in Laacherhof soil and 26.1% AR in Höfchen im Tal soil. It was also noted that for samples collected from DAT 7 to DAT 70 the amount of radioactivity extracted with **organic extract 2** (harsher extraction) increased with time, while that extracted with **organic extract 1** (milder extraction) decreased.

The following compounds were identified in extracts from all three soils:

- Flufenacet,
- FOE Sulfonic acid,
- FOE Oxalate,

- FOE Thioglycolate sulfide,
- FOE Methylsulfoxide,
- FOE Methylsulfone,
- Other fraction consisting of 5-6 specified and several unspecified constituents.

The maximum concentrations of identified degradation products recorded in each test soil are given below in the table B.8.1.1.1.1._CA-5.

Table B.8.1.1.1.1._CA-5: The maximum amounts of identified degradation products of Flufenacet observed in each test soil.

Compound	Maximum concentration, expressed in %AR, observed in soil:		
	BBA 2.2 (Loamy sand)	Laacherhof (Silt loam)	Höfchen im Tal (Silt loam)
<i>FOE Sulfonic acid</i>	25.4 (DAT 100)	26.3 (DAT 100)	13.5 (DAT 100)
<i>FOE Oxalate</i>	6.6 (DAT 28)	15.6 (DAT 28)	10.0 (DAT 28)
<i>FOE Thioglycolate sulfide</i>	3.3 (DAT 56)	5.5 (DAT 28)	1.9 (DAT 28)
<i>FOE Methylsulfoxide</i>	1.1 (DAT 28, DAT 56)	3.5 (DAT 56)	1.5 (DAT 56)
<i>FOE Methylsulfone</i>	6.6 (DAT 100)	4.3 (DAT 120)	5.6 (DAT 120)

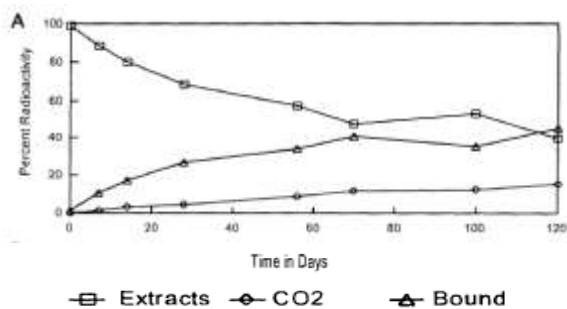

The detailed results are presented below, separately for each soil, in tables B.8.1.1.1.1._CA-6 – B.8.1.1.1.1._CA-8 (the values were rounded to one digit after the decimal point). Additionally they are presented in graphical form, on the paired graphs, presenting the distribution of radioactivity among extracts, NER fraction and CO₂ (left-hand side graph) and distribution of Flufenacet and its degradates (right-hand side graph) in each test soil, on figures B.8.1.1.1.1._CA-3 – B.8.1.1.1.1._CA-5, individually for each soil.

Table B.8.1.1.1.1._CA-6: The detailed results obtained in BBA 2.2 soil.

% AR		Results obtained for sample collected at DAT ¹⁾ :

Distribution of AR among extractable, NER and CO₂ fractions:*Distribution of Flufenacet and its degradation products:*

Figure B.8.1.1.1.-CA-5: Graphical presentation of the results obtained in Höfchen im Tal soil (copied from the study report).

The results of the further examination of Bound Residues (NER) fraction are presented below, in the table B.8.1.1.1.-CA-9. For all three soils was performed a two-step extraction:

- **Step 1:** Soxhlet extraction with 0.1N HCl_{aq}:CH₃CN solution;
- **Step 2:** Stir heating extraction with 1N NaOH.

Only for Höfchen im Tal soil, in which the amount of the formed NER fraction was the highest – 58.0% AR, the additional steps were included.

The **Step 1** extraction resulted in extracting additional 2.6 – 3.5% TAR (theoretically applied radioactivity). The chromatographic (HPLC) analysis of that fraction demonstrated that it consisted mainly of degradation products, as shown on figure B.8.1.1.1.-CA-6.

Step 2 extraction enabled to recover further 19.9 – 31.4% TAR, consisting mostly of degradation products, as demonstrated chromatographic (HPLC) analysis of the extract. It was however pointed out that results of the identification and quantitation of that extract's constituents were of limited reliability, because the extraction method was demonstrated to be too harsh and destructive for Flufenacet (it was shown that Flufenacet added to Höfchen im Tal soil and then extracted using that method was partly degraded).

No further attempts to identify the NER fraction were undertaken.

Table B.8.1.1.1.-CA-9: The results of characterisation of NER fraction in DAT 120 samples.

Figure B.8.1.1.1._CA-6: The results of the HPLC analysis of Step1 extracts from each test soil (copied from the study report).

The results obtained for Flufenacet in each soil were kinetically evaluated to obtain the kinetic endpoints – DT_{50} and DT_{90} values. Although that kinetic analysis was presented in details in the study report, it was not included into the summary as not complying with the current standards.

The results were kinetically re-examined, and the results of that examination presented in the separate report, which will be summarised under the relevant point of this Assessment Report – B.8.1.1.2.1.1.

Conclusions:

The obtained results showed that Flufenacet was extensively degraded in all three soils during 120 days, reaching the level of 2.8 – 10.0% AR at the end of the study.

Several degradation products were detected, of which five were identified: FOE Sulfonic acid, FOE Oxalate, FOE Thioglycolate sulfoxide, FOE Methylsulfoxide and FOE Methylsulfone. Three of them are considered major according to the current Guidelines: FOE Sulfonic acid (max. 13.5 – 26.3% AR), FOE Oxalate (max. 6.6 – 15.6% AR) and FOE Methylsulfone (max. 4.3 – 6.6% AR). It shall be noted that FOE Methylsulfone met the relevance criteria due to the fact that it was still forming, with concentrations increasing, at the end of the study. All other detected degradates, both identified and unknown, may be considered as minor degradates and transformation products.

The level of mineralization, measured by the amounts of $^{14}CO_2$ formed, was 12.0 – 23.8% AR. Formation of NER was significant, reaching the level of 37.1 – 58.0% AR. The additional extraction using the non-destructive methods enabled to obtain only 2.6 – 3.5% of additional AR, mainly identified as degradation products.

Extraction of NER with much harsher method, destructive for Flufenacet, led to additional extraction of 20 – 31.5% AR, mainly in form of degradation products.

On the basis of obtained results the Applicant proposed the following transformation pathway of Flufenacet in aerobic soil, determined for the compound radiolabelled uniformly in phenyl ring – Fig B.8.1.1.1._CA-7. It shall be noted that the proposed transformation scheme takes into account also the findings of the earlier study by Pangilinan and Smith [1994], summarised below as **Study 2**. It contains two degradation products – FOE Chloroacetanilide and FOE Alcohol not found in this study, but in that by Pangilinan and Smith [1994]. It shall be also pointed out that the proposed by-product – FOE Cysteine Conjugate was not detected in any study examining the route of degradation of Flufenacet in soil, but it was assumed to be formed as a logical intermediate.

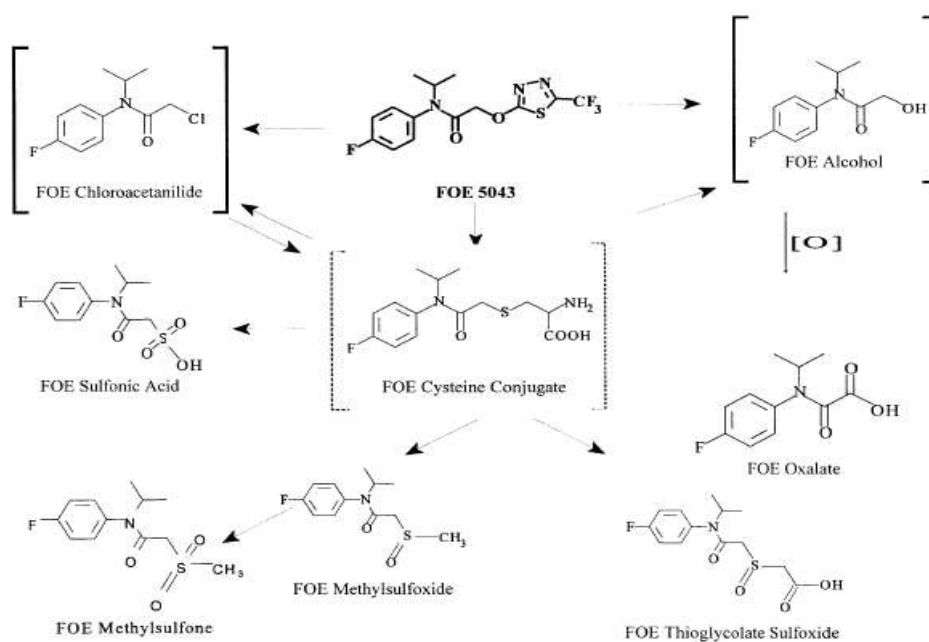

Figure B.8.1.1.1._CA-7: The transformation pathway of Flufenacet in aerobic soil, determined for the compound radiolabelled in phenyl ring (scheme copied from the study report).

The results obtained for Flufenacet were kinetically examined and the results of that kinetic assessment were presented as a part of the study report. However, as it did not comply with the current standards, set by FOCUS Kinetics Guidance Document [FOCUS, 2006] it was decided not to present it in the summary.

Study 2:

Report: Pangilinan N. C., Smith D. M., (1994): “Aerobic Soil Metabolism of [Phenyl-U-¹⁴C] FOE 5043”; Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3042102; unpublished Miles Report No. MR 106408; 12 May 1994; study reference number: M-002166-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1;

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its summary can be found under the point B.7.1.1.1.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. At present the study was evaluated for its compliance with OECD Guideline 307 – Aerobic and Anaerobic Transformation in Soil. Additionally RMS checked its compliance with the SETAC Guidelines on performing the laboratory test on aerobic degradation in soils, presented in *M. Lynch (ed.) “Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides.”*, SETAC, 1995. Also the US EPA Guideline indicated by the Applicant - US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1, was consulted. In course of that verification the following deviations from the Guidelines and problems were stated:

- The test soil displayed a very low average OM/OC content, well below the recommended OC = 0.5%, and highly variable. In the study report not only the declared average OM = 0.6%, corresponding to OC = 0.35%, but also it was in range 0.2 – 1.2%, depending on the year, in which the test soil was characterised. That may indicate that the test soil was very inhomogeneous with regard to OC content, what in turn might have influenced the obtained results. That feature was reported in the previous Assessment Report for Flufenacet prepared by the RMS – France, but not indicated as deviation disqualifying the study as not valid;
- There was a significant decrease in soil microbial activity observed in the test soil. It was stated that the phenomenon occurred at 30-th day after application of the test substance, when the collapse of the soil microbial activity was observed. Afterwards the steady decline in microbial activity occurred. The results however were not definitive, as two different methods of the determination of microbial activity in the test soil were used. The phenomenon was examined thoroughly by Applicant and the results of that examination presented in the study by Hellpointner (1995) in the report submitted as a part of the Dossier evaluated for the first authorisation of Flufenacet in the EU. The same study was evaluated and will be summarised under this point of the DRAR, as **Study 3**, immediately below the summary of this study. It shall be noted that the problem was noticed by the former RMS – France, but not considered as disqualifying the study;
- The test soil was preconditioned prior to its use by storing it in greenhouse in two 5-gallon (~19-L) buckets. Soybean plants were planted on the soil surface during that period to maintain its microbial viability. The samples of the test soil samples taken to the laboratory at the beginning of the experiment were pre-treated by sieving and air-drying, but afterwards they were not pre-conditioned as recommended by OECD 307 Guideline. That fact was not stated in the summary provided in the previous Assessment Report. It may possibly be the reason for the sudden collapse of soil microflora observed in the test systems ~30 days after the experiment started;
- Test substance was applied in form of the treatment solution being a mixture of CH₃CN: H₂O in ratio 1:4. That deviation from the Guidelines (OECD 307 Guideline recommends to prepare the treatment solution with water and only a small addition of any organic solvent not demonstrated to inhibit microbial activity; also the verification of the influence of such treatment solution on soil microbial activity is recommended prior to the treatment) was also not indicated in the previous DAR.

No other deviations were found in the study report. Despite those listed above RMS decided to consider the study acceptable, mainly because it provides the data on the route of degradation of Flufenacet in soil not reported in the summarised above **Study 1**. It is summarised below in its part related to the route of degradation, while for the rate of degradation the information is placed under the point B.8.1.1.2.1.

Summary:

The aim of the study was to investigate the fate – route and rate of degradation, of Flufenacet in soil incubated under controlled (in the laboratory) aerobic conditions. The experiment was performed using one test soil originating from the US (Howe, Indiana). Its characteristic is provided below in the table B.8.1.1.1.1_CA-10. It shall be noted that in the study report the table on soil characterisation provides the results for three different batches, then averaged. RMS decided to present all the results of that characterisation, as they were reported in the original study's report. The results of the determination of the microbial biomass are presented separately in the table B.8.1.1.1.1_CA-11 immediately following the main table presenting the test soil properties.

Table B.8.1.1.1.1_CA-10: The characteristic of soil used in the study.

Parameter		Soil: 395			
Soil origin		Howe, Indiana, USA			
Batch analysed		A ¹⁾	B ²⁾	C ³⁾	Average

Footnotes to the table:

- 1) The measurements performed specifically for the determination of the biomass in soil during the experiment;
- 2) The measurement performed independently at the Institute for Metabolism Research, Bayer AG, Germany, to determine the effects of storage on soil microbial population, on soils not treated with the test compound; samples were analysed using the method described by Anderson and Domsch;
- 3) Values calculated using the average OC content – 0.35%, reported in the table B.8.1.1.1.1_CA-10 above;
- 4) Value not reported as the samples were not analysed using either the method by Anderson and Domsch or that by Vance;
- 5) Analysis performed for soil sample collected on DAT 33, using the method by Vance;
- 6) Not available – the experiment was still ongoing when the currently summarised study report was finalised, so its full results will be presented as a summary of **Study 3** (Hellpointner; 1995).

Soil biomass in the test soil was determined using one of the following three methods:

- 1) analysis for ester-linked phospholipid fatty acids (PLFA);
- 2) soil fumigation method described by Vance et al;
- 3) method described by Anderson and Domsch.

The test soil was taken from a Miles Research Farm in Howe, Indiana, USA and placed in two ~19L buckets in the greenhouse. In order to maintain its microbiological viability soil was planted with soybean until the beginning of the study.

Immediately before the experiment began, ~2 kg of soil from the top 5-6 inch (corresponding to 12-15 cm) layer was taken to the laboratory, where the soybean plants were removed and moist soil sieved through 2-mm sieve. Then the test soil was air-dried for 2 hours to the level of 75% of $\frac{1}{3}$ bar (the soil moisture level kept throughout the experiment) and placed in the test vessels.

The test substance used in the experiment was the ^{14}C -FOE 5043 radiolabelled uniformly in phenyl ring, as shown below on figure B.8.1.1.1.1._CA-8.

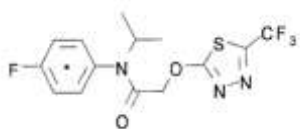

Figure B.8.1.1.1.1._CA-8.: The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 66.5 mCi/mmol and its radiochemical purity, determined with TLC, was 98.9%. Its radiochemical purity determined at the time of the treatment was 98.4%. It was applied to the test soil in incubation vessels in form of the application solution prepared in the following way: 296 μg of [phenyl- ^{14}C]-Flufenacet was evaporated to dryness under gentle stream of nitrogen and then redissolved in 2 mL of CH_3CN (acetonitrile), to which 8 mL of distilled water was added next. The so prepared solution was stirred and 60 mL of $\text{CH}_3\text{CN}:\text{H}_2\text{O}$ 1:4 solution was added. The concentration of so prepared solution was verified by LSC. It was determined to be 55.06 mg Flufenacet/L.

The experiment was performed using the glass biometer flasks, presented below on figure B.8.1.1.1.1._CA-9.

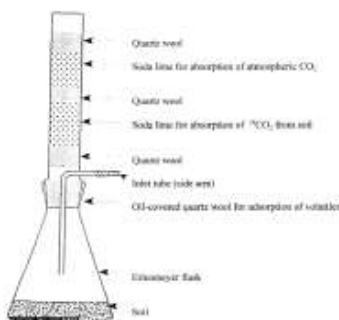

Figure B.8.1.1.1.1._CA-9: The biometer flask used in the experiment (scheme copied from the study report).

They consisted of 250-mL Erlenmeyer flasks with wide-diameter glass tube adapters, sealed with traps for volatile compounds. The traps consisted of a glass adapter containing ~1g plug of glass wool soaked with 2% mineral oil in hexane to absorb possible VOC, and soda lime layer (~10 g.) to capture formed $^{14}\text{CO}_2$. These sorbents were capped with a layer of glass wool (separator) above which further ~4-grams layer of soda lime was placed to prevent soda-lime sorbent from being saturated with atmospheric CO_2 . On the top 4-grams layer of glass wool was placed. The side-arm inlet tube, sealed with a rubber septum was set to enable the adjustment of soil moisture by adding the necessary amounts of distilled water during the study.

Each test vessel contained the equivalent of 100 grams of oven-dried test soil, adjusted to soil moisture content of 75% of $\frac{1}{3}$ bar by addition of the appropriate amount of the distilled water. That level was maintained throughout of the incubation period, lasting up to 365 days.

In total 43 incubation flask were prepared, of which 25 were used for kinetic tests, 3 for the non-sterile control, 3 for microbial biomass determination, 7 as test spares and 5 for metabolite isolation.

The test flasks were treated with the test substance, applied to the soil surface in form of the application solution described above, at a rate of 1.101 mg/kg. Applicant declared that it corresponded to approximately field application rate of 0.8 lbs a. i./acre, assuming soil depth of 3 inches and soil bulk density of 1.33 g/cm^3 . When recalculated by the RMS as g/ha, assuming soil depth of 5 cm and soil bulk density of 1.5 g/cm^3 , the exact

application rate was **825.75** g Flufenacet/ha. The use of the measured average soil bulk density – $d = 1.37 \text{ g/cm}^3$, resulted in the application rate of **754.185** g Flufenacet/ha.

The amount of the application solution introduced into each test vessel was 2 mL, applied dropwise to the soil surface using Hamilton 500 μL syringue, what resulted in 110 μg Flufenacet per flask. Each flask was gently shaken after introducing each 500 μL -portion of the application solution, to grant the even distribution of the test compound in soil.

Control and microbial biomass flasks were treated with 2-mL portions of blank solvent carrier ($\text{CH}_3\text{CN}:\text{H}_2\text{O}$ 1:4 v/v).

After treatment the appropriate amount of distilled water was added to each test vessel to establish a soil moisture of 75% of $\frac{1}{3}$ bar.

After treatment the Erlenmeyer incubation flask were sealed with traps for volatile compounds, weighed and covered with aluminium foil to exclude light.

So prepared incubation systems were placed in an incubator chamber and incubated in the darkness at $T = 21 \pm 1^\circ\text{C}$ (temperature range $T = 20.7 - 21.6^\circ\text{C}$) for up to 365 days. The temperature in the incubation chamber was monitored continuously. Soil moisture was monitored every week and corrected adequately, when necessary.

Trapping towers for formed volatile compounds were replaced at 6th month of incubation. Additionally, at the 11th month of incubation top layer of the soda lime (trap for atmospheric gasses) was replaced.

Samples were removed for the analysis at DAT (Days After Treatment) 0, 7, 14, 21, 28, 44, 65, 76, 91, 180, 271 and 365. In case of DAT 0 sampling point triplicate analysis was performed, while for all remaining 11 sampling points duplicate samples were prepared. In case of DAT 0 samples the traps for volatile compounds were not set and the soils were analysed almost immediately (1 hour) after treatment with the test compound.

The adjustment of soil moisture was performed in 1-week intervals by weighing the incubation flasks and, when necessary, introducing the appropriate amounts of distilled water through the side-arm inlet tube.

At the designated time points duplicate test flasks were removed from the incubation chamber and for 10 minutes purged with N_2 , administered at the flow rate of 500 mL/min, in order to flush the produced CO_2 and VOCs into the traps.

The collected traps for volatile compounds were removed and analysed for their content of trapped radioactivity. That was done in a following way: the traps were dissected, mineral oil coated glass wool transferred into 250-mL Erlenmeyer flask and extracted by sonication for at least 30 min with 50 mL of $\text{CH}_3\text{COOC}_2\text{H}_5$. The organic extract was then collected by decantation and its triplicate aliquots analysed by LSC. Soda lime traps were transferred to 150-mL flasks, being a part of a specially designed extraction apparatus, shown below on figure B.8.1.1.1.1.-CA-10, to which 10 mL of water was added next.

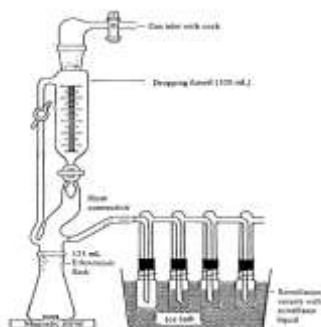

Figure B.8.1.1.1.1.-CA-10: The apparatus used for the liberation of $^{14}\text{CO}_2$ (copied from the study report).

The system was put under the constant flow of N_2 (~20 mL/min) and 50 mL of 12N HCl was gently added. The released CO_2 was trapped in three vessels, each containing 10 mL of the mixture of Carbo-sorb E and Permafluor-E⁺ (3:5), and analysed by LSC.

Next soils from each test vessel were analysed. That was done by extracting the entire soil samples in a sequential multistep extraction procedure, shown below on figure B.8.1.1.1.1.-CA-11. ACN stands for acetonitrile (CH_3CN).

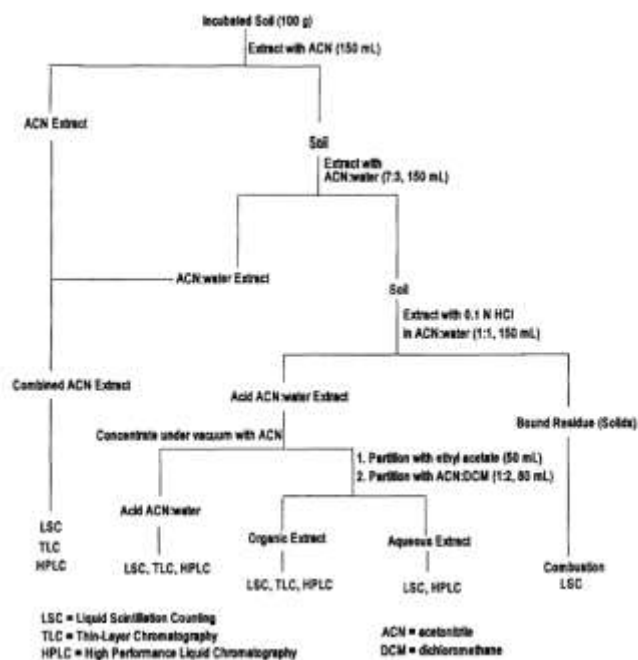

Figure B.8.1.1.1.-CA-11: A multistep soil extraction procedure used in the experiment (scheme copied from the study report).

The ACN and ACN:H₂O extracts were combined and concentrated under vacuum, then analysed. The acid extracts – 0.1N HCl_{aq}:ACN (1:1), were treated in three different ways:

- Acid extracts from DAT 0, DAT 7 and DAT 14 samples were evaporated under vacuum to ~50 mL and fractionated with ethyl acetate (CH₃COOC₂H₅). The ethyl acetate fractions were collected, dried over anhydrous Na₂SO₄ and halved. One half of each extract was concentrated under the stream of N₂ and passed through pre-conditioned Sep-Pak C-18 cartridges, subsequently eluted with CH₃CN and CH₃CN:H₂O (3:7 v/v). The cleaned-up residues were dissolved in CH₃CN:H₂O (3:7 v/v) and analysed by HPLC.
- All acid extracts from DAT 28 and DAT 65 and ½ of those from DAT 21 and DAT 44 were azeotropically concentrated using CH₃CN under vacuum. That was done to minimise the would be losses from excessive sample work-up. Extracts were concentrated, without prior partitioning with any organic solvent, to ~5 mL and transferred quantitatively, by subsequent flushing the evaporation vessels with small portions of MeOH, to 13-mL centrifuge tubes. The aliquots were analysed, after filtration through 5-µm PTFE filters, by HPLC. No losses of radioactivity were observed as a result of azeotropic concentration followed by filtration procedure.
- Acid extracts from DAT 76, DAT 91, DAT 180, DAT 271 and DAT 365 samples were initially concentrated to 60 mL, partitioned with 100 mL of CH₂Cl₂, followed by partitioning twice with CH₃CN:CH₂Cl₂ (1:2) solution (~80 mL). Organic and aqueous extracts were radioassayed and concentrated under vacuum to ~5 mL, after what quantitatively transferred to 13-mL centrifuge tubes.

In some extracts soil residues were observed upon their concentration. In such cases residues were repeatedly washed with either CH₃CN:H₂O (3:7 v/v) solution or MeOH and obtained extracts combined with supernatant solutions. Remaining residues were analysed by LSC for radioactivity content.

In case of solely DAT 180 samples the post-extraction residues were additionally extracted for ~1 hour with 150 mL of 0.1N NaOH solution in CH₃CN:H₂O. Extracts were then fractionated 3 times with 150 mL of CH₃CN:CH₂Cl₂ (1:2) solution. That extraction step was not repeated for any other samples as it was considered too harsh and expected to produce the analytical artefacts.

The extracted soil pellets were subsequently analysed for NER fraction. To do that each soil sample was allowed to air-dry overnight, after what its triplicate aliquots (50 – 100 mg) were oxidized by combustion. Formed ¹⁴CO₂ was trapped in alkaline solution and, after mixing with scintillation cocktail, analysed by LSC.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid scintillation counting) analysis was performed using a Packard Tri-Carb Model 4640 counter equipped with automatic external standardisation.

Liquid samples were radioassayed after addition of 15-20 mL of Ultima Gold solution to their 100 – 1000 μL aliquots, depending on sample. The minimum sensitivity of LSC analysis for these samples was 2.488 E-4 ppm , corresponding to $0.0226 \% \text{AR}$. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm ($\text{LAGC} = 2 \cdot \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 9.24\%$.

Solid samples were oxidised using Packard Model 306 sample oxidizer, generated $^{14}\text{CO}_2$ trapped on 6 mL Carbo-sorb E and 15 mL Perma Fluor E. The minimum sensitivity of LSC analysis for those samples was 8.735 E-6 ppm , corresponding to $7.95 \text{ E-4 } \% \text{AR}$, and when expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm ($\text{LAGC} = 2 \cdot \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 9.24\%$.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- TLC – secondary quantitation method for the parent compound and its degradation products;
- LC-MS – identification method for parent compound and its degradation products;
- GC/MS – supplementary identification method for parent compound and its degradation products.

The HPLC analysis was performed using a Hewlett Packard Model 1090 chromatograph coupled to Ramona 5-LS radioactivity monitor. Three following HPLC methods were used:

- Method A: gradient mode analysis performed using PRP-1, 5 μm , 150 x 4.1 mm chromatographic column (Hamilton Co., Reno) and PRP-1 cartridge as a guard column. The mobile phase consisted of water + 0.4% CH_3COOH as **Solvent A** and CH_3CN + 0.4% CH_3COOH as **Solvent B**. Gradient elution lasted 95 minutes. Its parameters are shown below in the table B.8.1.1.1.1._CA-12. The flow rate was set to 2 mL/min. The method was used generally, to analyse all extracts and was able to detect and radioactive residues $>1.0\% \text{ AR}$.
- Method B: gradient mode analysis performed using Selectosil 5, C-18, 5 μm , 250 x 4 mm chromatographic column (Phenomenex, California) and Brownlee cartridge, 5 μm , RP-18, as a guard column. The mobile phase consisted of water + 0.4% CH_3COOH as **Solvent A** and CH_3CN + 0.4% CH_3COOH as **Solvent B**. Gradient elution lasted 95 minutes. Its parameters are shown below in the table B.8.1.1.1.1._CA-12. The flow rate was set to 1 mL/min. The method was developed as first, but subsequently replaced by Method A, demonstrated to give the better resolution of Flufenacet from its degradation products. As a result only DAT 0 acid extracts were analysed using that method.
- Method C: gradient mode analysis performed using Spherisorb 32 (ODS2), 3 μm , 70 x 10 mm chromatographic column (Phenomenex, California) and RP-18 Spheri-5 cartridge as a guard column. The mobile phase consisted of water as **Solvent A** and CH_3OH as **Solvent B**. Gradient elution lasted 40 minutes. Its parameters are shown below in the table B.8.1.1.1.1._CA-12. The flow rate was set to 1 mL/min. The method was used to further purify the degradation products isolated from acid $\text{CH}_3\text{CN}:\text{H}_2\text{O}$ extracts from DAT 28 samples.

The LOD for the listed above chromatographic methods, in reference to the performance of the used radioactivity detector, was determined to be 1000 dpm, what corresponded to $1.0\% \text{ AR}$. The value was determined experimentally on the basis of the comparison of radioactivity injected and eluted (expressed in dpm, as determined by LSC). The results of that examination, aimed on the determination of both LOD and the linearity of HPLC analysis, are presented below in the table B.8.1.1.1.1.-CA-13. The linearity of the analysis, expressed as r^2 was: $r^2 = 0.999983$.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards. The retention times of each examined compound and for each HPLC method used in the experiment are presented below in the table B.8.1.1.1.1._CA-14.

Table B.8.1.1.1.1_CA-12: The HPLC gradient modes used in the study.

Method A:		
Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH₃COOH</i>
0	100	0
0-25	Linear gradient	
25	75	25
25 - 40	75	25
40 - 75	Linear gradient	
75	30	70
75 - 85	Linear gradient	
85	0	100
85 - 95	0	100
Method B:		
Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH₃COOH</i>
0	100	0
0-25	Linear gradient	
25	75	25
25 - 40	75	25
40 - 75	Linear gradient	
75	30	70
75 - 85	Linear gradient	
85	5	95
85 - 95	5	95
Method C:		
Time [min]	Solvent ratio	
	<i>Solvent A – Water</i>	<i>Solvent B – MeOH</i>
0	40	60
0 - 20	40	60
20 - 40	Linear gradient	
40	10	90

Table B.8.1.1.1.1_CA-13: The results of the determination of linearity and LOD of the HPLC analysis.

Sample No.	Radioactivity in [dpm]:		Integration ^{3, 4)}

Footnotes to the table:

1) n. a. = not analysed using that method;

The TLC analysis of the extracts was performed in two modes:

- as RP-TLC (reversed phase TLC);
- as NP-TLC (normal phase TLC).

The RP-TLC analysis was performed using Whatman KC₁₈F TLC plates, having a dimensions 20x20 cm and 200- μ m thick, with a fluorescent indicator. The solvent system used in the analysis was CH₃CN:CH₃OH:0.5N NaCl_{aq} 2:2:1 (v/v) solution.

The NP-TLC analysis was performed using silica gel TLC plates, having a dimensions 20x20 cm and 250- μ m thick, with a fluorescent indicator. The solvent system used in the analysis was CHCl₃:CH₃COOC₂H₅:CH₃COOH 75:25:1 (v/v) solution.

The LOD was set to 1% AR for each individual compound detected. The quantitative analysis was performed using RITA 68000 Radio-TLC analyser. The LOD for this detector was determined to be 150 dpm. The results of determination of linearity and LOD of the detector are presented below in the table B.8.1.1.1.1.-CA-15.

The identification was performed by means of the comparison with the R_f values of the known standards. These values are provided below in the table B.8.1.1.1.1.-CA-16.

Table B.8.1.1.1.1_CA-15: The results of the determination of linearity and LOD of the TLC analysis.

The LC-MS analysis was performed using Varian 5040 HPLC equipped with a Regis Spherisorb S50DS column working in a gradient mode and Berthold LB 505-HPLC Radioactivity Monitor, coupled with Finnigan MAT 90 MS detector. The parameters of gradient were following:

- Mobile phase A: Water,
- Mobile phase B: CH₃OH,
- Gradient mode: linear from 0% B at 0 min to 100% B at 30 min.

The flow rate was set to 0.8 mL/min.

The reported parameters of MS detector were following:

- Spectrometer operated in either positive or negative mode,
- aerosol temperature: 210°C,
- 0.2 M ammonium acetate added post column at rate of 0.2 mL/min.

The identification of Flufenacet and its degradation products in LC/MS analysis was performed by comparison of mass spectra of each chromatographic peaks with those obtained for the standards, for which base peaks and protonated molecular ion peaks were identified. These are presented below in the table B.8.1.1.1.1_CA-17.

Table B.8.1.1.1.1_CA-17: LC/MS identification of Flufenacet and its degradation products in the study.

Compound	Representative signals used in identification	
	Position – m/z	Description
Flufenacet	364	Protonated molecular ion $[M+H]^+$
	381	Ammonia adduct $[M + NH_4]^+$
FOE Sulfonic acid	274	Peak for $[M - H]^-$ (negative-ion mode)
FOE Oxalate	226	Protonated molecular ion $[M+H]^+$
	243	Ammonia adduct $[M + NH_4]^+$
	224	Peak for $[M - H]^-$ (negative-ion mode)
FOE Methylsulfoxide	275	Protonated molecular ion $[M+H]^+$
	291	Ammonia adduct $[M + NH_4]^+$
FOE Alcohol	212	Protonated molecular ion $[M+H]^+$
FOE Thioglycolate sulfoxide	302	Protonated molecular ion $[M+H]^+$
	316	Protonated molecular ion $[M+H]^+$ for methylated derivative
FOE Chloroacetanilide	230	Protonated molecular ion $[M+H]^+$
	247	Ammonia adduct $[M + NH_4]^+$

GC/MS analysis was performed to confirm the identity of Flufenacet and FOE chloroacetanilide. It was carried out with HP Model 5995 Gas Chromatograph/Mass Spectrometer. GC was equipped with an Ultra-1 column (12 m x 0.2 mm x 0.3 µm film thickness).

Two different programmes were used:

- for Flufenacet GC oven was programmed to start at $T = 90^{\circ}\text{C}$, held at that level for $t = 1$ min, then the temperature increased linearly at rate of $20^{\circ}\text{C}/\text{min}$ up to $T = 250^{\circ}\text{C}$ and held at that level for $t = 1$ min; the injector's temperature was $T = 250^{\circ}\text{C}$; MS detector operated in the electron impact mode with a mass range 50 – 400 amu;
- for FOE Chloroacetanilide GC oven was programmed to start at $T = 85^{\circ}\text{C}$, held at that level for $t = 1$ min, then the temperature increased linearly at rate of $10^{\circ}\text{C}/\text{min}$ up to $T = 210^{\circ}\text{C}$ and held at that level for $t = 3$ min; the injector's temperature was $T = 255^{\circ}\text{C}$; MS detector operated in the electron impact mode with a mass range 50 – 400 amu.

Additionally two tests were carried out to determine the mechanism of the formation of FOE Chloroacetanilide – biotic (microbial degradation of Flufenacet or one of its degradation products) or abiotic (chemical degradation of Flufenacet or one of its degradation products) process.

Test 1 was performed in a test system with soil. Four flask were prepared, each containing 100 g (d.w.) of the test soil. Two flask were treated with [^{14}C]-Flufenacet at rate 1 ppm, the other two with [^{14}C]-FOE Alcohol at the same application rate. Since FOE Chloroacetanilide was primarily detected in acid extracts from samples collected at DATs 21, 28, 48 and 65, the samples in that experiment were similarly extracted and analysed by HPLC.

Test 2 was performed to determine the possibility of the formation of FOE Chloroacetanilide as a result of chemical reactions taking place during the sample processing. For that purpose the remaining acid extracts from DAT 44 samples were partitioned with $\text{CH}_3\text{CN}:\text{CH}_2\text{Cl}_2$ (1:2) solution. The resulting organic extracts were then partitioned and analysed by HPLC in the manner similar to that used for acid extracts obtained from samples collected at DATs 76, 91, 180, 271 and 365.

Results and their discussion:

The stability tests performed using DAT 0 samples demonstrated that the Flufenacet was stable during application and routine extraction procedure. It was also stated that the acidic extraction with 0.1N $\text{HCl}_{\text{aq}}:\text{ACN}$ (1:1) followed by the direct azeotropic concentration under vacuum may have resulted in some degradation of Flufenacet, but the phenomenon is expected to have a small impact on the obtained results.

As it was indicated, the extraction with 1N NaOH resulted in the decomposition of the test compound.

The analysis of the soil biomass showed that it was $> 1\%$ OC, although it shall be noted that the level of soil OC was very low – 0.35% on average, at the beginning of the study. Its sudden collapse was observed ~4 weeks after the beginning of incubation. At 30th day of incubation it was determined that ~30% die-out of the microbial population occurred and the process continued until ~3 months of incubation, when the steady state was reached. That might have influenced the obtained results, in particular the rate of degradation of Flufenacet, what demonstrated itself in bi-phasic degradation pattern.

The recovery of the applied radioactivity in the experimental soil was generally good, in line with the recommendations of the relevant Guidelines: 91.5 – 99.6% AR (average 95.4% AR).

The level of mineralization gradually increased throughout the study, to reach at its end (DAT 365) 5.9% AR. At the same time it shall be noted that it was not very high, in comparison to the results of other experiments with the compound radiolabelled at the same position, probably due to the significant decrease of microbial soil activity with time.

The amount of NER fraction also increased with time from 0.3% AR on DAT 0 to 17.7% AR on DAT 271. A slight decrease in the content of that fraction was observed at the end of the study. Also between the DAT 76 and DAT 271 it fluctuated – after reaching the level of 17.0% AR on DAT 76 it declined to 15.8% AR on DAT 180 to increase once again to 17.7% AR on DAT 271.

The amount of AR present as combined extractable fraction decreased with time, to reach at the end of the study (DAT 365) the level of 73.0% AR. It was also noted that while the amount of radioactivity extracted in combined acetonitrile (CH_3CN extract and $\text{CH}_3\text{CN}:\text{H}_2\text{O}$ 7:3 extract) extract decreased from 93.9% AR on DAT 0 to 52.7% AR on DAT 365, it increased in acidic 0.1N $\text{HCl}_{\text{aq}}:\text{ACN}$ (1:1) extracts from 0.9% AR on DAT 0 to 20.3 % AR on DAT 365.

The following compounds were identified in extracts:

- Flufenacet,
- FOE Sulfonic acid,
- FOE Oxalate,

- FOE Alcohol,
- FOE Thioglycolate sulfide,
- FOE Methylsulfoxide,
- FOE Chloroacetanilide,
- Other 7 unknown degradation products or degradation products fractions.

Of the compounds listed above the following may be considered as major on the basis of the criteria set by SANCO/211/2000 Guidance Document on the Assessment of the Relevance of Metabolites:

- FOE Oxalate: max 26.5% AR (DAT 365);
- FOE Sulfonic acid: max. 7.7% AR (DAT 180), with highest-occurrence profile on DATs: DAT 65 – 4.7% AR, DAT 76 – 6.0 % AR, DAT 91 – 5.5% AR, DAT 180 – 7.% AR, DAT 271 – 5.8 % AR.

The remaining four identified degradation products should be considered as minor with regard to their relevance to GW, and occurred in max amounts:

- FOE Alcohol: 2.1% AR (DAT 44 and DAT 65),
- FOE Thioglycolate sulfide: 3.7% AR (DAT 180),
- FOE Methylsulfoxide: 0.6% AR (DAT 28),
- FOE Chloroacetanilide: 5.1% AR (DAT 44).

The detailed results are presented below, in table B.8.1.1.1.1._CA-18 (the values were rounded to one digit after the decimal point) and additionally in graphical form, on figure B.8.1.1.1.1._CA-12.

Table B.8.1.1.1.1._CA-18: The detailed results obtained in the study.

% AR		Results obtained for sample collected at DAT ¹⁾ :

Footnotes to the table:

- 1) Values presented are the averages of triplicate analysis for DAT 0 and of duplicate analysis for remaining time points;
- 2) Represents combined CH₃CN and CH₃CN:H₂O (7:3 v/v) extracts;
- 3) Represents 0.1N HCl in CH₃CN:H₂O (1:1 v/v) extract;
- 4) FOE TGS = FOE Thioglycolate sulfide;
- 5) It was postulated that FOE Chloroacetanilide might have formed in soil as a genuine degradation product and/or during sample work-up as a result of chemical transformation of either Flufenacet or FOE Alcohol;
- 6) The difference between the Total Extracted AR the Total identified AR was declared in the study report to be possibly due to three following factors: rounding of figures (1), presence of other HPLC resolvable degradation products, individually not exceeding 0.1% AR (2), presence of radiocarbon residues in acidic extracts that were below LOD for HPLC method (3);
- 7) n. d = not detected;
- 8) Includes residues released by alkaline extraction with 0.1N NaOH in CH₃CN:H₂O (1:1 v/v);
- 9) n. a. = not analysed – it was assumed that at that time point no volatile degradates were formed;
- 10) Value calculated by the RMS by adding the results obtained for VOC and those for CO₂;
- 11) Expressed as % of theoretically applied radioactivity.

Total ⁽⁵⁾	0.8	7.9	8.7	10.0	11.0	12.3	14.0	16.1	10.1	16.3	17.8	18.4

Footnotes to the table:

- 1) Values presented are the averages of triplicate analysis for DAT 0 and duplicate analysis for remaining time points;
- 2) Represents 0.1N HCl in CH₃CN:H₂O (1:1 v/v) extract;
- 3) FOE TGS = FOE Thioglycolate sulfoxide;
- 4) It was postulated that FOE Chloroacetanilide might have formed in soil as a genuine degradation product and/or during sample work-up as a result of chemical transformation of either Flufenacet or FOE Alcohol;
- 5) The difference between the **Total** value reported here and the (**extracted as:**) **Acidic extracts** reported in the table B.8.1.1.1.1. CA-18 above, was postulated in the study report to be possibly due to the three following factors: rounding of figures (1), presence of other HPLC resolvable degradation products, individually not exceeding 0.1% AR (2), presence of radiocarbon residues in acidic extracts that were below LOD for HPLC method (3);
- 6) n. d = not detected.

The results of the additional TLC analysis were following:

- **NP-TLC** enabled the identification and quantitation of Flufenacet and following four fractions:
 - **Metabolite 1:** the mixture of FOE Oxalate, FOE Sulfonic acid and FOE Thioglycolate sulfoxide, detected in extracts from all sampling points, in most of them in amounts >10% AR and in max. amount of 37.5% AR in DAT 44 sample;
 - **Metabolite 2:** FOE alcohol, detected in some of the analysed samples and in none of them in amounts ≥1.5% AR, the maximum amount quantified was 1.2% AR in DAT 271 sample;
 - **Metabolite 3:** not further identified fraction, reaching max. amount of 1.0% AR (DAT 180 sample);
 - **Others:** fraction characterised in the study report as “*resolvable FOE 5043 metabolites, none of which individually contained as much as 1% of applied radioactivity*”, however detected continuously throughout the study in low quantities (~0.0 – 3.6% AR), reaching the maximum amount of 3.6% AR in DAT 44 sample.
- **RP-TLC** enabled the identification and quantitation of Flufenacet and following six fractions:
 - **FOE Chloroacetanilide**, the fraction once surpassing the level of 5% AR, in DAT 44 sample (5.6% AR);
 - **Metabolite 1:** the mixture of FOE Oxalate and FOE Sulfonic acid, detected in extracts from all sampling points, in most of them in amounts >10% AR and in max. amount of 33.8% AR in DAT 365 sample;
 - **Metabolite 2:** postulated to be possibly “*a mixture of FOE 5043 metabolites that were retained at the origin by the soil matrix*”, never surpassing the amount of 5% AR (max. amount 3.2% AR in DAT 28 sample);
 - **Metabolite 3:** fraction not further identified, unless it was postulated mixture of FOE Alcohol and FOE Methoxysulfoxide mistakenly assigned to **Metabolite 4**, the fraction detected for the first time in DAT 44 samples, then detected continuously, although in low quantities – max. 1.5% AR (DAT 65 and DAT 91 samples);
 - **Metabolite 4:** postulated to be possibly a mixture of FOE Alcohol and FOE Methoxysulfoxide, however that identification in the study report is uncertain as the reference is given to **Metabolite 3**, the fraction sporadically detected and in max. amounts of 1.0% AR (DAT 44 and DAT 65 samples);
 - **Others:** fraction characterised in the study report as “*resolvable FOE 5043 metabolites, none of which individually contained as much as 1% of applied radioactivity*”, however detected continuously throughout the study in low quantities (~0.0 – 2.5% AR), reaching the maximum amount of 2.5% AR in DAT 28 sample.

The examination of the possible mechanisms of formation of FOE Chloroacetanilide showed that the formation of that compound may be possibly attributed to the chemical transformation of Flufenacet, but not FOE alcohol, during the sample work-up. It was demonstrated that although FOE Alcohol was stable in worked-up extracts, the same cannot be stated for Flufenacet, which was transformed, in 2 - 4% of its initial dose, to FOE Chloroacetanilide during the processing of the extracts. At the same time it was indicated, on the basis of the analysis of the data from acidic extraction of DAT 21, DAT 28, DAT 44 and DAT 65 samples, that the process of chemical degradation of Flufenacet to FOE Chloroacetanilide varied in intensity.

It was also stated that although the results suggest that FOE Chloroacetanilide was an analytical artefact formed during the sample processing, its microbial formation in soil could not be ruled out, as that compound was identified in another experiment – an outdoor soil metabolism study, in which soils were extracted only with acetonitrile, so chlorine atoms were not involved. That implicated that the process was biologically mediated, what in turn was conformed by open literature studies.

All that taken into account it was proposed in the study report to consider both microbial and chemical transformation during sample work-up transformation processes of Flufenacet as responsible for formation of FOE Chloroacetanilide, without however indicating which of them is considered to be predominating.

Additional attempt was made to further identify the **Unknown 1** fraction found in HPLC analysis using **Method A**. That was done by means of purification using HPLC **Method C**, followed by LC/MS analysis. It was demonstrated that that fraction consisted of two peaks: **Peak 1** having $R_t = 11.5$ min, and **Peak 2** having $R_t = 32$ min. **Peak 1** was the major component of the mixture – it accounted for 84% of it (1.1% AR). Further attempts to identify it by LC/MS did not provide sufficient information to enable its proper identification. **Peak 2** accounted for 16% of the mixture (0.2% AR). The MS spectrum of that peak was very similar to that obtained for Flufenacet, although not identical. However it was not explained why that fraction displayed R_t different from that determined for Flufenacet in HPLC **Method 1**. As a result no definitive conclusion with regard to the identity of that fraction was drawn.

There were no further attempts to identify the remaining Unknowns (2, 3, 4, 5, 6, 7). That was due to the fact that each of them was detected in amounts < 2.5% AR throughout the study.

On the basis of the obtained results the possible transformation pathway of Flufenacet in soil was proposed. It was also stated that the degradation was predominantly, if not exclusively biotically mediated.

The sudden collapse in the soil microbial activity was observed 4 weeks after the initiation of the experiment, followed by further, gentler decline. It was attributed to the natural factors rather than to the influence of the test compound or of the treatment solution's solvents.

Finally, it was postulated that, because of the collapse of the soil microbial activity ~4 weeks after the initiation of the experiment, the degradation should have followed bi-phasic pattern and the kinetic endpoints were calculated accordingly.

Conclusions:

The obtained results showed that Flufenacet was extensively degraded in the experimental soil during 365 days of the experiment, reaching the level of ~35% of the initial dose at the end of the study. There was a slow-down in degradation observed at the later time points, attributed to the sudden collapse of the soil microbial activity around 30th day after the beginning of the incubation.

Applicant explained that by the natural factors, not related to the experiment set-up, or influence of any of the constituents of the treatment solution. It shall be pointed out that the test soil was not pre-conditioned after being prepared for the experiment (atmosphere-dried and sieved), but before being treated with the test compound. That might have contributed to the observed collapse. It shall be also pointed out that the OC content of the test soil was very low, below the recommended 0.5%, although the results presented in that area are not very clear.

The level of mineralisation was relatively low, in comparison to the results obtained in other soils for the same radiolabelling position – 5.9% AR (approx. half of the level reached in other soils). That may also be explained by low soil microbial activity, especially at later time points.

The level of NER formed was also lower than in other soils treated with the compound radiolabelled in the same position, what may be explained not only by slowed degradation of the test compound and its degradation products, but also by the fact that the test soil displayed low OC content.

Several degradation product were detected, of which six were identified. Of them FOE Sulfonic acid, FOE Oxalate, FOE Thioglycolate sulfoxide and FOE Methylsulfoxide were found in other soils. The remaining two – FOE Alcohol and FOE Chloroacetanilide, were identified solely in this experiment. It shall be noted that FOE Chloroacetanilide was postulated to be both genuine degradation product, resulting from microbially-mediated transformation of Flufenacet, and the analytical artefact formed during the sample processing after acidic extraction. However, as it was not possible to determine which process was predominant, RMS, on the basis of

the weight of evidence and the worse-case principle, proposes to consider it being a **genuine degradation product**.

Of the compounds listed above two should be considered major, in line with the recommendations given by SANCO/221/2000 Guidance Document – FOE Oxalate, peaking at 26.5 % AR on DAT 365 and FOE Sulfonic acid, peaking at 7.7% AR on DAT 180, but being detected in amounts > 5% AR on several consecutive time points from DAT 76 to DAT 365.

It shall be noted that, due to the stated problems with soil microbial activity the metabolite profiling may not fully reflect the situation really occurring in soil. Therefore in practice other degradation products identified in the study, but not demonstrated to be major, may be formed in amounts enabling their classification as major with regard to their relevance for GW exposure and risk assessment.

On the basis of the results obtained in this study the following transformation pathway of Flufenacet in aerobic soil, shown on the Fig B.8.1.1.1.1._CA-13, was proposed:

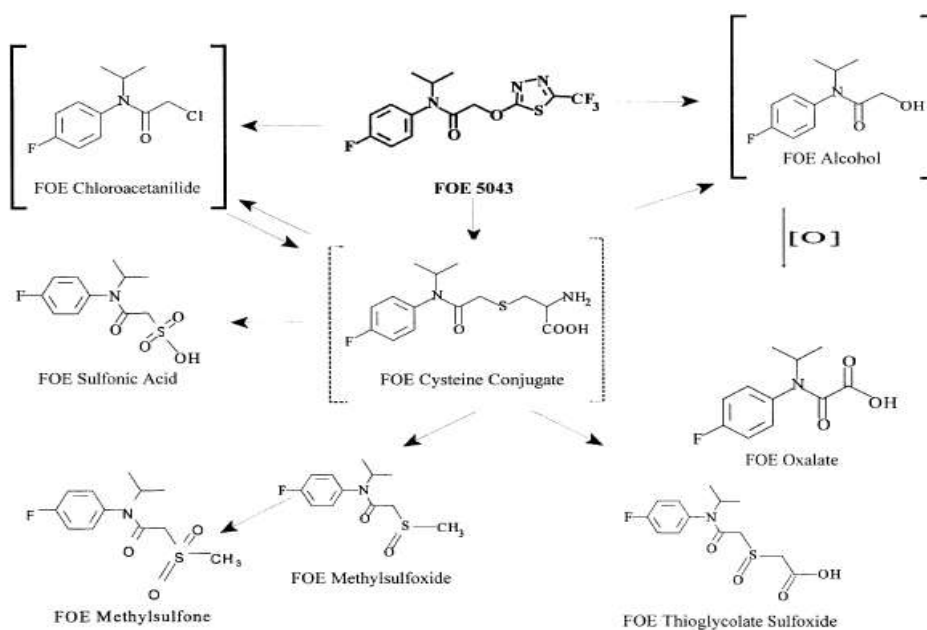

Figure B.8.1.1.1.1._CA-13: The transformation pathway of Flufenacet in aerobic soil, determined for the compound radiolabelled in phenyl ring (scheme copied from the study report).

RMS's conclusions with regard to the validity of the study:

On the basis of the thorough examination of the study protocol RMS proposes to consider the study valid, despite the deficiencies it displays, because it provides vital information in the area of the determination of the route of degradation of Flufenacet in soil. It shall be pointed out that the results of that study in the area of identification of the degradation products and elucidation of the degradation pathway of Flufenacet within its phenyl moiety were conformed by the results of the other, open literature studies, summarised further down this Assessment Report.

The problem of the sudden collapse of the soil microbial activity observed in the experimental soil was thoroughly examined and satisfactorily explained in an independent study, summarised below as **Study 3**. In light of the findings of that study, the study summarised above can be considered acceptable and relevant for the purpose of the regulatory assessment of Flufenacet.

Study 3:

Report: Hellpointner E., (1995): “Evolution of the microbial biomass in the biometer flask system (supportive to study no. F3042102, aerobic metabolism of FOE 5043).”; Bayer AG, Agrochemicals Division, Development, Institute for Metabolism Research & Residue Analysis, D51368 Leverkusen; Germany; unpublished Report No. PF 4066; 20 June 1995; study reference number: M-002164-01-1;

Guidelines: The study was not declared to follow any specific Guidelines, but it was indicated that it was performed in order to meet the specific requirements set by the US EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1 - Aerobic Soil Metabolism;

GLP: Yes – study was declared to be conducted in compliance with GLP standards;

RMS comments: The study was submitted as an additional explanatory study, examining the reasons for the sudden collapse of soil microbial activity observed in the study by Pangilinan and Smith [1994], examining the degradation of [¹⁴C-phenyl] Flufenacet in aerobic soil (**Study 1**). The study was evaluated and found acceptable by the RMS. It is summarised below. It shall be noted that tit was referred to in the previous Assessment Report, prepared by the RMS – France, for the purpose of the first authorisation of Flufenacet in the EU.

Summary:

The aim of the study was to examine the survival of the living, metabolically active, microbial biomass in a moist loamy sand soil incubated in the dark under aerobic conditions at $T = 20 \pm 1^{\circ}\text{C}$ for 1 year. The additional aim of the study was to determine the reasons for the sudden collapse of the soil microbial activity, observed in the study by Pangilinan and Smith [1994], examining the degradation of [¹⁴C-phenyl] Flufenacet in aerobic soil (**Study 1**), after ~ 4 weeks of incubation.

The experiment was performed in the premises of Bayer AG in Monheim, Germany, on the same soil as used in two studies by Pangilinan and Smith [1994, 1994a], examining the degradation of Flufenacet radiolabelled in two different positions – in phenyl ring (**Study 1**) and in C2-thiadazole position (**Study 2**), in one soil incubated under aerobic conditions.

The characteristic of the test soil is presented below in the table B.8.1.1.1.1._CA-21.

Table B.8.1.1.1.1._CA-21: The characteristic of soil used in the study.

Parameter		Soil:		
		395 (A)		
Soil origin		Howe, Indiana, USA		
Soil type (USDA)		Sandy loam		
Particle size distribution	Sand [%]	77.5		
	Silt [%]	17.2		
	Clay [%]	5.3		
pH value (in water, 1:1)		6.4		
Organic matter content (OM) [%]		0.4		
Organic carbon content (C _{org}) [%] ¹⁾		0.23		
Cation Exchange Capacity – CEC [mEq/100g]		7.4		
Bulk density (disturbed) [g/cm ³]		1.33		
Moisture holding capacity at ½ bar [%]		13.1		
Moisture holding capacity at 15 bar [%]		3.4		
Available nutrients ²⁾	Ca	1700 [lb/ac]	1905.053 [kg/ha]	1884.70 [mg/kg]
	Mg	250 [lb/ac]	280.155 [kg/ha]	277.16 [mg/kg]
	Na	24 [lb/ac]	26.895 [kg/ha]	26.61 [mg/kg]
	K	312 [lb/ac]	349.633 [kg/ha]	345.90 [mg/kg]
	H	34 [lb/ac]	38.101 [kg/ha]	37.69 [mg/kg]
P (Olsen)		57 [lb/ac]	63.875 [kg/ha]	63.19 [mg/kg]
Total N [%]		0.062		
Soluble Salts [mmhos/cm]		0.24		

Footnotes to the table:

- 1) Value recalculated by the RMS from that reporting OM content given in the study report using the following equation: $\text{OM} = 1.724 * \text{OC}$;
- 2) In the study report only the values in [lb/ac] (US pound/US acre) were given. RMS recalculated them to first kg/ha and then to mg/kg soil using the following assumptions: for transformation to kg/ha it was assumed that 1 kg = 0.4535 US pound and 1 ha = 0.4046873 US acre; to calculate the amount in mg/kg soil Escape modelling tool was used with the following assumptions: soil density $d = 1.33 \text{ g/cm}^3$ and soil depth 7.6 cm – the equivalent to 3 inches (value used to calculate the application rate in lb/ac in the **Study 2**).

The test soil was treated in the similar way to that described in the summary of the **Study 2** [Pangilinan and Smith; 1994] – after shipment by air to the test facility in Germany, the test soil was stored, for a not defined

period, in a greenhouse. In order to maintain it biologically viable until being used, the soil surface was planted with grass. Immediately before the experiment began ~1.5 kg of the test soil was taken to the laboratory where the plant material was removed and moist soil was swiftly air-dried. Next it was sieved through 2-mm sieve. The dry weight of sieved soil was determined to be 92.5% of the moist one.

So prepared soil was introduced, in amounts of 100 g d.w./incubation vessel (108.1 g sieved soil/incubation vessel) to the biometer flasks, identical to those used in the **Study 1**, shown below on figure B.8.1.1.1.1._CA-14. After placing the soil in incubation vessels its moisture content was brought to the level of 75% of $\frac{1}{3}$ bar (~9.83 g H₂O/100 g soil) by adding 1.73g of Milli-Q water to each incubation flask. Soil moisture was controlled in 1-month intervals by reweighing the test vessels and, if necessary adjusting that factor by introducing the adequate amount of water.

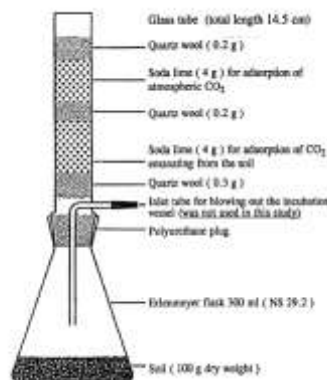

Figure B.8.1.1.1.1._CA-14: The biometer flask used in the experiment (scheme copied from the study report).

The incubation vessels were prepared in duplicate for each sampling point. The incubation flask were then placed in the dark, in the incubation chamber, and incubated at $T = 20 \pm 1^{\circ}\text{C}$ for up to 52 weeks (1 year). At the designated intervals duplicate samples were taken for the determination of the soil biomass. The detailed information on the sampling protocol is presented below in the table B.8.1.1.1.1._CA-22.

Table B.8.1.1.1.1._CA-22: The detailed information on the sampling protocol.

Sampling date (dd/mm/yyyy)	Duration of aerobic incubation [weeks]	Number of vessels collected	Termination date of Biomass Evaluation (dd/mm/yyyy)
06/12/1993	0	2	08/12/1993
20/12/1993	2	2	21/12/1993
03/01/1994	4	2	05/01/1994
31/01/1994	8	2	01/02/1994
07/03/1994	13	2	08/03/1994
06/06/1994	26	2	07/06/1994
07/09/1994	39	2	09/09/1994
05/12/1994	52		07/12/1994
----	Total duration: 1 year	Total = 16	----

Soil samples taken at each sapling point were analysed for viable soil microbial biomass and pH within 3 days after sampling. The determination of the soil microbial biomass was performed using Anderson&Domsch method. Soil pH was measured in 1M KCl. Also the soil moisture of sampled soils was determined at the time of sampling.

Results and their discussion:

It was stated that aerobic conditions were maintained in the test vessels during the study via the diffusion of air through the trapping towers, what was also conformed in other experiments using the same incubation vessels' system.

The observed at the adjustment points decrease in soil moisture content during the study was to the level of 57% of $\frac{1}{3}$ bar – 62% of $\frac{1}{3}$ bar, so it dropped by 17 - 24% in comparison to the assumed level of 75% of $\frac{1}{3}$ bar.

The incubation temperature was demonstrated to be stable throughout the experiment – $T = 20 \pm 1^\circ\text{C}$. All relevant numerical results of the experiment are presented below in the table B.8.1.1.1.1_CA-23.

Table B.8.1.1.1.1_CA-23: The numerical results of the experiment

Sampling point – weeks after incubation	Soil moisture determined [%] ¹⁾		Soil pH in 1N KCl		Soil microbial biomass [mg C/kg soil d.w.] ²⁾		
	Replicate A	Replicate B	Replicate A	Replicate B	Replicate A	Replicate B	Average ³⁾
0	9.45	8.85	5.6	5.6	266	258	262
2	7.75	8.10	5.6	5.6	211	202	207
4	9.60	8.55	5.6	5.6	181	181	181
8	9.10	9.00	5.8	5.8	186	188	187
13	7.50	8.50	6.0	6.0	149	148	149
26	7.00	7.10	6.0	6.1	102	123	113
39	7.20	7.50	6.7	6.9	66	89	78
52	7.25	7.40	6.2	6.4	95	37	66

Footnotes to the table:

- 1) expressed as g H₂O/100 g soil d.w.;
- 2) d.w. stands for dry weight;
- 3) the value is mean value of the Replicates 1 and 2.

The soil pH was stable during initial four weeks of incubation. After that it increased to peak at 6.8 on 39th week after the beginning of incubation. Afterwards it decreased. That change is demonstrated in graphical form on figure B.8.1.1.1.1.-CA-15.

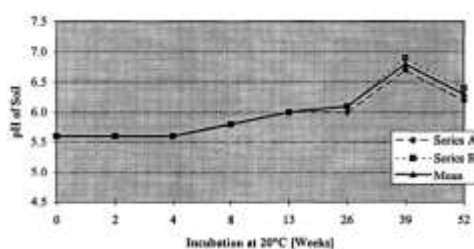

Figure B.8.1.1.1.1_CA-15: The change in the soil pH during the incubation (as presented in the study report).

In general the decrease in soil microbial biomass was observed in the test soil during the 52-weeks lasting incubation. On average the microbial biomass decreased from 262 mg C/kg soil d.w. at the beginning of the study (0 week) to 66 mg C/kg soil d.w., so by 74.81%. It shall be noted that while the soil biomass accounted for 11.29% OC at the beginning of the experiment, at its end, after 52 weeks, it was on the level of 2.87% OC, so within the limits set by the OECD 307 Guidance.

For the individual replicates the decrease looked as follows:

- for replicate A from 266 mg C/kg soil d.w. at the beginning of the study (0 week) to 95 mg C/kg soil d.w., so by 64.29%; the soil biomass in that replicate accounted for 11.46% OC at the beginning of the experiment, at its end, after 52 weeks, it was on the level of 4.09% OC;
- for replicate B from 258 mg C/kg soil d.w. at the beginning of the study (0 week) to 37 mg C/kg soil d.w., so by 85.57%; the soil biomass in that replicate accounted for 11.12% OC at the beginning of the experiment, at its end, after 52 weeks, it was on the level of 1.59% OC.

In graphical form the results are presented below on figure B.8.1.1.1.1_CA-16. It shall be noted that the decline in soil microbial biomass was not linear – after steady decrease up to the 4th week of incubation, the level of soil microbial carbon stabilised up to the 8th week on the level of 180-200 mg C/kg soil d.w., to then drop significantly within the remaining incubation period.

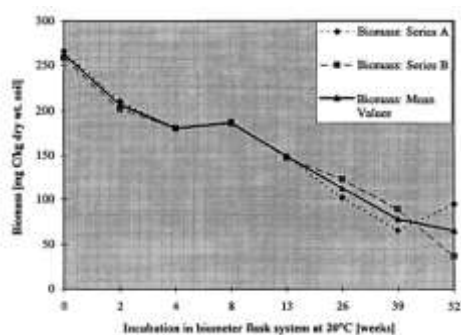

Figure B.8.1.1.1._CA-16: The decrease of the microbial biomass in the test soil during incubation (as presented in the study report).

Additionally the linearity of the decrease of microbial biomass, rate constant and a “half-life” for that process, in each replicate series (A and B) as well as for averaged results was determined. The graphical and numerical results are presented below on figure B.8.1.1.1._CA-17.

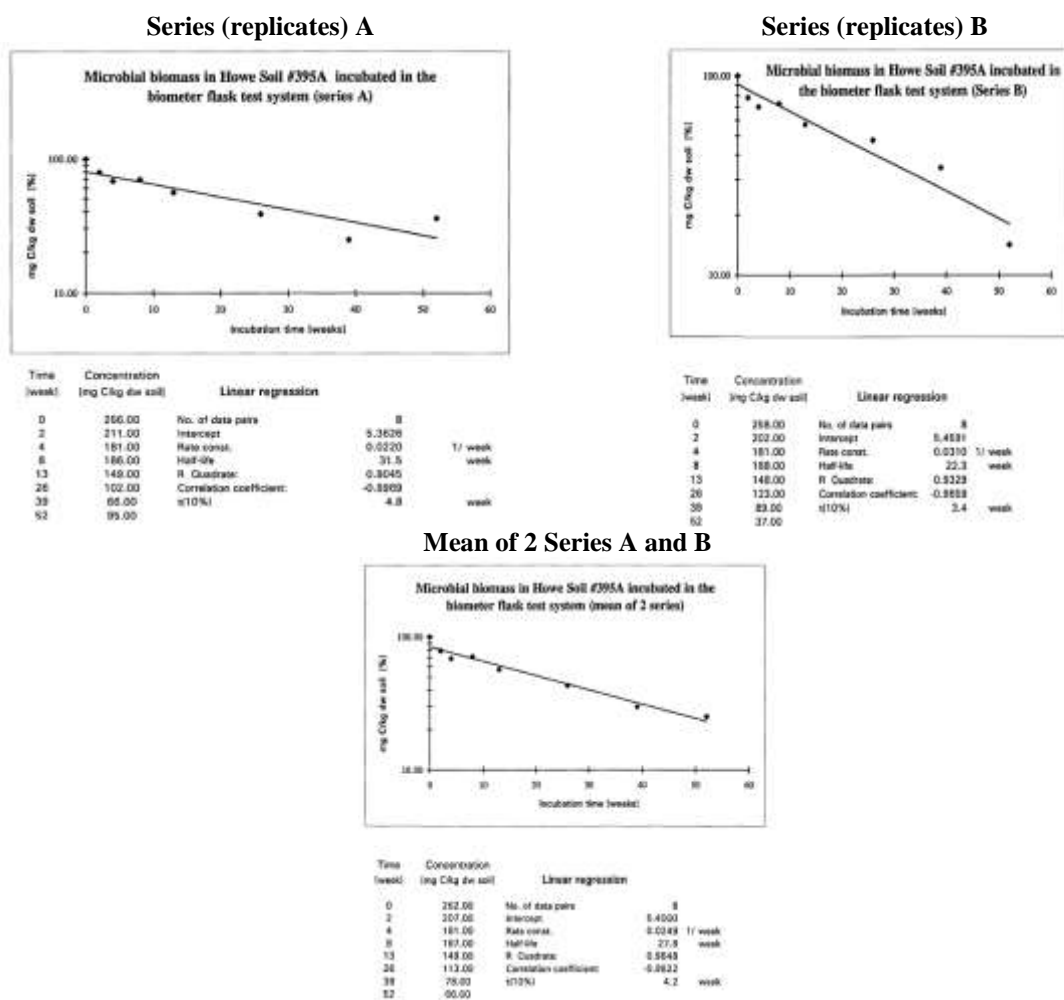

Figure B.8.1.1.1._CA-17: The linearity and kinetic parameters of the decline of microbial biomass in the test soil (as presented in the study report).

Conclusions:

In conclusions to the study it was stated that the decrease of the living microbial biomass during 1 year incubation of small portions of soil in isolated test systems could be attributed to the exhaustion of available carbon and other nutrients in soil and consequent starvation and death of microbial cells – the explanation usually given for that phenomenon. It was stated that that fact, in general and in case of Howe soil in particular, should be taken into account in examining the degradation kinetics – in order to get reliable kinetic endpoints the study should not exceed 6 months.

The possible causes of sudden collapse of soil microbial activity during the first 4 weeks of incubation were not given in the study report, but as the decline pattern in soil microbial activity similar to that determined in the study by Pangilinan and Smith [1994] was observed here, it may be assumed that it was not related to the solvent system used in the application solution, but rather was due to the incubation conditions.

The results of the study conform that the observed in the studies by Pangilinan and Smith [1994, 1994a] (**Study 2** and **Study 4**) decrease in soil microbial activity with time is a natural phenomenon. Therefore, from that point of view, both studies may be considered valid.

Study 4:

Report: Pangilinan N. C., Smith D. M., (1994): “Aerobic Soil Metabolism of [Thiadiazole -2-¹⁴C] FOE 5043”; Miles Inc., Agriculture Division, Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3042103; unpublished Miles Report No. MR 106420; 30 June 1994; study reference number: M-002165-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1;

GLP: Yes

RMS comments: The study has been evaluated for the previous authorisation of Flufenacet in the EU. Its summary can be found under the point B.7.1.1.1.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. At present the study was evaluated for its compliance with OECD Guideline 307 – Aerobic and Anaerobic Transformation in Soil. Additionally RMS checked its compliance with the guidelines on performing the laboratory test on aerobic degradation in soils, presented in *M. Lynch (ed.) “Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides.”, SETAC, 1995*. Also the US EPA Guideline indicated by the Applicant - US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1, was consulted. During that verifications the following deviations from the Guidelines and problems were stated:

- The test soil displayed a very low average OM/OC content, well below the recommended OC = 0.5%, and highly variable. In the study report not only the declared average OM = 0.6%, corresponding to OC = 0.35%, but also it was in range 0.2 – 1.2%, depending on the year in which the test soil was characterised. That may indicate that the test soil was very inhomogeneous with regard to OC content, what in turn might have influenced the obtained results. That feature was signalled in the previous Assessment Report for Flufenacet prepared by the RMS – France, but not indicated as deviation disqualifying the study;
- There was a significant decrease in soil microbial activity observed in the test soil. It accounted for 62.8% after 8 months of incubation and 77.5% after 12 months of incubation. As the soil microbial biomass was measured only at three time points during the study – at the beginning, and at 8th and 12th month of incubation, it was not possible to determine how it was looking like in time. However, the good insight to the phenomenon provides the supplementary study by Hellpointner [1995], summarised above as **Study 3**. The report of that study was submitted for evaluation as a part of the Dossier evaluated for the first authorisation of Flufenacet in the EU. It shall be noted that the problem was noticed by the former RMS – France, but not considered as disqualifying the study;
- The test soil was preconditioned prior to its use by storing it in greenhouse in two 5-gallon (~19-L) buckets. Soybean plants were planted on the soil surface during that incubation period to maintain its microbiological viability. The test soil samples taken to the laboratory prior to the beginning of the experiment were pre-treated by sieving and air-drying, but afterwards were not pre-conditioned as recommended by OECD 307 Guideline. That fact was not stated in the summary provided in the previous Assessment Report, but may be the reason for the substantial decrease of soil microflora observed after 8 months of incubation;
- Test substance was applied in form of the treatment solution being a mixture of CH₃CN: H₂O in ratio 1:4. That deviation from the Guidelines (OECD 307 Guideline recommends to prepare the treatment solution with water and only a small addition of any organic solvent not demonstrated to inhibit microbial activity; also the verification of the influence of such treatment solution on soil microbial activity is recommended prior to the treatment) was also not indicated in the previous DAR.

No other deviations were found in the study report. Despite those listed above the study may still be considered acceptable and as such is summarised below in its part related to the route of degradation, while for the rate of degradation the information is placed under the point B.8.1.1.2.1.

Summary:

The aim of the study was to investigate the fate – route and rate of degradation, of Flufenacet in soil incubated under controlled (in the laboratory) aerobic conditions. The experiment was performed using one test soil originating from the US (Howe, Indiana). Its characteristic is provided below in the table B.8.1.1.1.1._CA-24. It shall be noted that in the study report the table on soil characterisation provides the results of the soil characterisation performed for three different batches, then averaged. RMS decided to present all the results of that characterisation, as they were reported in the original study's report.

Table B.8.1.1.1.1._CA-24: The characteristic of soil used in the study.

Parameter		Soil: 395			
Soil origin		Howe, Indiana, USA			
Batch analysed		A ¹⁾	B ²⁾	C ³⁾	Average

- 2) Analysis performed by Agvise Inc. on 4 February 1992;
- 3) Analysis performed by A&L Great Lakes Laboratories Inc. on 29 March 1993;
- 4) Value recalculated by the RMS using the following equation: $pH_{H_2O} = 0.982 pH_{CaCl_2} + 0.648$;
- 5) Value calculated from the corresponding pH in water;
- 6) Value calculated by RMS using the following relationship: $OC = OM/1.724$.
- 7) The soil microbial biomass was determined in soil samples using Anderson and Domsch method;
- 8) Values calculated using the average OC content – 0.35%;

The test soil was taken from a Miles Research Farm in Howe, Indiana, USA, and placed in two ~19L buckets in the greenhouse. In order to maintain its microbiological viability soil was planted with soybean prior to the conduct of the study.

Immediately before the experiment began, ~2 kg of soil from the top 5-6 inch (corresponding to 12-15 cm) layer was taken to the laboratory, where the soybean plants were removed and moist soil sieved through 2-mm sieve. Then the test soil was air-dried for 2 hours to the level of 75% of ½ bar (the soil moisture level kept throughout the experiment) and placed in the test vessels.

The test substance used in the experiment was the ¹⁴C-FOE 5043 radiolabelled in 2-thiadiazole position, as shown below on figure B.8.1.1.1.1._CA-18.

**Figure B.8.1.1.1.1._CA-18.:** The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment (scheme copied from the study report).

The specific radioactivity of the test compound used in the experiment was 18.47 mCi/mmol and its radiochemical purity, determined with TLC, was 99.5%. Its radiochemical purity determined at the time of the treatment was 97.5%. It was applied to the test soil in incubation vessels in form of the application solution prepared in the following way: 366 µg of [Thiadiazole-2-¹⁴C]-Flufenacet was evaporated to dryness under gentle stream of nitrogen and then redissolved in first 5 mL of CH₃CN (acetonitrile), to which 20 mL of distilled water was added next. The so prepared solution was stirred and then was controlled for its concentration by radioassaying. It was determined that the concentration was 291 mg Flufenacet/L.

The experiment was performed using the glass biometer flasks, presented below on figure B.8.1.1.1.1._CA-19.

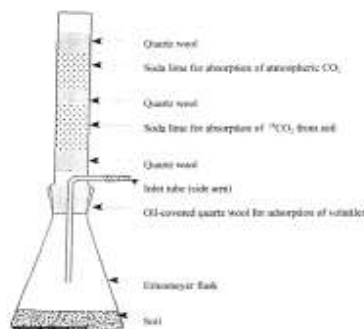

Figure B.8.1.1.1.1._CA-19: The biometer flask used in the experiment (scheme copied from the study report).

They consisted of 250-mL Erlenmeyer flasks with wide-diameter glass tube adapters, sealed with traps for volatile compounds. The traps were glass tubes with adapter containing of ~1g plug of glass wool soaked with 2% mineral oil in hexane to absorb possible VOC and soda lime layer (~10 g.) to capture formed ¹⁴CO₂, capped with a layer of glass wool (separator) above which further ~4-grams. layer of soda lime was placed to prevent soda-lime sorbent from being saturated with atmospheric CO₂. On the top 4-grams of glass wool was placed. The side-arm inlet tube, sealed with a rubber septum, was set to enable the adjustment of soil moisture by adding the necessary amounts of distilled water during the study.

Each test vessel contained the equivalent of 100 grams of oven-dried test soil, adjusted to 75% of ½ bar by addition of the appropriate amount of the distilled water. That level was maintained throughout the incubation period, lasting up to 365 days.

In total 28 incubation flask were prepared, of which 21 were treated with the test compound (4 of them were test spares), 3 were used for the non-sterile control and remaining 4 for microbial biomass determination.

The test flasks were treated with the test substance, applied to the soil surface in form of the application solution described above, at rate of 2.9 mg/kg. Applicant declared that that rate corresponded to approx. three times field application rate of 0.8 lbs a. i./acre – i. e. 2.32 lbs a. i./acre, assuming soil depth of 3 inches and soil bulk density of 1.33 g/cm³. When recalculated by the RMS as g/ha, assuming soil depth of 5 cm and soil bulk density of 1.5 g/cm³, the exact application rate was **2175 g Flufenacet/ha**. The use of the measured average soil bulk density – d = 1.37 g/cm³, resulted in the application rate of **1986.5 g Flufenacet/ha**.

The amount of the application solution introduced into each test vessel was 1 mL, applied dropwise to the soil surface. Control and microbial biomass flasks were treated with 1-mL portions of blank solvent carrier (CH₃CN:H₂O 1:4 v/v).

After treatment the appropriate amount of distilled water was added to each test vessel to establish soil moisture of 75% of ½ bar.

After treatment the Erlenmeyer incubation flask were sealed with traps for volatile compounds, weighed and covered with aluminium foil to exclude light.

So prepared incubation systems were placed in an incubation chamber and incubated in the darkness at T = 21 ± 1°C for up to 368 days. The temperature in the incubation chamber was monitored continuously. Soil moisture was monitored every week and corrected adequately, when necessary.

Trapping towers for formed volatile compounds were replaced on 4th month of incubation.

Samples were removed for the analysis on DATs (Days After Treatment) 0, 7, 14, 32, 90, 181, 27 and 368. In case of DAT-0 sampling point triplicate analysis was performed, while for all remaining sampling points duplicate samples were prepared. Also in case of two DAT-0 replicates the traps for volatile compounds were not set and the soils were analysed almost immediately (1 hour) after treatment with the test compound.

The adjustment of soil moisture was performed in 1-week intervals by weighing the incubation flasks and, when necessary, introducing the appropriate amounts of distilled water through the side-arm inlet tube.

At the designated time points duplicate test flasks were removed from the incubation chamber and for 5 minutes purged with N₂ in order to flush the produced CO₂ and VOCs into the traps.

The collected traps for volatile compounds were analysed for their content of trapped radioactivity. That was done in a following way: first the traps were dissected, mineral-oil-coated glass wool transferred into 250-mL Erlenmeyer flask and extracted by sonication for at least 30 min with 50 mL of CH₃COOC₂H₅. The organic extract was then collected by decantation and its triplicate aliquots analysed by LSC. Soda lime traps were transferred to 125-mL flasks, being a part of a specially designed extraction apparatus, shown below on figure B.8.1.1.1.1.-CA-20, to which 10 mL of water was added next.

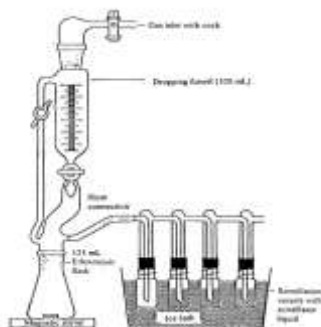

Figure B.8.1.1.1.-CA-20: The apparatus used for the liberation of ¹⁴CO₂ (scheme copied from the study report).

The system was put under the constant flow of N₂ (~20 mL/min) and 50 mL of 12N HCl was gently added. The released CO₂ was trapped in three vessels, each containing 10 mL of the mixture of Carbo-sorb E and Permafluor-E⁺ (3:5), and analysed by LSC.

Next soils from each test vessel were analysed. That was done by extracting the entire soil samples in a sequential multistep extraction procedure. Initially it consisted of the following extraction steps:

- **Step 1:** 1-hour extraction with 150 mL of CH₃CN, and the collection (decantation) of the liquid phase,
- **Step 2:** 1-hour extraction with 150 mL of CH₃CN: H₂O (7:3) solution and the collection (decantation) of the liquid phase,
- **Step 3:** 2-hours extraction with 0.1N HCl in CH₃CN: H₂O (1:1) solution and the collection (decantation) of the liquid phase.

The procedure was identical to that used in the summarised above **Study 2** [Pangilinan and Smith, 1994], but was applied solely to DAT 0 samples. The reason for that was the fact that although it displayed good efficiency – the amount of extracted AR was >90%, it was determined that Thiadone – the expected degradation product of Flufenacet, was potentially volatile. Since it was necessary to process the CH₃CN: H₂O (7:3) extracts by azeotropic concentration prior to chromatographic analysis, what implied possible losses of the volatile Thiadone, that step was removed from the extraction procedure. The modified extraction procedure, used to process all samples collected at the remaining time points, is shown below on figure B.8.1.1.1.1.-CA-21. ACN stands for acetonitrile (CH₃CN).

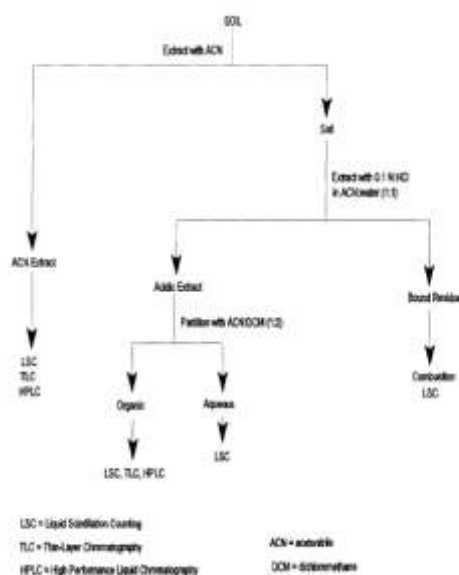

Figure B.8.1.1.1.-CA-21: A multistep soil extraction procedure used in the experiment (scheme copied from the study report).

Additionally, to maintain the consistency of the analytical procedure, also the analysis of DAT 0 samples was repeated. That was done in the following way:

The test soil was prepared and treated with the test compound in the same manner as presented above. The purity of Flufenacet used to prepare the treatment solution, determined by TLC, was 98.8% and its concentration in soil, determined by LSC, was 2.7 ppm. When recalculated by the RMS to application rate in g/ha, assuming soil depth of 5 cm and soil bulk density of 1.5 g/cm³, it was **2025 g** Flufenacet/ha. The use of the measured average soil bulk density – $d = 1.37 \text{ g/cm}^3$, resulted in the application rate of **1849.5 g** Flufenacet/ha. Volatile traps were not set as it was demonstrated that in the volatile traps from the initial DAT 0 samples <0.1% AR was detected.

The extracted soil pellets were analysed for NER fraction. To do that each soil sample was allowed to air-dry overnight, after what its triplicate aliquots (50 – 100 mg) were oxidized by combustion, and formed ¹⁴CO₂ trapped in alkaline solution. That solution, after mixing with scintillation cocktail, was analysed by LSC.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid scintillation counting) analysis was performed using a Packard Tri-Carb Model 4640 counter equipped with automatic external standardisation.

Liquid samples were radioassayed after addition of 15 mL of Ultima Gold solution. The minimum sensitivity of LSC analysis for those samples was 8.96 E-6 ppm, corresponding to 3.08 E-4% AR. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm (LAGC = 2*BCGK and LANC = LAGC – BCGK). The greatest probable error GPE = 9.24%.

Solid samples were oxidised using Packard Model 306 sample oxidizer, generated ¹⁴CO₂ trapped on 6 mL Carbo-sorb E and 15 mL Perma Fluor E. The minimum sensitivity of LSC analysis for those samples was 3.15 E-3 ppm, corresponding to 0.11% AR. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm (LAGC = 2*BCGK and LANC = LAGC – BCGK). The greatest probable error GPE = 9.24%.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- TLC – secondary quantitation method for the parent compound and its degradation products;
- LC-MS – identification method for parent compound and its degradation products;
- GC/MS – supplementary identification method for parent compound and its degradation products.

The RP-HPLC analysis was performed in a gradient mode. The system consisted of Hewlett Packard 1090 chromatograph coupled with Ramona 5-LS radioactivity monitor, equipped with RP-18 Spheri-5 cartridge in function of the guard column and Spherisorb 3 μ ODS2 (7 cm * 10 mm) chromatographic column. It worked in the following gradient regime:

- Mobile phase A: Water + 0.4% CH₃COOH,
- Mobile phase B: CH₃OH
- Gradient mode: linear from 100% AB at 0 min to 30% AB at 40 min, hold for next 20 min and linear to 0% A at 70 min.

The flow rate was set to 1 mL/min.

The LOD for the chromatographic method, in relation to the performance of the used radioactivity detector, was determined to be 500 dpm, corresponding to 1.0% AR. That value was determined experimentally on the basis of the comparison of radioactivity injected and eluted (expressed in dpm, as determined by LSC). The results of that examination, aimed on the determination of both LOD and the linearity of HPLC analysis, are presented below in the table B.8.1.1.1.1.-CA-25. The linearity of the analysis, expressed as r^2 , was: $r^2 = 0.9995$.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards. The HPLC retention times of each of the examined compounds are presented further down the document, in the table B.8.1.1.1.1.-CA-27, together with R_f values for NP-TLC and RP-TLC methods.

Table B.8.1.1.1.1.-CA-25: The results of the determination of linearity and LOD of the HPLC analysis.

Sample No.	Radioactivity in [dpm]:		Integration ^{3, 4)}
	Injected ¹⁾	Eluted ²⁾	
1	330204	308860	57035
2	211148	196266	37931
3	141516	129698	23364
4	64073	67713	10874
5	35191	n. d. ⁶⁾	5928
6	10495	10191	1872
7	4939	4806	682
8	3704	n. d. ⁶⁾	748
9 ⁵⁾	468	559	86

Footnotes to the table (for 1,2,3, as given in the study report):

- 1) Values determined by LSC analysis of the aliquots of the [¹⁴C]-Flufenacet standard solution injected, radioassayed prior to HPLC analysis;
- 2) Values determined by LSC analysis of the aliquots of HPLC eluents;
- 3) Regions of interest were integrated with background correction, determined at the beginning and the end of analysis;
- 4) Linearity of the analysis, expressed as r^2 value, was determined to be $r^2 = 0.9995$;
- 5) The value corresponding to LOD (by averaging the amount of injected and eluted it was set to LOD = 500 dpm);
- 6) n. d. = represents not determined.

The TLC analysis of the extracts was performed in two modes:

- as RP-TLC (reversed phase TLC);
- as NP-TLC (normal phase TLC).

The RP-TLC analysis was performed using Whatman KC₁₈F TLC plates, having a dimensions 20x20 cm and 200- μ m thick, with a fluorescent indicator. The solvent system used in the analysis was CH₃CN:CH₃OH:0.5N NaCl_{aq} 2:2:1 (v/v) solution.

The NP-TLC analysis was performed using silica gel TLC plates, having a dimensions 20x20 cm and 250- μ m thick, with a fluorescent indicator. The solvent system used in the analysis was CHCl₃:CH₃COOC₂H₅:CH₃COOH 75:25:1 (v/v) solution.

The LOD was set to 1 %AR for each individual compound detected. The quantitative analysis was performed using RITA 6800 Radio-TLC analyser. The LOD for this detector was determined to be 150 dpm, corresponding to 1.0% AR. The complete results of the determination of linearity and LOD of the detector are presented below in the table B.8.1.1.1.1.-CA-26.

The identification was performed by means of the comparison with the R_f values of the known standards. These values are provided below in the table B.8.1.1.1.1.-CA-27, together with R_t values for HPLC method.

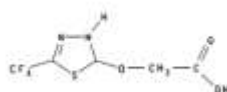

Table B.8.1.1.1.1._CA-26: The results of the determination of linearity and LOD of the TLC analysis.

Sample No.	LSC Counts Total dpm/band	Scanner Counts

Table B.8.1.1.1.1._CA-27: Chromatographic identification of Flufenacet and its degradation products in the study.

Compound	Chromatographic identification – retention time R_t [min] (HPLC)/ R_f value (TLC) determined for:		
	HPLC Method	RP-TLC Method	NP-TLC Method
<i>Flufenacet (FOE 5043)</i>	52	0.45	0.47
<i>FOE Thiadone</i>	35.5	0.74	0.17
<i>WAK-5958</i>	23.0	0.93	0.00

WAK-5958 is 3-Trifluoromethyl-1,3,4-thiadiazol-2-oxy acetic acid, presented below (structural formula) on figure B.8.1.1.1.1._CA-22.

**Figure B.8.1.1.1.1._CA-22:** Structural formula of WAK-5958 (scheme copied from the study report).

The LC-MS analysis was performed using Varian 5040 HPLC equipped with a Regis Spherisorb S50DS column working in a gradient mode and Berthold LB 505-HPLC Radioactivity Monitor, coupled with Finnigan MAT 90 MS detector. The parameters of gradient were following:

- Mobile phase A: Water,
- Mobile phase B: CH₃OH,
- Gradient mode: linear from 0% B at 0 min to 100% B at 30 min.

The flow rate in the system was set to 0.8 mL/min.

The reported parameters of MS detector were following:

- Spectrometer operated in either positive or negative mode,
- aerosol temperature: 210°C,
- 0.2 M ammonium acetate added post column at rate of 0.2 mL/min.

The identification of Flufenacet and its degradation products in LC/MS analysis was performed by comparison of mass spectra of each chromatographic peaks with those obtained for the standards, for which base signals and protonated molecular ion signals were identified. These are presented below in the table B.8.1.1.1.1._CA-28.

Table B.8.1.1.1.1._CA-28: LC/MS identification of Flufenacet and its degradation products in the study.

Compound	Representative signals used in identification	
	Position – m/z	Description
Flufenacet	364	Protonated molecular ion $[M+H]^+$
	381	Ammonia adduct $[M + NH_4]^+$
Thiadone	169	Peak for $[M - H]^-$ (negative-ion mode)

GC/MS analysis was performed to conform the identity of Flufenacet. It was carried out on HP Model 5990A Gas Chromatograph/Mass Spectrometer. GC was equipped with a DB5-MS column (15 m x 0.25 mm x 0.25 µm film thickness).

The following chromatographic programme was used in analysis:

- GC oven was programmed to start at $T = 80^{\circ}\text{C}$, held at that level for $t = 1$ min, then the temperature increased linearly at rate of $20^{\circ}\text{C}/\text{min}$ up to $T = 250^{\circ}\text{C}$ in 20 min and held at that level for $t = 1$ min; the injector's temperature was $T = 250^{\circ}\text{C}$; MS detector operated in the electron impact mode with a mass range 50 – 400 amu.

Results and their discussion:

The stability tests, performed using DAT-0 samples, demonstrated that the Flufenacet was stable during application, routine extraction procedure and chromatographic analysis of the sample. The same was demonstrated for the acid extraction procedure - with 0.1N HCl_{aq} :ACN (1:1) followed by organic solvent partitioning.

The analysis of the soil biomass showed its decline from 129 mg microbial C/kg soil to 48 mg microbial C/kg soil – 37.21% of initial level, after 8-months lasting incubation (decrease by 62.79%) and further down to 29 mg microbial C/kg soil – 22.48% of the initial level after 12 months of incubation (decrease by 77.52%). That decline pattern was examined in detail in another study, summarised above as **Study 3**. It shall be noted that the microbial biomass throughout the incubation period accounted for 3.7% OC on DAT 0, 1.4% OC after 8 months of incubation and 0.8% OC after 12 months of incubation, but that was due to the low level of soil OC – 0.32% on average. That might have influenced the obtained results, in particular the rate of degradation of Flufenacet.

The recovery of the applied radioactivity in the experimental soil was generally good, in line with the recommendations of the relevant Guidelines: 96.3 – 106.5% AR (average 101.46 % AR).

The level of mineralization for that radiolabelling position was high – it reached 50.9% AR at the end of the study (DAT 368) and gradually increased throughout the study.

The amount of NER fraction also increased with time, from 0.3% AR on DAT 0 to 6.9% AR on DAT 270. A slight decrease in the content of that fraction was observed at the end of the study. It can be stated that the level of NER formed for that radiolabelling position was not very high and ~3 times lower than that observed in the same soil for the compound radiolabelled in phenyl ring.

That may indicate that, unlike the phenyl moiety of the molecule, for the thiadone moiety mineralisation was more important ultimate transformation process in comparison to the formation of NER.

The amount of AR present as combined extractable fraction decreased with time, to reach at the end of the study (DAT 368) the level of 45.5% AR. It was also noted that the AR recovered as extracted was found predominantly in ACN extracts, although it decreased with time, while the amount of AR extracted with acidic extract increased.

The following compounds were identified in extracts:

- Flufenacet,
- Thiadone,
- Other 5 unknown degradation products or degradation products fractions.

Of the compounds listed above none may be considered as major on the basis of the criteria set by SANCO/211/2000 Guidance Document on the Assessment of the Relevance of Metabolites.

The detailed results are presented below, in table B.8.1.1.1.1_CA-29 (the values were rounded to one digit after the decimal point) and additionally in graphical form, on figure B.8.1.1.1.1_CA-23.

Table B.8.1.1.1.1._CA-29: The detailed results obtained in the study.

Total^{3,4)}	6.5	12.1	12.8	12.3	15.1	14.7	14.9	15.8

Footnotes to the table:

- 1) Values presented are the averages of triplicate repeated analysis for DAT 0 and of duplicate analysis for remaining time points;
- 2) Represents 0.1N HCl in CH₃CN:H₂O (1:1 v/v) extract;
- 3) The difference between the **Total** value reported here and the (**extracted as**): **Acidic extracts** reported in the table B.8.1.1.1.1_CA-29 above, was postulated in the study report to be possibly due to the two following factors: rounding of figures (1), presence of other HPLC resolvable degradation products, individually not exceeding 0.1% AR (2);
- 4) Value corresponds to radiocarbon residues in organic acid extracts of soil. All aqueous extracts contained <0.9% AR and were not analysed by HPLC.
- 5) n. d = not detected.

The results of the additional TLC analysis were following:

- **NP-TLC** enabled the identification and quantitation of Flufenacet and following two fractions:
 - **Thiadone:** detected in extracts from all sampling points, in most of them in amounts <1.0% AR and in max. amount of 2.3% AR in DAT 7 sample;
 - **Origin:** not further characterised fraction having $R_f = 0.00$, detected in extracts from all sampling points, in none of them in amounts $\geq 2.0\%$ AR (the maximum amount quantified was 1.8% AR in DAT 270 sample).
- **RP-TLC** enabled the identification and quantitation of Flufenacet and following five fractions:
 - **Thiadone:** detected in extracts from all sampling points, in max. amount of 1.5% AR in DAT 14 sample;
 - **Metabolite 1:** not further identified fraction having $R_f = 0.00$, detected in almost all analysed sample extracts, with exception of DAT 0 sample, in amounts 0.2 – 0.3% AR;
 - **Metabolite 2:** not further identified fraction having $R_f = 0.64$, detected only in DAT 181 and DAT 368 samples in amounts of 0.1% AR;
 - **Metabolite 3:** not further identified fraction having $R_f = 0.75$, detected in almost all analysed sample extracts, with exception of DAT 0 and DAT 270 samples, usually not surpassing 0.4% AR and in one sample – DAT 7 detected in max. amount of 1.2% AR;
 - **Metabolite 4:** not further identified fraction having $R_f = 0.87$, detected in almost all analysed sample extracts, with exception of DAT 90, DAT 270 and DAT 360 samples, in amount 0.1% AR.

There were no further attempts to identify any of the detected Unknowns. That was due to the fact that none of them was detected in amounts $\geq 2.5\%$ AR throughout the study.

On the basis of the obtained results the possible transformation pathway of Flufenacet in soil was proposed. It was also stated that the degradation was predominantly, if not exclusively, biotically mediated.

In case of the degradation product Thiadone it was stated that when detected in DAT 0 samples it could possibly be the, at least partly, impurity of the treatment solution. At later time points it was solely a product of microbial transformation of Flufenacet.

Conclusions:

The obtained results showed that Flufenacet was extensively degraded in the experimental soil during 368 days of the experiment, reaching the level of 43.7% of the initial dose at the end of the study.

Also the level of mineralisation was high, comparing to the experiments with Flufenacet radiolabelled in phenyl ring, reaching ~52% AR at the study's end (DAT 368), while the formation of NER fraction was low.

One degradation product was identified – Thiadone, and 5 other, not further identified fractions detected, none of which reached individually the level of 2.5% AR.

The postulated mechanism for degradation of Flufenacet within Thiadiazole moiety was biologically mediated transformation. On the basis of the results obtained in this study the following transformation pathway of Flufenacet in aerobic soil, shown on the Fig B.8.1.1.1.1._CA-24, was proposed:

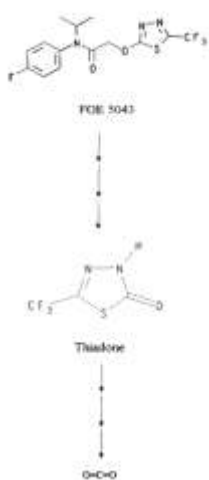

Figure B.8.1.1.1._CA-24: The transformation pathway of Flufenacet in aerobic soil, determined for the compound radiolabelled in thiadiazole moiety (scheme copied from the study report).

RMS's conclusions with regard to the validity of the study:

On the basis of the thorough examination of the study protocol RMS proposes to consider the study valid, despite the deficiencies it displays, as providing vital information in the area of the determination of the route of degradation of Flufenacet in soil.

The problem of the decline of soil microbial activity observed in the experimental soil, was thoroughly examined and satisfactorily explained in an independent study, summarised above as **Study 3**. In light of the findings of that study, the study summarised above can be considered acceptable and relevant for the purpose of the regulatory assessment of Flufenacet.

Two new studies specifically submitted for the purpose of this evaluation are summarised below.

Study 5:

Report: Hein E.-M., (2012): “[Thiadiazole-5-¹⁴C] Flufenacet: Aerobic Degradation/Metabolism in One European Soil.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany, Study M1251994-1; unpublished Study Report No. MEF-11/937; 2012. 09. 19, amended (Amendment No 1) 2013. 04. 10; study reference number: M-439105-02-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Commission Directive 95/36/EC amending Council Directive 91/414/EEC (Annexes II and III, Fate and Behaviour in the Environment), 1995;
- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

No deviations were stated in the study report.

GLP: Yes

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to investigate the fate – route and rate of degradation, of Flufenacet in soil incubated under controlled (in the laboratory) aerobic conditions. The experiment was performed using one European test soil originating from Germany (Hoefchen am Hohenseh). Its characteristic is provided below in the table B.8.1.1.1.1_CA-32.

Table B.8.1.1.1.1_CA-32: The characteristic of soil used in the study.

Parameter		Soil:	
		<i>Hoefchen am Hohenseh 4a</i>	
Soil origin		<i>Burscheid/ North Rhine-Westphalia/ Germany</i>	
Soil type (USDA)		Silt loam	
Particle size distribution	Sand (50 µm – 2 mm) [%]	29	
	Silt (2 – 50 µm) [%]	56	
	Clay (< 2 µm) [%]	15	
pH value in water (soil:water ratio 1:1)		7.0	
pH value in 1N KCl		6.3	
pH value in 0.01M CaCl ₂ (soil:solution ratio 1:2)		6.7	
Organic carbon content (C _{org}) [%] ¹⁾		2.5	
Organic matter content (OM) [%] ²⁾		4.3	
Cation Exchange Capacity – CEC [mEq/100g]		12.9	
Bulk density (disturbed) [g/cm ³]		1.04	
Water holding capacity	Maximum [g H ₂ O/100 g soil d. w.]	61.1	
	at ½ bar (pF 2.5) [%]	23.7	
	at 0.1 bar (pF 2.0) [%]	29.8	
Soil biomass expressed in mg microbial C/kg soil in samples collected on DAT ³⁾ :	0 ⁵⁾	841 (BIO -) ⁶⁾	n. r. (BIO+) ⁷⁾
	60	693 (BIO -) ⁶⁾	638 (BIO+) ⁷⁾
	120	563 (BIO -) ⁶⁾	506 (BIO+) ⁷⁾
Soil biomass expressed as %OC ⁴⁾ in samples collected on DAT:	0 ⁵⁾	3.36 (BIO -) ⁶⁾	n. r. (BIO+) ⁷⁾
	60	2.77 (BIO -) ⁶⁾	2.55 (BIO+) ⁷⁾
	120	2.25 (BIO -) ⁶⁾	2.02 (BIO+) ⁷⁾

Footnotes to the table:

- 1) Measured value;
- 2) Value calculated by the Applicant using the following equation: OM = 1.724*OC;
- 3) Determined using the method by Anderson&Domsch;
- 4) Recalculated by the RMS, using the reported OC = 2.5%;
- 5) For that sampling point only the results for “BIO -” samples were available (please refer to the footnote 6) below);
- 6) “BIO -” stands for samples not treated with blank application solution - 358 µL of CH₃OH/H₂O 1:1 v/v solution;
- 7) “BIO +” stands for samples treated with blank application solution - 358 µL of CH₃OH/H₂O 1:1 v/v solution;

The test soil, representative for the agriculturally used area of the region of sampling, was taken from the field of the history of cropping system and Plant Protection Products use known for the 5 years before sampling. It was determined that during that period the plant cover of that designated field was grassland on which no pesticides were used. Soil used in the experiment was taken with shovel from the top 20-cm layer, placed in plastic container (bag or bucket) and transferred to the experimental facility, where it was sieved through 2-mm sieve.

The aliquots of the test soil were taken for the soil characterisation (soil texture, pH, CEC OC content and water holding capacity). Its results are reported above, in table B.8.1.1.1.1_CA-32. Soil moisture was determined in three 22 – 25g aliquots using an automated halogen moisture analyser.

Soil biomass was determined using Anderson & Domsch's method in the samples taken at the beginning of the incubation period – on DAT 0, on DAT 60 (in the middle of the incubation period) and on DAT 120 (the study's end).

The experiment was performed using the glass biometer flasks, presented below on figure B.8.1.1.1.1_CA-25.

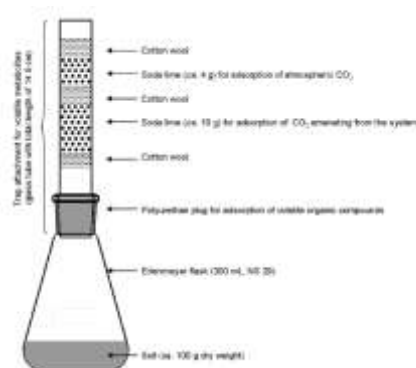

Figure B.8.1.1.1.1_CA-25: The biometer flask used in the experiment (copied from the study report).

They consisted of 300-mL Erlenmeyer flasks with wide-diameter glass tube adapters, sealed with traps for volatile compounds, permeable for oxygen. The traps contained polyurethane foam to absorb possible VOC and soda lime layer (~10 g.) to capture formed $^{14}\text{CO}_2$. The trapping system was capped with ~4-grams. layer of soda lime between two cotton-wool separators, placed to prevent soda-lime sorbent from being saturated with atmospheric CO_2 .

Each test vessel contained the equivalent of 100 grams of oven-dried test soil, adjusted to $55 \pm 5\%$ MWHC by addition of the appropriate amount of the distilled water. That level was maintained throughout of the incubation period, lasting up to 120 days. It was controlled on DAT 56 (prior to that time point it was assumed and then conformed that no significant losses in soil moisture were expected), when the remaining flasks were weighed, the loss of moisture from the system determined and the soil moisture in remaining incubation vessels adjusted to the pre-determined level by addition of the appropriate amount of distilled water.

So prepared incubation flasks were equilibrated to study conditions, in a temperature-controlled walk-in climatic chamber in the dark and at $T = 20 \pm 2^\circ\text{C}$, prior to the treatment of soil with the test compound.

The incubation flask were prepared for the following examinations: kinetic samples – in duplicate per each time point, samples for the determination of soil microbial biomass and those for the identification of transformation products.

The test compound used in the experiment was the ^{14}C -FOE 5043 radiolabelled in C5-thiadiazole position, as shown below on figure B.8.1.1.1.1_CA-26.

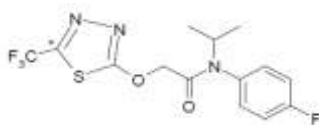

Figure B.8.1.1.1.1_CA-26.: The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 1.54 MBq/mg and its radiochemical purity, determined using both HPLC and TLC, was > 99%. Also the chemical purity of the test compound, determined using HPLC equipped with UV detector, was > 99%.

It was used to prepare its stock solution by dissolving the total delivered amount in 12 mL of methanol. The so obtained solution had a nominal concentration of ~1 mg/mL (1540 kBq/mL). The exact concentration was verified by LSC, while the identity of the test compound and its purity was verified by means of ¹H-NMR and HPLC-MS(/MS).

It was stated that the exact concentration of the stock solution was 1423.08 kBq/mL and its radiochemical purity 100%.

Next two application solutions were prepared from the stock solution. One of them having the target nominal concentration of 616.0 kBq/mL was designated to be used in kinetic samples (further called **Application Solution 1**). The second one, having the same target nominal concentration – 616.0 mBq/mL was designated to treat samples for identification of transformation products (further called **Application Solution 2**).

Application Solution 1 was prepared by transferring 7.79 mL of the stock solution to a glass bottle and diluting it with 1.21 mL of methanol and 9.00 mL of deionised water to obtain the total volume of 18.00 mL. The so prepared solution had the experimentally determined (by LSC) concentration of 688.1 kBq/mL, corresponding to 446.8 µg Flufenacet/mL.

Application Solution 2 was prepared by transferring 3.64 mL of the stock solution to a glass bottle and diluting it with 0.04 mL of methanol and 3.675 mL of deionised water to obtain the total volume of 7.35 mL. The so prepared solution had the experimentally determined (by LSC) concentration of 748.8 kBq/mL, corresponding to 486.2 µg Flufenacet/mL.

The **Application Solution 1** was applied dropwise onto the soil surface in pre-equilibrated test vessels in amount of 358 µL/test vessel to obtain the application dose in the kinetic samples of 160 µg Flufenacet/100 g soil d. w. (1.6 mg Flufenacet/kg soil d. w.). According to the Applicant that corresponded to the application rate of 600 g Flufenacet/ha, assuming soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 2.5 \text{ cm}$. RMS recalculated the assumed application rate using the standard assumptions: soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 5.0 \text{ cm}$. The resulting application rate $A = 1200 \text{ g Flufenacet/ha}$, the application rate five times higher than that proposed in the EU-representative GAP prepared for the purpose of the current evaluation. When the measured soil bulk density - $d = 1.04 \text{ g/cm}^3$ was used the calculated application rate was $A = 832 \text{ g Flufenacet/ha}$.

The **Application Solution 2** was applied dropwise onto the soil surface in pre-equilibrated test vessels, in amount of 3290 µL/test vessel to obtain the application dose in the samples for identification of transformation products of 1600 µg Flufenacet/100 g soil d. w. (16 mg Flufenacet/kg soil d. w.). According to the Applicant that corresponded to the application rate of 6000 g Flufenacet/ha, assuming soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 2.5 \text{ cm}$ – ten-fold the accepted field application rate of that compound. RMS recalculated the assumed application rate using the standard assumptions: soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 5.0 \text{ cm}$. The resulting application rate $A = 12000 \text{ g Flufenacet/ha}$, the application rate fifty times higher than that proposed in the EU-representative GAP prepared for the purpose of the current evaluation. The justification for such high application dose was that it enabled the proper identification of the formed degradation products. When the measured soil bulk density - $d = 1.04 \text{ g/cm}^3$, was used, the calculated application rate was $A = 8320 \text{ g Flufenacet/ha}$.

After application of the test compound the kinetic samples, except DAT-0 samples were fitted with traps for volatile compounds and placed in the temperature-controlled walk-in climatic chamber to be incubated in the dark and at constant temperature $T = 20 \pm 2^\circ\text{C}$ for up to 120 days. The sampling points were designated on DATs (Days After Treatment) 0, 2, 4, 7, 10, 14, 35, 60, 87 and 120. On those specific time points duplicate samples were removed from the incubation chamber for the further examination.

The samples for identification of transformation products after application of the test compound were handled in the same way as described above for the kinetic samples.

The homogeneity of the application in these samples was determined before, during and after application, by pipetting 358 µL- aliquots of the **Application Solution 1** into 20-mL volumetric flasks filled to the volume with CH₃CN. The so prepared solutions were then tested for their radioactivity content using LSC method.

The exact application rate for kinetic samples was determined by measuring the amount of the radioactivity in DAT-0 samples by LSC before, during and after application. The determined level of radioactivity was considered to be 100% AR

The biomass samples were placed alongside the kinetic samples and those for identification of transformation products. They were prepared in the following way: the pre-equilibrated test vessels were divided into two groups: native soil biomass test systems – “BIO-”, and solvent control biomass test systems – “BIO+”. The “BIO-” samples were left untreated, while to the “BIO+” samples 358 μL aliquots of the blank application solution – 1:1 MeOH/H₂O solution not containing the test compound, were pipetted. So prepared samples, except DAT-0 “BIO-” samples, were then handled in the same manner as kinetic samples. On DAT 60 and DAT 120 “BIO-” and “BIO+” samples were taken for the determination of the soil biomass content using Anderson&Domsch’s method.

All samples were incubated under aerobic conditions in the dark, under the constant temperature $T = 20 \pm 2^\circ\text{C}$ and soil moisture $55 \pm 5\%$ MWHC. Soil moisture was controlled at the beginning of the study and on DAT 56 by weighing test systems and adjusting it, if necessary, to the designated level by adding the appropriate amount of deionised water.

The samples removed at the designated sample points were processed in the following way: prior to opening the incubation vessels all volatiles possibly present in the area between soil surface and the volatile trap filling were purged into the trap columns. Next the incubation vessels were dissected into Erlenmayer flasks containing soil and volatile traps, and further processed following the conceptual scheme presented below on Figure B.8.1.1.1._CA-27. The entire soil samples were taken for the analysis. They were quantitatively transferred, using the first extraction solvent, to centrifuge beakers used as the extraction vessels.

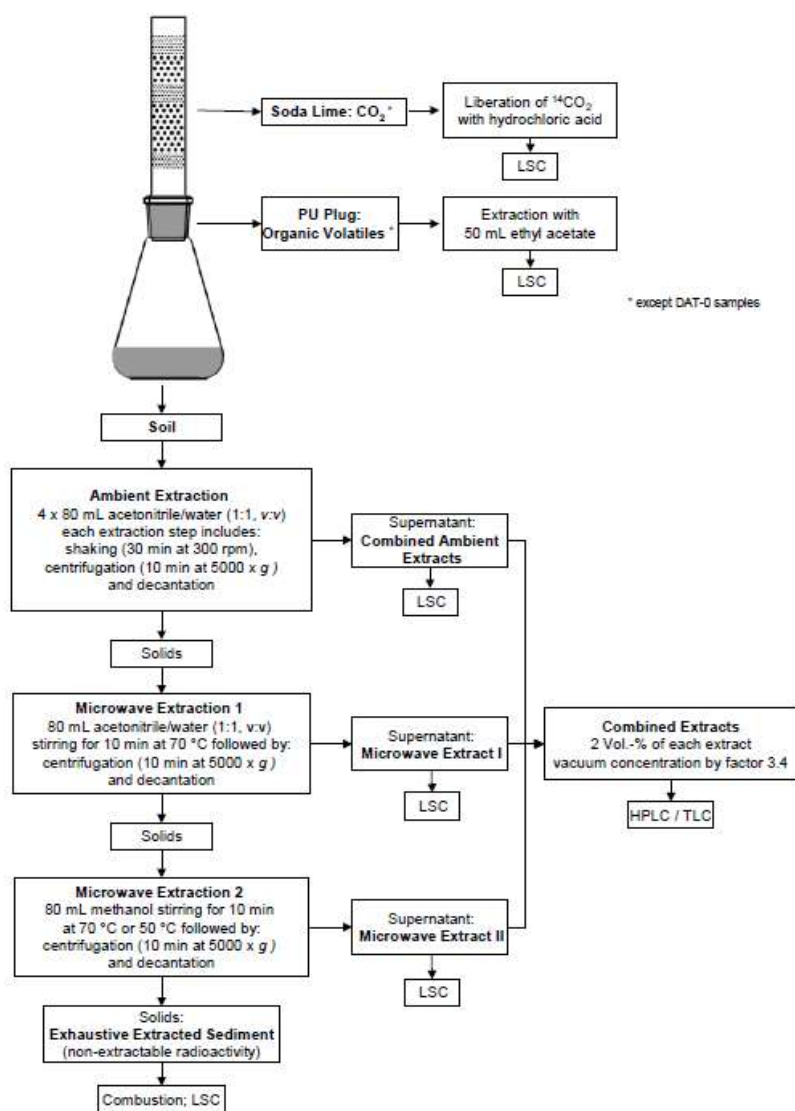

Figure B.8.1.1.1.-CA-27: The conceptual scheme of sample processing procedure (copied from the study report).

The extracted soil pellets were lyophilized, homogenised and three 1-g aliquots analysed for NER fraction, after combustion, using LSC.

That procedure was applied to kinetic samples. The samples for the identification of transformation products were not processed. Instead the isolation and identification of the transformation products was performed using concentrated combined extracts from DAT 35 samples, which were analysed by HPLC and the chromatographic eluates divided into six fractions which were further processed and analysed.

The extracted soil pellets were analysed for NER fraction. To do that each soil sample was allowed to air-dry overnight, after what its triplicate aliquots (50 – 100 mg) were oxidized by combustion. The formed $^{14}\text{CO}_2$ was trapped in alkaline solution which, after mixing with scintillation cocktail, was analysed by LSC. The further characterisation of NER fraction was not performed, because of its low content – max. 13.5% AR.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using LS6000 LL/6500 or LKB-Wallac 1219 Spectral counters.

The radioactivity in soil extracts and other liquid samples from HPLC analysis was determined in either:

- mini-vials, using the sample aliquots of up to 1 mL and 2 mL of Quicksafe[®] A solution containing 5% of water; the counting time was 10 min and the background 13 – 16 cpm;
- maxi-vials, using the sample aliquots of up to 5 mL and 7 mL of Quicksafe[®] A solution containing 5% of water; the counting time was 10 min and the background 22 – 23 cpm.

The $^{14}\text{CO}_2$ recovered from soda lime was absorbed in Oxysolve scintillation cocktail, in three vials per sample and radioactivity measured in each vial. The results were summed up. The counting time was 10 min and the background 17 – 20 cpm.

The radioactivity in extracts from PU plugs was determined in maxi-vials using the sample aliquots of up to 5 mL and 7 mL of Quicksafe[®] A solution containing 5% of water. The counting time was 10 min and the background 22 – 23 cpm.

The radioactivity in solid samples – extracted soil pellets, was determined after combustion of three 1-g aliquots of dried and homogenised material. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxysolve C400 liquid. The counting time was 10 min and the background 17 – 20 cpm.

The instrumental limit of detection – LOD_i was set to twice maximum instrument background count rate and instrumental limit of quantitation – LOQ_i to three times maximum instrument background count rate. Maximum instrument background count rate was determined to be 0.3 – 0.5 Bq. Therefore, for different types of liquid samples the instrumental LOD_i and LOQ_i were as follows:

- samples with scintillation cocktail of 2 mL Quicksafe A + 5% water, $\text{LOD}_i = 0.5$ Bq and $\text{LOQ}_i = 0.8$ Bq;
- samples with scintillation cocktail of 7 mL Quicksafe A + 5% water, $\text{LOD}_i = 0.8$ Bq and $\text{LOQ}_i = 1.2$ Bq;
- samples with scintillation cocktail of 15 mL Oxysolve C400, $\text{LOD}_i = 0.7$ Bq and $\text{LOQ}_i = 1.0$ Bq.

When calculated for different types of analysed samples, the determined LOD and LOQ values for LSC analysis were as presented below in the table B.8.1.1.1.1._CA-33:

Table B.8.1.1.1.1._CA-33: The LOD and LOQ values for different types of samples analysed using LSC.

Type of sample	max. total amount – volume or mass	min. aliquots analysed – volume or mass	LOD (worst case) expressed in:		LOQ (worst case) expressed in:	
			Bq	% AR	Bq	% AR
<i>Ambient extract</i>	380 mL	0.5 mL	405.3	0.2	608.0	0.2
<i>Microwave extract 1</i>	81 mL	0.5 mL	86.4	<0.1	129.6	<0.1
<i>Microwave extract 2</i>	78 mL	0.5 mL	83.2	<0.1	124.8	<0.1
<i>PU foam plug extract</i>	50 mL	5 mL	7.7	<0.1	11.5	<0.1
<i>Solid sample (combustion)</i>	101 g	0.9 g	75	<0.1	112.6	0.1
<i>$^{14}\text{CO}_2$ from soda lime traps</i>	Sample entirely used for LSC analysis		----	<0.1	----	<0.1

Sample extracts were analysed using the following analytical methods:

- HPLC – primary identification and quantitation method for parent compound and its degradation products;
- TLC – primary and conformatory quantitation method for the parent compound and its degradation products;
- LC-MS – identification method for parent compound and its degradation products;
- ^1H -NMR – supplementary identification method for parent compound in stock solution.

The RP-HPLC analysis was performed in a gradient mode. The system consisted of HP 1200 chromatograph equipped with a quaternary pump, autosampler, on-line degasser, column oven and a Variable Wavelength UV detector set at $\lambda = 254$ nm, coupled with Ramona 2000 radioactivity detector. Chromatographic separation was performed on and Purosphere Star C_{18e} 250 mm * 4.6 mm * 5 μ m chromatographic column, preceded by Purosphere Star C_{18e} 4 mm * 4 mm * 5 μ m guard column. It worked in the following gradient regime:

- **Mobile phase A:** 985 mL Water + 10 mL HCOOH + 5 mL NH₄COOH_(aq) (5 mM NH₄COOH/265 mM HCOOH);
- **Mobile phase B:** 985 mL CH₃CN + 10 mL HCOOH + 5 mL NH₄COOH_(aq) (5 mM NH₄COOH/265 mM HCOOH);
- **Gradient mode:** 0% B for the first 5 min., then linear gradient 95% B on 55th min., hold for next 5 min., linear gradient to 0% B at 62nd min. and hold until 65th min;
- Total run time was 65 minutes.

The flow rate was set to 1.0 mL/min. The chromatographic column was kept under the constant temperature T = 40°C.

The method had following performance parameters:

- mean recovery of 98.4%;
- good linearity – $R^2 > 0.9999$ for the injected amounts of the radiolabelled test compound ([Thiadiazole-5-¹⁴C] Flufenacet) in range 3.0 Bq – 504.0 Bq;
- LOD = 3.0 Bq, corresponding to LOD = 0.5% AR;
- LOQ = 3 * LOD – 9.0 Bq, corresponding to 1.5% AR.

The quantitative TLC analysis of polar fraction was performed as NP-TLC (Normal Phase TLC). It was carried out at ambient temperature, in saturated chamber, on silica gel Merck Si60, F₂₅₄, TLC plates. The solvent system used in the analysis was CH₃COOC₂H₅/CH₃CHOHCH₃/H₂O/CH₃COOH 65:24:11:1 (v/v/v/v) solution (CH₃CHOHCH₃ stands for 2-propanol).

Two detectors were used:

- UV cabinet (Camag) detector working at two wavelengths: $\lambda = 254$ nm or $\lambda = 366$ nm;
- Bio-Imaging Analyser “BAS-2000” for analysis of radioactivity.

The conformatory TLC method was also performed as NP-TLC (Normal Phase TLC). It was carried out at ambient temperature, in saturated chamber, on silica gel Merck Si60, F₂₅₄, TLC plates. Two detectors were used:

- UV cabinet (Camag) detector working at two wavelengths: $\lambda = 254$ nm or $\lambda = 366$ nm;
- Bio-Imaging Analyser “BAS-2000” for analysis of radioactivity.

Two solvent system were used in the analysis:

- eluent 1 (**Method D**) – CH₂Cl₂/CH₃COOC₂H₅ 8:2 (v/v) solution;
- eluent 2 (**Method A**) – CH₃COOC₂H₅/CH₃CHOHCH₃/H₂O/CH₃COOH 65:24:11:1 (v/v/v/v) solution (CH₃CHOHCH₃ stands for 2-propanol).

Method D was used to separate the non-polar compounds – Flufenacet and FOE Thiadone, while **Method A** for separation of the polar ones – FOE Trifluoroethanesulfonic acid and Trifluoroacetic acid (TFA).

The LC-MS analysis was performed using HP1000 HPLC system equipped with a Nucleodur Gravity C₁₈ chromatographic column (250 * 2 mm, 3 μ m), UV detector followed by the Ramona Star radiodetector and the LTQ Orbitrap XL mass spectrometer detector. The parameters of chromatographic analysis were following:

- column temperature: 40°C,
- flow rate: 0.2 mL/min,
- elution mode: gradient,
- mobile phase:
 - Solvent A: H₂O + 0.1% HCOOH,
 - Solvent B: CH₃CN + 0.1% HCOOH.
- two gradient programmes used, presented below in the table B.8.1.1.1.1._CA-34:
 - Gradient 1,
 - Gradient 2.

Table B.8.1.1.1.1._CA-34: Gradient programmes used in LC/MS analysis.

Gradient 1			Gradient 2		
Time [min]	% solvent A (H ₂ O + 0.1% HCOOH)	% solvent B (CH ₃ CN + 0.1% HCOOH)	Time [min]	% solvent A (H ₂ O + 0.1% HCOOH)	% solvent B (CH ₃ CN + 0.1% HCOOH)
0	95	5	0	100	0
1	95	5	5	100	0
25	5	95	25	5	95
35	5	95	35	5	95

Results and their discussion:

The monitoring of the experimental conditions demonstrated that the samples were incubated at the mean temperature 19.7⁰C, ranging from 19.4⁰C to 19.9⁰C. These values were within the limits of the assumed constant temperature T = 20 ± 2⁰C.

The soil moisture content was demonstrated to be within the assumed value of 55 ± 5% MWHC and no significant losses were observed throughout the study duration.

The change in soil biomass looked as follows:

- in soil not treated with blank application solution it decreased during the incubation period by 17.6% until the mid-point of the study (DAT60) and by 33.1% at its end – DAT 120;
- in soil treated with blank application solution it decreased during the incubation period by 24.1% until the mid-point of the study (DAT60) and by 39.8% at its end – DAT 120.

It shall be noted that the decrease in soil microbial activity was greater in soil treated with blank application solution. It was stated however, that it cannot be attributed to the influence of the application solution on the soil biomass, because of small difference in that parameter between treated and not treated samples. As a result, it can be stated that the decrease in soil microbial activity may be related predominantly to the natural phenomena. It was within the acceptability limits – the soil microbial biomass was throughout the study duration above the recommended level of 1% OC, making the obtained results reliable.

The LSC analysis of the homogeneity of application of the kinetic samples showed that it was homogenous, with RSD = 0.7%

The stability tests, performed using DAT-0 samples, demonstrated that the Flufenacet was stable during application and that the radiochemical purity of the application solution was 100%.

The application dose determined for DAT 0 samples was (average) 249885 Bq, equal to 162.3 µg Flufenacet/sample. That value was set as 100% AR for the kinetic samples.

The recovery of the applied radioactivity in experimental soil was generally good, in line with the recommendations of the relevant Guidelines: on average 99.5% AR with RSD = 1.2%, and range of 97.0% AR – 101.6% AR (values given as the means of two replicates).

The level of mineralization was not very high in comparison to the results obtained in another study with Flufenacet radiolabelled in thiadiazole moiety – it reached 5.6% AR at the end of the study (DAT 120).

The amount of NER fraction also increased with time from 0.5% AR on DAT 0 to max. 13.5% AR on DAT 60 (study's mid-point), to then slightly decrease to 12.5% AR at the study's end (DAT 120). It shall be noted that the fraction formed in higher amounts than in the earlier study with Flufenacet radiolabelled in thiadiazole moiety.

The amount of AR present as combined extractable fraction decreased with time from 99.7% at the beginning of the study – DAT 0 to 78.8% AR at its end (DAT 120). It was recovered predominantly in ambient extracts, while microwave extracts did not significantly contribute to the amounts of AR extracted.

The following compounds were identified in extracts:

- Flufenacet,
- FOE Thiadone - max. 5.8% AR on DAT 10,
- FOE 5043-Trifluoroethanesulfonic acid - max. 6.0% AR on DAT 14,
- Trifluoroacetic acid (TFA) – max. 77.7% AR on DAT 87.

The small fraction of unidentified radioactivity was detected, not surpassing 2% AR at any sampling point.

All identified degradation products listed above may be considered as major according to the criteria set by SANCO/211/2000 Guidance Document on the Assessment of the Relevance of Metabolites.

The detailed results are presented below, in table B.8.1.1.1.1._CA-35 (the means of the two replicates; values were rounded to one digit after the decimal point) and additionally in graphical form, on two figures - B.8.1.1.1.1._CA-28 for radioactivity distribution and B.8.1.1.1.1._CA-29 for identified compounds/fractions profiling.

Table B.8.1.1.1.1._CA-35: The detailed results obtained in the study.

% AR		Results obtained for sample collected at DAT ¹⁾ :									
		0	2	4	7	10	14	35	60	87	120
Extracted as:	Ambient extract	97.8	96.1	96.6	93.6	90.8	88.2	81.7	78.6	78.3	77.0

Footnotes to the table:

- 1) Values presented are the means of two replicates for each sampling point;
- 2) A sum of all minor degradation products;
- 3) The difference between the Total Extracted AR and the Total identified AR was declared in the study report to be possibly due to the following factors: rounding of figures (1), cleanup and chromatographic losses (2);
- 4) Value calculated by adding the results obtained for VOC and those for CO₂
- 5) n. d. = not detected;
- 6) n. a. = not analysed, because of the assumption made that at that sampling point neither mineralisation nor formation of volatile degradation products is expected to occur.

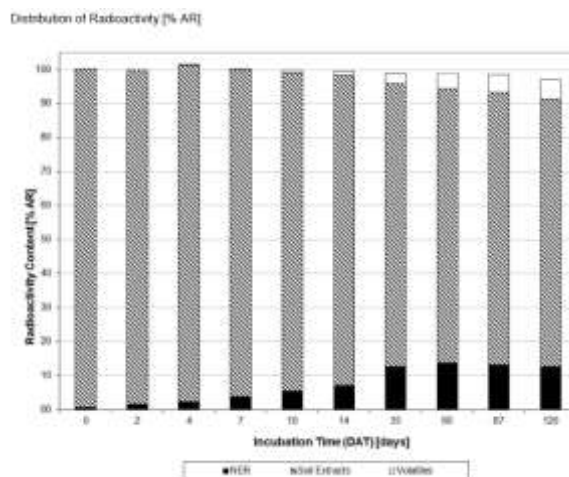

Figure B.8.1.1.1.1._CA-28: Graphical presentation of the obtained results - distribution of radioactivity (copied from the study report).

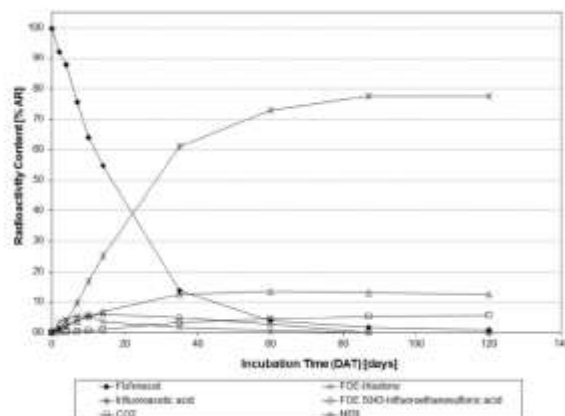

Figure B.8.1.1.1._CA-29: Graphical presentation of the obtained results – concentration profiles of identified degradation products (copied from the study report).

On the basis of the obtained results the Applicant proposed the transformation scheme presented below on figure B.8.1.1.1._CA-30. Mechanistically, it consisted of the following steps:

- cleavage of the test item on bridging oxygen of the thiadiazole heterocycle and tautomerisation of keto-enol functional group, resulting in formation of FOE Thiadone,
- hydrolytical opening of Thiadone ring and further oxidation resulting in formation of either FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA), or else simple products of mineralisation and NER fraction – ultimate transformation products;
- further transformation of FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA) to the simple products of mineralisation and NER fraction – ultimate transformation products.

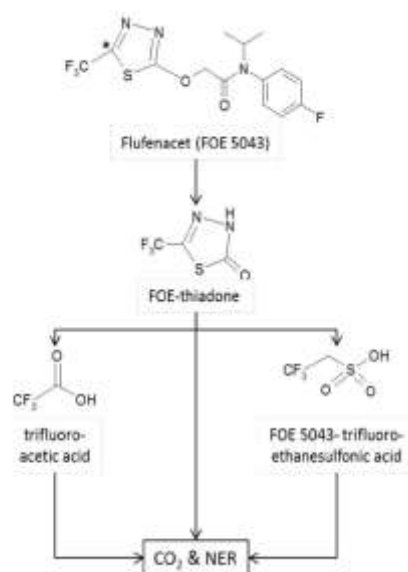

Figure B.8.1.1.1._CA-30: The conceptual scheme of the transformation of Flufenacet radiolabelled in thiadiazole moiety (copied from the study report).

The results obtained for Flufenacet were kinetically examined and the results of that examination presented as a part of the study report. The performed kinetic analysis complied with the current standards, set by FOCUS Kinetics Guidance Document [FOCUS, 2006]. It was however decided, in order to maintain the coherence of the Report, to present it under the relevant point of this document – B.8.1.1.2.1.1.

Study 6:

Report: Hein E.-M., (2012): “[Thiadiazole-5-¹⁴C] Flufenacet: Aerobic Degradation/Metabolism in Three European Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany, Study M1252037-0; unpublished Study Report No. MEF-11/938; 2012. 10. 18, amended (Amendment No 1) 2013. 01. 28; study reference number: M-440348-02-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

GLP: Yes

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to investigate the fate – route and rate of degradation, of Flufenacet in soil incubated under controlled (in the laboratory) aerobic conditions. The experiment was performed using three European test soils. Their characteristic is provided below in the table B.8.1.1.1.1._CA-36.

Table B.8.1.1.1.1._CA-36: The characteristic of soils used in the study.

Parameter		Soil		
		<i>Laacherhof AXx</i> (AX)	<i>Dollendorf II</i> (DD)	<i>Laacherhof Wurmweise</i> (WW)
Soil origin		Monheim/North Rhine-Westphalia/Germany	Blankenheim/North Rhine-Westphalia/Germany	Monheim/North Rhine-Westphalia/Germany
Soil type (USDA)		Loamy sand	Clay Loam	Loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	75	29	49
	Silt (2 – 50 µm) [%]	20	38	34
	Clay (< 2 µm) [%]	5	33	17
pH value in 0.01M CaCl ₂ (soil/solution ratio 1:2)		6.1	7.2	5.4
pH value in H ₂ O (soil/solution ratio 1:1)		6.4	7.4	5.7
pH value in 1N KCl		5.9	7.0	5.2
Organic carbon content (OC) [%]		2.4	5.3	2.2
Organic matter content (OM) [%] ¹⁾		4.1	9.1	3.8
Cation Exchange Capacity – CEC [mEq/100g]		9.9	20.9	10.8
Water holding capacity	Maximum [g H ₂ O/100 g soil]	49.1	79.8	59.9
	at 0.1 bar (pF 2.0) [%]	18.7	46.0	23.3
	at ½ bar (pF 2.5) [%]	12.0	35.9	16.3
Bulk density (disturbed) [g/cm ³]		1.19	0.95	1.12
Soil biomass expressed in mg microbial C/kg soil	“Bio - ” ³⁾	Initial (DAT 0)	1077	862
		Final (DAT 121)	451	341
	“Bio +” ⁴⁾	Initial (DAT 0)	n. d. ⁵⁾	n. d. ⁵⁾
		Final (DAT 121)	422	338
Soil biomass expressed as %OC ²⁾	“Bio - ” ³⁾	Initial (DAT 0)	4.49	3.92
		Final (DAT 121)	1.88	1.55
	“Bio +” ⁴⁾	Initial (DAT 0)	n. c. ⁶⁾	n. c. ⁶⁾
		Final (DAT 121)	1.76	1.54

Footnotes to the table:

- 1) Value calculated by the RMS using the following equation: OM = 1.724 * OC;
- 2) Values calculated by RMS;
- 3) “Bio - ” stands for samples not treated with blank application solution - 346 µL of CH₃OH/H₂O 1:1 v/v solution;
- 4) “Bio +” stands for samples treated with blank application solution - 346 µL of CH₃OH/H₂O 1:1 v/v solution;
- 5) Value not determined – at that time point the influence of application solution on soil biomass considered negligible;
- 6) Value not calculated due to the lack of the relevant experimental value;

The test soils, representative for the agriculturally used areas of the regions of sampling, were taken from the fields of the history of cropping system and Plant Protection Products use known for the 5 years before sampling. It was determined that during that period the plant cover of those designated fields was grassland on

which no pesticides were used. Soils used in the experiment were taken with shovel from the top 20-cm layer, placed in plastic containers (bag or bucket) and transferred to the experimental facility, where they were sieved through 2-mm sieve.

The aliquots of the test soils were taken for the soil characterisation (soil texture, pH, CEC OC content and water holding capacity), reported above in table B.8.1.1.1.1._CA-36. Soil moisture for each test soil was determined in three 10 – 20-g aliquots, using an automated halogen moisture analyser.

Soil biomass was determined using Anderson & Domsch's method in the samples taken at the beginning of the incubation period – on DAT 0 and at its end – on DAT 121.

The experiment was performed using the glass biometer flasks, presented below on figure B.8.1.1.1.1._CA-31.

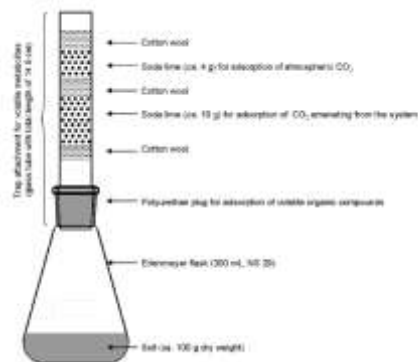

Figure B.8.1.1.1.1._CA-31: The biometer flask used in the experiment (scheme copied from the study report).

They consisted of 300-mL Erlenmeyer flasks with wide-diameter glass tube adapters, sealed with traps for volatile compounds, permeable for oxygen. The traps contained polyurethane foam to absorb possible VOC and soda lime layer (~10 g.) to capture formed $^{14}\text{CO}_2$. The trapping system was capped with ~4-grams. layer of soda lime between two cotton-wool separators, placed to prevent soda-lime sorbent from being saturated with atmospheric CO_2 .

Each test vessel contained the equivalent of 100 grams of oven-dried test soil, adjusted to $55 \pm 5\%$ MWHC bar by addition of the appropriate amount of the distilled water. That level was maintained throughout of the incubation period, lasting up to 121 days. It was controlled on DAT 67 (prior to that time point it was assumed, and then conformed, that no significant losses in soil moisture were expected), when the remaining flasks were weighed, the loss of moisture from the system determined and the soil moisture in remaining incubation vessels adjusted to the pre-determined level by addition of the appropriate amount of distilled water.

So prepared incubation flasks were equilibrated to study conditions, in a temperature-controlled walk-in climatic chamber in the dark and at $T = 20 \pm 2^\circ\text{C}$, prior to the treatment of soil with the test compound.

The incubation flask were prepared for the following examinations: kinetic samples – in duplicate per each time point, samples or the determination of soil microbial biomass and those for the identification of transformation products.

The test compound used in the experiment was the ^{14}C -FOE 5043 radiolabelled in C5-thiadiazole position, as shown below on figure B.8.1.1.1.1._CA-32.

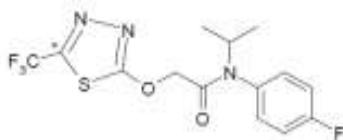

Figure B.8.1.1.1.1._CA-32: The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 1.54 MBq/mg and its radiochemical purity, determined using both HPLC and TLC, was $> 99\%$. Also the chemical purity of the test compound, determined using HPLC equipped with UV detector, was $> 99\%$.

It was used to prepare its stock solution by dissolving the total delivered amount in 17 mL of methanol. The so obtained solution had a nominal concentration of ~2 mg/mL (3047 kBq/mL). The exact concentration was verified by LSC, while the identity of the test compound and its purity by means of ¹H-NMR and HPLC-MS/MS).

It was stated that the exact concentration of the stock solution was 3081.54 kBq/mL and radiochemical purity 100%.

Next two application solutions were prepared from the stock solution. One of them, having the target nominal concentration of 616.0 kBq/mL, was designated to for treating of the kinetic samples (further called **Application Solution 1**). The other one, having the target nominal concentration of 6160.0 mBq/mL, was designated to treat the samples for identification of transformation products (further called **Application Solution 2**)

Application Solution 1 was prepared by transferring 8.8 mL of the stock solution to a glass bottle and diluting it with 13.2 mL of methanol and 22.0 mL of deionised water to obtain the total volume of 44.0 mL. The so prepared solution had the experimentally determined (by LSC) concentration of 711.5 kBq/mL, corresponding to 462.0 µg Flufenacet/mL.

Application Solution 2 was prepared by transferring 5.60 mL of the stock solution to a glass bottle and evaporating it to dryness under the constant stream of nitrogen. The residue was reconstituted in 1.4 mL of methanol and 1.4 mL of deionised water to obtain the total volume of 2.8 mL. The so prepared solution had the experimentally determined (by LSC) concentration of 6445.8 kBq/mL, corresponding to 4185.6 µg Flufenacet/mL.

The **Application Solution 1** was applied dropwise onto the soil surface in pre-equilibrated test vessels, in amount of 346 µL/test vessel, to obtain the application dose in the kinetic samples of 160 µg Flufenacet/100 g soil d. w. (1.6 mg Flufenacet/kg soil d. w.). According to the Applicant that corresponded to the application rate of 600 g Flufenacet/ha, assuming soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 2.5 \text{ cm}$. RMS recalculated the assumed application rate using the standard assumptions: soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 5.0 \text{ cm}$. The resulting application rate $A = 1200 \text{ g Flufenacet/ha}$ – five times higher than that proposed in the EU-representative GAP prepared for the purpose of the current evaluation. When the measured soil bulk density, specific for each test soil was used, the calculated application rates were following:

- for **Laacherhof AXXa (AD)** soil, having the bulk density $d = 1.19 \text{ g/cm}^3$, calculated application rate was $A = 952 \text{ g Flufenacet/ha}$;
- for **Dollendorf II (DD)** soil, having the bulk density $d = 0.95 \text{ g/cm}^3$, calculated application rate was $A = 760 \text{ g Flufenacet/ha}$;
- for **Laacherhof Wurmweise (WW)** soil, having the bulk density $d = 1.12 \text{ g/cm}^3$, calculated application rate was $A = 896 \text{ g Flufenacet/ha}$.

The **Application Solution 2** was applied dropwise onto the soil surface in pre-equilibrated test vessels in amount of 382 µL/test vessel to obtain the application dose in the samples for identification of transformation products equal to 1600 µg Flufenacet/100 g soil d. w. (16 mg Flufenacet/kg soil d. w.). According to the Applicant that corresponded to the application rate of 6000 g Flufenacet/ha, assuming soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 2.5 \text{ cm}$, ten-fold the accepted field application rate of that compound. RMS recalculated the assumed application rate using the standard assumptions: soil bulk density $d = 1.5 \text{ g/cm}^3$ and the thickness of the soil layer $l = 5.0 \text{ cm}$. The resulting application rate $A = 12000 \text{ g Flufenacet/ha}$ – fifty times higher than that proposed in the EU-representative GAP prepared for the purpose of the current evaluation. The justification for such high application dose was that it enabled the proper identification of the formed degradation products. When the measured soil bulk density, specific for each test soil was used, the calculated application rates were following:

- for **Laacherhof AXXa (AD)** soil, having the bulk density $d = 1.19 \text{ g/cm}^3$, calculated application rate was $A = 9520 \text{ g Flufenacet/ha}$;
- for **Dollendorf II (DD)** soil, having the bulk density $d = 0.95 \text{ g/cm}^3$, calculated application rate was $A = 7600 \text{ g Flufenacet/ha}$;
- for **Laacherhof Wurmweise (WW)** soil, having the bulk density $d = 1.12 \text{ g/cm}^3$, calculated application rate was $A = 8960 \text{ g Flufenacet/ha}$.

After application of the test compound the kinetic samples, except DAT-0 samples, were fitted with traps for volatile compounds and placed in the temperature-controlled walk-in climatic chamber to be incubated in the dark and at constant temperature $T = 20 \pm 2^\circ\text{C}$ for up to 121 days. The sampling points were designated on DATs (Days After Treatment) 0, 1, 2, 4, 7, 10, 14, 35, 63, 91 and 121. On those specific time points the duplicate samples were removed from the incubation chamber for the further examination.

The samples for identification of transformation products after application of the test compound were handled in the same way as described above for the kinetic samples.

The homogeneity of the application in kinetic samples was determined before, during and after application, by pipetting 346- μ L aliquots of the **Application Solution 1** into 20-mL volumetric flasks filled to the volume with CH₃CN. The so prepared solutions were then tested for their radioactivity content using LSC method.

The exact application rate of kinetic samples was determined by measuring the amount of the radioactivity in DAT-0 samples by LSC before, during and after application. The determined level of radioactivity was considered to be 100% AR

The biomass samples were placed alongside the kinetic samples those for identification of transformation products. They were prepared in the following way: the pre-equilibrated test samples were divided into two groups: native soil biomass test samples – “BIO-”, and solvent control biomass test samples – “BIO+”. The “BIO-” samples were left untreated, while “BIO+” samples received 346- μ L aliquots of the blank application solution – 1:1 MeOH/H₂O solution not containing the test compound. So prepared samples, except DAT-0 “BIO-” samples, were handled in the same manner as kinetic samples. On DAT 121 “BIO-” and “BIO+” samples were taken for the determination of the soil biomass content using Anderson&Domsch’s method.

All samples were incubated under aerobic conditions in the dark, under the constant temperature $T = 20 \pm 2^{\circ}\text{C}$ and soil moisture $55 \pm 5\%$ MWHC. Soil moisture was controlled at the beginning of the study and on DAT 67 by weighing test systems and, if necessary, adjusting it to the designated level by adding the appropriate amount of deionised water.

The samples removed at the designated sample points were processed in the following way: prior to opening the incubation vessels all volatiles, possibly present in the area between soil surface and the volatile trap filling, were purged into the trap columns. Next the incubation vessels were dissected into Erlenmeyer flasks containing soil and volatile traps and further processed following the conceptual scheme presented below on Figure B.8.1.1.1.1.-CA-33. The entire soil samples from the dissected incubation vessels were taken for the analysis and quantitatively transferred, using the first extraction solvent, to centrifuge beakers used as the extraction vessels.

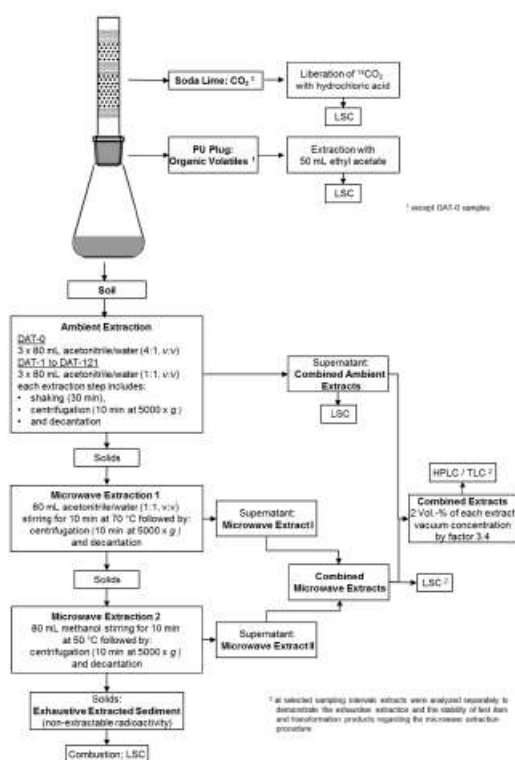

Figure B.8.1.1.1.-CA-33: The conceptual scheme of sample processing procedure (copied from the study report).

The extracted soil pellets were lyophilized, homogenised and three 1-g aliquots analysed for NER fraction after combustion using LSC.

The procedure was applied to kinetic samples, while the samples for identification of transformation products were not processed. Instead the isolation and identification of the transformation products was performed using concentrated combined extracts from DAT 10 samples, which were analysed by HPLC and the chromatographic eluates divided into three to four fractions which were further processed and analysed.

The extracted soil pellets were analysed for NER fraction. To do that each soil sample was allowed to air-dry overnight, after what its triplicate aliquots (50 – 100 mg) were oxidized by combustion. The formed $^{14}\text{CO}_2$ was trapped in alkaline solution which, after mixing with scintillation cocktail, was analysed by LSC. The further characterisation of NER fraction was not performed, because of its low content – max. 18.6% AR in Laacherhof AXXa (AX) soil, 11.5% AR in Dollendorf II (DD) soil and 18.6% AR in Laacherhof Wurmweise (WW) soil.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a LS6000 LL/6500 or LKB-Wallac 1219 Spectral counters.

The radioactivity in soil extracts and other liquid samples from HPLC analysis was determined in either:

- mini-vials, using the sample aliquots of up to 1 mL and 2 mL of Quicksafe[®] A solution containing 5% of water; the counting time was 10 min and the background 12 – 16 cpm;
- maxi-vials, using the sample aliquots of up to 5 mL and 7 mL of Quicksafe[®] A solution containing 5% of water; the counting time was 10 min and the background 22 – 23 cpm.

The $^{14}\text{CO}_2$ recovered from soda lime was absorbed in Oxsolve scintillation cocktail, in three vials per sample, and radioactivity measured in each vial. The results were summed up. The counting time was 10 min and the background 17 – 20 cpm.

The radioactivity in extracts from PU plugs was determined in maxi-vials using the sample aliquots of up to 5 mL and 7 mL of Quicksafe[®] A solution containing 5% of water. The counting time was 10 min and the background 22 – 23 cpm.

The radioactivity in solid samples – extracted soil pellets, was determined after combustion of three 1-g aliquots of dried and homogenised material, the resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxsolve C400 liquid. The counting time was 10 min and the background 17 – 20 cpm.

The instrumental limit of detection – LOD_i was set to twice maximum instrument background count rate and instrumental limit of quantitation – LOQ_i to three times maximum instrument background count rate. The maximum instrument background count rate was determined to be 0.3 – 0.5 Bq. Therefore for different types of liquid samples the instrumental LOD_i and LOQ_i were as follows:

- samples with scintillation cocktail of 2 mL Quicksafe A + 5% water, $\text{LOD}_i = 0.5$ Bq and $\text{LOQ}_i = 0.8$ Bq;
- samples with scintillation cocktail of 7 mL Quicksafe A + 5% water, $\text{LOD}_i = 0.8$ Bq and $\text{LOQ}_i = 1.2$ Bq;
- samples with scintillation cocktail of 15 mL Oxsolve C400, $\text{LOD}_i = 0.7$ Bq and $\text{LOQ}_i = 1.0$ Bq.

When calculated for different types of analysed samples, the determined LOD and LOQ values for LSC analysis were as presented below in the table B.8.1.1.1.1_CA-37:

Table B.8.1.1.1.1_CA-37: The LOD and LOQ values for different types of samples analysed using LSC.

Type of sample	max. total amount – volume or mass	min. aliquots analysed – volume or mass	LOD (worst case) expressed in:		LOQ (worst case) expressed in:	
			Bq	% AR	Bq	% AR
<i>Ambient extract</i>	240 mL	0.5 mL	256.0	0.1	384.0	0.2
<i>Microwave extract 1</i>	233 mL	0.5 mL	248.5	0.1	372.8	0.2
<i>Microwave extract 2</i>	77 mL	0.5 mL	82.1	<0.1	123.2	<0.1
<i>PU foam plug extract</i>	50 mL	5 mL	7.7	<0.1	11.5	<0.1
<i>Solid sample (combustion)</i>	105 g	0.9 g	77.5	<0.1	116.2	0.1
<i>$^{14}\text{CO}_2$ from soda lime traps</i>	Sample entirely used for LSC analysis		----	<0.1	----	----

Sample extracts were analysed using the following analytical methods:

- HPLC – primary identification and quantitation method for parent compound and its degradation products;
- TLC – primary and conformatory quantitation method for the parent compound and its degradation products;
- LC-MS (either HPLC/MS or IEC/MS) – identification method for parent compound and its degradation products;
- ^1H -NMR – supplementary identification method for parent compound in stock solution.

The RP-HPLC analysis was performed in a gradient mode. The system consisted of HP 1100 chromatograph equipped with a binary pump, autosampler, on-line degasser, column oven and a Variable Wavelength UV detector set at $\lambda = 254$ nm, coupled with Ramona Star radioactivity detector. The chromatographic separation was performed on Purosphere Star RP 18e 250 mm * 4.6 mm * 5 μ m chromatographic column. It worked in the following gradient regime:

- **Mobile phase A:** 985 mL Water + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ (5 mM NH_4COOH /265 mM HCOOH),
- **Mobile phase B:** 985 mL CH_3CN + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ (5 mM NH_4COOH /265 mM HCOOH),
- **Gradient mode:** 0% B for first 5 min., then linear gradient to 95% B on 55th min., hold for next 5 min., linear gradient to 0% B on 62nd min. and hold until 75th min.,
- Total run time was 75 minutes.

The flow rate was set to 1.0 mL/min. The chromatographic column was kept under the constant temperature $T = 40^\circ\text{C}$.

The method had the following performance parameters:

- **mean recovery:** 99.7% for Laacherhof AXXa (AX) soil, 99.5% for Dollendorf II (DD) soil and 98.8% for Laacherhof Wurmweise (WW) soil;
- **good linearity** – $R^2 = 1.0$ for the injected amounts of the radiolabelled test compound ([Thiadiazole-5- ^{14}C] Flufenacet) in range 3.0 Bq – 490.8 Bq;
- **LOD** = 3.0 Bq, corresponding to LOD = 0.4% AR;
- **LOQ** = 3 * LOD – 1.3% AR.

The quantitative TLC analysis of polar fraction was performed as NP-TLC (Normal Phase TLC). It was carried out at ambient temperature, in saturated chamber, on silica gel Merck Si60, F_{254} , TLC plates. The solvent system used in the analysis was $\text{CH}_3\text{COOC}_2\text{H}_5/\text{CH}_3\text{CHOHCH}_3/\text{H}_2\text{O}/\text{CH}_3\text{COOH}$ 65:24:11:1 (v/v/v/v) solution ($\text{CH}_3\text{CHOHCH}_3$ stands for 2-propanol).

Two detectors were used:

- UV cabinet (Camag) detector working at two wavelengths: $\lambda = 254$ nm or $\lambda = 366$ nm;
- Bio-Imaging Analyser “BAS-2000” for analysis of radioactivity.

The conformatory TLC method was also performed as NP-TLC. It was carried out at ambient temperature, in saturated chamber, on silica gel Merck Si60, F_{254} , TLC plates. Two detectors were used:

- UV cabinet (Camag) detector working at two wavelengths: $\lambda = 254$ nm or $\lambda = 366$ nm;
- Bio-Imaging Analyser “BAS-2000” for analysis of radioactivity.

Two solvent system were used in the analysis:

- eluent 1 (**Method D**) – $\text{CH}_2\text{Cl}_2/\text{CH}_3\text{COOC}_2\text{H}_5$ 8:2 (v/v) solution;
- eluent 2 (**Method A**) – $\text{CH}_3\text{COOC}_2\text{H}_5/\text{CH}_3\text{CHOHCH}_3/\text{H}_2\text{O}/\text{CH}_3\text{COOH}$ 65:24:11:1 (v/v/v/v) solution ($\text{CH}_3\text{CHOHCH}_3$ stands for 2-propanol).

Method D was used to separate the non-polar compounds – Flufenacet and FOE Thiadone, while **Method A** for separation of the polar ones – FOE Trifluoroethanesulfonic acid and Trifluoroacetic acid (TFA).

The LC-MS analysis was performed as either HPLC/MS or IEC/MS analysis.

HPLC/MS analysis was carried out using HP1000 HPLC system equipped with a Nucleodur Gravity C_{18} chromatographic column (250 * 2 mm, 3 μ m), UV detector followed by the Ramona Star radiodetector and one of the following two MS detectors:

- LTQ Orbitrap XL mass spectrometer,
- Q-Exactive mass spectrometer.

The parameters of chromatographic analysis were following:

- column temperature: 40°C ,
- flow rate: 0.2 mL/min,
- elution mode: gradient,
- mobile phase:
 - Solvent A: H_2O + 0.1% HCOOH,
 - Solvent B: CH_3CN + 0.1% HCOOH.
- two gradient programmes used, presented below in the table B.8.1.1.1.1_CA-38:
 - Gradient 1 – used in the system equipped with LTQ Orbitrap XL mass spectrometer,
 - Gradient 2 – used in the system equipped with Q-Exactive mass spectrometer.

Table B.8.1.1.1.1_CA-38: Gradient programmes used in HPLC/MS analysis.

Gradient 1			Gradient 2		
Time [min]	% solvent A (H ₂ O + 0.1% HCOOH)	% solvent B (CH ₃ CN + 0.1% HCOOH)	Time [min]	% solvent A (H ₂ O + 0.1% HCOOH)	% solvent B (CH ₃ CN + 0.1% HCOOH)
0	95	5	0	100	0
1	95	5	5	100	0
25	5	95	25	5	95
35	5	95	35	5	95

The IEC/MS (Ion Exchange Chromatography) analysis was performed using Dionex ICS-500 system equipped with AS20 column (250 * 2 mm), Ramona Star radiodetector and Q-Exactive mass spectrometer.

The parameters of chromatographic analysis were following:

- column temperature: 30⁰C,
- flow rate: 0.25 mL/min,
- elution mode: isocratic,
- mobile phase: 20mM KOH in water.

Results and their discussion:

The monitoring of the experimental conditions demonstrated that the samples were incubated at the mean temperature 19.8⁰C, ranging from 19.5⁰C to 20.2⁰C. The average incubation temperature and its range were within the limits of the assumed constant temperature T = 20 ± 2⁰C.

The soil moisture content was demonstrated to be within the assumed value of 55 ± 5% MWHC and no significant losses were observed throughout the study duration.

The determination of the soil biomass showed that:

- in **Laacherhof AXXa (AX)** it decreased during the incubation period by 58.1% in soil not treated with blank application solution ("BIO-") and by 60.8% in soil treated with blank application solution ("BIO+"), as determined at DAT 121;
- in **Dollendorf II (DD)** soil it decreased during the incubation period by 37.2% in soil not treated with blank application solution ("BIO-") and by 41.1% in soil treated with blank application solution ("BIO+"), as determined at DAT 121;
- in **Laacherhof Wurmwiess (WW)** soil it decreased during the incubation period by 60.4% in soil not treated with blank application solution ("BIO-") and by 60.8% in soil treated with blank application solution ("BIO+"), as determined at DAT 121.

It shall be noted that the decrease in soil microbial activity was greater in soil treated with blank application solution. It was stated however that it could not be attributed to the influence of the application solution on the soil biomass, because the difference between the decrease in "BIO-" and "BIO+" samples was not greater than 5%. As a result, it can be stated that the decrease in soil microbial activity may be related predominantly to the natural phenomena. It was within the acceptability limits - throughout the study duration it was above the recommended level of 1% OC in all test soils, so the obtained results may be considered reliable.

The LSC analysis of the homogeneity of application of the kinetic samples showed that it was homogenous, with RSD = 0.9%

The stability tests performed using DAT-0 samples demonstrated that Flufenacet was stable during application and the radiochemical purity of the application solution was 100%.

The application dose determined for DAT-0 samples was (average) 234072 Bq, equal to 152.0 µg Flufenacet/sample. That value was set as 100% AR for the kinetic samples.

The recovery of the applied radioactivity in the experimental soil was generally good, in line with the recommendations of the relevant Guidelines and looked as follows:

- in **Laacherhof AXXa (AX)** soil on average 99.1% AR with RSD = 0.9%, and range 97.1% AR – 100.9% AR (values given as the means of the two replicates);
- in **Dollendorf II (DD)** soil on average 99.7% AR with RSD = 1.8%, and range 95.7% AR – 103.0% AR (values given as the means of the two replicates);
- in **Laacherhof Wurmwiess (WW)** soil on average 98.7% AR with RSD = 1.2%, and range 96.2% AR – 99.8% AR (values given as the means of the two replicates).

The level of mineralization was not very high in comparison to the results obtained in another study with Flufenacet radiolabelled in thiadiazole moiety – at the end of the study (DAT 121) it reached 5.6% AR in Laacherhof AXXa (AA) soil, 6.5% AR in Dollendorf II (DD) soil and 4.5% AR in Laacherhof Wurmwielse (WW) soil.

The amount of NER fraction also increased with time and was as follows:

- in **Laacherhof AXXa (AX)** soil it increased from 0.4% AR on DAT 0 to max. 18.6% AR on DAT 63, to then slightly decrease to 17.2% AR at the study's end (DAT 121);
- in **Dollendorf II (DD)** soil it increased from 1.1% AR on DAT 0 to max. 11.5% AR on DAT 63, to then slightly decrease to 10.6% AR at the study's end (DAT 121);
- in **Laacherhof Wurmwielse (WW)** soil it increased from 0.7% AR on DAT 0 to max. 18.6% AR on DAT 35 and DAT 63, to then slightly decrease to 17.2% AR at the study's end (DAT 121).

NER fraction was not further characterised in any of the experimental soils.

The amount of AR present as combined extractable fraction decreased with time from 98.7% - 99.9% AR (depending on the test soil) at the beginning of the study – DAT 0, to 75.0 – 82.1% AR (depending on the test soil) at the study's end (DAT 121). It was recovered predominantly in ambient extracts, while microwave extracts contributed insignificantly to the amounts of radioactivity extracted.

The following compounds were identified in extracts:

- Flufenacet,
- FOE Thiadone,
- FOE 5043-Trifluoroethanesulfonic acid,
- Trifluoroacetic acid (TFA).

The small fraction of unidentified radioactivity, not surpassing 2.5% AR at any sampling point in any of the test soils, was also detected.

Of the identified degradation products listed above only TFA may be considered as major on the basis of the criteria set by SANCO/211/2000 Guidance Document on the Assessment of the Relevance of Metabolites.

The detailed results are presented below, individually for each test soil, in numerical (tabularised) and graphical forms.

The results obtained in Laacherhof AXXa (AX) soil are presented below in the table B.8.1.1.1.1_CA-39 (the means of the two replicates; values were rounded to one digit after the decimal point) and in graphical form on two figures - B.8.1.1.1.1_CA-33 for radioactivity distribution and B.8.1.1.1.1_CA-34 for identified compounds/fractions profiling.

Table B.8.1.1.1.1_CA-39: The detailed results obtained in the study with Laacherhof AXXa soil.

Figure B.8.1.1.1._CA-38: Graphical presentation of the results obtained in Laacherhof Wurmwiese soil – concentration profiles of identified degradation products (copied from the study report)..

On the basis of the obtained results the Applicant proposed the transformation scheme presented below on figure B.8.1.1.1._CA-39. It consisted of the following steps:

- cleavage of the test item on bridging oxygen of the thiadiazole heterocycle and tautomerisation of keto-enol functional group, resulting in formation of FOE Thiadone,
- hydrolytical opening of thiadiazole ring and further oxidation resulting in formation of either FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA) or else simple products of mineralisation and NER fraction – ultimate transformation products;
- further transformation of FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA) to the simple products of mineralisation and NER fraction – ultimate transformation products.

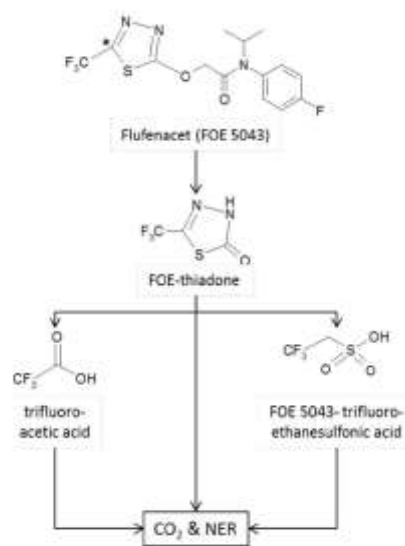

Figure B.8.1.1.1.1_CA-39: The conceptual scheme of the transformation of Flufenacet radiolabelled in thiadiazole moiety (copied from the study report).

The results obtained for Flufenacet were kinetically examined and the results of that examination presented as a part of the study report. The performed kinetic analysis complied with the current standards, set by FOCUS Kinetics Guidance Document [FOCUS, 2006]. It was however decided, in order to maintain the coherence of the Report, to present it under the relevant point of this document – B.8.1.1.2.1.1.

Additionally two publications relevant in the area of determination of the route and rate of degradation of flufenacet in soil under aerobic conditions were found. They are summarised below. To maintain the coherence of the document they are consecutively numbered as studies 7 and 8. The order in which the studies are reported reflects their relevance for the evaluation process. Also, in order to maintain the coherence of the Report, the numbering of the tables and figures follows the format and order of appearance adopted in this document.

Study 7:

Report: Bloomberg A. M., Shadrick B. A., Ellen A. L., Clay V. E. (2002): „Outdoor Soil Metabolism of [Phenyl- ^{14}C] Flufenacet on California Soils.”; Bayer Corporation, 17745 South Metcalf Avenue, Stilwell, KS, 66085, USA; published study – published in: *Phelps W. (ed.) “ACS Symposium Series, vol. 813: Pesticide Environmental Fate”, chapter 12, pp 167 – 182*; American Chemical Society, Washington, DC, 2002, publication date March 1, 2002;

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes. However, examination of the study protocol, also in cross-reference to other studies submitted by the Applicant, demonstrated that it complied with the following guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1, Aerobic Soil Metabolism;

GLP: the study was declared to be a non-GLP study, but it followed the analytical protocol same as other, GLP studies, carried out in the same research facility.

RMS comments: The paper describes the study bridging the laboratory and field studies examining the fate and behaviour of Flufenacet in soil. Although not performed according to any specific Guidelines it was found to comply with the provisions of US EPA 162-1 Guideline. It was generally well documented, although only general information concerning test soil were presented, and it provides important information with regard to the route of degradation of Flufenacet in soil. Its results may be also used, as supplementary, in determination of the rate of degradation of that compound under realistic – field conditions. RMS considers the study valid for the regulatory purposes. Its extended summary is provided below.

Summary:

The abstract of the publication provided by the publisher – American Chemical Society, is presented below. It is reprinted with permission from: *Annette M. Bloomberg, Barbara A. Shadrick, Ellen L. Arthur et al. "Outdoor Soil Metabolism of [Phenyl U-¹⁴C]Flufenacet on California Soils.", ACS Symposium Series, 2002, vol 813: Pesticide Environmental Fate, chapter 12, pp. 167-182; Copyright 2002 American Chemical Society, reprinted with editor's permission.*

Abstract:

An outdoor soil metabolism study with [phenyl-U-¹⁴C] flufenacet was conducted on two sandy loams collected from Chualar and Fresno sites in California. This study involved more natural environmental conditions than a laboratory study and was conducted to obtain information on flufenacet residue identification and leaching potential. Vessels filled with approximately 13 cm of each soil were placed in an outdoor plot at Pan-Agricultural Laboratories in Madera, California, and treated with radioactive flufenacet at an equivalent rate of 0.89 lb a.i. per acre. Samples were collected in duplicate immediately after application and at 1, 4, 7, 11, 15, 19, 27, 35, 46, and 88 days after treatment. At each sampling interval, the top 3 cm (approximately) of soil was removed, extracted, and analyzed by high-pressure liquid chromatography for parent compound and metabolites. The total [¹⁴C]residues recovered from the vessels remained above 85.9% in the Fresno soil and 92.8% in the Chualar soil throughout the 88-day study with the greatest percentage of the radioactivity remaining in the top 0- to 3-cm layers. The extracted [¹⁴C]residues in the top layer decreased to 44.3% of the applied radioactivity in the Fresno soil and 62.6% in the Chualar soil at the 88-day interval, with 19.5% and 25.3% remaining bound to the soil, respectively. Residues of parent compound decreased to 17.8% and 29.0% at the 88-day interval in the Fresno and Chualar soils, respectively. The flufenacet alcohol and oxalate were the two major metabolites detected in this study. The flufenacet alcohol reached a maximum level of 21.2% in the Chualar 88-day sample, whereas the flufenacet oxalate reached a maximum of 13.0% in the Fresno 46-day sample. The half-lives for flufenacet in the Fresno and Chualar soil were calculated to be 36.1 days ($k = 0.0192 \text{ days}^{-1}$) and 49.9 days ($k = 0.0139 \text{ days}^{-1}$), respectively.

The extended summary of the publication, written by the RMS, is presented below.

The aims of the study were:

- to examine the rate of degradation of Flufenacet in soil by determining its half-life and first-order degradation rate constant k ;
- to identify the degradation products;
- to evaluate the leaching potential of Flufenacet and its soil degradation products under field conditions.

The study was conceived and performed as the outdoor metabolism study in order to bridge the results of laboratory and field studies and therefore conform that the results of the former are representative for what may be expected for Flufenacet with regard to its fate and behaviour in soil under realistic, field conditions.

The experiment was performed using two US soils collected on the fields on which soil dissipation studies had been performed, but from the untreated areas. The characteristic of the test soils is given in the table below in the table B.8.1.1.1.1._CA-42. It reproduces the data given in the source publication in the **Table 1. Pertinent characteristics of soils used in the ¹⁴C-flufenacet outdoor metabolite study.**

Table B.8.1.1.1.1._CA-42: The characteristic of the test soils used in the experiment.

Determined soil property		Test soil	
		<i>Chualar</i>	<i>Fresno</i>
Soil type ¹⁾		Sandy loam	Fine sandy loam
Soil type (USDA) ²⁾		Sandy loam	Sandy loam
Particle size distribution	Sand [%]	70.0	64.7
	Silt [%]	18.0	31.3
	Clay [%]	12.0	4.0
pH		6.4	7.5
Organic matter content (OM) [%]		1.3	0.5
Organic carbon content (OC) [%] ³⁾		0.75	0.29
Soil biomass [CFU/ g soil d. w.] ⁴⁾		1.08 E6	1.03 E6

Footnotes to the table:

- As given in the source paper;
- Verified by the RMS;
- Recalculated by the RMS using the following equation: $OM = 1.724 * OC$;
- [CFU/g soil d. w.] stands for Colony Forming Units per gram soil (dry weight), quantified on plate count agar.

The test soils were sieved through 2-mm sieve before the experiment started and placed in experimental vessels – jars having a volume of ~3.79 L (1 gallon), diameter of ~15.24 cm (6 inches), the same height and

closed bottom. They were brought to 50 – 90% MWHC, the level maintained throughout the study by daily irrigation. The test vessels were filled with ~12.7 – 13.97 cm (5 - 5½ inch) layer of the test soils and placed in the ground, on the experimental plot of Pan-Agricultural Laboratories, Inc, in Madera, California. The total amount of the test vessels was 44 – 22 per each test soil, placed two parallel double rows. Additionally between the rows two vessels containing a mixture of the test soils and three moisture sensors were placed. The scheme of the test plot is presented below on figure B.8.1.1.1.1. CA-40 (the figure is reproduced directly from: Annette M. Bloomberg, Barbara A. Shadrick, Ellen L. Arthur et al. "Outdoor Soil Metabolism of [Phenyl U-¹⁴C]Flufenacet on California Soils.", ACS Symposium Series, 2002, vol 813: Pesticide Environmental Fate, chapter 12, pp. 167-182; Copyright 2002 American Chemical Society, reprinted with editor's permission.).

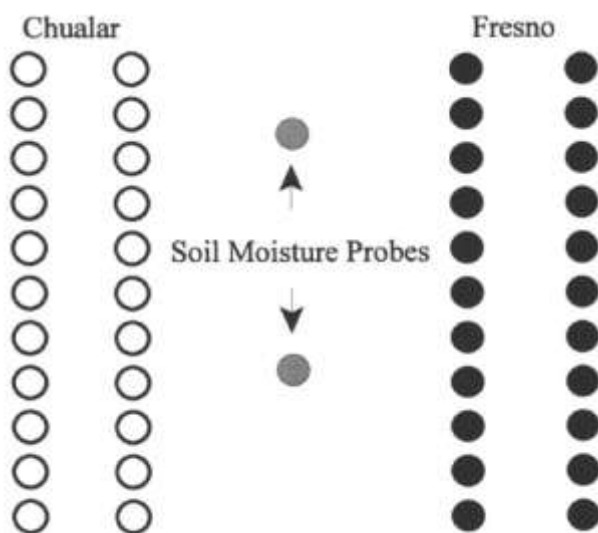

Figure 1. Test plot diagram for ¹⁴C-flufenacet outdoor metabolism study.

Figure B.8.1.1.1.1. CA-40: The scheme of the test plot (Reprinted with permission from Annette M. Bloomberg, Barbara A. Shadrick, Ellen L. Arthur et al. "Outdoor Soil Metabolism of [Phenyl U-¹⁴C]Flufenacet on California Soils.", ACS Symposium Series, 2002, vol 813: Pesticide Environmental Fate, chapter 12, pp. 167-182; Copyright 2002 American Chemical Society.

The test soils in each of the test vessels were treated with the radiolabelled test compound – [Phenyl U-¹⁴C] Flufenacet, applied to the soil surface in form of the application CH₃CN-solution by means of 2-mL syringe. The declared application rate was 0.89 lb a. s./acre, corresponding to 997.35 g a. s./ha.

The outdoor part of the experiment lasted from 16th July 1992 to 12th October 1992. The test vessels were kept open to the atmosphere. To avoid the overflow from excessive rainfall the plots were covered with a water-proof material when wet weather was forecasted. Also the experimental plot was maintained constantly bare by weeding it around the test vessels on DAT 29.

At the designated time points – on DATs (Days After Treatment) 0, 1, 4, 7, 11, 15, 19, 27, 35, 46 and 88 duplicate samples of each treated test soil were collected for further analysis. At these time points top layers of soil - 0-3 cm, were removed from the test vessels placed in 1-gallon (3.79-L) jars to which 700 mL of CH₃COOC₂H₅ was added immediately. Next they were freeze-dried and transported on dry ice to the laboratories of Bayer Corp. for further analysis.

In the laboratory the samples were extracted using the extraction procedure shown below on the figure B.8.1.1.1.1. CA-41 (the figure is reproduced directly from: Annette M. Bloomberg, Barbara A. Shadrick, Ellen L. Arthur et al. "Outdoor Soil Metabolism of [Phenyl U-¹⁴C]Flufenacet on California Soils.", ACS Symposium Series, 2002, vol 813: Pesticide Environmental Fate, chapter 12, pp. 167-182; Copyright 2002 American Chemical Society, reprinted with editor's permission.). It was indicated that the soil samples collected on DATs 0, 1, 4, 7, 11, 15 and 19 were subjected only to one step extraction – with ethyl acetate. For the samples collected at later time points – from DAT 27 onwards, the extraction with CH₃CN/H₂O 7:3 extracting solution at reflux was introduced as an additional step.

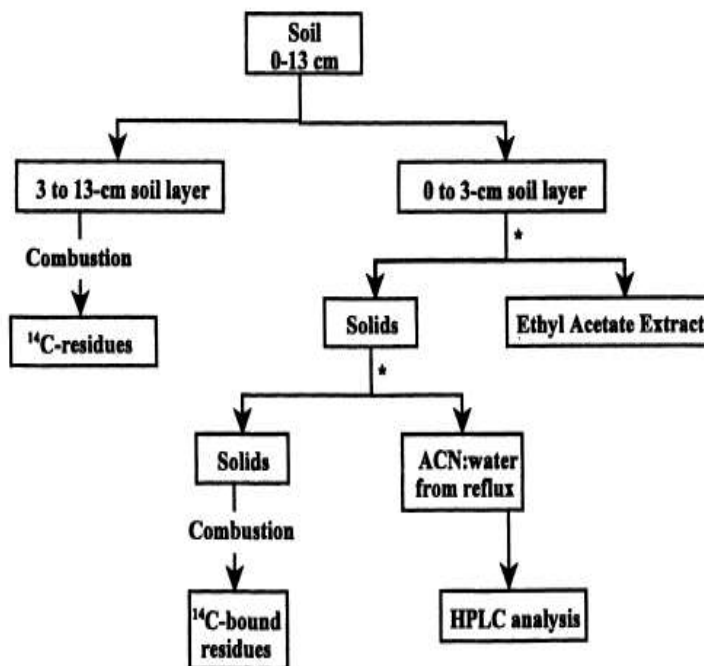

Figure 3. Analytical scheme for samples from the ^{14}C -flufenacet outdoor metabolism study (* denotes soil extraction occurring at this step).

Figure B.8.1.1.1._CA-41: The extraction procedure used in the experiment (Reprinted with permission from Annette M. Bloomberg, Barbara A. Shadrick, Ellen L. Arthur et al. "Outdoor Soil Metabolism of [Phenyl U- ^{14}C]Flufenacet on California Soils.", ACS Symposium Series, 2002, vol 813: Pesticide Environmental Fate, chapter 12, pp. 167-182; Copyright 2002 American Chemical Society.

The extracts and other liquid samples were analysed for their content of radioactivity using LSC method. Additionally they were analysed chromatographically, by TLC, HPLC and LC/MS in order to identify and quantify the extracted compounds.

The extracted soil pellets were air-dried and analysed for the content of the bound radioactivity (NER fraction) by LSC, after their oxidation.

Also in the samples collected on later time points – from DAT 15 onwards, the remaining 3 – 13 cm soil layers were analysed for the content of radioactivity – NER fraction, by LSC after combustion. In case of the samples collected at DATs 15 – 46 the whole 3-13-cm layers were taken for the analysis of NER, while for DAT-88 samples, the collected 3-13 cm layers were divided into 2-cm sections, each analysed separately for the radioactivity content.

The LSC analysis was performed using Packard Tricarb LS Counter Model 4640.

The TLC analysis was performed to determine the purity of the application solution. It was carried out using Merck Silica gel 60 F₂₅₄ plates, 0.25-mm thick, developed in $\text{CHCl}_3/\text{CH}_3\text{OH}$ 9:1 solvent system. The detection of radioactive zones was performed using Raytest Rita 6800 TLC radioactivity scanner.

HPLC was used to analyse qualitatively and quantitatively all extracts. It was performed using either Shimadzu SCL-6A liquid chromatograph or HP1090 liquid chromatograph, equipped with variable UV detector and Raytest Ramona 90 radioactivity monitor.

The chromatographic analysis was performed in a gradient mode on Hamilton PRP-1, 305*7 mm chromatographic column preceded by Hamilton PRP-1 guard column. The solvents were:

- **Solvent A:** 0.4% CH_3COOH in H_2O ,
- **Solvent B:** 0.4% CH_3COOH in CH_3CN .

The elution gradient used in the analysis is presented below in the table B.8.1.1.1._CA-43. The flow rate was 2 mL/min.

Table B.8.1.1.1.1_CA-43: The HPLC gradient modes used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH₃COOH</i>
0	100	0
15	70	30
65	40	60
70	0	100
80	0	100
90	100	0

The LC/MS analysis was performed using Varian 5040 HPLC equipped with Hamilton PRP-1 (150 * 4.1 mm) chromatographic column, coupled with a Berthold LB 505 radioactivity monitor and Finnigan MAT 90 mass spectrometer with a thermospray interface. The chromatographic elution was performed in a linear gradient from 100% H₂O to 100% CH₃OH over 30 min at a flow rate of 0.8 mL/min. 0.2M CH₃COONH₄ solution was added post-column at a rate of 0.2 mL/min. MS analysis was performed in either positive-ion or negative-ion mode and the source temperature T = 210°C.

Results and their discussion:

It was stated that the radioactivity recovered from the test vessels was generally above the level of 85.9% of applied for Fresno soil and 92.8% of applied for Chualar soil. The volatile compounds were not collected, because the preliminary tests showed minimal volatility of the test compounds. Though such conclusion was not drawn by the authors, it may be assumed, on the basis of the other studies examining the fate and behaviour of Flufenacet in aerobic soil, that the losses in radioactivity may be attributed to mineralization of the test compound. It was also stated that the residues of Flufenacet were predominantly confined to the top 3 cm of soil and the migration down the soil profile was limited. That showed the results of the profiling of 3-13 cm layer of soil in samples collected on later time points. It was also noted that it was greater in case of Fresno soil, having lower OC and clay content and higher pH. However, in absence of more detailed results of soil characterization it may be difficult to draw more definitive conclusions.

The detailed results of the characterization of radioactivity in test soils is presented below in two tables – B.8.1.1.1.1_CA-44 for Fresno soil and B.8.1.1.1.1_CA-45 for Chualar soil.

Table B.8.1.1.1.1_CA-44: The results obtained in Fresno soil.

The results obtained for Flufenacet, presented in the tables above, were kinetically examined. The analysis was performed using first order kinetics (most probably SFO model). The obtained results were following:

- for Fresno soil: $k = 0.0192$ [days⁻¹] and half life = 36.1 days, with $r^2 = 0.99$;
- for Chualar soil: $k = 0.0139$ [days⁻¹] and half life = 49.9 days, with $r^2 = 0.96$.

The values were stated to be in range of kinetic parameters of degradation (lab studies) or dissipation (field studies) of Flufenacet in soil determined in other studies.

Three degradation products, considered major by the authors, were identified in the study:

- FOE Alcohol,
- FOE Oxalate,
- FOE Sulfonic Acid.

Finally, it was stated that residues of Flufenacet displayed low leaching potential in soil, what was in line with findings of performed subsequently field dissipation studies.

RMS comments to the study and its evaluation:

The paper reproduced the results presented in the following unpublished study:

Shadrick B. A., Kasper A. M., (1995): "Outdoor soil Metabolism of [Phenyl-U-¹⁴C] Thiafluamide (FOE 5043) on California Soils."; Pan-Agricultural Laboratories Inc., 32380 Avenue 10, Madera, California 93638, USA for Bayer Corporation (formerly Miles Inc.), Agriculture Division, Environmental Research, 17745 South Metcalf Avenue, Stilwell, Kansas 66085, USA; unpublished study No. MR 106210; 7 July 1995.

The study was declared to be a non-GLP study, performed to meet the criteria of the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1, Aerobic Soil Metabolism;
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (supplemental).

That source study was not provided by the Applicant as a part of a dossier submitted for the completeness check. Instead it was placed on the negative list for the Flufenacet renewal approval. The Applicant, in course of the subsequent e-mail exchange with the RMS, provided the following rationale for that (text copied directly from the Applicant's explanatory e-mail):

The study design and sample processing used in this outdoor soil metabolism study is very special and the study itself has some deficiencies/ uncertainties. Thus, we do not believe that the results are representative for the aerobic metabolism of FFA in soil for the following reasons:

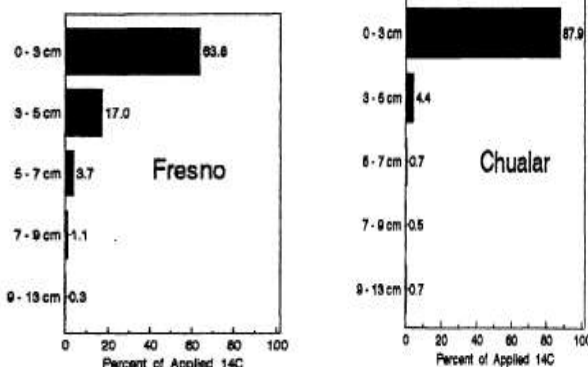

- RMS decided however to present the more detailed soil extraction procedure, provided by the source study. It is given below on figure B.8.1.1.1.1. CA-42.

Additionally copied from the report were numerical and graphical results of the determination of the distribution of the residues of Flufenacet in the whole soil profiles of DAT-88 samples. They are presented below on figure B.8.1.1.1.1. CA-43.

Graphical results

9-13	3.5-5.0	0.3	0.7
TOTAL		85.9	94.2

80

As no significant differences between the unpublished report and its published open-literature version were stated, the RMS decided to base the following assessment on what was presented in the literature, peer-reviewed, study.

The thorough analysis of the analytical protocol of the study presented in the paper demonstrated that it followed the more general scheme also used in the studies by Pangilinan and Smith [1994] and Kelley et al [1995]. It shall be noted that, despite the fact that the volatile traps were not set, the recovery of AR was good, within the limits set by OECD 307 Guideline. The lower AR recovery at later time points may be attributed to two factors:

- 1) until DAT 15 only the top - 0-3 cm, layer of soil was examined;
- 2) the observed decrease of recovered AR with time may be due to increasing mineralization and resulting from it formation of (highly volatile) $^{14}\text{CO}_2$, the process not taken into account in the experiment.

The level of would-be mineralization, assuming minimal losses of AR during extraction and homogenous application, is estimated to be following:

- in Fresno soil the estimated mineralization level, on DAT 88, is 14.1% AR;
- in Chualar soil the estimated mineralization level on DAT 88 is 5.8% AR.

It is worth of noting that that mineralization level is in line with findings of the studies by Pangilinan and Smith [1994] and Kelley et al. [1995].

It was noted that the change in extraction procedure, by addition of a second extraction step, resulted in slight reduction of the non-extracted fraction in samples examined when/after that change occurred. That may indicate that in case of the DAT-11, DAT-15 and DAT- 19 samples extracted only with ethyl acetate, such extraction was not sufficient. It is also probable that introduction of that step from the beginning might have resulted in some change in metabolite profiling. Similar result might have given earlier analysis of the subsoil (3-13 cm layer), and extraction in particular.

The results obtained for FOE Sulfonic acid were comparable to those obtained in studies by Pangilinan and Smith [1994] and Kelley et al. [1995]. Different situation however was observed in case of two other identified degradation products – FOE Alcohol and FOE Oxalate. FOE Alcohol was formed early in the study and observed throughout it in significant amounts – up to 8.1% AR on DAT 88 (at increase) in Fresno soil and up to 21.2% AR on DAT 88 (at increase) in Chualar soil. That indicated the possibility of FOE Alcohol of becoming, under specific conditions, therefore requiring to be taken into consideration in the assessment. RMS also noted that the formation of FOE Alcohol was correlated with low OC content and lower microbial activity of the test soils, what may indicate that being in general transient, in weak, sandy soils, on which some cereals may be grown, it may become potentially relevant. That conclusion seems to be conformed by the results by other two studies – the **Study 1** [Kelley et al; 1995] and **Study 2** [Pangilinan and Smith; 1994].

FOE Oxalate was formed later in the study, but reached by its end levels enabling to classify this compound as a major degradate according to the criteria set by SANCO/221/2000 Guidance Document. It cannot be excluded that FOE Oxalate started to form earlier in both soils, but because of the extraction procedure applied, in the earlier sampling points it remained in the “bound fraction”. The relative sequence of formation of FOE Alcohol and FOE Oxalate seems to conform the degradation scheme proposed by the Applicant, according to which FOE Oxalate was formed as a product of further oxidation of FOE Alcohol, the process commonly observed during microbial fermentation of saccharides.

The kinetic examination of the data obtained for Flufenacet enabled to determine the SFO k and DT_{50} values. It shall be noted however that the analysis pre-dated the issuing FOCUS Kinetics Guidance document, therefore the kinetic analysis should be repeated in order to obtain kinetic endpoints fully complying with current standards. The open-literature publication does not provide the data enabling the running of the normalisation procedure leading to the derivation of modelling endpoints, the appropriate weather data, although requiring some processing, can be found in the source study report.

All that taken into account, in RMS opinion the study is of a sufficient quality to provide the data possible to be used for regulatory purposes, in particular in the area of the examination of the route of degradation of Flufenacet in soil and metabolite profiling.

Final conclusion: Study is fully reliable and its results in the area of metabolite profiling are proposed to be used for the regulatory purposes – to derive the regulatory endpoints.

Study 8:

Report: Lam C. K., McKinney M. K., Clay V. E., (2002): "Evaluation of Laboratory and Field Extraction Methods: Extraction of [Phenyl-U-¹⁴C] Flufenacet from Aged Soils."; Agriculture Division, Bayer Corporation, 17745 South Metcalf, Stilwell, KS 66085-9104, USA; published study – published in: *Phelps W. (ed.) "ACS Symposium Series, vol. 813: Pesticide Environmental Fate", chapter 11, pp 153 – 166*; American Chemical Society, Washington, DC, 2002, publication date March 1, 2002;

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes. However, examination of the study protocol, also in cross-reference to other studies submitted by the Applicant, demonstrated that it complied with the following guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1, Aerobic Soil Metabolism;

GLP: the publication bears the declaration that the experiment it describes was a GLP study;

RMS comments: The study was performed on the same soil as used in two other studies submitted specifically for the regulatory purposes – by Pangilinan and Smith [1994] and Pangilinan and Smith [1994a]. It also follows the analytical protocol similar to that described in both studies listed above. Therefore it can be considered acceptable in the assessment of the fate and behaviour of Flufenacet in aerobic soil. Due however to the aim it had – the comparison of the performance of two extraction procedures developed for examining the fate and behaviour of Flufenacet in aerobic soil, it should be regarded as a supplementary and conformatory study, providing important information with regard to the acceptability of the results of other studies for Flufenacet in the same area, but not to be used to derive the regulatory endpoints.

Summary:

The abstract of the publication provided by the publisher – American Chemical Society, is presented below. It was reprinted with permission from: *Christopher K. Lam, Mary K. McKinney, Val E. Clay "Evaluation of Laboratory and Field Extraction Methods: Extraction of [Phenyl U-¹⁴C]Flufenacet from Aged Soils.", ACS Symposium Series, 2002, vol 813: Pesticide Environmental Fate, chapter 11, pp. 153-166; Copyright 2002 American Chemical Society.*

Abstract:

A study was conducted to compare the extraction efficiency of [phenyl-U-¹⁴C] flufenacet from aged soil using both laboratory and field extraction methods. Soil (sandy loam) was obtained from Howe, Indiana and treated with [phenyl-U-¹⁴C] flufenacet at the application rate of 0.9 ppm (equivalent to 0.8 lb. a.i./acre). After treatment, soils were aged aerobically in an environmental chamber at 21 ± 1 °C for 32 days. Extraction methods were compared. The laboratory extraction method employs a more aggressive procedure which involves three extraction steps while the field extraction method involves a single extraction step. At day 0, the laboratory method extracted 97.8% of applied radioactivity while the field method extracted 86%. At day 32, laboratory and field methods extracted 81.9% and 73.1% of applied radioactivity, respectively. The results demonstrated that the field extraction method could extract around 90% of the residues when compared with the laboratory extraction method. Degradates detected using both extraction methods were identical. The distribution of degradates in the extract when calculated based on the percent of analytes from the high-performance liquid chromatography (HPLC) instead of the percent of applied radioactivity were comparable with approximately 61% flufenacet, 27% flufenacet oxalate, and 5% flufenacet sulfonic acid.

The extended summary of the publication, written by the RMS, is presented below.

The aim of the study was to perform the comparative examination of the performance of two extraction methods used in the experiments examining the fate and behaviour of radiolabelled Flufenacet in aerobic soil performed under controlled – laboratory, conditions. The examined extraction methods were further called **laboratory extraction method** and **field extraction method**. The test soil used in this experiment was sandy loam soil obtained from Bayer Research Farm in Howe, Indiana, further called Howe soil. It was the same soil as used in the studies by Pangilinan and Smith [1994, 1994a]. Its characteristic is given below in the table B.8.1.1.1.1_CA-46.

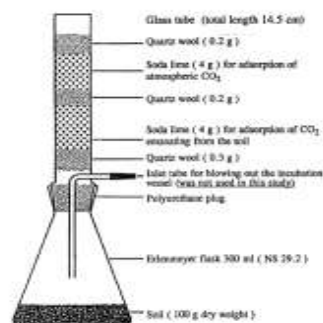

Table B.8.1.1.1.1_CA-46: The characteristic of soil used in the study.

Parameter	Soil:
Soil origin	Howe, Indiana, USA
Soil type (as reported in the study)	Sandy loam
Soil type (USDA, calculated by RMS)	US Sandy loam
Particle size distribution	Sand [%]
	Silt [%]
	Clay [%]
pH	6.2
Organic matter content (OM) [%]	1.6
Organic carbon content (C _{org}) [%] ¹⁾	0.93
Cation Exchange Capacity – CEC [mEq/100g]	12.1
Bulk density (disturbed) [g/cm ³]	1.35
Moisture holding capacity at ½ bar [%]	14.0
Moisture holding capacity at 15 bar [%]	6.2
Available nutrients [%]	Ca
	Mg
	Na
	K
	H
Total N [%]	0.094
Soluble Salts [mmhos/cm]	1.35

Footnotes to the table:

- 1) Value recalculated by the RMS from that reporting OM content given in the study report using the following equation: OM = 1.724 * OC;

The test soil was sieved through 2-mm sieve before being used, and its 100-g (d. w.) portions placed in incubation vessels – biometer flasks capped with traps for volatile compounds, very similar to those used in all studies examining the degradation of Flufenacet in aerobic soil. The example of such biometric flask system (closest to that used in this study) is presented in the summary of the study by Hellpointner [1995] as figure B.8.1.1.1.1_CA-14, reproduced below on figure B.8.1.1.1.1_CA-44. The differences consisted on higher volume of Erlenmeyer flask (500 mL), use of oil –covered glass wool instead of polyurethane plug for absorption of VOCs and the use of inlet tube for ventilating flask before opening it.

**Figure B.8.1.1.1.1_CA-44 (14):** The biometer flask used in the experiment (scheme copied from the study report by Hellpointner, 1995).

In total twenty biometer flask were prepared, six for testing **laboratory extraction method** and another six for examining **field extraction method**. The remaining flasks were spares.

The test soil in biometer flasks was treated with phenyl-¹⁴C Flufenacet applied in form of the application solution to the soil surface. The application dose was 0.9 ppm (0.9 mg/kg), corresponding to 0.8 lb Flufenacet/acre (896 g Flufenacet/ha). The test soil in each biometer flask was brought to the moisture content of 75% of ½ bar by adding the appropriate amount of water (~3.2 mL per flask). At the beginning of the experiment six biometer flasks were taken for the analysis. These samples were further called DAT-0 samples.

All remaining biometer flasks were incubated for 32 days in the dark, under aerobic conditions and at constant temperature $T = 21 \pm 1^{\circ}\text{C}$.

The biometer flasks, after being removed from the incubation chamber, were dissected and the volatile traps were analysed for the content of radioactivity it contained in the same manner as described in the summaries of the studies by Pangilinan and Smith [1994, 1994a].

Next whole portions of the test soil from the given biometric flask were extracted using one of the following tested extraction procedures:

- **laboratory extraction method:** three step extraction method consisting of the following steps:
 - extraction with 150 mL of CH₃CN,
 - extraction with 150 mL of CH₃CN/H₂O 7:3 solution,
 - extraction with 150 mL 0.2N HCl_{aq}/ CH₃CN 1:1 solution,
 each extract was filtered and analysed by LSC; the extraction procedure was identical to that used by Pangilinan and Smith [1994] and shown on figure B.8.1.1.1.1.-CA-11.
- **field extraction method:** a single-step extraction procedure in which 200 mL of 0.1N HCl_{aq}/ CH₃CN 1:1 solution was used; the extracts were evaporated and reconstituted in MeOH, then analysed by LSC and after filtration by HPLC.

The extracted soil pellets were dried, homogenised and analysed for radioactivity content by LSC, after being oxidised by combustion.

The LSC analysis was performed in a way identical to that used in other studies summarised above, e. g. in studies by Kelley et al. [1995] and by Pangilinan and Smith [1994, 1994a].

HPLC analysis for identification and quantitation of the constituents of obtained extracts was performed on HP 1090 HPLC equipped with autosampler and Hamilton PRP-1 (305* 7 mm, 10-µm) chromatographic column, coupled with Raytest Ramona 5-LS radioactivity detector. The elution was performed in a gradient mode, very similar to that used by Pangilinan and Smith [1994] and presented in the table B.8.1.1.1.1._CA-12 as Method A. It is presented below in the table B.8.1.1.1.1.-CA-47. The flow rate was set to 2 mL/min.

Table B.8.1.1.1.1._CA-47: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH₃COOH</i>
0	100	0
0-25	Linear gradient	
25	75	25
25 - 40	75	25
40 - 75	Linear gradient	
75	30	70
75 - 85	Linear gradient	
85	10	90
85 - 95	10	90

The DAT-0 samples were treated in the same way with exception that for them the traps for volatile radioactivity were not examined as they were not set. That was because it was assumed that no volatiles should be formed at that time point.

Results and their discussion:

The results of the analysis are presented below, separately for each extraction method, in two tables: B.8.1.1.1.1.-CA-48 for **laboratory extraction method** and B.8.1.1.1.1._CA-49 for **field extraction method**.

Table B.8.1.1.1.1._CA-48: The detailed results obtained for the **laboratory extraction method**.

% AR		Results obtained for sample collected at:

Total AR recovered		97.4	101.6

The comparison of the efficiency of both extraction methods showed that the **field extraction method**, simpler, faster, cheaper and according to authors covering all three steps of the **laboratory extraction method**, was able to extract ~90% of AR extracted using more sophisticated **laboratory extraction method**. It had 87.9% relative efficiency for DAT-0 samples and 89.3% relative efficiency for DAT-32 samples. In addition, the amounts of degradation products extracted using each of the extraction method were comparable. It shall however be noted that in case of **field extraction method** the level of NER determined at the beginning of the study – on DAT 0, was relatively high – 11.4% AR, what may indicate that that fraction may be overestimated when this method is used.

Two degradation products were identified in the study:

- FOE Oxalate, reaching the level of 19.5 – 22.7% AR on DAT 32 (end of incubation period),
- FOE Sulfonic acid, reaching the level of 4.0 – 4.3% AR on DAT 32 (end of incubation period).

The level of mineralisation was very low, reaching 0.5% AR at the end of incubation period – on DAT 32. The amounts of NER fraction was 10.5% AR when **laboratory extraction method** was used. The almost triple that level of NER fraction determined with **field extraction method** may not fully reflect the actual situation in soil.

RMS comments to the study and its evaluation:

The thorough analysis of the analytical protocol of the study showed that it may be considered acceptable in line of the current standards. Its results indicate that the change of extraction procedure in the study by Pangilinan and Smith [1994a], made in order to limit losses related to high volatility of the detected compounds, had little impact on the overall results of the study. From that point of view it may be considered a conformatory study for that by Pangilinan and Smith [1994a] in the area of the analytical protocol adopted.

The results of the study, with regard to the identification and quantitation of the extracted compounds and the level of mineralisation are in line with the results obtained by Pangilinan and Smith [1994]. They are however not recommended to be used as regulatory endpoints.

Summary – Route of degradation of Flufenacet in aerobic soil:

The route of degradation of the acetanilide herbicide Flufenacet in aerobic soil was extensively examined in eight agricultural soils – seven originating from the EU and one from US. The test compound – Flufenacet, was radiolabelled in one of the following three following positions:

- uniformly in phenyl ring – compound tested on four soils,
- position C2 in thiadiazole moiety – test performed on one soil,
- position C5 in thiadiazole moiety – examined in four soils.

These data were presented in five unpublished studies submitted specifically for the purpose of this assessment. Additionally the data relevant for determining transformation pattern of Flufenacet in aerobic soil, relevant for regulatory purposes, were found in one scientific paper, examining the degradation of Flufenacet radiolabelled uniformly in phenyl ring in two US soils. That study was based on a non-GLP regulatory study, conceived as a bridging study for laboratory and field experiments on the degradation of Flufenacet in soil. That study was verified by RMS and found acceptable. Therefore the results of the literature study based on it were included into evaluation.

The key results of the examination of transformation of Flufenacet are presented in the tabularised form below (tables B.8.1.1.1.1_CA-50 – B.8.1.1.1.1_CA-53), separately for the compound radiolabelled in phenyl ring and in thiadiazole moiety.

Table B.8.1.1.1.1_CA-50: The levels of mineralisation and NER fraction formed, and identified degradation products in experiments with [Phenyl-U-¹⁴C] Flufenacet.

Footnotes to the table:

1) Justification based on the criteria set by the Guideline SANCO/221/2000, listed under the point 4 on page 6:

“As a minimum, degradation products must be characterized and identified by the notifiers to the extent that it is technically feasible and their relevance must be assessed, if one of the following conditions applies:

- Metabolites, which account for more than 10% of the amount of active substance added in soil at any time during the studies; or*
- which account for more than 5% of the amount of active substance added in soil in at least two sequential measurements during the studies; or*
- for which at the end of soil degradation studies the maximum of formation is not yet reached.*

2) Compound not detected in that soil.

The transformation pattern of Flufenacet in soil was examined only on biologically viable soil. That was due to the fact that, on the basis of available results it was assumed that all transformation processes were predominantly or solely biologically-mediated. It was postulated that the initial step of the degradation was the cleavage of the test item on bridging oxygen of the thiadiazole heterocycle. The further sequence for the thiadiazole moiety is presented below:

- tautomerisation of keto-enol functional group, resulting in formation of FOE Thiadone,
- hydrolytical opening of thiadone ring and further oxidation resulting in formation of either FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA), or else simple products of mineralisation and NER fraction – ultimate transformation products;
- further transformation of FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA) to the simple products of mineralisation and NER fraction – ultimate transformation products.

In case of the moiety containing fluorophenyl ring next postulated step was the formation of the transient FOE Cysteine- or FOE Glutathione conjugates, undergoing subsequent quick transformation to FOE Methylsulfoxide, FOE Alcohol and FOE Chloroacetanilide. As possible side-processes were postulated direct formation of FOE Chloroacetanilide and FOE Alcohol. It shall be noted that FOE Chloroacetanilide may be not only a genuine degradation product, but also, and possibly to greater extent, analytical artefact. However, as the issue was not satisfactorily clarified, the RMS's proposal is to consider FOE Chloroacetanilide a genuine degradation product.

The proposed transformation pathway of Flufenacet in aerobic soil, resulting from the data presented above, is presented on figure B.8.1.1.1.1_CA-45.

Additionally, as in course of evaluation FOE Alcohol was identified to be a potentially major degradation product, the additional assessment was performed to determine whether, in absence of data for that compound, the exposure assessment for FOE Alcohol may be considered to be covered by that for its immediate degradate – FOE Oxalate.

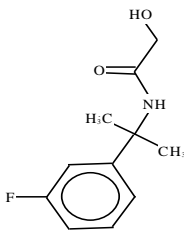

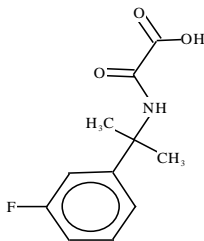

The Applicant in course of the discussion on the nature of FOE Alcohol made a following statement (the text is copied directly from the Applicant's e-mail; the “outdoor soil metabolism study” refers to the cited study by Shadrick and Kasper [1995]):

We cannot reconstruct what the reason for the accumulation or artificial formation of FOE alcohol (aka FOE hydroxy) was in that outdoor soil metabolism study, but we have several other laboratory studies, as well as EU and US field studies, which demonstrate, that FOE alcohol is a minor, transient metabolite, not accumulating at all, but rather being further oxidized quickly to FOE oxalate.

RMS having analysed the results provided by the study by Shadrick and Kasper [1995], reproduced in the publication by Bloomberg et al. [2002], noted that the compound was formed in greater amounts in Chualar soil, having lower OC content and slightly lower microbial activity of the two soils used in the experiment. Taking into account the fact that FOE Alcohol was also detected only in the study by Pangilinan and Smith [1994], performed on another soil having low OC content and microbial activity, but not in the study by Kelley et al [1995], all that may indicate that FOE Alcohol is indeed a transient, fast degrading compound, that would appear in higher amounts and for longer only in weak soils.

To further demonstrate that it was possible to cover the exposure assessment for FOE Alcohol with that for its immediate degradate – FOE Oxalate, RMS performed the comparative analysis by means of QSAR calculations, carried out with EPI Suite ver. 4.10 (September 2010) tool. The detailed results of the calculations are presented in the Appendix 3 of this report, while the summary output for both compounds is presented below in the table B.8.1.1.1.1._CA-54.

The presented results indicate that the properties of both compounds relevant for their environmental fate and behaviour are comparable. Therefore the exposure assessment performed for FOE Oxalate may be considered as covering that for FOE Alcohol. The Applicant also indicated that, according to the results of toxicological and ecotoxicological studies, submitted for the purpose of the current evaluation, Foe Alcohol was demonstrated not to be toxicologically or ecotoxicologically relevant degradation product.

The proposed transformation pathway of Flufenacet in aerobic soil, resulting from the data presented above, is presented below on figure B.8.1.1.1.1_CA-45.

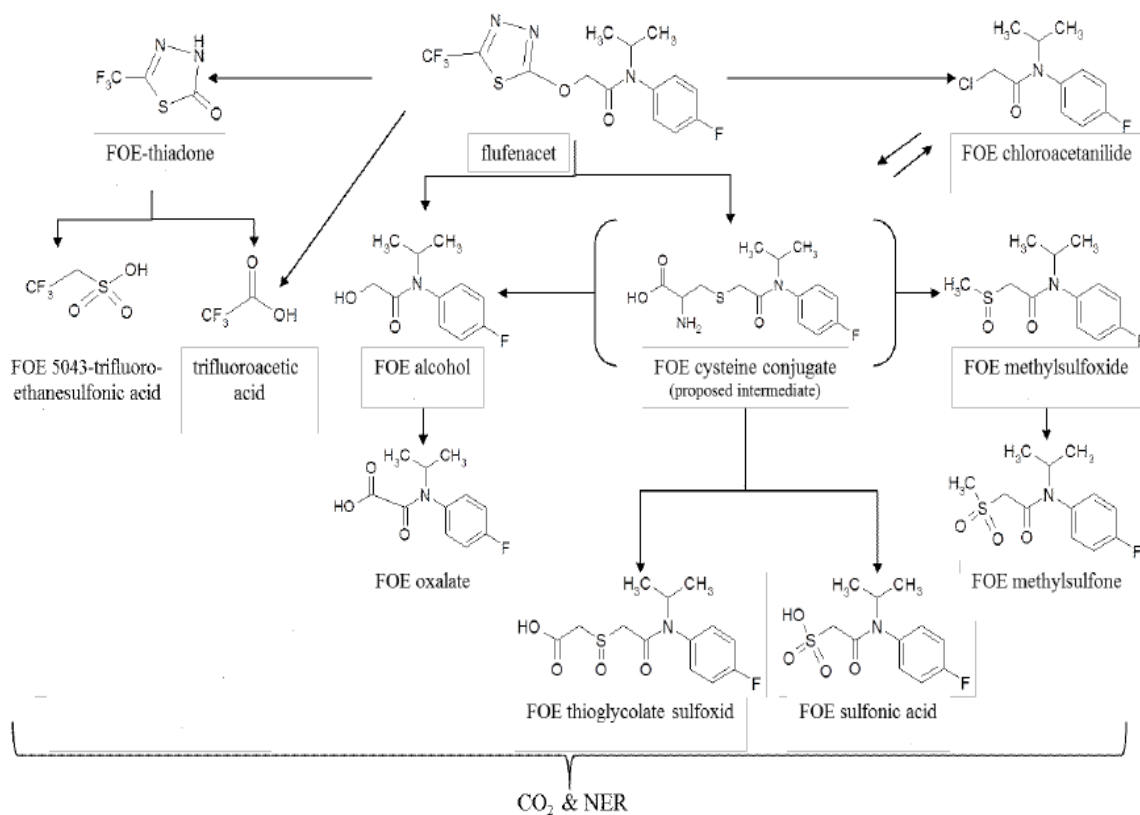

Figure B.8.1.1.1.1_CA-45: Postulated transformation pathway of Flufenacet in soil as proposed by the Applicant (modified by the RMS).

The proposed final set of endpoints is presented below, in format recommended for the EU-agreed endpoints (SANCO/12483/2014-rev.2; 12 December 2014).

Route of degradation (aerobic) in soil (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.1)

Mineralisation after 100 days	<p>2.7% after 91 d, [¹⁴C-<i>U-Phenyl</i>]-label (n= 1) 10.2 – 20.8% after 100 d, [¹⁴C-<i>U-Phenyl</i>]-label (n= 3) 31.9% after 90 d, [¹⁴C-<i>2-Thiadiazole</i>]-label (n= 1) 4.5 – 6.5% after 120-121 d, [¹⁴C-<i>5-Thiadiazole</i>]-label (n= 4)</p>
Non-extractable residues after 100 days	<p>16.3% after 91 d, [¹⁴C-<i>U-Phenyl</i>]-label (n= 1) 29.9 – 56.2% after 100 d, [¹⁴C-<i>U-Phenyl</i>]-label (n= 3) 6.2% after 90 d, [¹⁴C-<i>2-Thiadiazole</i>]-label (n= 1) 10.6 – 17.2% after 120-121 d, [¹⁴C-<i>5-Thiadiazole</i>]-label (n= 4)</p>
Metabolites requiring further consideration - name and/or code, % of applied (range and maximum)	<p><i>FOE Sulfonic acid</i> – max. 26.3% at 100 d (n= 6); [¹⁴C-<i>U-Phenyl</i>] label; <i>FOE Alcohol</i> – max. 21.2% at 88 d (n= 3); [¹⁴C-<i>U-Phenyl</i>] label; <i>FOE Oxalate</i> – max. 26.5% at 365 d (n= 6); [¹⁴C-<i>U-Phenyl</i>] label; <i>FOE Methylsulfone</i> – max. 6.6% at 100 d (n= 3); [¹⁴C-<i>U-Phenyl</i>] label; <i>FOE Thiadone</i> – max. 5.8% at 10 d (n= 5); [¹⁴C-<i>2-Thiadiazole</i>] & [¹⁴C-<i>5-Thiadiazole</i>] labels <i>FOE 5043-Trifluoroethanesulfonic acid</i> – max. 6.0% at 14 d (n= 4); [¹⁴C-<i>5-Thiadiazole</i>] label <i>Trifluoroacetic acid (TFA)</i> – max. 81.5% at 91 d (n= 4); [¹⁴C-<i>5-Thiaiazole</i>] label Sterile conditions: <i>not examined</i></p>

B.8.1.1.1.2. – Anaerobic degradation

In the previous evaluation of Flufenacet for its authorisation in the EU it was stated that the studies on the degradation in anaerobic soil were not supplied. The following statement was given in the DAR as a justification of that: *“Due to the proposed patterns (application as pre- or early post-emergence herbicide in maize and cereals) it can be justified that FOE 5043 will not be exposed to anaerobic conditions. Therefore, a study on anaerobic degradation is considered as being not relevant.”*

However, for the purposes of the present evaluation the proposed EU-representative GAP was substantially changed. The proposed use pattern was limited to those in winter and spring cereals. On the other hand the application timing was extended to cover both autumn- and spring uses. As a result, the occurrence of anaerobic conditions, especially for the autumn applications, cannot be ruled out. For that reason the Applicant submitted two studies covering the issue of the degradation of Flufenacet in soil under anaerobic conditions. These studies are summarised below.

Study 1:

Report: Pangilinan N. C., Smith D. M., (1995): “Anaerobic Soil Metabolism of [Phenyl-U-¹⁴C] FOE 5043”; Bayer Corporation (formerly Miles Inc.), Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3042106; unpublished Miles Report No. MR 106645; 20 June 1995; study reference number: M-002162-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-2, Anaerobic Soil Metabolism (Expanded).

GLP: Yes

RMS comments: From the point of view of evaluation of Flufenacet in the EU this is a new study. It was submitted specifically for the purpose of the renewal of authorisation. In the study report it was declared that it was carried out to address the requirements set forth in the EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-2 as required by 40 CFR, 158.130, despite the fact that at the time of submission two valid anaerobic aquatic metabolism studies for Flufenacet were provided. However, as indicated in US EPA Rejection Rate Criteria (*“the aerobic preincubation would certainly be indicated for those compounds, which degrade somewhat rapidly under aerobic conditions”*) the study had to be submitted, because Flufenacet displayed short half-life under aerobic conditions, so the fate of its aerobic metabolites under anaerobic conditions had to be addressed. It shall be therefore assumed that, although the study is newly submitted for the purpose of the registration in the EU, it could already have been evaluated for the registration purposes elsewhere, e.g. in the US, and found acceptable.

RMS evaluated the study for its validity and compliance with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-2, Anaerobic Soil Metabolism;
- OECD 307 Guideline – Aerobic and Anaerobic Transformation in Soil;
- US EPA OPPTS Guideline 835.4100 – Aerobic Soil Metabolism/835.4200 – Anaerobic Soil Metabolism.

The study was found to be fully compliant with these three Guidelines. As such it may be considered fully valid. It is summarised below in its part related to the examination of the route of degradation in soil under anaerobic conditions. The assessment of the degradation kinetics is provided under the point B.8.1.1.2.1.

Summary:

The aim of the study was to examine the degradation of Flufenacet and its aerobic soil degradation products in anaerobic soil system (waterlogged soil) established after 30-days aerobic preincubation of the treated test soil. The experiment was performed with one test soil – Howe Sandy loam soil, used in two other experiments aimed on the examination of the transformation of Flufenacet in aerobic soil - [Pangilinan and Smith; 1994] and [Pangilinan and Smith; 1994a], summarised above, under the point B.8.1.1.1.1. as **Study 2** and **Study 4**. The characteristic of the test soil used in the experiment is presented below in the table B.8.1.1.1.2._CA-1.

Table B.8.1.1.1.2._CA-1: The characteristic of soil used in the study.

Parameter		Soil:			
		395			
Soil origin		Howe, Indiana, USA			
Batch analysed		A ¹⁾	B ²⁾	C ³⁾	Average

- 16) Analysed in a sample set as a non-sterile control, incubated during anaerobic phase in a flow-through system.

The test soil was taken from a Miles Research Farm in Howe, Indiana, USA, and placed in two 5-gallon (~19L) buckets in the greenhouse. In order to maintain its microbiological viability soil was planted with soybean prior to the conduct of the study.

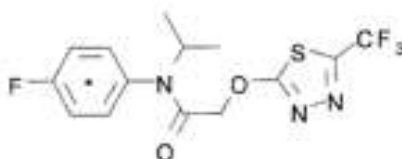

Immediately before the experiment began, 10-kg portion of soil from the top 5-6 inch (corresponding to 12-15 cm) layer was taken to the laboratory, where soybean plants were removed and moist soil sieved through 2-mm sieve. Then the test soil was air-dried for 2 hours to the level of 75% of ½ bar (the soil moisture level kept throughout the experiment) and placed in the test vessels.

Water used in anaerobic phase to waterlog soil was rainwater collected at Bayer Research Farm in Stillwell, KS in June and July 1994. It was collected in five 5-gallon (~19L) buckets, placed on the field located in some distance from research buildings to avoid water contamination with material possibly emitted from them. The collected water was stored frozen until the beginning the anaerobic phase of the study. Just before initialisation of that phase water was thawed, filtered through 250-µm sieve and its aliquots shipped for characterisation. The characteristic of water used in the experiment is presented below in the table B.8.1.1.1.2._CA-2.

Table B.8.1.1.1.2._CA-2: The characteristic of water used in the study.

Parameter	Measured value
<i>pH</i>	7.7
<i>Conductivity [mS/cm]</i>	0.06
<i>Total Suspended Solids [mg/mL]</i>	3
<i>Alkalinity [mg CaCO₃/L]</i>	28
<i>Hardness [mg CaCO₃/L]</i>	28
<i>COD [mg O₂/L]</i>	16

The test substance used in the experiment was the ¹⁴C-FOE 5043 radiolabelled uniformly in phenyl ring, as shown below on figure B.8.1.1.1.2._CA-1.

**Figure B.8.1.1.1.2._CA-1.:** The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 66.5 mCi/mmol (4.064 E5 dpm/μg) and its radiochemical purity, determined with TLC, was 99.2%. It was prepared as a benzene solution having a concentration 0.837 mg Flufenacet/mL.

The test compound was applied to the test soil in incubation vessels in form of the application solution prepared in a following way: 4.6 mL of benzene solution of [phenyl-U-¹⁴C]-Flufenacet in was evaporated to dryness under gentle stream of nitrogen and then redissolved in 7.6 mL of CH₃CN (acetonitrile), to which 30.4 mL of distilled water was added next. The so prepared solution was stirred and its concentration measured. It was determined to contain 103 μg Flufenacet/mL. That application solution, further called **Application solution 1**, was used to treat the kinetic samples.

Additionally, for samples prepared for metabolite profiling (identification), another application solution was prepared, having three times higher concentration of Flufenacet. It was prepared by first evaporating to dryness, under the gentle stream of nitrogen, 2.2 mL of benzene solution of [phenyl-U-¹⁴C]-Flufenacet. The residue was reconstituted in 24 μL of non-radiolabelled Flufenacet ([isopropyl-1,3-¹³C] Flufenacet) in CH₃CN, to which 1.6 mL of CH₃CN was added next, to give a 3:1 mixture of [¹⁴C]-Flufenacet/[¹³C]-Flufenacet. The solution was thoroughly mixed and 6.4 mL of distilled water was added to it. After that the solution was once again mixed and analysed by LSC and LC/MS. The concentration of Flufenacet in so prepared solution was determined to be 303 μg/mL and the solution's specific activity was 304637 dpm/μL. That application solution is further referred to as **Application solution 2**.

The experiment consisted of two phases:

- aerobic incubation phase, which was the first phase of the experiment;
- anaerobic incubation phase, following the aerobic phase.

For both phases 100-g (d. w.) portions of the test soil were weighed into 250-mL Erlenmeyer flask. In total 71 flasks were prepared, of which 35 as kinetic samples, 6 for metabolite isolation (further in the text that number was changed to 8), 25 as non-sterile controls and 5 for microbial evaluation.

For the aerobic phase of the experiment the incubation was performed in biometric flasks, presented below on figure B.8.1.1.1.2._CA-2. For the incubation under anaerobic conditions the setup of the incubation vessels was changed, by replacing the traps for volatile compounds with glass stoppers having inlet and outlet branch, as shown on the figure B.8.1.1.1.2._CA-3. The samples were then incubated in either flow-through incubation system, presented on figure B.8.1.1.1.2._CA-4, or in a static system.

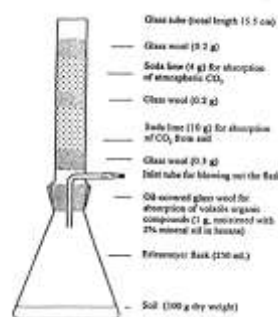

Figure B.8.1.1.2._CA-2: The biometer flask used in the aerobic phase of the experiment (scheme copied from the study report).

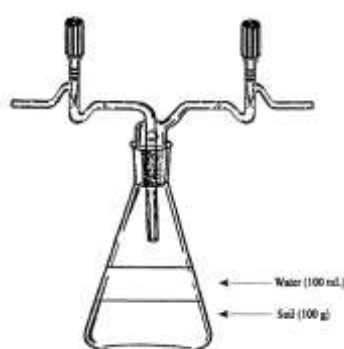

Figure B.8.1.1.2._CA-3: The incubation vessel used in the anaerobic phase of the experiment (scheme copied from the study report).

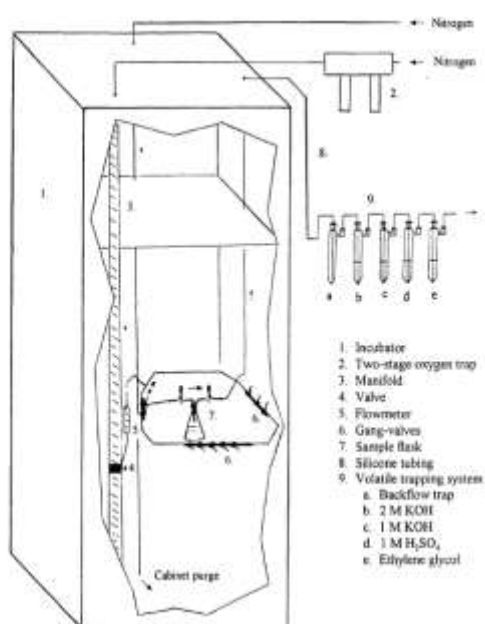

Figure B.8.1.1.2._CA-4: The flow-through incubation system used in the anaerobic phase of the experiment (scheme copied from the study report).

Kinetic samples were treated with the test substance, applied to the soil surface in form of the **Application solution 1**, at rate of 1.03 mg Flufenacet /kg. Applicant declared that it corresponded to approximately field application rate of 0.8 lbs a. i./acre, assuming soil depth of 3 inches and soil bulk density of 1.33 g/cm³. When recalculated by the RMS as expressed in g/ha, assuming soil depth of 5 cm and soil bulk density of 1.5 g/cm³, the exact application rate was **772.5** g Flufenacet/ha. The use of the measured average soil bulk density – $d = 1.37 \text{ g/cm}^3$, resulted in the application rate of **705.55** g Flufenacet/ha.

Samples for metabolite identification were treated with the **Application solution 2** at rate of 3 ppm, corresponding to the application rate, calculated by RMS assuming soil depth of 5 cm and soil bulk density of 1.5 g/cm³, of **2250** g Flufenacet/ha. The use of the measured average soil bulk density – $d = 1.37 \text{ g/cm}^3$, resulted in application rate of **2055** g Flufenacet/ha. These samples were further called **Metabolite ID** samples.

The amount of the **Application solution 1** introduced into each test vessel for kinetic samples and **Application solution 2** introduced into each test vessel for **Metabolite ID** samples, was 1 mL. It was applied dropwise to the soil surface using Hamilton 500 μL syringe. The treated flask was shaken after introducing each 500 μL -portion of the application solution to grant the even distribution of the test compound in soil.

Control and microbial-biomass flasks were treated with 2-mL portions of blank solvent carrier ($\text{CH}_3\text{CN}:\text{H}_2\text{O}$ 1:4 v/v).

After treatment the appropriate amount of distilled water was added to each test vessel to establish a soil moisture of 75% of $\frac{1}{3}$ bar. For that purpose 80 μL of water was added to each flask.

After treatment the Erlenmeyer incubation flask were sealed with traps for volatile compounds, weighed and covered with aluminium foil to exclude light. They were placed in the dark in a controlled environmental chamber and incubated for 30 days under aerobic conditions at constant temperature $T = 21 \pm 1^\circ\text{C}$. The soil moisture during that period was controlled in 7-days intervals and adjusted, if needed to the fixed level of 75% of $\frac{1}{3}$ bar. That phase of the experiment was called **aerobic phase**, during which samples were taken for the analysis at the following time-points DAT 0, DAT 7, DAT 15 and DAT 30 (DAT stands for Days After Treatment). At these time points, with exception of DAT 0 point, duplicate samples were taken for the analysis. The initial processing procedure was identical to that used in the examination of the aerobic degradation of [Phenyl- $\text{U-}^{14}\text{C}$] Flufenacet performed by Pangilinan and Smith [1994] and described under the point B.8.1.1.1.1. of this Report, in the summary of the **Study 2**. DAT 0 samples were analysed in triplicate and the traps for volatile compounds were not set, as for that time point no volatile compounds were expected to be formed.

On DAT 30 the **anaerobic phase** of the experiment begun. All remaining test vessels were dissected in a way identical to that used for aerobic phase samples, volatile traps collected for further analysis of the radioactivity they contained and each flask waterlogged with 100 mL of rain water characterised above in the table B.8.1.1.1.2_CA-2. Water was enriched with glucose (5 mg/mL) to enhance soil microbial growth and facilitate the attainment of anaerobic conditions. The amount of so prepared water added to each flask was such to give ~2-cm water layer above the soil surface. After waterlogging flask were capped with stoppers shown above on figure B.8.1.1.1.1_CA-3, the joints sealed with lubricant and additionally with parafilm. So prepared incubation vessels were purged with N_2 for ~5 minutes to remove the oxygen and induce the anaerobic conditions, after what the stopcocks on inlet and outlet branches were closed tight. Incubation vessels were then wrapped with aluminium foil to exclude light, and returned to incubator. The anaerobic incubation phase lasted for 6 months.

The samples were incubated during that phase in two separate incubation systems:

- **Flow-through system**, presented above on figure B.8.1.1.1.2_CA-4. The samples in the incubator's chamber were placed on four shelves, each containing at least 10 flasks. Anaerobic conditions were maintained by constant passing of the oxygen-free N_2 gas through the headspace of each flask to the trapping solutions for volatile compounds at initial rate 10 mL/min, but from 15th day of anaerobic incubation onwards reduced, to avoid a build-up of gasses in the headspace; the loss of mass, presumably water, resulting from constant purging was monitored by weighing the flask at sampling points and comparing their current weight with the initial;
- **Static system** set, in separate incubation chamber, for eight treated samples and six non-sterile control samples to provide the data for material balance in case the losses in the flow-through system, mainly related to not capturing the formed methane, were observed. The incubation vessels in that system, after being purged with nitrogen to induce anaerobic conditions, were kept sealed and the gasses formed during the incubation were removed by purging and trapped in the special sample bags. The purging took place weekly during first month of anaerobic incubation, then from 2nd to 6th months in 1-month intervals; the scheme of purging device used in a static incubation system is shown below on figure B.8.1.1.1.1_CA-5.

All samples were incubated in the dark at constant, monitored temperature $T = 21 \pm 1^\circ\text{C}$. To maintain anaerobic conditions in both incubation chambers they were continuously flushed with N_2 at rate 500 mL/min for the first 4 months of incubation and afterwards until the end of the 6th month of incubation, at rate 1 mL/min. At designated sampling points – DAFs 15, 30, 67, 123 and 180 (DAF stands for Days After Flooding), triplicate

(DAF 15) or duplicate (remaining time points) samples were taken for the analysis from the flow-through system. In case of the static system duplicate samples were taken for the analysis on DAFs 62, 123 and 180.

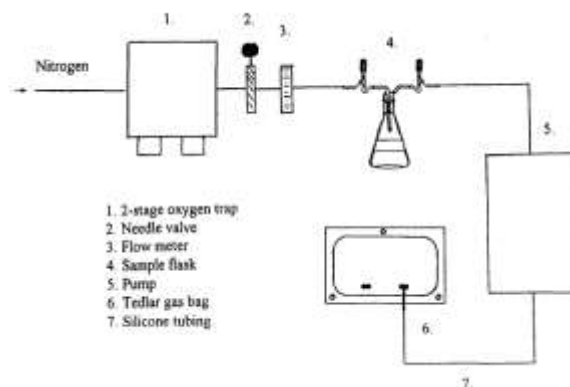

Figure B.8.1.1.2 CA-5: The purging device used to collect the volatile compounds formed in test vessels incubated in a static incubation system (scheme copied from the study report).

The maintenance of anaerobic conditions was monitored by measuring pH, redox potential and dissolved oxygen (DO) content in non-sterile controls, incubated in a flow-through system, on DAF's 0, 7, 15, 30, 67, 123 and 180.

Volatile compounds produced in flasks incubated in the flow-through system were captured in a following sequence of trapping solutions (each having volume of 30 mL): 2M KOH_{aq} (1), 1M KOH_{aq} (2), 1M H₂SO₄ (3), ethylene glycol (4). The traps were filled with fresh portions of trapping solutions after 4 months of incubation and the collected solutions analysed for content of radioactivity by LSC (triplicate aliquots analysis).

In case of static incubation system, volatile compounds collected in Tedlar gas bag were transferred to the set of trapping solutions identical to those used for capturing volatiles in a flow-through system. The trapping solutions were next radioassayed by LSC for their radioactivity content. The volatiles not captured by any of the solutions were passed through a quartz tube containing CuO, placed inside the furnace heated to ~700°C, where they were combusted and the combustion product (¹⁴CO₂) trapped in three 10-mL portions of scintillation cocktail (CarboSorbE/Permafluor-E⁺ 2:5) set in a sequence. The solutions were then radioassayed. The same method was used to remove and collect the volatile compounds directly (not using Tedlar bag) from vessels head-space at sampling points.

After the dissection of incubation vessels the content of the Erlenmeyer flasks – soil for **aerobic phase** and soil and water overlying it for **anaerobic phase**, was analysed qualitatively and quantitatively for the radioactivity it contained.

In case of soil from **aerobic phase** whole 100-g portions of test soil were extracted in three-step sequential extraction procedure, identical to that used by Pangilinan and Smith in the **Study 2**, which examined the transformation of Flufenacet in soil under aerobic conditions.

Samples collected during **anaerobic phase** of the experiment were treated in the following way:

- Water was separated from soil using Buchner funnel and Whatman #42 filter paper, collected and its volume measured, then triplicate aliquots were radioassayed by LSC. Next 10-mL aliquots were filtered through 0.45 µm Nylon acrodics and analysed by HPLC. Finally at least 50-mL portions of water were processed before being analysed by TLC.
- Remaining soil was processed and analysed in a way identical to that used for **aerobic-phase** samples.

The whole procedure of processing water and soil samples prior to their LSC and chromatographic analysis is presented below on figure B.8.1.1.2.-CA-6.

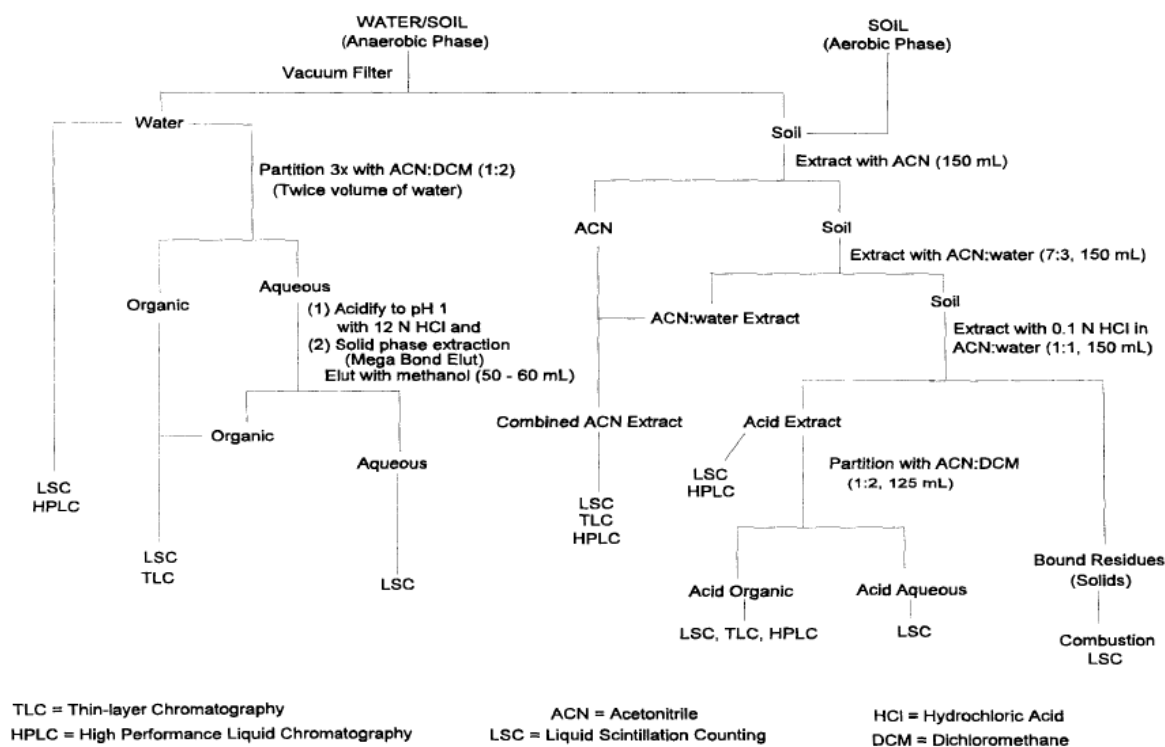

Figure B.8.1.1.2._CA-6: The schematic presentation of sample-processing procedure used in the study (scheme copied from the study report).

The obtained acetonitrile extracts were combined, concentrated under vacuum and analysed by LSC, HPLC and TLC. Acid extracts were halved. One part was radioassayed by LSC and analysed by HPLC. The remaining one was partitioned with three portions of $\text{CH}_3\text{CN}/\text{CH}_2\text{Cl}_2$ 1:2. Organic fractions were combined, their aliquots radioassayed by LSC, then concentrated and analysed by HPLC and TLC. Aqueous fractions were radioassayed by LSC.

The extracted soil pellets were analysed for NER fraction. To do that each soil sample was allowed to air-dry overnight, after what its triplicate aliquots (50 – 100 mg) were oxidized by combustion. The formed $^{14}\text{CO}_2$ was trapped in alkaline solution which, after mixing with scintillation cocktail, was analysed by LSC.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a Packard Tri-Carb Model 4640 counter equipped with automatic external standardisation.

Liquid samples were radioassayed in triplicate, after addition of 15 mL of Ultima Gold scintillation cocktail. The minimum sensitivity of LSC analysis for those samples was 2.488 E-4 ppm , corresponding to $0.02416 \% \text{AR}$. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm ($\text{LAGC} = 2 \times \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 9.24\%$.

Solid samples were oxidised using Packard Model 306 sample oxidizer (50 – 200 mg aliquots were used) and generated $^{14}\text{CO}_2$ trapped on 6 mL Carbo-sorb E and 15 mL Perma Fluor E, to be quantified by LSC. The minimum sensitivity of LSC analysis for those samples was 8.735 E-6 ppm , corresponding to 8.498 E-4 \%AR . When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 64 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 32 cpm, assuming average background (BCGK) of 32 cpm ($\text{LAGC} = 2 \times \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 9.24\%$.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- TLC – secondary quantitation method for the parent compound and its degradation products;
- LC-MS – identification method for parent compound and its degradation products;
- GC/MS – supplementary identification method for parent compound and its degradation products.

The HPLC analysis was performed using a Hewlett Packard Model 1090 chromatograph equipped with UV detector set at the wavelength $\lambda = 254$ nm, coupled to Ramona 5-LS radioactivity monitor. Three following HPLC methods were used:

- **Method A:** gradient mode analysis performed using PRP-1, 5 μm , 150 x 4.1 mm chromatographic column (Hamilton Co., Reno) and PRP-1 cartridge as a guard column. The mobile phase consisted of water + 0.4% CH_3COOH as **Solvent A** and CH_3CN + 0.4% CH_3COOH as **Solvent B**. Gradient elution lasted 95 minutes. Its parameters are shown in the table B.8.1.1.1.2._CA-2. The flow rate was set to 2 mL/min. The method was used as a main method for identification and quantitation of ^{14}C residues in analysed extracts and was able to detect and radioactive residues >1.0% AR.
- **Method B:** gradient mode analysis performed using PRP-1, 5 μm , 150 x 4.1 mm chromatographic column (Hamilton Co., Reno) and PRP-1 cartridge as a guard column. The mobile phase consisted of water + 0.4% CH_3COOH as **Solvent A** and CH_3CN + 0.4% CH_3COOH as **Solvent B**. Gradient elution lasted 95 minutes. Its parameters are shown in the table B.8.1.1.1.2._CA-2. The flow rate was set to 2 mL/min. The method was used to isolate and purify degradation products formed in the experiment, in **Metabolite ID** samples.
- **Method C:** gradient mode analysis performed using Selectosil 5, C-18, 5 μm , 250 x 4.6 mm chromatographic column (Phenomenex, California) and RP-18 Spheri-5, 5 μm , guard column. The mobile phase consisted of water as **Solvent A** and CH_3OH as **Solvent B**. Gradient elution lasted 60 minutes. Its parameters are shown in the table B.8.1.1.1.2._CA-2. The flow rate was set to 1 mL/min. Method was used for further purification of the degradation products isolated using **Method B**.
- **Method D:** gradient mode analysis performed using Selectosil 5, C-18, 5 μm , 250 x 4.6 mm chromatographic column (Phenomenex, California) and RP-18 Spheri-5, 5 μm , guard column. The mobile phase consisted of water as **Solvent A** and CH_3CN as **Solvent B**. Gradient elution lasted 25 minutes. Its parameters are shown in the table B.8.1.1.1.2._CA-2. The flow rate was set to 1 mL/min. Method was used for further purification of the degradation products isolated using **Method B**.
- **Method E:** gradient mode analysis performed using Selectosil 5, C-18, 5 μm , 250 x 4.6 mm chromatographic column (Phenomenex, California) and RP-18 Spheri-5, 5 μm , guard column. The mobile phase consisted of water as **Solvent A** and CH_3CN as **Solvent B**. Gradient elution lasted 35 minutes. Its parameters are shown in the table B.8.1.1.1.2._CA-2. The flow rate was set to 1 mL/min. Method was used for further purification of the degradation products isolated using **Method B**.

The LOD for the listed above chromatographic methods, in reference to the performance of the used radioactivity detector, was determined to be 1000 dpm, what corresponded to 1.0% AR. The value was determined experimentally on the basis of the comparison of radioactivity injected and eluted (expressed in dpm, as determined by LSC). The results of that examination, aimed on the determination of both LOD and the linearity of HPLC analysis, are presented in the table B.8.1.1.1.2._CA-3. The linearity of the analysis, expressed as r^2 , was: $r^2 = 0.999983$.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards. The retention times of each of the examined compounds for the HPLC **Method A** and **Method B** are presented in the table B.8.1.1.1.2._CA-4.

Table B.8.1.1.1.2._CA-2: The HPLC gradient modes used in the study.

Method A:

Footnotes to the table:

- 1) n. a. = not analysed using that method;

The TLC analysis of the extracts was performed in two modes:

- as RP-TLC (reversed phase TLC);
- as NP-TLC (normal phase TLC).

The RP-TLC analysis was carried out using Whatman KC₁₈F TLC plates, having a dimensions 20x20 cm and 200-μm thick, with a fluorescent indicator. The solvent system used in the analysis was CH₃CN:CH₃OH:0.5N NaCl_{aq} 2:2:1 (v/v) solution.

The NP-TLC analysis was carried out using silica gel TLC plates, having a dimensions 20x20 cm and 250-μm thick, with a fluorescent indicator. The solvent system used in the analysis was CHCl₃:CH₃COOC₂H₅:CH₃COOH 75:25:1 (v/v) solution.

The LOD was set to 1.0% AR for each individual compound detected. The quantitative analysis was performed using RITA 68000 Radio-TLC analyser. The LOD for this detector was determined to be 150 dpm. The complete results of the determination of linearity and LOD of the detector are presented in the table B.8.1.1.1.2._CA-5.

The identification was performed by means of the comparison of R_f values of the detected fractions with those of the known standards. These values are provided below in the table B.8.1.1.1.2._CA-6.

Table B.8.1.1.1.2._CA-5: The results of the determination of linearity and LOD of the TLC analysis.

The LC-MS analysis was performed using Varian 5040 HPLC equipped with a Regis Spherisorb S5 ODS column working in a gradient mode and Berthold LB 505-HPLC Radioactivity Monitor, coupled with Finnigan MAT 90 MS detector. The parameters of gradient were following:

- **Mobile phase A:** Water,
- **Mobile phase B:** CH₃OH,
- **Gradient mode:** linear from 0% B at 0 min to 100% B at 30 min.

The flow rate in the system was set to 0.8 mL/min.

The reported parameters of MS detector were following:

- Spectrometer operated in either positive or negative mode,
- aerosol temperature: 210⁰C,
- 0.2 M ammonium acetate added post column at rate of 0.2 mL/min.

The identification of Flufenacet and its degradation products in LC/MS analysis was performed by comparison of mass spectra of each chromatographic peaks with those obtained for the standards, for which base peaks and protonated molecular ion peaks were identified. These are presented in the table B.8.1.1.1.2._CA-7.

Table B.8.1.1.2._CA-7: LC/MS identification of Flufenacet and its degradation products in the study.

Compound	Representative signals used in identification	
	Position – m/z	Description
Flufenacet	364	Protonated molecular ion [M+H] ⁺
	381	Ammonia adduct [M + NH ₄] ⁺
FOE Sulfonic acid	274	Peak for [M – H] ⁻ (negative-ion mode)
FOE Oxalate	226	Protonated molecular ion [M+H] ⁺
	243	Ammonia adduct [M + NH ₄] ⁺
FOE Methylsulfoxide	258	Protonated molecular ion [M+H] ⁺
	275	Ammonia adduct [M + NH ₄] ⁺
FOE Alcohol	212	Protonated molecular ion [M+H] ⁺
FOE Thioglycolate sulfoxide	316	Protonated molecular ion [M+H] ⁺ for methylated derivative

GC/MS analysis was performed to conform the identity of Flufenacet and its degradation products. It was carried out with HP Model 5890A Gas Chromatograph/Finnigan Incos 50 Mass Spectrometer. GC was equipped with DB5-MS column (152 m * 0.25 mm x 0.25 µm film thickness).

The oven programme used was following:

- GC oven was programmed to start at T = 80⁰C and it was held at that level for t = 1 min. Then the temperature increased linearly at rate of 20⁰C/min up to T = 250⁰C and held at that level for t = 1 min. The injector's temperature was T = 250⁰C. MS detector operated in the electron impact mode with a mass range 50 – 400 amu.

To facilitate MS identification the degradation products were methylated. That was accomplished by direct addition of 0.3 M (0.5 mL) of diazomethane or 2.0 M (0.05 mL) of (trimethylsilyl)diazomethane to at least 0.1mL of MeOH solution of HPLC-purified degradation products. The solution was left for ~1 hour at room temperature to allow the reaction to complete. Before being analysed by LC/MS methylated degradation products were purified using HPLC Method E.

Results and their discussion:

The results of the determination of soil microbial biomass has been presented in the table B.8.1.1.2._CA-1. It can be stated that it was within the recommended limits throughout the study and no significant decrease was observed during either aerobic or anaerobic incubation period.

The results of the monitoring of anaerobic conditions in the test vessels during anaerobic incubation phase are presented in the table B.8.1.1.2._CA-8. All reported values are those measured in soil layer. The presented values clearly indicate that the anaerobic conditions were maintained during whole that phase.

Table B.8.1.1.1.2_CA-8: The results of monitoring of anaerobic conditions in incubation vessels during anaerobic incubation phase.

Time point (DAF) ¹⁾	Incubation system ²⁾	Replicate	Measured value for:

		2	6.8	-366	-312	0.7	0.3

Footnotes to the table:

- 1) DAF – Days After Flooding;
- 2) The measurements performed either solely in Flow-through system (DAFs 0 – 30) or in both Flow-through and Static systems; both systems described in detail on p.96 of the report;
- 3) Measured using Cole-Parmer combination electrode;
- 4) Measured using Corning redox combination electrode;
- 5) Measured using YSI Model 58 DO-Meter;
- 6) Measured using Orion Model 820 DO-Meter ;

The examination of the stability of test compound demonstrated that Flufenacet was stable throughout application, extraction and chromatographic analysis.

The recovery of applied radioactivity at application (DAT 0) was 97% AR and throughout the aerobic incubation phase (DAT 0 – DAT 30) it was in range of 96 – 105% AR. For anaerobic incubation phase the average recovery of radioactivity was 93% AR, with range of 91 – 94% AR. As in samples incubated in Flow-through system around DAF 60 the recover decreased to 88.9% AR, what suggested losses due to probable leakage in the system, both samples from Flow-through system and Static system were analysed for the incubation period between DAF 60 – 180 (last three sampling points). The comparative analysis of the results showed that recoveries of radioactivity in samples from both systems were comparable (same reduction level). Therefore the theory about the possible loss of volatile compounds due to the leakage was discounted.

The level of mineralisation and of formation of other volatile compounds was low during both aerobic and anaerobic phases. The formation of NER fraction was low during aerobic incubation phase, reaching the level of 8.4% AR on DAT 30 (end of incubation period). It increased significantly during anaerobic incubation period to reach the level of 32.6% AR at the end of that incubation phase – DAF 180 (the termination of the whole study).

During the aerobic incubation phase the radioactivity in the system remained mainly in extractable form – as Flufenacet and its degradation products. The concentration of Flufenacet declined steadily to reach the level of 69.0% AR on DAT 30 (end of aerobic incubation phase). The following degradates were identified in soil during aerobic incubation period:

- FOE Oxalate – max. 11.2% AR on DAT 30,
- FOE Sulfonic acid – max 6.6% AR on DAT 30,
- FOE Thioglycolate sulfoxide – max 2.7% AR on DAT 15,
- FOE Alcohol – max 0.4% AR on DAT 0.

Additionally a small fraction of other metabolites, comprising up to 12 compounds, was detected, not surpassing the level of 0.2% AR at any sampling point.

During anaerobic incubation phase the amount of extractable radioactivity (sum of that recovered in water phase and extracted from soil) decreased from 89.7% AR at the beginning of that phase to 56.8% AR at its end. It shall be noted that the distribution of radioactivity between water and soil was at relatively constant ratio: 3:4 – 3:5, throughout the whole incubation period.

Concentration of Flufenacet steadily decreased during anaerobic phase from the level of 69.0% AR at its beginning to 39.0% AR at the end. One new degradation product was identified – FOE Thioglycolate. In case of other degradates, already identified during aerobic incubation phase the metabolite profiles looked as follows:

- The amounts of FOE Oxalate initially increased up to 30th day of anaerobic incubation, to steadily decrease afterwards;
- Also increase in concentration was observed for FOE Alcohol, although in that case the formation-decline pattern was not very clear;
- The remaining two degradation products – FOE Sulfonic acid and FOE Thioglycolate sulfoxide were on the decline phase.

The detailed results of the experiment are presented in the table B.8.1.1.1.2._CA-9. RMS decided to present the results for aerobic and anaerobic phases together in one table, differentiating them by delicately shading grey the cells containing the results obtained for aerobic phase. The concentrations of identified compounds are those obtained using HPLC. The quantitative results of TLC are not presented as they did not differ significantly from HPLC results. Additionally the results are presented in graphical form on figure B.8.1.1.1.2_CA-7. The graphs present: the distribution of radioactivity in the test system (top left-hand), the concentrations of the identified compounds in function of time recorded in aerobic phase (top, right-hand) and the concentrations of the identified compounds in function of time recorded in anaerobic phase (bottom graph).

**Figure B.8.1.1.2.CA-7:** The graphical results of the experiment (schemes copied from the study report).

On the basis of the results obtained in this experiment the following transformation scheme for [Phenyl- ^{14}C] Flufenacet was proposed by the Applicant – Figure B.8.1.1.2._CA-8. The scheme comprises processes that occur during both aerobic phase (solid lines) and anaerobic phase (dashed lines).

**Figure B.8.1.1.2._CA-8:** The proposed transformation scheme of Phenyl- ^{14}C] Flufenacet in aerobic/anaerobic soil. Solid lines represent processes occurring in aerobic soil, dashed lines those observed in anaerobic soil (scheme copied from the study report).

The kinetic analysis of the results of this study will be presented under the relevant point, further down this report – please refer to the point B.8.1.1.2.1.2.

Study 2:

Report: Heinemann O., (2012): “[Thiadiazole-5-¹⁴C] FOE 5043: Anaerobic Degradation/Metabolism in Two European Soils.”; Bayer CropScience AG, Development Environmental Safety-Testing, Alfred-Nobel-Str. 50, D-40789 Monheim am Rhein, Germany; Study M1262057-3; unpublished Study Report No. MEF-11/908; 2012. 08. 16; amended by: Amendment No. 1 on 2013. 02. 28 and Amendment No. 2 on 2013. 11. 27; study reference number: M-437443-03-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

GLP: Yes.

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to examine the transformation of [Thiadiazole-5-¹⁴C] Flufenacet in soil under anaerobic conditions, in order to establish a transformation pathway of so radiolabelled compound under these conditions, including the identification and quantitation of the degradation products, and to determine the kinetics of the degradation of Flufenacet in anaerobic soil.

The experiment was performed on two soils, used also to examine the transformation of [Thiadiazole-5-¹⁴C] Flufenacet in aerobic soil. Their characteristic is provided, in two tables – table B.8.1.1.2._CA-10 for physicochemical properties, and table B.8.1.1.2._CA-11 for soil microbial activity. It shall be noted that microbiological activity of the test soils was determined independently for aerobic and anaerobic phases of the experiment, using two different methods – SIR method for aerobic phase and Plate Account Assay method for anaerobic phase.

Table B.8.1.1.2._CA-10: The characteristic of soils used in the study.

Parameter		Soil	
		<i>Hoefchen am Hohenseh 4a</i>	<i>Dollendorf II</i>
Soil origin		Burscheid/ North Rhine-Westphalia/ Germany	Blankenheim/North Rhine-Westphalia/ Germany
Soil type (USDA)		Silt loam	Loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	22	48
	Silt (2 – 50 µm) [%]	62	28
	Clay (< 2 µm) [%]	16	42
pH value in 0.01M CaCl ₂ (soil/solution ratio 1:2)		6.1	7.0
pH value in H ₂ O (soil/solution ratio 1:1)		6.3	7.1
pH value in 1N KCl		5.8	6.7
Organic carbon content (OC) [%]		2.0	4.6
Organic matter content (OM) [%] ¹⁾		3.4	7.9
Cation Exchange Capacity – CEC [mEq/100g]		11.1	19.5
Water holding capacity	Maximum [g H ₂ O/100 g soil]	54.8	79.1
	at 0.33 bar (½ bar WHC - pF2.5)	20.9	35.1
	[g H ₂ O/100 g soil]		
Bulk density (disturbed) [g/cm ³]		1.09	1.03

Footnotes to the table:

1) Value calculated by the RMS using the following equation: OM = 1.724 * OC.

Table B.8.1.1.1.2._CA-11: The results of the determination of soil microbial activity.

Parameter						Results obtained for soil:	
						Hoefchen am Hohenseh 4a	Dollendorf II
Aerobic phase	Soil biomass [mg microbial C/kg soil] in samples collected on DAT ¹⁾ :	0	Not treated sample			1089	3789

Footnotes to the table:

- 1) DAT = Days After Treatment;
- 2) Calculated by RMS using the declared OC content given in the table B.8.1.1.1.2._CA-10 above;
- 3) CFU = Colony Forming Units
- 4) DAT – Days After Treatment – descriptor for the whole experiment duration; DASF – Days After Soil Flooding – descriptor for the duration of anaerobic phase;
- 5) MeOH/water 1:1 solution applied in amount 369 µL/sample;
- 6) Not countable.

The test soils, representative for the agriculturally used area of the region of sampling, were taken from the fields of the history of cropping system and Plant Protection Products use known for the 5 years before sampling. It was determined that during that period the plant cover of that designated field was grassland on which no pesticides were used 5 years prior to soil sampling. Soil used in the experiment was taken with shovel from the top 20-cm layer, placed in plastic container (bag or bucket) and transferred to the experimental facility, where it was sieved through 2-mm sieve.

Water used in the experiment to flood the test soil at the beginning of anaerobic phase was ultrapure deionised water, generated by TKA Gen Pure UV/TOC water purification system. It was deoxygenated using N₂ for 4 days before use.

The test compound used in the experiment was the ¹⁴C-FOE 5043 radiolabelled in C5-Thiadiazole position, as shown below on figure B.8.1.1.1.2._CA-9.

**Figure B.8.1.1.1.2._CA-9:** The structural formula of the radiolabelled Flufenacet (FOE 5043) used in the experiment; the asterisk (*) indicates radiolabelling position (copied from the study report).

The specific radioactivity of the test compound used in the experiment was 1.54 MBq/mg. Its radiochemical purity, determined using both HPLC and TLC, was > 98%. The chemical purity of the test compound, determined using HPLC equipped with UV detector, was > 99%.

The test compound was used to prepare the **Stock solution** by dissolving the total delivered amount in methanol, to obtain the solution having a concentration of 2.09 mg Flufenacet/mL.

The **Stock solution** was used to prepare the **Application solution**, by diluting its aliquot in an adequate amount of CH₃OH/H₂O 1:1 (v/v) solvent, to obtain a solution having a concentration of 0.434 mg Flufenacet/mL and specific activity of 669 kBq/mL. The **Application solution** was prepared just before the treatment of the test soil in incubation vessels.

The study was performed in a static incubation test system, consisting of 300-mL Erlenmeyer flasks, to which test soil was introduced, and the traps for volatile compounds. In case of **aerobic incubation phase** the traps for volatile compounds were in form of glass columns filled with adequate sorbents. They were open on the top to grant the access of oxygen to incubation vessels. The aerobic-phase incubation vessels – biometer flask, is shown below, on figure B.8.1.1.1.2._CA-10.

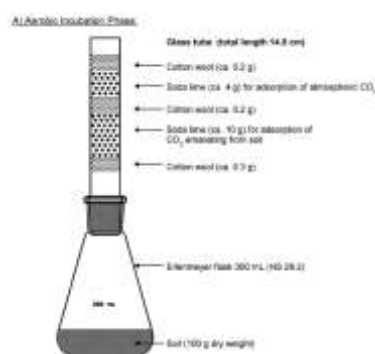

Figure B.8.1.1.1.2._CA-10: The biometer flask used in the aerobic phase of the experiment (scheme copied from the study report).

For purpose of **anaerobic incubation phase** the glass-column traps for volatiles were replaced with two-valve glass stoppers, introduced after flooding of the test soil in Erlenmeyer flasks, to which the plastic bags collecting volatiles were attached. The example incubation vessel used in that phase is presented below on figure B.8.1.1.1.2._CA-11.

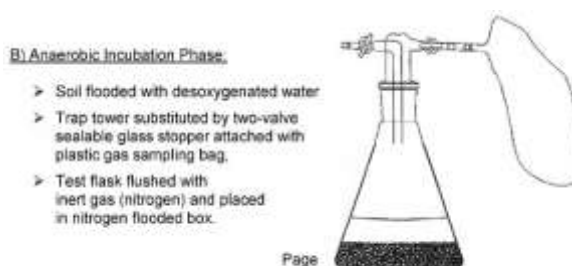

Figure B.8.1.1.1.2._CA-11: The incubation vessel used in the anaerobic phase of the experiment (scheme copied from the study report).

The incubation samples were prepared by weighing ~120 g of sieved soil (corresponding to 100 g d. w.) into each Erlenmeyer flask. Next the soil moisture in each flask was adjusted to ~55% MWHC by addition of the appropriate amount of deionised water. In case of Hoefchen am Hohenseh 4a soil it was 11.4 mL water/flask and for **Dollendorf II soil** – 21.6 mL water/flask.

Soil in the incubation vessels was treated in with characterised above **Application solution**, applied in amount 369 µL/flask, evenly to the soil surface, using Eppendorf pipette. That amount was assumed to correspond to the nominal application dose of 160 µg Flufenacet /100 g soil (d. w.). The exact application dose, measured during application by LSC and conformed by HPLC-radiodetection method, was 151.2 µg Flufenacet/100 g soil (d. w.) – 232 kBq/flask when expressed in radioactivity units. It was further called **actual application dose**. The

Applicant declared that the nominal application dose - 160 µg Flufenacet /100 g soil (d. w.), corresponded to the nominal application rate of 600 g Flufenacet/ha, assuming soil density of 1.5 g/cm³ and depth of the topsoil layer of 2.5 cm.

RMS repeated the calculations of the application rate using the **actual application dose**, to obtain the **actual application rate – A**. In calculations the depth of the soil layer was assumed to be 5 cm. Initially the soil density of 1.5 g/cm³ was used. As a next, refinement step the measured soil density values were used for each test soil to obtain the **actual application rates related to soil properties – A'**.

The resulting **actual application rate – A** = 1134 g/ha. When recalculated using the exact soil bulk densities of the test soils – 1.09 g/cm³ for Hoefchen am Hohenseh 4a soil and 1.03 g/cm³ for Dollendorf II soil, the application rates were as follows:

- for Hoefchen am Hohenseh 4a soil **A' = 824.04 g/ha**;
- for Dollendorf II soil **A' = 778.68 g/ha**.

The amount of so prepared incubation vessels was such, to grant duplicate samples per each sampling point. The sampling points were set to DAT (Days After Treatment) 0 and 15 for **aerobic incubation phase**, and DAT 15, 17, 21, 29 35, 48, 77, 107 and 135, corresponding to DASF (Days After Soil Flooding) 0, 2, 6, 14, 20, 33, 62, 90 and 120, for **anaerobic incubation phase**. The whole incubation period lasted for 135 days, of which 120 days covered incubation under anaerobic conditions.

After treatment all incubation vessels were closed with the tower traps for volatile compounds and placed in the dark, in the temperature-controlled incubation chamber, set to maintain the experimental conditions $T = 20 \pm 2^{\circ}\text{C}$ and $55 \pm 5\%$ MWHC. During that initial aerobic incubation period samples were taken for the analysis twice – on DAT 0 (beginning of aerobic incubation) and DAT 15 (end of aerobic incubation). Samples removed from incubation chamber were first gently ventilated, to transfer all volatiles formed in the head-space of Erlenmeyer flask to the traps for volatiles. They were then dissected into traps for volatiles and incubation flask containing test soil, and processed following the procedure presented on figure B.8.1.1.1.2._CA-12. It shall be noted that in case of DAT 0 samples, processed almost immediately after treatment with the test compound, the traps for volatile compounds were not set. That was due to the assumption made that no volatiles would be formed that early in the test system.

The soil in each vessel was extracted and analysed as entire sample. The extracted soil pellets were analysed for their content of NER fraction by LSC following combustion. Further characterization of NER fraction was not performed.

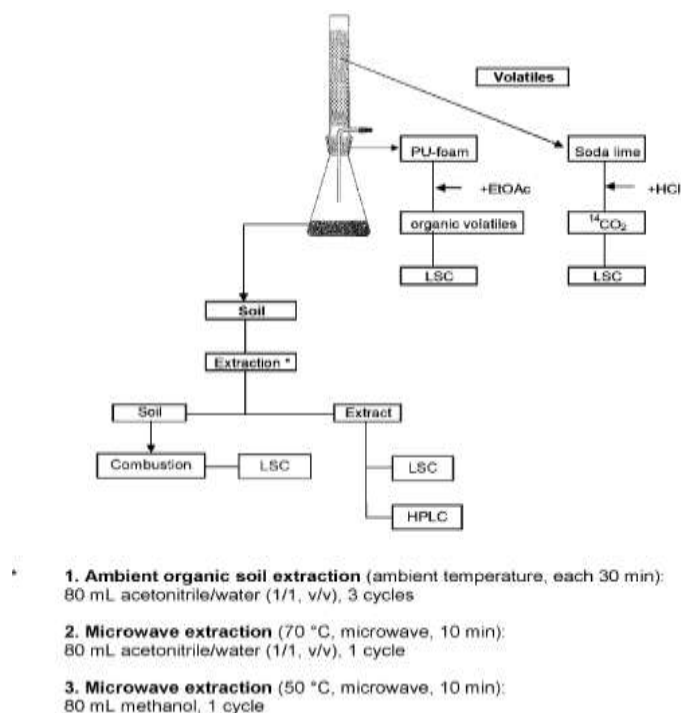

Figure B.8.1.1.1.2._CA-12: The schematic presentation of sample-processing procedure used for **aerobic-phase** samples (scheme copied from the study report).

The remaining incubation flasks, designated to be further incubated under anaerobic conditions, were dissected on DAT 15 in exactly the same way as described above. The removed traps were stored for later analysis. The soil in each flask was flooded with ~150 mL of de-oxygenated deionised water, to obtain the water layer of ~3 cm above the soil surface. Next vessels were gently shaken and sealed with double-valve glass stoppers, to get the incubation system presented above on figure B.8.1.1.1.2._CA-13. The flask were then flushed for 1 minute with argone, connected to air-tight plastic bag, flushed with N₂ to collect volatile degradates and the inlet valve was closed to grant anaerobicity of the incubation vessel throughout incubation period. The outlet valve – connected with plastic bag, was left open. Finally, so prepared incubation vessels were placed within incubation chamber, in a box flooded initially with Ar, then with N₂. The incubation temperature was the same as that for aerobic pre-incubation stage – $T = 20 \pm 2^\circ\text{C}$.

The incubation chamber used in **anaerobic incubation phase** is presented on figure B.8.1.1.1.2._CA-13.

Figure B.8.1.1.1.2._CA-13: The anaerobic incubation chamber used in the experiment (copied from the study report).

At the designated time points samples were removed from incubation chamber and connected to the volatiles-combustion oven unit, shown on figure B.8.1.1.1.2._CA-14, to remove all formed volatile compounds from the vessels' headspace and sampling bag.

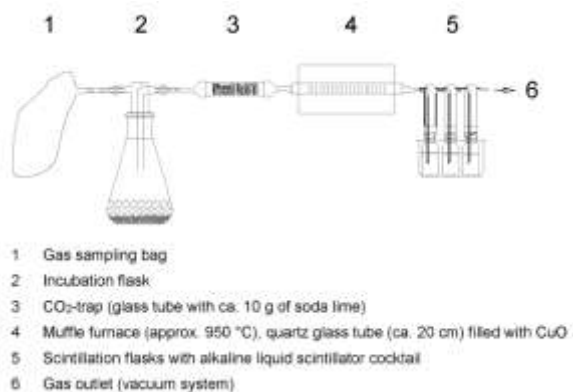

Figure B.8.1.1.1.2._CA-14: The scheme of the device used to evacuate and capture volatile compounds from anaerobic incubation vessels (copied from the study report).

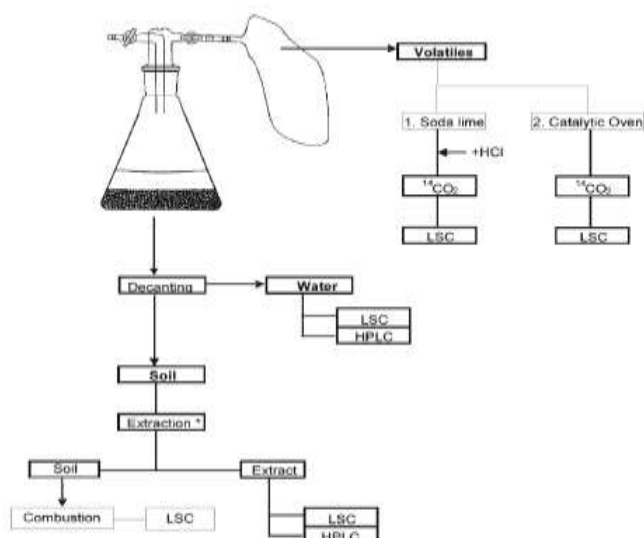

After that the flask were opened and anaerobic conditions monitored by measuring pH, oxygen content and redox potential of water layer, as well as redox potential of soil.

Then the whole samples were processed as shown below on figure B.8.1.1.1.2._CA-15. The water phase after decantation was centrifuged for ~10 min at ~4550xg to remove suspended soil particles. Cleared supernatants, after determination of their volume, were analysed for their content of radioactivity without being further concentrated, using HPLC and LSC.

The centrifugation pellets were added to remaining soil for further extraction.

The applied soil extraction procedure was the same as for aerobic soil. The whole soil portions from each vessels were subjected to extraction. The extracted soil pellets were analysed for their content of NER fraction by LSC following combustion. Further characterization of NER fraction was performed in DAT-135

(DASF-120) samples following the procedure presented on figure B.8.1.1.1.2._CA-16. For that purpose 25-g aliquots of both replicates were used.

1. Ambient organic soil extraction (ambient temperature, each 30 min):
80 mL acetonitrile/water (1/1, v/v), 3 cycles

2. Microwave extraction (70 °C, microwave, 10 min):
80 mL acetonitrile/water (1/1, v/v), 1 cycle

3. Microwave extraction (50 °C, microwave, 10 min):
80 mL methanol, 1 cycle

Figure B.8.1.1.1.2._CA-15: The schematic presentation of sample-processing procedure used for anaerobic-phase samples (scheme copied from the study report).

Figure B.8.1.1.1.2._CA-16: The schematic presentation of sample-processing procedure used for NER characterisation (scheme copied from the study report).

Also duplicate samples for determination of soil microbial activity were prepared. The samples were prepared in two variants – as not treated samples and samples treated with blank application solution. Three sets of incubation vessels were prepared, to cover three sampling points – two for aerobic phase (DAT-0 and DAT-15 samples) and one for anaerobic phase – DAT-135/DASF-120 sample. They were incubated in exactly the same way as other samples.

The determination of soil microbial activity during **aerobic incubation phase** was based on the method of substrate-induced initial respiratory response (SIR) and followed methodology described by Anderson & Domsch.

The method of the determination of soil microbial activity in anaerobic soil was based on a plate count assay for colony forming units.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a LS6500 or LKB-Wallac 1219 Spectral counters.

The radioactivity in organic extracts and other liquid samples from HPLC analysis was determined in either:

- mini-vials, using the adequate (depending on expected RA content) sample aliquots and 2 mL of Quicksafe® A solution containing 5% of water; the counting time was 10 min and the background 12 – 16 cpm;
- maxi-vials, using the adequate (depending on expected RA content) sample aliquots and 7 mL of Quicksafe® A solution containing 5% of water; the counting time was 10 min and the background 22 – 23 cpm.

The same scintillation cocktail was used to determine the radioactivity in alkaline extracts, obtained during fractionation for characterisation of NER fraction in extracted DAT-135/DASF-120 soil pellets. The background for these measurements was 12 – 16 cpm.

The $^{14}\text{CO}_2$ captured in soda traps during aerobic phase of the experiment was liberated with 18% HCl_{aq} and released from the solution by flushing for 30 min with stream of N_2 , while samples were gently stirred.

The liberated $^{14}\text{CO}_2$, also that formed during anaerobic phase, was absorbed in Oxysolve 400 scintillation cocktail and radioactivity measured using LKB-Wallac 1219 Spectral counter. The counting time was 10 min and the background 17 – 20 cpm.

The radioactivity in solid samples – extracted soil pellets, was determined after combustion of three 1-g aliquots of dried and homogenised material. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxysolve C400 liquid. The counting time was 10 min and the background 17 – 20 cpm.

The instrumental limit of quantitation – LOQ_i , was set to double maximum instrument background count rate, defined as *max. background [cpm]*3/60* – equation used for conversion of cpm to Bq. The so determined instrumental LOQ_i values for different types of liquid samples were as follows:

- samples with scintillation cocktail of 2 mL Quicksafe A + 5% water: $\text{LOQ}_i = 0.8 \text{ Bq}$;
- samples with scintillation cocktail of 7 mL Quicksafe A + 5% water: $\text{LOQ}_i = 1.2 \text{ Bq}$;
- samples with scintillation cocktail of 15 mL Oxysolve C400, $\text{LOD}_i = 0.7 \text{ Bq}$ and $\text{LOQ}_i = 1.0 \text{ Bq}$.

Sample extracts were analysed using the following techniques:

- HPLC – primary identification and quantitation method for parent compound and its degradation products;
- TLC – primary and conformatory identification and quantitation method for the parent compound and its degradation products;
- LC-MS – identification method for parent compound and its degradation products;
- $^1\text{H-NMR}$ – supplementary identification method for parent compound in stock solution.

The RP-HPLC analysis was performed in a gradient mode. The system consisted of Agilent 1100 chromatograph equipped with Ramona Star radiodetector and DAD detector, set to $\lambda = 254 \text{ nm}$. The chromatographic separation was performed on a system consisting of Purospher Star $\text{C}_{18\text{e}}$ 4 mm * 4 mm * 5 μm guard column and Purospher Star $\text{C}_{18\text{e}}$ 250 mm * 4.6 mm * 5 μm chromatographic column. It worked in the following gradient regime:

- **Mobile phase A:** 5 mM aqueous ammonium formate +1% formic acid (985 mL Water + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ – 5 mM $\text{NH}_4\text{COOH}/265 \text{ mM HCOOH}$);
- **Mobile phase B:** 5 mM ammonium formate in acetonitrile +1% formic acid (985 mL CH_3CN + 10 mL HCOOH + 5 mL $\text{NH}_4\text{COOH}_{(\text{aq})}$ – 5 mM $\text{NH}_4\text{COOH}/265 \text{ mM HCOOH}$),
- **Gradient mode** used in elution is shown below in the table B.8.1.1.1.2._CA-12,
- Total run time was 65 minutes.

The flow rate was set to 1.0 mL/min. The chromatographic column was kept under the constant temperature $T = 40^\circ\text{C}$.

Table B.8.1.1.1.2._CA-12: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	Solvent A	Solvent B
0 - 5	100	0
5 - 55	Linear gradient	
55	5	95
5 - 60	5	95
60 - 62	Linear gradient	
62	100	0
62 - 65	100	0

The method had the following performance parameters:

- LOD = 10.6 Bq, corresponding to 0.33% AR;
- LOQ = 3* LOD – 31.8 Bq, corresponding to 1.0% AR.

The primary quantitation TLC analysis of polar fraction was performed in NP-TLC (normal phase TLC) mode. It was carried out on at ambient temperature, in saturated chamber, on silica gel Merck Si60, F₂₅₄, TLC plates. The solvent system used in the analysis was CH₃COOC₂H₅/CH₃CHOHCH₃/H₂O/CH₃COOH 65:24:11:1 (v/v/v/v) solution (CH₃CHOHCH₃ stands for 2-propanol). Separation distance for analysed material and reference compounds was 160 mm.

Two detectors were used:

- UV cabinet detector working at a wavelength $\lambda = 254$ nm;
- Bio-Imaging Analyser “BAS-2000” to detect and quantify radioactivity.

The conformatory TLC method was also performed in NP-TLC (normal phase TLC) mode. It was carried out on at ambient temperature, in saturated chamber and on silica gel Merck Si60, F₂₅₄, TLC plates. Two detectors were used:

- UV cabinet detector working at a wavelength $\lambda = 254$ nm;
- Bio-Imaging Analyser “BAS-2000” to detect and quantify radioactivity.

Two solvent system were used in the analysis:

- Eluent 1 (**Method A**) – CH₂Cl₂/CH₃COOC₂H₅ 8:2 (v/v) solution; separation distance was 160 mm;
- Eluent 2 (**Method B**) – CH₃COOC₂H₅/CH₃CHOHCH₃/H₂O/CH₃COOH 65:24:11:1 (v/v/v/v) solution (CH₃CHOHCH₃ stands for 2-propanol); separation distance was 80 mm.

The TLC method used for quantitative analysis of polar fraction had the following performance parameters:

- LOD = 0.30% AR;
- LOQ = 0.9% AR.

The LC-MS analysis was performed as either HPLC/MS or IEC/MS analysis.

HPLC/MS analysis was carried out using Agilent HP1000 HPLC system equipped with a Nucleodur Gravity C₁₈ chromatographic column (250 * 2 mm, 3 μ m), UV detector followed by the Ramona Star radiodetector and Q-Exactive mass spectrometer.

The parameters of chromatographic analysis were following:

- flow rate: 0.2 mL/min,
- elution mode: gradient,
- mobile phase:
 - **Solvent A:** H₂O + 0.1% HCOOH,
 - **Solvent B:** CH₃CN + 0.1% HCOOH.
- gradient programme is presented below in the table B.8.1.1.1.2._CA-13.

Table B.8.1.1.1.2._CA-13: Gradient programme used in HPLC/MS analysis.

<i>Time [min]</i>	<i>% solvent A (H₂O + 0.1% HCOOH)</i>	<i>% solvent B (CH₃CN + 0.1% HCOOH)</i>
0	95	5
1	95	5
25	5	95
35	5	95

The IEC/MS (Ion Exchange Chromatography) analysis was performed using Dionex ICS-500 system equipped with AS20 column (250 * 2 mm), Ramona Star radiodetector and MS spectrometer.

The parameters of chromatographic analysis were following:

- flow rate: 0.25 mL/min,
- elution mode: isocratic,
- mobile phase: 20mM KOH in water,
- elution time: 15 minutes.

Results and their discussion:

The monitoring of the experimental conditions demonstrated that the samples were incubated at the mean temperature $T = 19.7^{\circ}\text{C}$, ranging from 19.4°C to 19.9°C . The average incubation temperature and its range was within the limits of the assumed constant temperature $T = 20 \pm 2^{\circ}\text{C}$.

The soil moisture content during **aerobic incubation phase** was not monitored, as it was assumed that the incubation period was too short for substantial water losses to occur.

In case of **anaerobic incubation phase**, to justify not performing such control, the following assumptions were made:

- a) as soil was flooded no moisture maintenance was required throughout entire incubation period;
- b) incubation in a static system excluded any substantial losses of water from the test vessels.

The determination of the soil biomass in the test soils during the **aerobic incubation period** demonstrated no decrease of that parameter. It was also determined that during that period soil biomass was well above the recommended minimum level of 1% OC.

For **anaerobic incubation period** the test soil demonstrated to be fully viable.

The LSC analysis of the homogeneity of application of the kinetic samples conformed that it was homogenous, with $\text{RSD} = 1.8\%$

The application dose determined for DAT-0 samples was, on average, 232.8 kBq, equal to 151.2 μg Flufenacet/sample. That value was set as 100% AR.

The verification of the conditions during **anaerobic incubation phase** demonstrated that anaerobicity was maintained throughout that phase. The following changes in measured parameters were recorded (means of two replicates are given):

- for test system containing Hoefchen am Hohenseh 4a soil:
 - the concentration of O_2 in water layer decreased from 5.3 mg/L (60.5%) on DASF 0 to 0.3 mg/L (3.5%) on DASF 120;
 - the redox potential of water layer, expressed as E_{obs} , decreased from 203.5 mV on DASF 0 to -114.5 mV on DASF 120;
 - the redox potential of soil layer, expressed as E_{obs} , decreased from 241 mV to -170 mV on DASF 120;
 - pH of water phase increased from ~ 7.2 to ~ 7.8 during incubation period.
- for the test system containing Dollendorf II soil:
 - the concentration of O_2 in water layer decreased from 6.0 mg/L (67%) on DASF 0 to 0.1 mg/L (1.0%) on DASF 120;
 - the redox potential of water layer, expressed as E_{obs} , decreased from 168.5 mV on DASF 0 to -105.5 mV on DASF 120;
 - the redox potential of soil layer, expressed as E_{obs} , decreased from 183 mV to -133.5 mV on DASF 120;
 - pH of water phase decreased during incubation period from 8.5 to ~ 7.5 to then increase to 7.9.

The detailed results of these measurements are presented below, separately for each test soil system, in tables B.8.1.1.1.2._CA-14 (Hoefchen am Hohenseh 4a soil) and B.8.1.1.1.2._CA-15 (Dollendorf II soil).

Table B.8.1.1.1.2._CA-14: The results of the verification of the anaerobic conditions in test vessels containing Hoefchen am Hohenseh 4a soil.

Sample collected on:		Replicate	Results obtained for:

		2	0.1	1	-102	88	7.9	-132	58	

The recovery of the applied radioactivity in the experimental soils was generally good, in line with the recommendations of the relevant Guidelines:

- for Hoefchen am Hohenseh 4a soil: on average 96.2% AR, with RSD = 1.4% and range of 93.3% AR – 98.3% AR (values given as the means of the two replicates);

- for Dollendorf II soil: on average 96.5% AR, with RSD = 2.0% and range of 92.9% AR – 98.9% AR (values given as the means of the two replicates).

The level of mineralization was low – up to 1.7% AR in test system with Hoefchen am Hohenseh 4a soil and up to 1.9% AR in test system containing Dollendorf II soil. It shall be noted that in case of samples incubated under aerobic/anaerobic conditions, all captured $^{14}\text{CO}_2$ was formed during aerobic pre-incubation phase. No other volatile compounds were found in the test systems.

The amount of NER fraction increased with time. For Hoefchen am Hohenseh 4a soil it reached the level of 16.9% AR during **aerobic incubation phase**, to then increase to 24.5% AR at the end of **anaerobic incubation phase** (DAT 135). In case of Dollendorf II soil it reached the level of 10.1% AR at the end of **aerobic incubation phase**, to then increase to 31.6% AR at the end of **anaerobic incubation phase** (DAT 135).

The results of further characterisation of NER fraction is presented below in the table B.8.1.1.1.2._CA-16.

Table B.8.1.1.1.2._CA-16: The results of characterisation of NER fraction.

AR determined as:		Results obtained for:							
		Hoefchen am Hohenseh 4a soil				Dollendorf II soil			
		Replicate 1		Replicate 2		Replicate 1		Replicate 2	
		[% AR]	[% NER]	[% AR]	[% NER]	[% AR]	[% NER]	[% AR]	[% NER]
Total NER (determined by LSC)		24.6	100	24.4	100	32.4	100	30.7	100
Fraction	Fulvic acids fraction	12.7	51.7	13.9	56.8	11.4	35.2	10.7	35.0
	Humic acids fraction	4.1	16.8	4.0	16.4	1.9	5.9	1.8	5.9
	Humin fractions	9.0	36.6	8.8	36.0	14.0	43.1	14.2	46.2
	Total recovered	25.8	105.1	24.6	109.2	27.3	84.2	26.7	87.0

It can be stated that in both soils the lowest amount of AR identified as NER fraction was associated with humic acids fraction. For Hoefchen am Hohenseh soil the amount of AR as NER associated with fulvic acids fraction was greater than that associated with humans, while in Dollendorf II soil that relationship was reversed. It was noted however that, while for Hoefchen am Hohenseh soil the HPLC-recoveries of AR identified as NER were good, even slightly above 100%, in case of Dollendorf soil they were well below 90% for both replicates.

During the aerobic incubation phase the radioactivity in the both systems remained mainly in extractable form – as Flufenacet and its degradation products. The concentration of Flufenacet declined sharply to reach the level of ~31 – 44% AR on DAT 15 (end of aerobic incubation phase). The following degradates were identified in soil during aerobic incubation period:

- FOE Thiadone – 4.3 – 5.9% AR on DAT 15,
- FOE Trifluoroethane sulfonic acid – 2.5 – 6.0% AR on DAT 15,
- Trifluoroacetic acid – 28.0 – 37.5% AR on DAT 15.

Additionally the small fraction of other metabolites – the so-called “Unidentified/Diffused Radioactivity”, was detected, not surpassing the level of 2.4% AR.

During anaerobic incubation phase the amount of extractable radioactivity (sum of that recovered in water phase and extracted from soil) was initially higher than that recovered at the same time point before soil flooding, what may indicate that the NER fraction at the end of aerobic incubation period contained some potentially extractable radioactivity. It decreased afterwards steadily to the level of 59.4 – 68.3% AR at the study's end (DAT 135/DASF 120).

Flufenacet steadily decreased during anaerobic phase from the level of ~35 – 43% AR at its beginning to ~3 – 6% AR at the end. No new degradation products were found and in case of those identified the amounts FOE Trifluoroethane sulfonic acid declined in both soils, while the concentration of Trifluoroacetic acid (TFA) increased. In case of FOE Thiadone no clear tendency was observed – in Hoefchen am Hohenseh 4a soil it steadily increased during that phase, while in Dollendorf II soil after initial increase its concentration declined.

The fraction of “other”, not identified degradates, if detected at all, was at a very low level and decreasing.

The detailed results of the experiment are presented below, separately for each test soils, in two sets of tables and graphs. In the table B.8.1.1.1.2._CA-17 and on figure B.8.1.1.1.2._CA-17 (the distribution of radioactivity in the test system on left-hand graph and the concentrations of the identified compounds in function of time on the right-hand one) are presented the results of the experiment with Hoefchen am Hohenseh 4a soil. Next set – table B.8.1.1.1.2._CA-18 and figure B.8.1.1.1.2._CA-18 the distribution of radioactivity in the test system on left-hand graph and the concentrations of the identified compounds in function of time on the right-hand one) presents the results of the experiment with Dollendorf II soil. Presenting the numerical results of the study RMS

decided to differentiate those obtained for aerobic and anaerobic phases by delicately shading grey the cells containing the former.

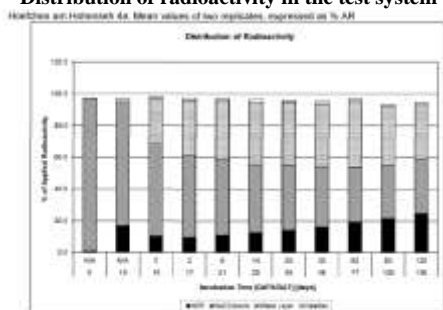

Table B.8.1.1.1.2._CA-17: The detailed results obtained for the test system with Hoefchen am Hohenseh 4a soil.

Distribution of radioactivity in the test system

Concentrations of identified compounds in function of time

Figure B.8.1.1.1.2._CA-18: The graphical presentation of the results obtained for the test system with Dollendorf II soil (schemes copied from the study report).

The results presented above show that, in line with the criteria set by SANCO/211/2000 Guidance Document on the Assessment of the Relevance of Metabolites, FOE Thiadone and Trifluoroacetic acid should be considered as major degradation products for the degradation of Flufenacet within Thiadiazole moiety in soil under anaerobic conditions. On the basis of the results obtained in this experiment the following transformation scheme for the [Thiadiazole-5-¹⁴C] Flufenacet was proposed by the Applicant (Figure B.8.1.1.2._CA-18). The scheme comprises processes occurring during both aerobic and anaerobic phases.

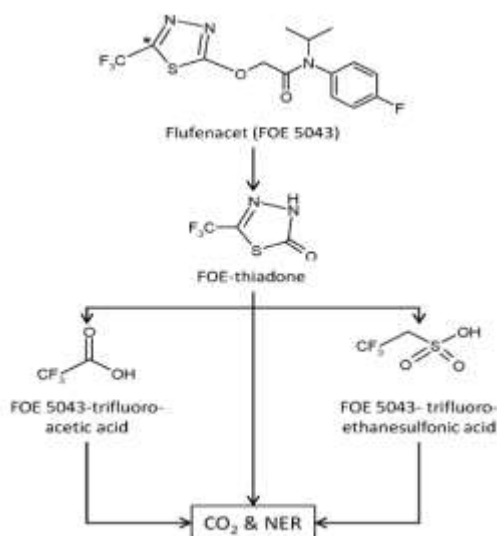

Figure B.8.1.1.2._CA-18: The proposed transformation scheme of [Thiadiazole-5-¹⁴C] Flufenacet in aerobic/anaerobic soil (scheme copied from the study report).

The kinetic analysis of the results of this study will be presented under the relevant point, further down this report – please refer to the point B.8.1.1.2.1.2.

Summary: degradation of flufenacet in soil under anaerobic conditions

The route of degradation of the acetanilide herbicide Flufenacet in anaerobic soil was examined in three soils – one from the US and two European. The test compound – Flufenacet, was radiolabelled in one of the following two positions:

- uniformly in phenyl ring – compound tested on one US soil,
- in position C5 of Thiadiazole moiety – examined in two EU soils.

The experiments performed to determine the transformation pattern of Flufenacet in soil under anaerobic conditions consisted of two phases – aerobic preincubation phase and anaerobic incubation phase. RMS decided to present the key results of the experiments taking into account both phases. In case of aerobic preincubation phase the results are given for the terminal time point of that phase.

The key results for the examination of transformation of Flufenacet in anaerobic soils in the area of formation of terminal degradation products – mineralisation expressed as CO₂ and NER fraction, are presented below in the table B.8.1.1.1.2._CA-19. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey. It shall be noted that under anaerobic conditions mineralisation, if occurred at all, was minimal. No other volatile compounds were identified during either aerobic or anaerobic phases. The level of NER formed under anaerobic conditions (net formation) was comparable to that observed in aerobic soils.

Table B.8.1.1.1.2._CA-19: The levels of the terminal degradation products – CO₂ and NER fraction formed in soil during examination of the transformation pattern of Flufenacet in soil under anaerobic conditions.

Study/ radiolabelling position	Soil		Results obtained for aerobic phase		Results obtained for anaerobic phase ¹⁾					
	Name	Type (USDA)	CO ₂ [%AR] – end of phase	NER [%AR] – end of phase	Mineralisation level – CO ₂ formed [% AR]			NER level [% AR]		
					Beginning of phase	Max.	Net anaero- bic ²⁾	Beginning of phase	Max.	Net anaero- bic ³⁾
Pangilinan & Smith [1994]/ ¹⁴ C-phenyl	Howe	Sandy loam	1.4 (DAT 30)	8.4 (DAT 30)	1.4 (DAT 30 DAF 0)	1.8 (DAT 210 DAF 180)	0.4	8.4 (DAT 30 DAF 0)	32.6 (DAT 210 DAF 180)	24.2 (DAT 210 DAF 180)
Heinemann [2012]/ ¹⁴ C-5- Thiadiazole	HH ⁴⁾	Silt loam	1.6 (DAT 15)	16.9 (DAT 15)	1.6 (DAT 15 DAF 0)	1.7 (DAT 105 DAF 90)	0.1	10.2 (DAT 15 DAF 0)	24.5 (DAT 135 DAF 120)	14.3 (DAT 135 DAF 120)
	DD ⁵⁾	Loam	1.9 (DAT 15)	10.1 (DAT 15)	1.8 (DAT 15 DAF 0)	1.9 (DAT 105 DAF 90)	<0.1 ⁶⁾	8.6 (DAT 15 DAF 0)	31.6 (DAT 135 DAF 120)	23.0 (DAT 135 DAF 120)

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase. In case of soils HH and DD they are different, because there were available the results obtained immediately after generating the anaerobic conditions;
- 2) "Net anaerobic" is a difference between the total amount of CO₂ formed and that determined in aerobic traps for volatiles;
- 3) "Net anaerobic" is a difference between maximum determined level of NER and that measured at the beginning of anaerobic phase;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) At the time point where maximum CO₂ level of 2.0% AR was recorded, the amount recovered for aerobic volatile traps was 1.9% AR and from anaerobic volatile traps <0.1 AR. The slightly higher total amount may be due to either rounding or losses during extraction. In that soil the level of mineralization, expressed as recovered CO₂ in anaerobic phase was <0.1% AR;

The examination of the extracted fraction enabled the identification of one new degradate, not identified in aerobic soils – FOE Thioglycolate. All other identified degradation products were those already found in aerobic soils. On that basis it can be stated that the transformation pattern of Flufenacet in soil under anaerobic conditions would not differ significantly from that determined in aerobic soils. The key results of the profiling of degradation products in anaerobic soils are presented below in table B.8.1.1.1.2._CA-20. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey.

Table B.8.1.1.2_CA-20: The results of the profiling of Flufenacet and its degradation products.

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase. In case of soils HH and DD they are different, because were available the results obtained immediately after generating the anaerobic conditions;
- 2) "Net anaerobic" is a difference between the maximum amount determined in anaerobic phase and that at its beginning;
- 3) FOE TGS – FOE Thioglycolate sulfonate;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) Flufenacet is the active substance, therefore not forming in soil. For that reason its concentration at the end of incubation period is given to show the level of decline;
- 7) In that soil the concentrations of FOE Trifluoroethane sulfonic acid initially decreased, to increase afterwards reaching maximum on the indicated time point. It was assumed that this maximum can be attributed totally to the amount of that compound formed under anaerobic conditions;
- 8) N/A – not applicable (parent compound);

The results of the determination of transformation pathway of Flufenacet in anaerobic soil demonstrated that it would not significantly differ, qualitatively and quantitatively, from that observed in aerobic soil.

The degradation products that may require further consideration for the risk assessment are the same as identified during examination of the degradation pattern of Flufenacet in aerobic soil: FOE Oxalate, FOE Thiadone and Trifluoroacetic acid. The proposed whole transformation pattern determined during examination of degradation of Flufenacet in anaerobic soil, is presented below on figure B.8.1.1.2_CA-20.

Route of degradation (anaerobic) in soil (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.2)

B.8.1.1.1.3. – Soil photolysis

For the purpose of the former evaluation of Flufenacet for its authorisation in the EU the Applicant submitted one study examining photodegradation of that compound on the soil surface. That study Flufenacet used as the test compound was uniformly radiolabelled in the phenyl ring. The study was found acceptable and briefly summarised in the assessment Report for Flufenacet prepared by the then-RMS – France. For the purpose of the current assessment the study was re-evaluated for its compliance with the current Guidelines and is summarised below as *Study 1*.

That study however did not address the issue of would-be phototransformation within the Thiadiazole moiety. To fill that GAP the Applicant submitted a study on soil photolysis of FOE-Thiadone. According to the Applicant, the study was performed on the request of US EPA, but in the EU it is evaluated for the first time, therefore it was considered a newly submitted study. It was evaluated and is summarised below as *Study 2*.

Study 1:

Report: Kasper A. M., Shadrack B. A., (1995): “Photolysis of [Phenyl-U-¹⁴C] FOE 5043 on Sandy Loam.”; Bayer Corporation (formerly Miles Inc.), Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3082101/F3082102 (Bayer); unpublished Miles Report No. MR 106247; 22 June 1995; study reference number: M-002145-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-3, Soil Photolysis Study.

GLP: Yes

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its summary can be found under the point B.7.1.1.2.2.1., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-3, Soil Photolysis Study (indicated as reference Guideline in the study report);
- US EPA Guideline OPPTS 835.2410 – Photodegradation on Soil;
- SETAC Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides, Part 1 – Fate and Behaviour in the Environment, chapter 2: Soil Photolysis, SETAC 1995;
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals on Soil Surface, Draft Document January 2002 (additional reference document);

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable and is summarised below.

Summary:

The aim of the study was to examine photodegradation of Flufenacet in soil surface through:

- a) determining the half-life of that compound when exposed to artificial sunlight;
- b) identifying the transformation pattern and in particular the degradation products formed in amounts greater than 10% AR.

The test soil used in the experiment was Howe Sandy loam soil, used also to examine the route of degradation of Flufenacet in aerobic and anaerobic soil. The characteristic of the test soil, as provided in the study report, is given below, in table B.8.1.1.1.3._CA-1. RMS noted that the test soil was Sandy loam, according to USDA classification. SETAC Guidelines and Draft OECD Guideline recommend to use Silty loam or Clay loam soil rather than any Sandy soil. On the other hand, according to these Guidelines, the test soil used in the experiment should be one of those used in the examination of transformation of the test compound in aerobic soils.

The US Guidelines list sandy loam soil as one of the recommended test soils, also indicating that the test soil should be the same as used to examine the transformation of the test compound in soil under aerobic conditions. As a result, it can be stated that the test soil, although being sandy soil, was selected correctly, in line with the provisions of the current Guidelines.

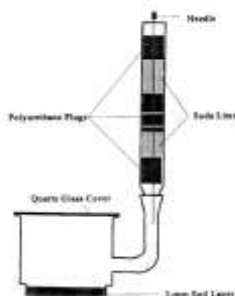

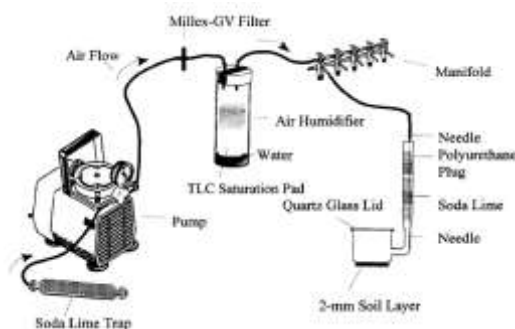

Table B.8.1.1.1.3._CA-1: The characteristic of soil used in the study.

Parameter	Soil:
Soil origin	Howe, Indiana, USA
Soil type (as reported in the study)	Shipshe Sandy loam
Soil type (USDA, calculated by RMS)	US Sandy loam
Particle size distribution	Sand [%]
	67.6
	Silt [%]
	20.0
	Clay [%]
	12.4
pH	6.4
Organic matter content (OM) [%]	1.16
Organic carbon content (C _{org}) [%] ¹⁾	0.67
Cation Exchange Capacity – CEC [mEq/100g]	5.44
Bulk density (disturbed) [g/cm ³]	1.62
Moisture holding capacity at ½ bar [%]	13.0
Soil microbial activity expressed as [CFU/g soil] ²⁾ at the beginning of the study (DAT 0)	2.3 E6

Footnotes to the table:

- 1) Value recalculated by the RMS from that reporting OM content given in the study report using the following equation: OM = 1.724 * OC;
 2) CFU/ g soil = Colony Forming Units/gram of test soil (determined using plate count agar method).

The test soil was sampled from 0-6 inch (0 – 15.24 cm) top layer, from the pesticide-free field (Bayer Research Farm in Howe, Indiana, USA). It was shipped to the test laboratory, placed outdoors and planted with alfalfa to maintain its microbiological viability until it was used. Immediately before the experiment began the test soil was taken to the laboratory where it was air-dried and sieved through a 2-mm sieve. Next its 3.1-g (d. w.) portions were placed in photolysis vessels presented below on figure B.8.1.1.1.3._CA-1. The amount of test soil per vessel was such, to obtain 2-mm thick soil layer. Each test vessels contained removable quartz glass cover and was equipped with a volatile trapping column, attached to the side-arm of the vessel, through which a needle was passed. The needle was joined to the air-humidifying apparatus, presented on figure B.8.1.1.1.3._CA-2. That way the adequate moisture content of the test soil was ensured, and hence its microbiological viability throughout incubation period.

**Figure B.8.1.1.1.3._CA-1:** Test vessel used in the experiment (copied from the study's report).**Figure B.8.1.1.1.3._CA-2:** The air-humidifying apparatus used to keep the test soil moist during the experiment (copied from the study's report).

The test compound was [Phenyl- $U\text{-}^{14}\text{C}$] Flufenacet, delivered in form of benzene stock solution, shown below on figure B.8.1.1.1.3._CA-3. It had a specific radioactivity of 66.5 mCi/mmol corresponding to 4.062 E5 dpm/ μg . The concentration of the stock solution was 11.82 mg Flufenacet/mL. Test compound was applied to the test soil in form of the **Application solution** prepared in 5 mL CH_3CN , containing 0.001278195 mmol of Flufenacet (0.085 mCi when expressed in specific radioactivity units). The nominal concentration of **Application solution** was 2.55639 E-4 mmol Flufenacet/mL (corresponding to 37,735,660.16 dpm/mL). The real concentration of **Application solution**, determined by LSC, was 37,970,325 dpm/mL, what corresponded to 2.57228 E-4 mmol Flufenacet/mL. Its radiochemical purity was 98.0% when determined by HPLC and 99.8% when determined by TLC.

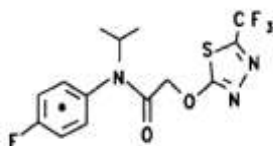

Figure B.8.1.1.1.3._CA-3: The structural formula of the test compound; radiolabelling position indicated with an asterisk (copied from the study report).

0.2 mL (7,594,065 dpm) of the **Application solution** was used to treat 3.1 g (d. w.) of soil in each photolysis vessel. The applicant declared that amount gave the application dose of 6.2 ppm Flufenacet, corresponding to application rate of ~0.9 lb/acre (~1008.55 g/ha – recalculated by RMS) assuming 1-cm soil layer. That value was verified by RMS and was demonstrated to be slightly lower – 6.03 ppm, what corresponded to 904.5 g/ha (~0.81 lb/acre), assuming the soil depth of 1 cm and soil bulk density of 1.5 g/cm³.

For standard EU assumptions with regard to calculation of application rate – soil layer depth of 5 cm and soil density (default) of 1.5 g/cm³, the application rate corresponding to application dose of 6.03 mg /kg would be **A = 4522.5 g/ha**.

The **Application solution** was applied to the soil surface using 0.25-mL Hamilton syringe. Solvent – acetonitrile was allowed to evaporate for 5 minutes. Then, to adjust soil moisture to the target value of **75% of ½ bar**, the appropriate amount of water (0.225 mL per test vessel) was added (it was assumed that ½ bar moisture is equivalent to field moisture capacity). Next vessels were covered with quartz glass covers, trapping columns attached and all joints sealed with Parafilm. The so prepared vessels were weighed and dark control samples wrapped with aluminium foil to exclude light.

In total twelve photolysis incubation vessels were prepared – 8 as irradiated samples and 4 as the dark controls.

Test vessels were placed in Suntest CPS unit, equipped with Heraeus xenon-arc lamp as light source. It is presented below on figure B.8.1.1.1.3._CA-4. The lamp was equipped with a UV-filter to cut-off all radiation below $\lambda = 290$ nm.

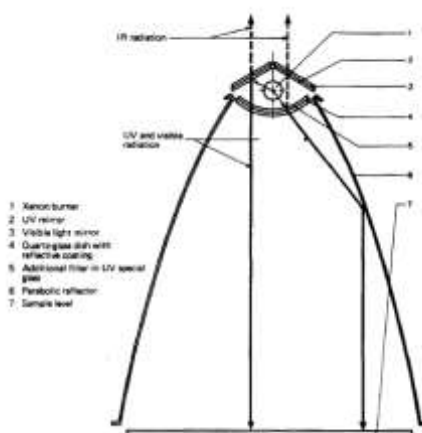

Figure B.8.1.1.1.3._CA-4: The Suntest CPS unit used in the experiment (copied from the study report).

The vessels were kept in the incubation chambers for up to 246 h, or 10.25 Suntest days (24-hours periods), under constant exposure to the light emitted by xenon-arc lamp. That exposure period was determined to match a 30-days exposure to sunlight at worst case conditions in Phoenix, Arizona. That estimate was based on the following assumptions:

- total irradiance <800 nm measured in a weather station in Phoenix, AZ (site: New River), on 23rd June 1988 was **681.7 W/m²** (68%),
- total radiant exposure measured at the same site on the same day was **29.5 MJ/m²**.

The calculated from these values daily “global irradiation” at noon on the 23rd June 1988 in Phoenix, AZ, was **20 MJ/m²**.

Using that value it was determined that simulating such irradiation conditions with Suntest unit operating at 680 W/m² would result in **8.2-h** exposure corresponding to one solar day under the worst case conditions assumed above. Using that value the time of irradiation corresponding to the required in Guidelines 30-days exposure to natural sunlight was determined.

The experiment was performed under the constant temperature of 25⁰C. Additionally, all test vessels – irradiated and dark controls (wrapped with aluminium foil to cut the light off), were placed in the water bath set to the constant temperature $T = 25 \pm 1^{\circ}\text{C}$.

The conditions in the irradiation chamber – temperature and light intensity were constantly monitored and recorded.

The samples were incubated for up to 10.25 days, period corresponding to 30 days of natural sunlight, calculated using the assumptions presented above. At designated sampling points two irradiated and one dark-control samples were taken for analysis. The sampling protocol (sampling dates and number of samples collected at each time point) is provided below in the table B.8.1.1.1.3._CA-2.

Table B.8.1.1.1.3._CA-2: The sampling protocol used in the study.

Sampling interval	Sampling time for:			Samples collected – type and number
	Suntest unit (real sampling dates)		Natural sunlight (calculated) [days]	
	[hours]	[days]		
1	0	0	0	Irradiated samples – 2 vessels; dark control – 1 vessel;
2	66	2.75	8	Irradiated samples – 2 vessels; dark control – 1 vessel;
3	123	5.13	15	Irradiated samples – 2 vessels; dark control – 1 vessel;
4	186	7.75	22.7	Irradiated samples – 2 vessels; dark control – 1 vessel;
5	246	10.25	30	Irradiated samples – 2 vessels; dark control – 1 vessel;

After sample removal, at specified sampling intervals, from the incubation/irradiation chamber, tower traps for volatile compounds removed and processed for the content of radioactivity. The test vessels were weighed and soil samples extracted entirely to characterise quantitatively and qualitatively the radioactivity in soil. The extraction procedure is presented schematically below on figure B.8.1.1.1.3._CA-5.

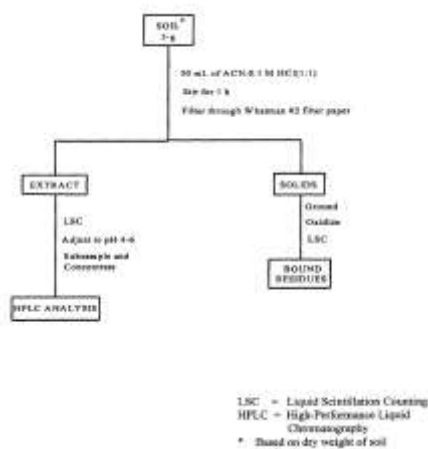

Figure B.8.1.1.1.3._CA-5: Soil extraction procedure used in the experiment (copied from the study report).

The collected extracts were concentrated and analysed by HPLC – method used for quantitation of extracted radioactivity and identification of extract's constituents, and TLC – conformatory method.

The extracted soil pellets were ground, oxidised and analysed by LSC for the content of radioactivity.

The collected traps for volatile compounds were analysed in a following way:

- Polyurethane plugs were removed, rinsed with 3 mL of CH_3CN and both rinse and the plug were analysed for the content of radioactivity using LSC;
- $^{14}\text{CO}_2$ captured in soda lime was liberated using the apparatus presented on figure B.8.1.1.3._CA-6. This was done by placing the whole 4-g portion of soda lime from each trapping column in 250-mL Erlenmeyer flask containing 10 mL of H_2O , to which 15 mL of concentrated HCl was added. The system was vented with N_2 and released $^{14}\text{CO}_2$ captured in a set of three scintillation vials, each containing 15 mL of scintillation cocktail – Carbo-Sorb E and Permafluor E⁺ 2:5 (v/v). The content of vials was analysed quantitatively by LSC.

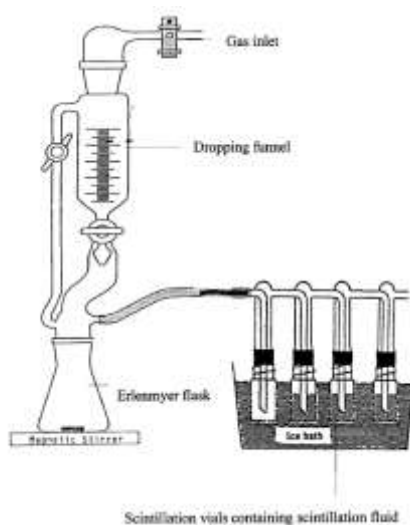

Figure B.8.1.1.3._CA-6: The apparatus used to liberate $^{14}\text{CO}_2$ from soda lime traps (copied from the study report).

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using a Packard Tri-Carb Model 4640 counter, equipped with automatic external standardisation.

Liquid samples were analysed in triplicate, with 15 of Ultima Gold solution added to 0.1-mL aliquots of the analysed sample. The minimum sensitivity of LSC analysis for those samples was $7.8 \text{ E-}4$ ppm. It corresponded to 60 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 30 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 30 cpm ($\text{LAGC} = 2 \times \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 9.54\%$.

Solid samples - ~100 mg aliquots, were oxidised using Packard Model 306 sample oxidizer. Generated $^{14}\text{CO}_2$ was trapped on 6 mL Carbo-sorb E and 15 mL Perma Fluor E⁺. The minimum sensitivity of LSC analysis for those samples was $7.8 \text{ E-}4$ ppm. It corresponded to 60 cpm when expressed as Lowest Acceptable Gross Count Rate (LAGC) and 30 cpm for Lowest Acceptable Net Count Rate (LANC), assuming Average Background (BCGK) of 30 cpm ($\text{LAGC} = 2 \times \text{BCGK}$ and $\text{LANC} = \text{LAGC} - \text{BCGK}$). The greatest probable error $\text{GPE} = 9.54\%$.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- TLC – conformatory method for the parent compound and its degradation products;
- LC-MS – conformatory identification method for parent compound and its degradation products.

The HPLC analysis was performed using a Shimadzu SCL-6A HPLC chromatograph coupled to Ramona 5-LS radioactivity monitor and Shimadzu SPD-6A UV detector set to $\lambda = 280 \text{ nm}$. The system was equipped with

PRP-1, 5 μ m, 150 x 4.1 mm chromatographic column (Hamilton Co., Reno) and PRP-1 cartridge as a guard column. The chromatographic separation was performed in a gradient mode, using the mobile phase consisting of:

- water + 0.4% CH₃COOH as **Solvent A**, and
- CH₃CN + 0.4% CH₃COOH as **Solvent B**.

Gradient elution lasted 90 minutes. Its parameters are shown below in the table B.8.1.1.1.3._CA-3. The flow rate was set to 2 mL/min.

Table B.8.1.1.1.3._CA-3: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH₃COOH</i>
0	100	0
0-15	Linear gradient	
15	70	30
15 - 65	Linear gradient	
65	40	60
65 - 70	Linear gradient	
70	0	100
70 - 80	0	100
80 - 90	Linear gradient	
90	100	0

The LOD for chromatographic method, in reference to the performance of the used radioactivity detector, was determined to be 4000 dpm, what corresponded to 1.0% AR. The value was determined experimentally on the basis of the comparison of radioactivity injected and integrated area under the chromatographic peak. The linearity of the analysis, expressed as r^2 , was: $r^2 = 1.00$. Sample recoveries from the column were on average 97.4%.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards. The retention times of the known reference standards are presented below in the table B.8.1.1.1.3._CA-4.

Table B.8.1.1.1.3._CA-4: HPLC identification of Flufenacet and its degradation products in the study.

Compound	HPLC identification – retention time (R_t) [min]:
<i>Flufenacet (FOE 5043)</i>	70.0
<i>FOE Alcohol</i>	33.7
<i>FOE Oxalate</i>	16 – 20 ¹⁾
<i>FOE Sulfonic acid</i>	18 – 23 ²⁾
<i>FOE Methylsulfoxide</i>	25.3
<i>FOE Methylsulfone</i>	38.4
<i>FOE 5043 N-isomer</i>	74.4

Footnotes to the table:

- 1) Due to the variability of R_t for that compound – it ranged from 16 min. to 20 min. overlapping the range of R_t for FOE Sulfonic acid, the co-chromatography was used to verify whether the compound was indeed present in the analysed sample;
- 2) Due to the variability of R_t for that compound – it ranged from 18 min. to 23 min. overlapping the range of R_t for FOE Oxalate, the co-chromatography was used to verify whether the compound was indeed present in the analysed sample.

The TLC analysis of the extracts was performed as RP-TLC (reversed phase TLC). It was carried out on Whatman KC₁₈F TLC plates, having a dimensions 20x20 cm and 200- μ m thick, with a fluorescent indicator. The solvent system used to develop the TLC plates was CH₃CN:CH₃OH:0.5N NaCl_{aq} 2:2:1 (v/v) solution. The identification of each individual constituent of the analysed extract was performed by means of the comparison of R_f values with those of the known standards. In case of Flufenacet the average $R_f = 0.52$.

The quantitative analysis was performed using RITA 68000 Radio-TLC analyser. The LOD of the method was experimentally determined to be 300 dpm, what enabled to detect the radioactivity residues at the level of at least 1 % AR. The linearity of the analysis, expressed as r^2 was: $r^2 = 0.9998$.

The LC-MS analysis was performed using Varian 5040 HPLC equipped with a Hamilton PRP-1 150 x 4.1 mm chromatographic column and Berthold LB 505-HPLC Radioactivity Monitor, coupled with Finnigan MAT 90 MS detector.

The parameters of gradient were following:

- **Mobile phase A:** Water,
- **Mobile phase B:** CH₃OH,
- **Gradient mode:** linear from 0% B at 0 min to 100% B at 30 min.

The flow rate was set to 0.8 mL/min.

The reported parameters of MS detector were following:

- Spectrometer operated in either positive or negative mode,
- aerosol temperature: 210⁰C,
- 0.2 M ammonium acetate added post column at rate of 0.2 mL/min.

The UV-Vis absorption spectra of Flufenacet were determined at different pH – pH = 5, pH = 7 and pH = 9, using Shimadzu UV 260 spectrometer with a slit of 0.8 nm. The absorption spectrum was scanned within the wavelength range of $\lambda = 190 - 400$ nm.

Results and their discussion:

The absorption spectrum of Flufenacet, recorded at various pH for the wavelength range of $\lambda = 190 - 400$ nm, is presented below on figure B.8.1.1.1.3._CA-7. It shows that the maximum absorption for the test compound occurred at $\lambda \approx 220$ nm and the effective absorption range may be estimated to occur within the range of $\lambda = 200 - 250$ nm. Within the environmentally relevant range of $\lambda = 290 - 400$ nm the absorption of radiation was residual, what may indicate that the direct photolysis of Flufenacet on the soil surface would be negligible.

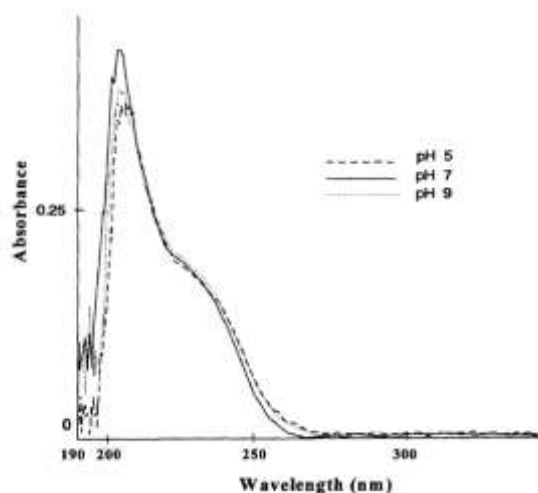

Figure B.8.1.1.1.3._CA-7: The UV-Vis absorption spectrum of Flufenacet recorded for $\lambda = 190 - 400$ nm (copied from the study report).

The examination of the microbial viability of the test soil showed that it was viable at the beginning of the study – it contained 2.3 E6 CFU/g. That parameter was not further examined.

The irradiated samples in the Suntest unit and dark control samples in the water bath were kept in the constant temperature $T = 25 \pm 1^{\circ}\text{C}$. The dark control samples in the Suntest unit were incubated at slightly lower temperature $T = 22 \pm 1^{\circ}\text{C}$. That slight -3°C , difference in incubation temperature of the two dark control samples sets was considered to have no impact on the obtained results.

The changes in the soil moisture of the samples were determined at sampling. That was done in order to check whether continuous purging of the photolysis vessels with humidified air to keep soil moisture at deserved level and by that maintain soil microbially active, was an adequate measure. The results are shown below in the table B.8.1.1.1.3._CA-5. They are presented as % change in soil moisture in comparison to the level determined on Day 0 of the incubation/irradiation. On their basis it can be stated that soil moisture was kept on the target, or even slightly higher, level, throughout the incubation phase in both irradiated and the dark control samples.

Table B.8.1.1.3_CA-5: The results of the determination of changes in soil moisture content during the experiment.

Sampling interval ¹⁾	Sampling time point		% change in soil moisture recorded in:	
	Suntest days	Natural sunlight days	Irradiated samples	Dark control
2	2.75	8.0	+12.5	+5.6
3	5.13	15.0	+12.2	+3.2
4	7.75	22.7	+8.6	+3.8
5	10.25	30.0	+9.4	+2.4

Footnotes to the table:

1) the results for sampling interval 1 – Day 0, are not given, as they serve as a reference point – 0% change;

The characteristics of the light source – xenon lamp, is presented below in graphical form on figures B.8.1.1.1.3_CA-8 – spectral irradiance graph, and B.8.1.1.1.3_CA-9 – comparison of spectral distribution of xenon lamp used in the experiment and that of the natural sunlight.

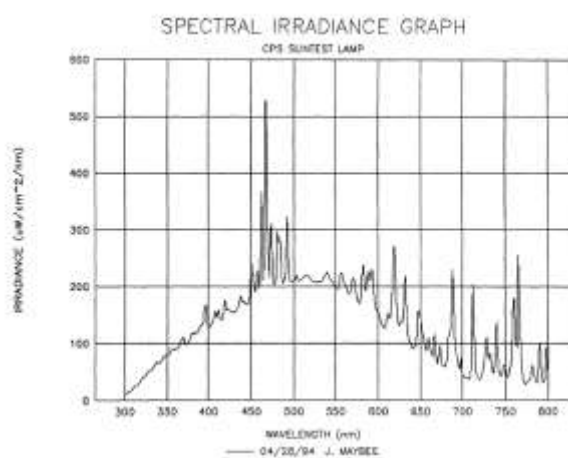

Figure B.8.1.1.3_CA-8: Spectral characteristic of the light source – xenon lamp, used in the study (copied from the study report).

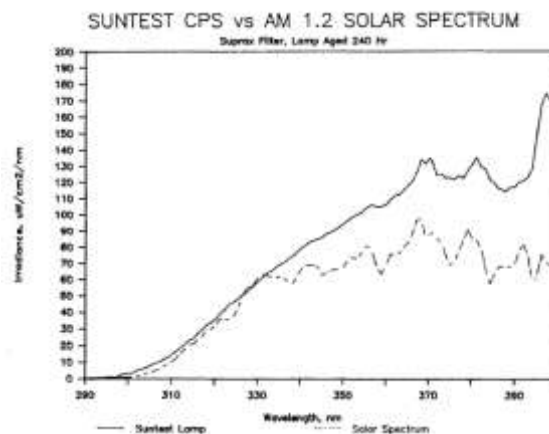

Figure B.8.1.1.3_CA-9: The comparison of the spectra of xenon lamp used in the study and of the natural sunlight (copied from the study report).

The quantitative analysis of extracts, extracted soil pellets and traps for volatile compounds, showed that the recovery of applied radioactivity throughout the study was within the recommended range:

- for irradiated samples it ranged from 98.6% AR to 102.7% AR;
- for dark control samples it was in range of 98.0 – 101.1% AR.

The recovered radioactivity was predominantly in form of extractable fraction, which slightly decreased during the experiment from 101.2% AR to 95.4% AR in irradiated samples and from 100.4% AR to 95.2 - 96.5% AR in the dark control. That decrease was correlated with increase of the amount of NER fraction formed during the experiment – up to 3.2% AR in irradiated samples and 4.4% AR in the dark control.

The level of mineralisation was not significant – 0.2% AR in irradiated samples and 0.1% AR in the dark control.

The decrease of the concentration of Flufenacet in the irradiated samples and in the dark control was comparable – from 98.4% AR at the beginning of the study to 91.2% AR at its end in irradiated samples and from 98.4% AR at the beginning of the study to 87.2% AR at its end in the dark control. The slightly faster decline in concentration of Flufenacet in the dark control samples may indicate that the degradation should be attributed rather to microbial degradation than light-induced transformation process, the conclusion drawn by the Applicant and presented in the study report.

The following degradation products were identified in both irradiated samples and dark control:

- FOE Oxalate,
- FOE Sulfonic acid,
- FOE Methylsulfoxide,
- FOE Alcohol,
- Flufenacet N-isomer.

In addition two “Unknown” fractions were found, not further identified because their concentrations at any sampling point in the study were <0.5% AR.

The compounds listed above were detected in both types of samples and in comparable amounts, what may indicate that the same transformation mechanisms were involved in degradation of Flufenacet in both irradiated and dark control samples. All that may indicate that photolysis on the soil surface is not a relevant mechanism of transformation of Flufenacet in soil. That conclusion was conformed by the results of the kinetic analysis presented in the study's report.

The detailed results of the experiment are presented below, in the table B.8.1.1.1.3_CA-6.

Table B.8.1.1.1.3_CA-6: The detailed results of the experiment.

AR		Results [%AR] obtained for:								
		Dark control samples – Suntest days					Irradiated samples – Suntest days (upper row) and Natural sunlight days ¹⁾ (bottom row)			
							0	2.75	5.13	7.75
Extracted		100.4	99.0	95.2	96.0	96.5	101.2	96.2	97.2	95.4

Footnotes to the table:

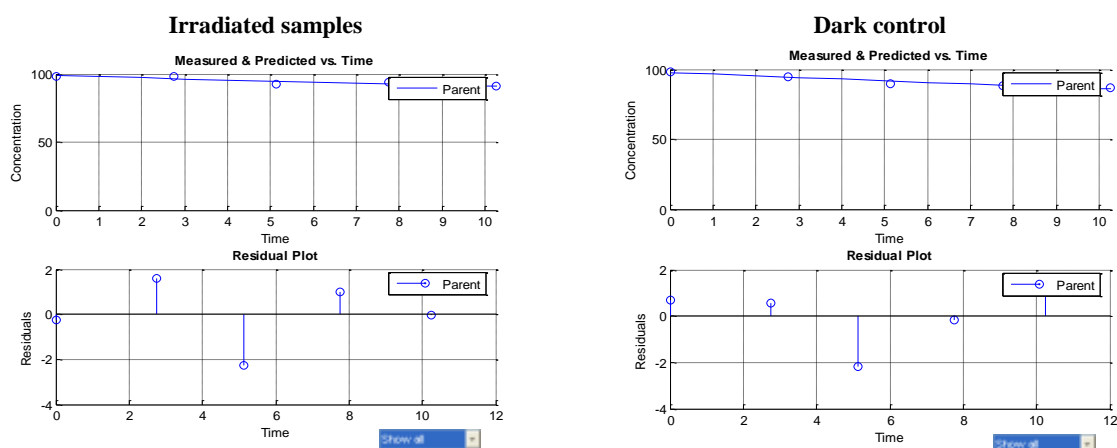

- 1) The Day 0 values for irradiated samples not reported here, as these are identical to those given for the dark control samples; all results for irradiated samples are the means of two replicates;
- 2) Sum of all volatiles as given in the study report;
- 3) n. d – not determined;
- 4) n. a. – not available, it was assumed that at the time point no volatiles would form;
- 5) n. an – not analysed, hence no value provided;
- 6) n. r – not reported; the analysis of the available results showed that the compound was not found in measurable amounts at that time point;

The data obtained for Flufenacet were further kinetically examined. The analysis was performed using first order kinetics and linear-regression model. As it does not comply with the current standards, set by FOCUS Kinetics Guidance (FOCUS, 2006) it was repeated by the RMS. It was performed using KinGUI 1.1 kinetic tool developed by Bayer. The input data used in the repeated kinetic analysis are presented below in the table B.8.1.1.1.3_CA-7. The analysis was performed using solely the SFO model.

Table B.8.1.1.1.3._CA-7: The data for Flufenacet used in the kinetic examination performed by RMS.

Irradiated sample			Dark control sample	
Time point [days]		Concentration of Flufenacet [% AR]	Time point [days]	Concentration of Flufenacet [% AR]
Suntest days (real time point)	Natural Sunlight Days (converted time point)		Suntest days (real time point)	
0.00	0.0	98.4	0.00	98.4
2.75	8.0	98.2	2.75	95.0
5.13	15.0	92.6	5.13	89.5
7.75	22.7	94.0	7.75	88.6
10.25	30.0	91.2	10.25	87.2

The results of the repeated kinetic analysis of the data obtained for Flufenacet are presented below in graphical form on figure B.8.1.1.1.3._CA-10 and in the numerical form in table B.8.1.1.1.3._CA-8.

**Figure B.8.1.1.1.3._CA-10:** The graphical results of the examination of the soil photolysis of Flufenacet.**Table B.8.1.1.1.3._CA-8:** The numerical results of the examination of the soil photolysis of Flufenacet.

Type of samples	Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2
					Lower	Upper			
Irradiated	SFO	M_0	98.670	1.355	94.359	102.982	-----	1.116	0.796
		k	0.0076	0.0022	5.3 E-4	0.0148	0.0209		
Dark control	SFO	M_0	97.723	1.2143	93.859	101.587	-----	1.027	0.923
		k	0.0124	0.0021	0.0059	0.0189	0.0046		

The degradation rate constant k was higher in the dark control than in irradiated sample, what indicated that in the dark control the degradation of Flufenacet was faster than in the sample exposed to the light. This was confirmed by the DT_{50} values calculated by the model, which were as follows:

- for irradiated sample $DT_{50} = 90.72$ days;
- for the dark control sample $DT_{50} = 55.90$ days

The more detailed results of the kinetic analysis of the data obtained for Flufenacet is presented further down the report, under the point B.8.1.1.2.1.3.

Conclusions:

On the basis of the obtained result it may be stated that Flufenacet is not prone to photolysis on the soil surface. The relevance of that process for the overall degradation of Flufenacet in soil is hence negligible.

Study 2:

Report: Lentz N. R., Bloomberg A. M., (2001): “Soil Photolysis of Thiadone on Loamy Sand (A Metabolite of FOE 5043).”; Ricerca LLC, Department of Environmental and Metabolic Fate, 7528 Auburn Road, Painesville, Ohio 44077, USA (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, MO 64120, USA; Ricerca document No. 7410-0055-EF-001, study No. F3082103 (Bayer); Bayer Report No. 108721; 21 June 2001; study reference number: M-106297-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-3, Soil Photolysis Study.

GLP: Yes;

RMS comments: This is a newly submitted study, the aim of which was to further examine the photolytic degradation of Flufenacet in soil through the determination of the would-be photodegradation of one of its major degradation products – FOE Thiadone. It was evaluated for its compliance with the following guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-3, Soil Photolysis Study (indicated as reference Guideline in the study report);
- US EPA Guideline OPPTS 835.2410 – Photodegradation on Soil;
- SETAC Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides, Part 1 – Fate and Behaviour in the Environment, chapter 2: Soil Photolysis, SETAC 1995;
- OECD Guidelines for the Testing of Chemicals, Proposal for a New Guideline – Phototransformation of Chemicals on Soil Surface, Draft Document January 2002 (additional reference document);

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable and is summarised below.

Summary:

The aim of the study was to examine photodegradation of FOE Thiadone – the metabolite of Flufenacet, on the soil surface through:

- a) determining the half-life of that compound when exposed to artificial sunlight;
- b) identifying the transformation pattern, and in particular the degradation products formed in amounts greater than 10% AR.

The test soil used in the experiment was loamy san soil from Janesville, Iowa, USA. That soil was declared to be also used to examine the rate of degradation FOE Thiadone in soil under aerobic conditions. Its characteristic, as provided in the study report, is given below, in table B.8.1.1.1.3._CA-9. RMS noted that the test soil was Loamy sand, according to USDA classification. SETAC Guidelines and Draft OECD Guideline recommend to use Silty loam or clay loam soil rather than any sandy soil. These Guidelines also recommend however, that the test soil should be the same as used in examination of the degradation of the test compound in soil under aerobic conditions. RMS stated that that requirement was fulfilled.

Additionally, the selected soil is admissible according to the provisions of US EPA Guideline OPPTS 835.2410 – Photodegradation on Soil, when cross-referenced to the US EPA Guideline OPPTS 835.4100 – Aerobic Degradation in Soil.

As a result, it can be stated that the test soil, although being sandy soil, was selected correctly, in line with the provisions of the current Guidelines.

The test soil was sampled from the area in Iowa, on which maize was grown and which was selected for monitoring of the residues of Flufenacet in GW compartment. In the study report it was declared to come from the field not being treated with any pesticide during the period 1995 - 1998. After being shipped to the test laboratory, the test soil was air-dried and sieved through 2-m sieve to remove all skeletal elements.

Table B.8.1.1.1.3._CA-9: The characteristic of soil used in the study.

Parameter	Soil:
Soil origin	Janesville, Iowa, USA
Soil type (as reported in the study)	Loamy sand
Soil type (USDA, calculated by RMS)	US Loamy sand
Particle size distribution	Sand [%]
	79.2
	Silt [%]
	12.0
	Clay [%]
	8.8
pH	7.2
Organic matter content (OM) [%]	1.91
Organic carbon content (C _{org}) [%] ¹⁾	1.11
Cation Exchange Capacity – CEC [mEq/100g]	5.64
Bulk density [g/cm ³]	1.34
Moisture holding capacity at ½ bar [%]	9.92
Soil microbial activity expressed as [CFU/g soil] ²⁾ determined:	at the beginning of the study (DAT 0)
	9.7 E6 – soil bacteria/ 0.12 E6 – soil fungi
	at the end of the study (DAT 14)
	13 E6 – soil bacteria/ 0.13 E6 – soil fungi

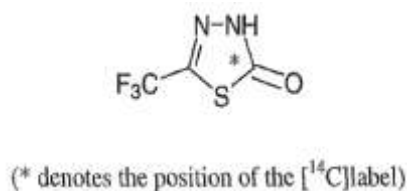

Footnotes to the table:

- 1) Value recalculated by the RMS from that reporting OM content given in the study report using the following equation: OM = 1.724 * OC;
 2) CFU/ g soil = Colony Forming Units/gram of test soil (determined using plate count agar method).

The experiment was performed in 59-mL (2 oz.) flint glass sample jars with either quartz glass lids (irradiated samples) or opaque screw caps (dark control samples). The number of these vessels was 36. To each of them were weighed 5-g. (d.w.) portions of the test soil, having a moisture content adjusted to 75% of ½ bar. These samples were treated with the test compound applied as **Application solution** characterised further down the report. The target application dose (theoretical) was 3.2 ppm – a half of the application dose of Flufenacet used in a previously summarised **Study 1**. 1 day later additional samples were prepared, assigned as A-H, micro1 and micro 2. They were treated in the same way as other samples in 59-mL flint glass jars.

Additionally, 4 separate samples were prepared for quantitation of volatile compounds formed during experiment (including CO₂). For that purpose were used larger flint glass jars, having a volume of 500 mL, also equipped with either quartz glass lids or opaque screw caps. To each of them was weighed 15-g. (d. w.) portion of the test soil, brought to a moisture content of 75% of ½ bar. These samples were treated with three times higher amount of the test compound, to obtain application dose of 9.6 ppm. The incubation vessels were equipped with modified lids/screw caps – in each were drilled two 1/8 inch (3.175 mm) holes, through which the incubation vessel was attached to the device collecting volatile compounds.

The test compound was [2-¹⁴C]-Thiadone, having a specific activity of 50 mCi/mmol, corresponding to 652680 dpm/μg. It was provided in form of a solution in acetone (**Stock solution**), having a volume of 9 mL and containing 6 mCi (0.12 mmol) of the test compound. **Stock solution** was shipped and stored frozen until being used. The structural formula of the test compound, with radiolabelling position indicated by an asterisk, is presented below on figure B.8.1.1.1.3._CA-11.

**Figure B.8.1.1.1.3._CA-11:** The structural formula of [2-¹⁴C]-Thiadone used in the experiment (copied from the study report).

Stock solution was used to prepare the a **Application solution**, used to treat soil in test vessels. To do that 650 μL of the **Stock solution**, containing 1.690 mg of FOE Thiadone, was transferred to 25-mL volumetric flask, evaporated to dryness under the stream of N₂, and the residue redissolved in 2.5 mL of CH₃CN. The solution was brought to volume with HPLC grade water and analysed by LSC to determine its exact concentration. Additionally the HPLC analysis (with LSC detection) was performed to determine the radiopurity of the so prepared **Application solution**. Its measured concentration was 16.9 μg/250 μL (11,030,600 dpm/250 μL) and radiochemical purity 95.3%.

The 250- μ L aliquots of so prepared **Application solution** were used to treat soil in each of the 36 sample jars. It was dispensed to the soil surface using 250- μ L Hamilton gas-tight syringe. The amount of the **Application solution** added to each jar was such to obtain the fortification level of 3.2 ppm FOE Thiadone. That value was calculated using the following assumptions: 100% conversion of Flufenacet to Thiadone, application dose for Flufenacet (from **Study 1**) of 6.9 ppm, molecular weight of Flufenacet $M = 363$ g/mol and that of FOE Thiadone $M = 170$ g/mol.

All samples designated to be irradiated were sealed immediately after treatment with quartz lids weighed and placed in the water bath set to $T = 20 \pm 1^\circ\text{C}$ in irradiation chamber. The dark control samples immediately after being treated with the test compound were sealed with opaque screw caps, weighed and stored in the dark at $T = 20 \pm 1^\circ\text{C}$ until being analysed.

The Day-0 samples were extracted immediately after treatment with the test compound.

Four larger samples, designated for determination of the volatile compounds, were treated each with 750 μ L of the **Application solution**. Two of them were then immediately sealed with drilled quartz glass lids, attached to the flow-through devices collecting volatile compounds and placed in the water bath set to $T = 20 \pm 1^\circ\text{C}$ in irradiation chamber. Two remaining samples, serving as dark controls, were also sealed immediately after treatment with opaque screw caps, attached to the devices collecting volatile compounds and placed in the dark under the constant temperature $T = 20 \pm 1^\circ\text{C}$.

The device for collecting volatile compound consisted of:

- a small pump pumping moisturized air thorough each sample placed at the beginning of the inlet branch (common for all samples);
- Carbotrap™ 400 cartridge, collecting VOC fraction, followed by three traps filled each with ~ 100 mL of 1N NaOH_{aq} to collect formed CO_2 , at the end of the outlet branch (separate for each vessel).

All samples designated to be irradiated were placed on a fibreglass tray filled with water up to the level of 2.54 cm. Water continuously circulated, at rate 15 L/min through a constant-temperature bath set to $T = 20 \pm 1^\circ\text{C}$. The area on which they were placed was ~ 50.8 cm in diameter, irradiated by a Xenon lamp (artificial light source). Samples were rotated at each sampling point in order to equalize the amount of radiation received by each of them. The samples were irradiated for up to 14 days in 12-hours light/12-hours darkness regime.

The light source used in the experiment was a 5000-W Xenon lamp, emitting light in range of $\lambda > 290$ nm – a range of natural sunlight reaching the soil surface. Lower wavelengths were eliminated using appropriate filters. It was monitored for the intensity of light emitted within the range of $\lambda = 250 - 750$ nm, subsequently compared to the intensity of the natural sunlight recorded for Painesville, OH, in June.

The design of the irradiation device used in the experiment is shown below on figure B.8.1.1.1.3._CA-12.

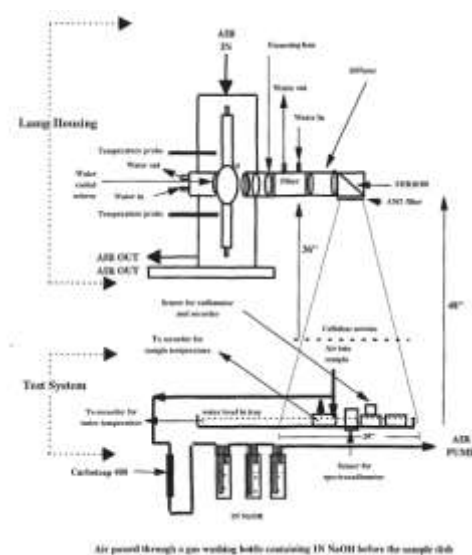

Figure B.8.1.1.1.3._CA-12: The schematic presentation of the photolysis system used in the experiment (copied from the study report).

At the designated time points – Day 0.5, Day 1, Day 2, Day 3, Day 5, Day 7, Day 10 and Day 14, duplicate irradiated and dark-control samples were taken for further analysis. On the same time points the alkaline solutions from CO_2 -traps were taken for analysis after being replaced with fresh portions of 1N NaOH_{aq} . The

Carbotrap cartridges for collecting VOCs were changed and analysed on the following sampling points: Day 3, Day 7, Day 10 and Day 14.

Soil from each sample collected at the designated time-points listed above was processed and analysed quantitatively and qualitatively for residues of [^{14}C] Thiadone using the analytical procedure presented below on figure B.8.1.1.1.3._CA-13. The 5-g portions of test soils were taken for the analysis.

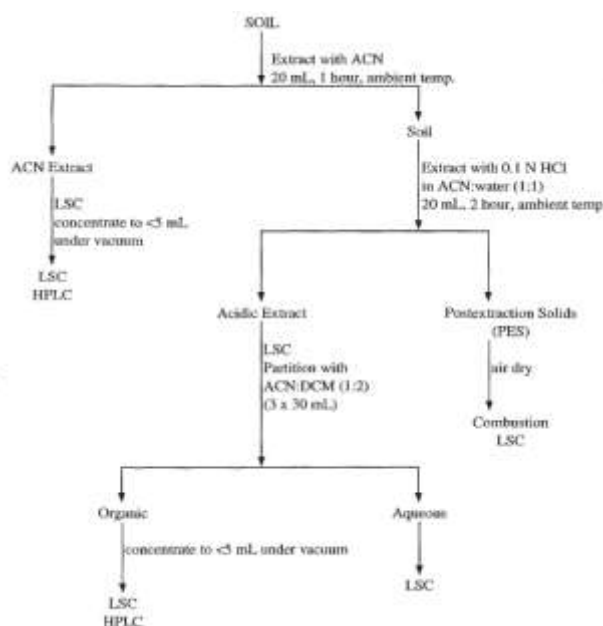

Figure B.8.1.1.1.3._CA-13: The sample-processing procedure used in the experiment (copied from the study report).

The extracted soil pellets were allowed to air dry at ambient temperature, ground and their three 500-mg aliquots analysed after combustion for radioactivity content.

The collected VOC-traps was analysed, after combustion of their content, for captured radioactivity using LSC method.

The radioactivity trapped in each alkaline trap for $^{14}\text{CO}_2$ was determined by LSC. That was done in 2-mL aliquots to which 10 mL of liquid scintillation cocktail was added. The conformation of that trapped radioactivity was $^{14}\text{CO}_2$, was done in a following way:

- the content of alkaline traps for $^{14}\text{CO}_2$ collected at each sampling point was pooled;
- next to its 2-mL aliquots was added 5 mL of 5% BaCl_2 /5% NH_4Cl aqueous solution;
- sample was then thoroughly mixed and formed solid precipitated by centrifugation;
- finally supernatants analysed by LSC.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using either Tractor Mark V Model 5303 LS counter or Beckman LS 6500 counter.

Liquid samples were analysed in duplicate with 5 mL or 10 mL of Ultima Gold liquid scintillation cocktail. The counting of each analysed sample lasted for 2 minutes. The detection limit was calculated to be 87 dpm with 95% confidence level. The average background level was set to 38 dpm.

Solid samples (500-mg aliquots) were analysed in triplicate by their combustion in biological oxidiser. The evolved $^{14}\text{CO}_2$ was trapped in 20 mL of Carbon 14 Cocktail and counted by LSC. The results were corrected for oxidiser efficiency, determined to be in range of 95-102%.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- LC-MS – conformatory identification method for parent compound and its degradation products.

The HPLC analysis was performed using a Waters™ HPLC system equipped with autosampler, Tunable Absorbance Detector and fraction collector, coupled to one of the following LSC detectors:

- Radiomatic A-500 Radio-chromatography Detector;
- IN/US β -RAM Radio-HPLC Detector.

The system was equipped with Phenomenex Luna™, 5 μ m C18, 150 x 4.6 mm chromatographic column and Zorbax® Rx-C18 10 x 4.6 mm guard column. The chromatographic separation was performed in a gradient mode, using the mobile phase consisting of:

- water + 0.4% CH₃COOH as **Solvent A**, and
- CH₃CN + 0.4% CH₃COOH as **Solvent B**.

Gradient elution lasted 70 minutes. Its parameters are shown below in the table B.8.1.1.1.3._CA-9. The flow rate was set to 1.0 mL/min.

Table B.8.1.1.1.3._CA-9: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.4% CH₃COOH</i>
0	100	0
0 – 40	Linear gradient	
40	30	70
40 – 60	Hold	
60	30	70
60 – 61	Gradient	
61	100	0
61 – 70	100	0

The minimum detection limit for HPLC method was 300 dpm and its linearity, expressed as r^2 , was: $r^2 = 0.99$. The average recovery of the chromatographed samples was 97.1%.

Using these values, the LOD for CH₃CN extracts, when 50- μ L sample was injected onto chromatographic column, was 0.6% AR. For CH₃CN/0.1N HCl extracts (the same analysed volume) the LOD was 2.8% AR.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards.

The LC-MS analysis was performed using Finnigan SSQ710 LC/MS device equipped with a Phenomenex Columbus 5 μ m C8 100 x 2 mm LC column. The chromatographic analysis was carried out in a gradient mode. Its parameters were following:

- **Mobile phase A:** 0.05% HCOOH in Water,
- **Mobile phase B:** CH₃OH,
- **Gradient mode:** A/B 1:1 hold 2 min to A/B 3:7 at 8 min, or A/B 100:0 hold 1 min to A/B 1:1 at 5 min.

The flow rate was set to 0.2 mL/min.

The reported parameters of MS detector were following:

- Ionization mode: (-)ESI;
- Mass range: 115 – 300 amu;
- Scan rate: 1.5 sec/scan;
- Source temperature: 220°C;
- ESI spray voltage: 4.0 kV.

The UV-Vis absorption spectrum of Thiadone was determined using GBC 918 UV-Vis spectrometer with a slit of 2 nm. The absorption spectrum was scanned within the wavelength range of $\lambda = 200 - 800$ nm at a scanning rate 720 nm/min.

Results and their discussion:

The absorption spectrum of FOE Thiadone recorded for the wavelength range of $\lambda = 200 - 800$ nm is presented below on figure B.8.1.1.1.3._CA-14. It shows that the effective absorption occurred within the wavelength range of $\lambda = 200 - 270$ nm. Within the environmentally relevant range of $\lambda = 290 - 800$ nm it was residual, although some absorption was observed at $\lambda = 290$ nm. That, according to the Applicant, possibly explained the observed slight enhancement of degradation of Thiadone in irradiated samples.

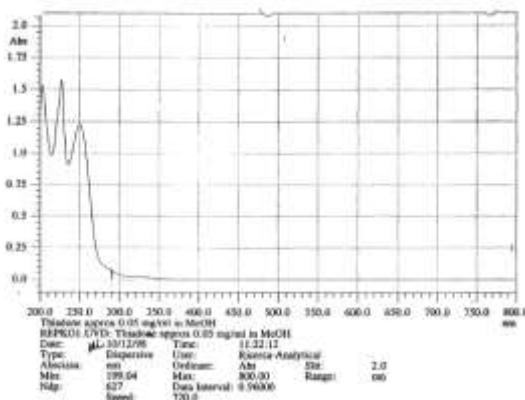

Figure B.8.1.1.3._CA-14: The UV-Vis absorption spectrum of FOE Thiadone recorded for $\lambda = 200 - 800$ nm (copied from the study report).

The examination of the microbial viability of the test soil showed that it was viable at the beginning of the study – it contained 9.7 E6 CFU/g of bacteria and 0.12 E6 CFU/g of fungi. It was demonstrated to be biologically viable throughout the study – measured at the end of irradiation/incubation content of bacteria was 13 E6 CFU/g and that of fungi – 0.13 E6 CFU/g of fungi.

The monitoring of incubation temperature showed that both irradiated and dark control samples were kept in the constant temperature $T = 20 \pm 1^\circ\text{C}$.

The changes in the soil moisture of the samples were determined at sampling. That was done in order to check whether continuous purging of the photolysis vessels with humidified air, to keep soil moisture at deserved level and by that maintain it microbially active, was an adequate measure. The results are shown below in the table B.8.1.1.3._CA-10, as % change in soil moisture in comparison to the level determined on Day 0 of the incubation/irradiation. On their basis it can be stated that soil moisture was kept on the target level throughout the incubation phase in both irradiated and the dark control samples.

Table B.8.1.1.3._CA-10: The results of the determination of changes in soil moisture content during the experiment.

Sampling interval ¹⁾	Sampling time point	% change in soil moisture recorded in:			
		Irradiated samples		Dark control	
		Replicate 1	Replicate 2	Replicate 1	Replicate 2
2	Day 0.5	+4.33	+7.38	-0.13	not recorded
3	Day 1	not recorded	not recorded	not recorded	not recorded
4	Day 2	-0.40	+2.95	-0.43	-0.34
5	Day 3	+2.78	+3.56	-0.19	-0.69
6	Day 5	-0.15	+3.80	+4.56	-0.35
7	Day 7	not recorded	+3.16	+0.09	+0.69
8	Day 10	+2.54	+2.27	-0.34	-0.37
9	Day 14	not recorded	not recorded	not recorded	not recorded

Footnotes to the table:

1) The results for sampling interval 1 – Day 0, are not given, as they serve as a reference point – 0% change;

The characteristics of the light source – xenon lamp, is presented in a graphical form on figure B.8.1.1.3._CA-15 (comparison of spectral distribution of xenon lamp used in the experiment and natural sunlight).

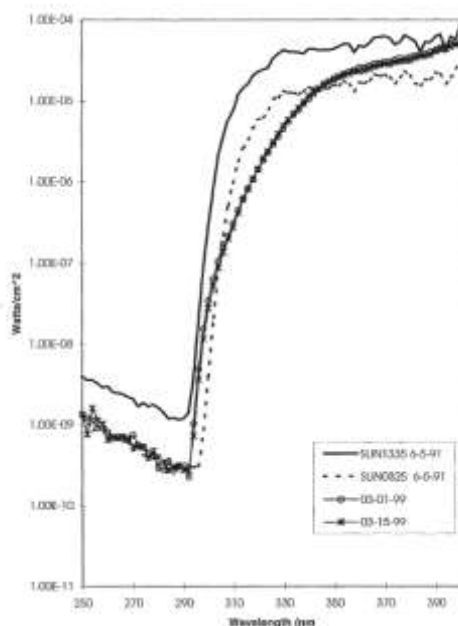

Figure B.8.1.1.1.3_CA-15: The comparison of the spectra of xenon lamp used in the study and of natural sunlight (copied from the study report).

The quantitative analysis of extracts, extracted soil pellets and traps for volatile compounds showed that the recovery of applied radioactivity throughout the study was within the recommended range:

- for irradiated samples it ranged from 93.8 – 102.1% AR, with mean recovery 97.7% AR;
- for dark control samples it was in range of 93.1 – 102.1% AR with mean recovery 97.9% AR.

The level of radioactivity extracted from soil decreased with time:

- in irradiated samples from 101.6% AR on Day 0 to 14.5 %AR on Day 14;
- in dark control samples from 101.6% AR on Day 0 to 17.3 %AR on Day 14.

It was correlated with the formation of volatile compounds, mainly CO₂, detected on Day 14 in amounts:

- 62.5% AR (total volatiles) in irradiated samples;
- 60.1% AR (total volatiles) in dark control samples.

It was also correlated with the formation of NER fraction, comparable in irradiated and dark control samples.

It reached the maximum level on DAT 10:

- 21.2% AR in irradiated samples,
- 17.1% AR in the dark control samples.

After that time point a slight decrease was observed.

The decrease of the concentration of FOE Thiadone in the irradiated samples and in the dark control was comparable, and looked as follows:

- for irradiated samples from 96.7% AR at the beginning of the study to 7.2% AR at its end (Day 14);
- for the dark control samples 96.7% AR at the beginning of the study to 13.3% AR at its end (Day 14).

The slightly faster decline in concentration of FOE Thiadone in the irradiated samples may be due to residual light absorption at $\lambda = 290$ nm, but in general it may be stated that the degradation should be attributed rather to microbial degradation than light-induced transformation process. Such conclusion was drawn by the Applicant and presented in the study report.

Apart from FOE Thiadone following compounds were identified in both irradiated samples and dark control:

- propionic acid conjugate of FOE Thiadone,
- Other fraction,
- fortification impurity (1),
- fortification impurity (2).

Propionic acid conjugate of FOE Thiadone was detected in higher amounts in dark control samples while the levels of the other fractions detected were comparable. That may indicate that the same transformation mechanisms were involved in degradation of FOE Thiadone in both irradiated and dark control samples. Therefore, photolysis on the soil surface does not seem to be a relevant mechanism of transformation of FOE

Thiadone in soil. That conclusion was conformed by the results of the kinetic analysis presented in the study's report.

The detailed results of the experiment are presented below, in two tables: B.8.1.1.1.3_CA-11 for irradiated samples and B.8.1.1.1.3_CA-12 for the dark control.

Table B.8.1.1.1.3_CA-11: The detailed results of the experiment obtained for irradiated samples.

AR		Results [%AR] obtained for the sampling time point ¹⁾ :

The data obtained for FOE Thiadone were further kinetically examined. The analysis was performed using first order kinetics and linear-regression model. As it does not comply with the current standards, set by FOCUS Kinetics Guidance (FOCUS, 2006) it is not presented here.

Instead RMS performed its own kinetic analysis of the data using KinGUI 1.1 kinetic tool developed by Bayer. The input data used in that analysis, identical with those used by the Applicant in the original study report, are presented below in the table B.8.1.1.1.3._CA-13. The average values were used in the fitting.

Table B.8.1.1.1.3._CA-13: The data for FOE Thiadone used in the kinetic examination performed by RMS.

Time point	Concentration of FOE Thiadone in:					
	Irradiated samples			Dark control samples		
	Replicate 1	Replicate 2	Average	Replicate 1	Replicate 2	Average
Day 0	96.52	96.92	96.7	96.52	96.92	96.7

The results of the repeated kinetic analysis of the data obtained for FOE Thiadone are presented below in graphical form on figure B.8.1.1.1.3._CA-16 and in the numerical form in table B.8.1.1.1.3._CA-14. Only results obtained using SFO model are presented. The detailed results of the kinetic analysis of the results of the study are provided under the point B.8.1.1.2.1.3.

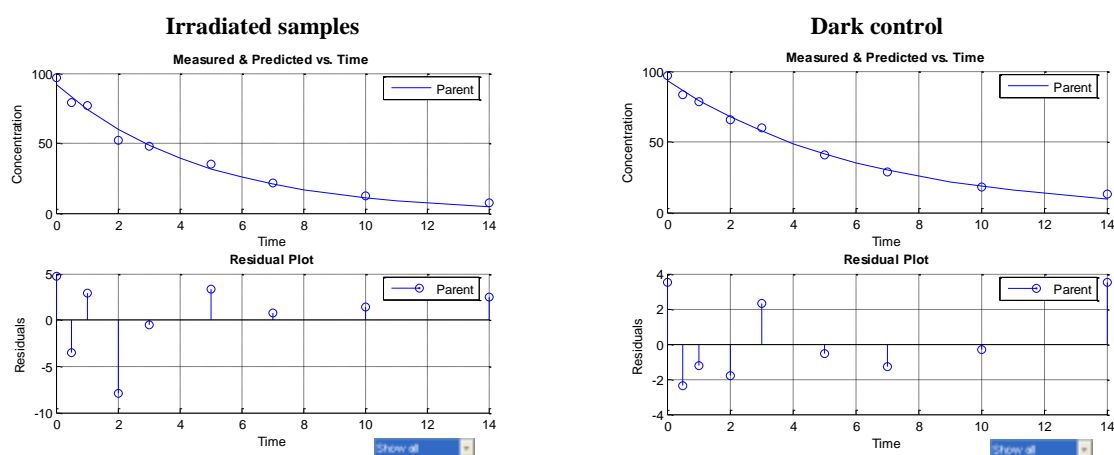

Figure B.8.1.1.1.3._CA-16: The graphical results of the examination of the soil photolysis of FOE Thiadone.

Table B.8.1.1.1.3._CA-14: The numerical results of the examination of the soil photolysis of FOE Thiadone.

Type of samples	Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2
					Lower	Upper			
Irradiated	SFO	M_0	91.999	2.887	85.174	98.826	----	6.250	0.985
		k	0.2120	0.0162	0.1736	0.2503	1.8 E-6		
Dark control	SFO	M_0	93.209	1.580	89.474	96.943	----	3.229	0.994
		k	0.1612	0.0070	0.1447	0.1776	3.6 E-8		

The degradation rate constant k was slightly higher in the irradiated samples than in the dark control, what indicates that in former samples the degradation was faster. That was conformed by the DT_{50} values calculated by the model, which were as follows:

- for irradiated sample $DT_{50} = 3.27$ days;
- for the dark control sample $DT_{50} = 4.30$ days

That phenomenon may be partly attributed to the fact that the residual absorption was observed for FOE Thiadone at $\lambda = 290$ nm. At the same time it was noted that dark controls were drier than irradiated samples, what may have influenced the activity of soil microorganisms and hence slow down the degradation of the test compound. It shall be also noted that the difference in DT_{50} values was not that significant to indicate substantial contribution of phototransformation processes to the degradation of FOE Thiadone in soil. Finally, the comparison of the metabolite profiles in irradiated and dark control samples does not seem to indicate that light-induced processes played a significant, if any, role in degradation of FOE Thiadone on the soil surface.

Conclusions:

On the basis of the obtained result it may be stated that FOE Thiadone may be prone to some photolysis on the soil surface, but the process is not expected to significantly contribute to the degradation of that compound in soil. It shall also be pointed out that the probability that FOE Thiadone occurs in significant amounts on the soil surface is minimal and hence the relevance of soil photolysis for the overall degradation of FOE Thiadone in soil should be considered negligible.

Summary: Photodegradation of Flufenacet on soil surface

The soil photolysis of Flufenacet was examined in one soil – US Sandy loam, using the test compound radiolabelled in one position – uniformly at phenyl ring. The experiment was performed using soil that was demonstrated to be biologically viable throughout the whole irradiation/incubation period. Samples were irradiated with artificial light (Xenon lamp) continuously for 10.25 days, corresponding to 30 days of natural summer sunlight (conditions relevant for Phoenix, Arizona, USA). The key results of the examination are presented below in the table B.8.1.1.1.3_CA-15.

Table B.8.1.1.1.3_CA-15: The key results obtained for Flufenacet in soil photolysis study

Parameter		Results obtained for:	
		Irradiated sample	Dark control
Terminal transformation products	Mineralisation (CO ₂) at the end of the study	0.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	0.1% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	Max. NER level	3.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	4.4% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾

Kinetics of the process	rate constant k [days ⁻¹]	0.0076	0.0124
	DT_{50} [days]	90.72	55.90

Footnotes to the table:

- 1) N-isomer of Flufenacet (for the structural formula, please refer to the table in Appendix 1 - List of Evaluated Compounds;
- 2) DAT stands for Days After Treatment, the real sampling point in the experiment;
- 3) DNS – Days of Natural Sunlight, the sampling point related to the Natural Summer Day sunlight conditions in Tucson Arizona, USA

On the basis of these results it was stated that Flufenacet is not prone to photolytical degradation on the soil surface, therefore soil photolysis will not be a relevant degradation mechanism of Flufenacet in soil.

Additionally the potential of phototransformation of FOE Thiadone – the major degradation product of Flufenacet, on soil surface was examined. This was done on one biologically viable soil – US Loamy sand, using the test compound radiolabelled in C2 position. The experiment lasted for 14 days and samples were irradiated with artificial light – emitted by Xenon lamp, bearing the characteristic (wavelength range and light intensity) comparable to that determined for natural summer sunlight at Painesville, OH, USA in June (averaged intensity). The irradiation was carried out in regime 12h irradiation/12 h darkness.

It was demonstrated that the degradation of FOE Thiadone was rapid in both irradiated and dark control samples, with high level of mineralisation – ~57% AR at the study's end (DAT 14) and up to 21% AR in form of NER. The concentrations of FOE Thiadone at the study's end were 7.2% AR in irradiated samples and 13.3% AR in the dark control. The determined kinetic parameters for the degradation of FOE Thiadone were:

- in irradiated samples $k = 0.2120 \text{ day}^{-1}$ and $DT_{50} = 3.27 \text{ days}$;
- in the dark control $k = 0.1612 \text{ day}^{-1}$ and $DT_{50} = 4.30 \text{ days}$.

Faster degradation of FOE Thiadone observed in irradiated samples was postulated in the study report to be due to the fact that the compound displayed residual absorption of UV-light at $\lambda = 290 \text{ nm}$. RMS however noticed that the difference was not substantial and it may be due to other factors, such as slightly lower microbial activity in dark control samples resulting from lower soil moisture content.

It was also stated that only one transformation product, common also to that radiolabelling position in examining degradation of Flufenacet in aerobic and anaerobic soils, was detected – propionic acid conjugate of Thiadone, formed in greater amounts in dark control samples.

All that may indicate that also in case of the Thiadiazole moiety of Flufenacet phototransformation on soil surface may not be a relevant degradation process of for that compound. The statement is valid also for the degradation products observed for Thiadiazole moiety, and FOE Thiadone in particular. That may also be due to the fact that it may not be present on the soil surface in amounts sufficient to make soil photolysis relevant transformation mechanism.

The proposed final set of endpoints is presented below, in format recommended for the EU-agreed endpoints (SANCO/12483/2014-rev.2; 12 December 2014).

Route of degradation (photolysis) on soil (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.3)

Metabolites that may require further consideration for risk assessment - name and/or code, % of applied (range and maximum)

Mineralisation at study end

Non-extractable residues at study end

Not relevant – Flufenacet was demonstrated to be not prone to photolytical degradation on the soil surface.

0.2 % after 10.25 days, [¹⁴C-Phenyl]-label (n= 1) – irradiated sample;

0.1 % after 10.25 days, [¹⁴C-Phenyl]-label (n= 1) – dark control

3.2 % after 10.25 days, [¹⁴C-Phenyl]-label (n= 1) – irradiated sample

4.4 % after 10.25 days, [¹⁴C-Phenyl]-label (n= 1) – dark control

B. 8.1.1.1.4. – Route of degradation in soil – summary and conclusions

The route of degradation of the acetanilide herbicide Flufenacet in aerobic soil was extensively examined in eight agricultural soils – seven originating from the EU and one from US. The test compound – Flufenacet, was radiolabelled in one of the following three following positions:

- uniformly in phenyl ring – compound tested on four soils,
- position C2 in thiadiazole moiety – test performed on one soil,
- position C5 in thiadiazole moiety – examined in four soils.

These data were presented in five unpublished studies submitted specifically for the purpose of this assessment. Additionally the data relevant for determining transformation pattern of Flufenacet in aerobic soil, relevant for regulatory purposes, were found in one scientific paper, examining the degradation of Flufenacet radiolabelled uniformly in phenyl ring in two US soils. That study was based on a non-GLP regulatory study, conceived as a bridging study for laboratory and field experiments on the degradation of Flufenacet in soil. That study was verified by RMS and found acceptable. Therefore the results of the literature study based on it were included into evaluation.

The key results of the examination of transformation of Flufenacet are presented in the tabularised form below (tables B.8.1.1.1.4._CA-1 – B.8.1.1.1.4._CA-4), separately for the compound radiolabelled in phenyl ring and in thiadiazole moiety.

Table B.8.1.1.1.4._CA-1: The levels of mineralisation and NER fraction formed, and identified degradation products in experiments with [Phenyl-U-¹⁴C] Flufenacet.

- c) for which at the end of soil degradation studies the maximum of formation is not yet reached.*

2) Compound not detected in that soil.

The transformation pattern of Flufenacet in soil was examined only on biologically viable soil. That was due to the fact that, on the basis of available results it was assumed that all transformation processes were predominantly or solely biologically-mediated. It was postulated that the initial step of the degradation was the cleavage of the test item on bridging oxygen of the thiadiazole heterocycle. The further sequence for the thiadiazole moiety is presented below:

- tautomerisation of keto-enol functional group, resulting in formation of FOE Thiadone,
- hydrolytical opening of thiadone ring and further oxidation resulting in formation of either FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA), or else simple products of mineralisation and NER fraction – ultimate transformation products;
- further transformation of FOE 5043-Trifluoroethanesulfonic acid or Trifluoroacetic acid (TFA) to the simple products of mineralisation and NER fraction – ultimate transformation products.

In case of the moiety containing fluorophenyl ring next postulated step was the formation of the transient FOE Cysteine- or FOE Glutathione conjugates, undergoing subsequent quick transformation to FOE Methylsulfoxide, FOE Alcohol and FOE Chloroacetanilide. As possible side-processes were postulated direct formation of FOE Chloroacetanilide and FOE Alcohol. It shall be noted that FOE Chloroacetanilide may be not only a genuine degradation product, but also, and possibly to greater extent, analytical artefact. However, as the issue was not satisfactorily clarified, the RMS's proposal is to consider FOE Chloroacetanilide a genuine degradation product.

Additionally, as in course of evaluation FOE Alcohol was identified to be a potentially major degradation product, the additional assessment was performed to determine whether, in absence of data for that compound, the exposure assessment for FOE Alcohol may be considered to be covered by that for its immediate degradate – FOE Oxalate.

The Applicant in course of the discussion on the nature of FOE Alcohol made a following statement (the text is copied directly from the Applicant's e-mail; the “outdoor soil metabolism study” refers to the cited study by Shadrack and Kasper [1995]):

We cannot reconstruct what the reason for the accumulation or artificial formation of FOE alcohol (aka FOE hydroxy) was in that outdoor soil metabolism study, but we have several other laboratory studies, as well as EU and US field studies, which demonstrate, that FOE alcohol is a minor, transient metabolite, not accumulating at all, but rather being further oxidized quickly to FOE oxalate.

RMS having analysed the results provided by the study by Shadrack and Kasper [1995], reproduced in the publication by Bloomberg et al. [2002], noted that the compound was formed in greater amounts in Chualar soil, having lower OC content and slightly lower microbial activity of the two soils used in the experiment. Taking into account the fact that FOE Alcohol was also detected only in the study by Pangilinan and Smith [1994], performed on another soil having low OC content and microbial activity, but not in the study by Kelley et al [1995], all that may indicate that FOE Alcohol is indeed a transient, fast degrading compound, that would appear in higher amounts and for longer only in weak soils.

To further demonstrate that it was possible to cover the exposure assessment for FOE Alcohol with that for its immediate degradate – FOE Oxalate, RMS performed the comparative analysis by means of QSAR calculations, carried out with EPI Suite ver. 4.10 (September 2010) tool. The results of that assessment indicate that the properties of both compounds relevant for their environmental fate and behaviour are comparable. Therefore the exposure assessment performed for FOE Oxalate may be considered as covering that for FOE Alcohol.

The route of degradation of the acetanilide herbicide Flufenacet in anaerobic soil was examined in three soils – one from the US and two European. The test compound – Flufenacet, was radiolabelled in one of the following two positions:

- uniformly in phenyl ring – compound tested on one US soil,
- in position C5 of Thiadiazole moiety – examined in two EU soils.

The experiments performed to determine the transformation pattern of Flufenacet in soil under anaerobic conditions consisted of two phases – aerobic preincubation phase and anaerobic incubation phase. RMS decided to present the key results of the experiments taking into account both phases. In case of aerobic preincubation phase the results are given for the terminal time point of that phase.

The key results for the examination of transformation of Flufenacet in anaerobic soils in the area of formation of terminal degradation products – mineralisation expressed as CO₂ and NER fraction, are presented below in the table B.8.1.1.1.4._CA-5. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey. It shall be noted that under anaerobic conditions mineralisation, if occurred at all, was minimal. No other volatile compounds were identified during either aerobic or anaerobic phases. The level of NER formed under anaerobic conditions (net formation) was comparable to that observed in aerobic soils.

Table B.8.1.1.1.4._CA-5: The levels of the terminal degradation products – CO₂ and NER fraction formed in soil during examination of the transformation pattern of Flufenacet in soil under anaerobic conditions.

Study/ radiolabelling position	Soil		Results obtained for aerobic phase		Results obtained for anaerobic phase ¹⁾					
	Name	Type (USDA)	CO ₂ [%AR] – end of phase	NER [%AR] – end of phase	Mineralisation level – CO ₂ formed [% AR]			NER level [% AR]		
					Beginning of phase	Max.	Net anaero- bic ²⁾	Beginning of phase	Max.	Net anaero- bic ³⁾
Pangilinan & Smith [1994]/ ¹⁴ C-phenyl	Howe	Sandy loam	1.4 (DAT 30)	8.4 (DAT 30)	1.4 (DAT 30 DAF 0)	1.8 (DAT 210 DAF 180)	0.4	8.4 (DAT 30 DAF 0)	32.6 (DAT 210 DAF 180)	24.2 (DAT 210 DAF 180)
Heinemann [2012]/ ¹⁴ C-5- Thiadiazole	HH ⁴⁾	Silt loam	1.6 (DAT 15)	16.9 (DAT 15)	1.6 (DAT 15 DAF 0)	1.7 (DAT 105 DAF 90)	0.1	10.2 (DAT 15 DAF 0)	24.5 (DAT 135 DAF 120)	14.3 (DAT 135 DAF 120)
	DD ⁵⁾	Loam	1.9 (DAT 15)	10.1 (DAT 15)	1.8 (DAT 15 DAF 0)	1.9 (DAT 105 DAF 90)	<0.1 ⁶⁾	8.6 (DAT 15 DAF 0)	31.6 (DAT 135 DAF 120)	23.0 (DAT 135 DAF 120)

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase; in case of soils HH and DD they are different, because were available the results obtained immediately after generating the anaerobic conditions;
- 2) Net anaerobic is a difference between the total amount of CO₂ formed and that determined in aerobic traps for volatiles;
- 3) Net anaerobic is a difference between maximum determined level of NER and that measured at the beginning of anaerobic phase;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) At the time point where maximum CO₂ level of 2.0% AR was recorded, the amount recovered for aerobic volatile traps was 1.9% AR and from anaerobic volatile traps <0.1 AR; the slightly higher total amount may be due to either rounding or losses during extraction; in that soil the level of mineralization, expressed as recovered CO₂ in anaerobic phase was <0.1% AR;

The examination of the extracted fraction enabled the identification of one new degradate, not identified in aerobic soils – FOE Thioglycolate. All other identified degradation products were those already found in aerobic soils. On that basis it can be stated that the transformation pattern of Flufenacet in soil under anaerobic conditions would not differ significantly from that determined in aerobic soils. The key results of the profiling of degradation products in anaerobic soils are presented below in table B.8.1.1.1.4._CA-6. To differentiate the results obtained for aerobic phase from those for anaerobic phase the former were shaded light grey.

Table B.8.1.1.1.4_CA-6: The results of the profiling of Flufenacet and its degradation products.

Study/ radiolabelling position	Soil		Results obtained for aerobic phase		Results obtained for anaerobic phase ¹⁾				
	Name	Type (USDA)	Identified compound	Amount [% AR] at the end of phase	Identified compound	Amount [% AR] measured at:			Anaerobic metabolite (yes/no)

Footnotes to the table:

- 1) In case of Howe soil the results for the beginning of anaerobic phase are the same as those for the end of aerobic phase; in case of soils HH and DD they are different, because were available the results obtained immediately after generating the anaerobic conditions;
- 2) Net anaerobic is a difference between the maximum amount determined in anaerobic phase and that at its beginning;
- 3) FOE TGS – FOE Thioglycolate sulfoxide;
- 4) HH stands for *Hoefchen am Hohenseh 4a* soil;
- 5) DD stands for *Dollendorf II* soil;
- 6) Flufenacet is the active substance, therefore not forming in soil; as a result its concentration at the end of incubation period is given to show the level of decline;
- 7) In that soil the concentrations of FOE Trifluoroethane sulfonic acid initially decreased, to increase afterwards reaching maximum on the indicated time point; it was assumed that this maximum can be attributed totally to the amount of that compound formed under anaerobic conditions;
- 8) N/A – not applicable (parent compound);

The results of the determination of transformation pathway of Flufenacet in anaerobic soil demonstrated that it would not significantly differ, qualitatively and quantitatively, from that observed in aerobic soil.

The degradation products that may require further consideration for the risk assessment are the same as identified during examination of the degradation pattern of Flufenacet in aerobic soil: FOE Oxalate, FOE Thiadone and Trifluoroacetic acid.

The soil photolysis of Flufenacet was examined in one soil – US Sandy loam, using the test compound radiolabelled in one position – uniformly at phenyl ring. The experiment was performed using soil that was demonstrated to be biologically viable throughout the whole irradiation/incubation period. Samples were irradiated with artificial light (Xenon lamp) continuously for 10.25 days, corresponding to 30 days of natural summer sunlight (conditions relevant for Phoenix, Arizona, USA). The key results of the examination are presented below in the table B.8.1.1.1.4._CA-7.

Table B.8.1.1.1.4._CA-7: The key results obtained for Flufenacet in soil photolysis study

Parameter		Results obtained for:	
		Irradiated sample	Dark control
<i>Terminal transformation products</i>	Mineralisation (CO ₂) at the end of the study	0.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	0.1% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	Max. NER level	3.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	4.4% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
<i>Identified compounds</i>	Flufenacet – amount at study's end	91.2 AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	87.2 AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	FOE Oxalate – max. amount	0.6% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾	4.6% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾
	FOE Sulfonic acid – max. amount	0.4% AR; DAT ²⁾ 5.13; 15 th DNS ³⁾	2.2% AR; DAT ²⁾ 10.25; 30 th DNS ³⁾

<i>Kinetics of the process</i>	rate constant k [days ⁻¹]	0.0076	0.0124
	DT ₅₀ [days]	90.72	55.90

Footnotes to the table:

- 1) N-isomer of Flufenacet (for the structural formula, please refer to the table in Appendix 1 - List of Evaluated Compounds);
- 2) DAT stands for Days After Treatment, the real sampling point in the experiment;
- 3) DNS – Days of Natural Sunlight, the sampling point related to the natural summer day sunlight conditions in Tucson Arizona, USA

On the basis of these results it was stated that Flufenacet is not prone to photolytical degradation on the soil surface, therefore soil photolysis will not be a relevant degradation mechanism of Flufenacet in soil. Additionally the potential of photodegradation of FOE Thiadone on soil surface was examined. Although it was demonstrated that the process might contribute to transformation of FOE Thiadone in soil, its relevance is estimated to be minimal, also because FOE Thiadone is not expected to occur on the soil surface in significant, if any, amounts.

On the basis of the results of the studies examining route of degradation of Flufenacet in soil under various conditions a following overall transformation scheme was proposed (figure B.8.1.1.1.4._CA-1):

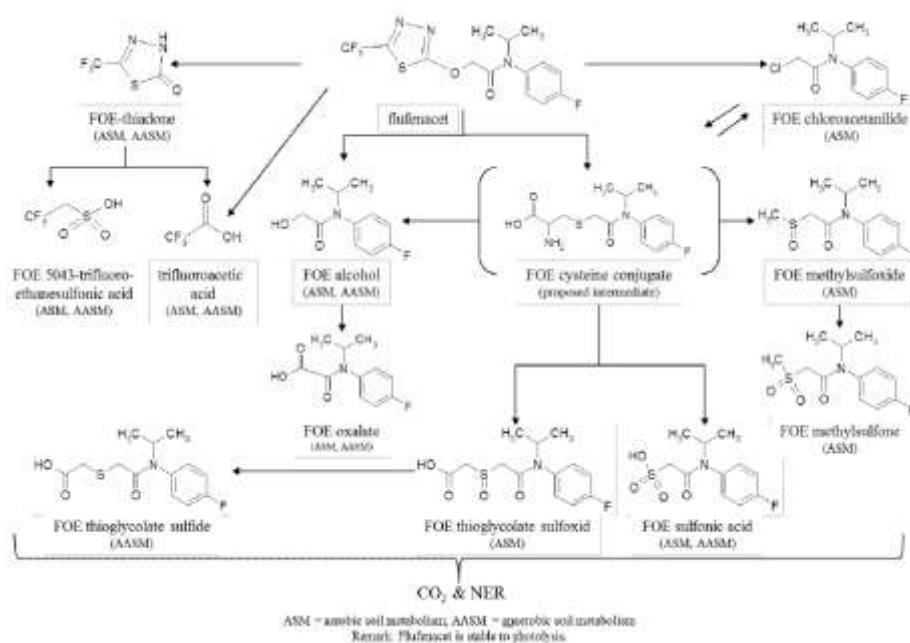

Figure B.8.1.1.1.4_CA-1: A postulated transformation scheme for Flufenacet in soil, as proposed by the Applicant, verified and approved by the RMS (scheme copied from the Applicant's documentation).

Finally the results considered to be definitive endpoints derived from the examination of the route of degradation of Flufenacet in soil are presented below (in format recommended for the EU-agreed endpoints – SANCO/12483/2014-rev.2; 12 December 2014).

Route of degradation (aerobic) in soil (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.1)

Mineralisation after 100 days	2.7 % after 91 d, [¹⁴ C- <i>U-Phenyl</i>]-label (n= 1) 10.2 – 20.8 % after 100 d, [¹⁴ C- <i>U-Phenyl</i>]-label (n= 3) 31.9 % after 90 d, [¹⁴ C-2- <i>Thiadiazole</i>]-label (n= 1) 4.5 – 6.5 % after 120-121 d, [¹⁴ C-5- <i>Thiadiazole</i>]-label (n= 4)
Non-extractable residues after 100 days	16.3 % after 91 d, [¹⁴ C- <i>U-Phenyl</i>]-label (n= 1) 29.9 – 56.2 % after 100 d, [¹⁴ C- <i>U-Phenyl</i>]-label (n= 3) 6.2 % after 90 d, [¹⁴ C-2- <i>Thiadiazole</i>]-label (n= 1) 10.6 – 17.2 % after 120-121 d, [¹⁴ C-5- <i>Thiadiazole</i>]-label (n= 4)
Metabolites requiring further consideration - name and/or code, % of applied (range and maximum)	FOE Sulfonic acid – max. 26.3 % at 100 d (n= 6); [¹⁴ C- <i>U-Phenyl</i>] label; FOE Alcohol – max. 21.2 % at 88 d (n= 3); [¹⁴ C- <i>U-Phenyl</i>] label; FOE Oxalate – max. 26.5 % at 365 d (n= 6); [¹⁴ C- <i>U-Phenyl</i>] label; FOE Methylsulfone – max. 6.6 % at 100 d (n= 3); [¹⁴ C- <i>U-Phenyl</i>] label; FOE Thiadone – max. 5.8 % at 10 d (n= 5); [¹⁴ C-2- <i>Thiadiazole</i>] & [¹⁴ C-5- <i>Thiadiazole</i>] labels FOE 5043-Trifluoroethanesulfonic acid – max. 6.0 % at 14 d (n= 4); [¹⁴ C-5- <i>Thiadiazole</i>] label Trifluoroacetic acid (TFA) – max. 81.5 % at 91 d (n= 4); [¹⁴ C-5- <i>Thiadiazole</i>] label Sterile conditions: <i>not examined</i>

Route of degradation (anaerobic) in soil (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.2)

Mineralisation after 100 days	0.5 % after 180 d, [¹⁴ C- <i>Phenyl</i>]-label (n= 1) <0.1 - 0.1 % after 90 d, [¹⁴ C-5- <i>Thiadiazole</i>]-label (n= 2)
Non-extractable residues after 100 days	24.2 % after 180 d, [¹⁴ C- <i>Phenyl</i>]-label (n= 1) 14.3 – 23.0 % after 120 d, [¹⁴ C-5- <i>Thiadiazole</i>]-label (n= 2)
Metabolites that may require further consideration for risk assessment - name and/or code, % of applied (range and maximum)	FOE Oxalate – 14.5 % at 30 d (n= 1); [¹⁴ C- <i>Phenyl</i>] label; FOE Thiadone – 8.8 % at 62 d (n= 2); [¹⁴ C-5- <i>Thiadiazole</i>] label; Trifluoroacetic acid (TFA) – 16.5 % at 120 d (n= 2); [¹⁴ C-5- <i>Thiadiazole</i>] label; Sterile conditions: <i>not examined</i>

Route of degradation (photolysis) on soil (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.3)

Metabolites that may require further consideration for risk assessment - name and/or code, % of applied (range and maximum)	<i>Not relevant – Flufenacet was demonstrated to be not prone to photolytical degradation on the soil surface.</i>
Mineralisation at study end	0.2 % after 10.25 days, [¹⁴ C- <i>Phenyl</i>]-label (n= 1) – irradiated sample; 0.1 % after 10.25 days, [¹⁴ C- <i>Phenyl</i>]-label (n= 1) – dark control
Non-extractable residues at study end	3.2 % after 10.25 days, [¹⁴ C- <i>Phenyl</i>]-label (n= 1) – irradiated sample 4.4 % after 10.25 days, [¹⁴ C- <i>Phenyl</i>]-label (n= 1) – dark control

B.8.1.1.2. – Rate of degradation

The degradation kinetics of Flufenacet and its degradation and transformation products in soil was thoroughly examined in several studies, both in the laboratory and under field conditions. The results of that examination, in form of the summaries of the submitted studies, are presented below, under the relevant data points.

B.8.1.1.2.1. – Laboratory studies

The degradation of Flufenacet in soil under aerobic conditions was extensively examined in five studies, three evaluated for the previous authorisation of Flufenacet in the EU (“old studies”) and two newly submitted studies, summarised in this Renewal Assessment Report under the point B.8.1.1.1.1. as respectively **Study 1**, **Study 2** and **Study 4** (“old studies”), and **Study 5** and **Study 6** (“new studies”). The two new studies contained the results of the kinetic evaluation of the data obtained for Florasulam performed according to the current standards (FOCUS Kinetics). Also, for the purpose of the present evaluation, the Applicant submitted a study that examined the rate of degradation of Flufenacet in one soil. The results of all these studies were further evaluated in five study reports, aimed specifically on the kinetic evaluation of the data in line with the current standards. Therefore, the Applicant submitted in total six studies examining the rate of degradation of Flufenacet, alone or together with its degradation products, in aerobic soils.

To cover the issue of the rate of degradation of the major soil degradation and transformation products of Flufenacet in aerobic soil the Applicant submitted another fourteen studies, of which three were the existing studies, assessed already during the previous evaluation of Flufenacet for its authorisation in the EU. The remaining eleven were new/newly submitted studies.

Of these, five were examining the rate of degradation of FOE Sulfonic acid, three were aimed on the determination of the kinetic endpoints for FOE Methylsulfone, two were performed for FOE Thiadone and remaining two for Trifluoroacetic acid. The remaining two were the old studies, submitted for the previous evaluation of Flufenacet in the EU, presenting the kinetic assessment of the data obtained for degradation products.

In total the Applicant submitted 22 studies specifically aimed on the determination of rate of degradation of Flufenacet and its degradation products in aerobic soil under laboratory conditions. All they are evaluated and summarised below, under the point B.8.1.1.2.1.1. of the Renewal Assessment Report.

The results of the kinetic analysis were further evaluated in three separate study reports aimed on the identification of the kinetic endpoints suitable for modelling exposure assessment. In case of the endpoints identified as suitable for GW and SW modelling they were also normalised and the assumptions and results of the normalisation procedure presented in the adequate reports. Although these three reports are closely associated with issues related to the representative formulation, RMS decided to summarise them, in their parts related to the critical evaluation of the kinetic endpoints determined in aerobic soil, in this part of the Renewal Assessment Report under the point B.8.1.1.2.1.1.

Additionally two peer-reviewed publications presenting the results of the determination of the kinetic endpoints for the degradation of Flufenacet in aerobic soil in the laboratory were identified by RMS as relevant for this assessment. RMS considers the studies supplementary and not to be used to derive the regulatory endpoints. Never the less, as they provide the values of reference conforming the findings of the evaluated study reports, their summaries are provided at the end of the subchapter.

The results of the two studies examining the transformation of Flufenacet in anaerobic soil were kinetically evaluated by the Applicant and presented in the study report issued specifically for that purpose. The study is summarised as **Study 1** under the point B.8.1.1.2.1.2. of this report. Additionally the Applicant presented the key results of the kinetic analysis of the data in the study by Heinemann [2012] already summarised as **Study 2** under the point B.8.1.1.1.2. of this report. They will be briefly evaluated under the point B.8.1.1.2.1.2.

In case of soil photolysis the Applicant has not submitted any new study examining the rate of photolytic transformation of Flufenacet or any of its degradation and transformation products on the soil surface. The RMS performed the kinetic analysis of the results obtained in the two studies summarised under the point B.8.1.1.1.3. of this report. The results are presented under the point B.8.1.1.2.1.3. of this report.

The last point in this section – B.8.1.1.2.1.4., is a summary of all findings in the area of the determination of the degradation kinetics in soil in the laboratory. It will provide the key results of that examination.

B.8.1.1.2.1.1. – Aerobic degradation

The rate of degradation of Flufenacet in soil under aerobic conditions was determined in twenty two studies submitted by the Applicant. The examination of the degradation kinetics of Flufenacet in aerobic soil was based on the results of five studies aimed also on the determination of the degradation pathway of Flufenacet in soil, which are summarised under the point B.8.1.1.1.1. as **Study 1** [Kelley et al; 1995], **Study 2** [Pangilinan & Smith; 1994], **Study 4** [Pangilinan & Smith; 1994a], **Study 5** [Hein; 2012] and **Study 6** [Hein; 2012a]. Additionally, the Applicant submitted one study aimed on the determination of the rate of degradation of Flufenacet in aerobic soil. That study is summarised below as **Study 1**. Kinetic evaluation of the data from that study, as well as from other studies listed above, in which [Phenyl-U-¹⁴C] Flufenacet was used, was performed according to provisions of FOCUS Kinetics Guideline [FOCUS; 2006] and presented in separate study report, summarised in this section as **Study 2**. Additionally the same data set was examined in order to derive trigger endpoints for FOE Oxalate and Flufenacet. The results are presented as **Study 3**. Also the results obtained in the studies performed with [Thiadiazole-2-¹⁴C] Flufenacet, and [Thiadiazole-5-¹⁴C] Flufenacet were kinetically evaluated in line with recommendations given by FOCUS. In case of the experiment with [Thiadiazole-5-¹⁴C] Flufenacet, the kinetic examination of the data for Flufenacet to determine the best-fit kinetics according to FOCUS was already performed and presented in the study reports **Study 5** [Hein; 2012] and **Study 6** [Hein; 2012a]. RMS decided to present that evaluation under this point as relevant for presentation of the results of kinetic evaluation of the data. Therefore those two studies, in the area of the kinetic assessment they provide, will be summarised here as **Study 4** and **Study 5**, respectively. Additionally, the data of those two studies were further kinetically examined in two separate studies summarised under this point:

- **Study 6**, aimed on the determination of trigger endpoints for FOE 5043-trifluoroethanesulfonic acid;
- **Study 7**, in which the kinetic endpoints for modelling were determined.

Finally the results of the kinetic examination of the data for [Thiadiazole-2-¹⁴C] Flufenacet, obtained in already evoked **Study 4** [Pangilinan & Smith; 1994a], will be presented as **Study 8**.

The Applicant also submitted fourteen study reports aimed specifically on the determination of the kinetic endpoints for the major soil degradation products of Flufenacet identified during examination of the route of degradation of that compound in soil. Of them three were submitted and evaluated for the previous authorisation of Flufenacet in the EU (“old” studies) while the remaining eleven are new/newly submitted studies. Two of the “old” studies were found to be not compliant with the provisions of FOCUS Kinetic Guideline. For that reason only their summaries given in the previous Assessment Report will be presented and these studies will not be taken into account in the assessment. The remaining twelve studies will be summarised according to the current standards as **Studies 9 – 20**.

It was noted that none of the listed above reports contained the results of the normalisation of the obtained endpoints. The Applicant decided to perform the normalisation of the modelling endpoints in two separate reports, issued in support of the main study reports presenting the results of the model exposure assessment for Groundwater and Surface Water compartments. The reports presented also the justification for the selection of all input parameters for modelling exposure assessment. The Applicant issued three such reports, one for each type of modelling exposure assessment, including soil. RMS decided to summarise them, in the area relevant for this assessment point, as **Studies 23 – 25**.

Finally, the literature search enabled the identification of two scientific papers relevant in the area of the determination of the rate of degradation of Flufenacet in aerobic soil. These studies are considered supplementary and indicated as not to be used to derive the regulatory endpoints. However, RMS decided to summarise them, as providing supplementary data, at the end of this section as **Study 26** and **Study 27**.

The following eight studies, summarised below as **Studies 1 – 8**, examine the rate of degradation of Flufenacet, alone or with its degradation products, in aerobic soil in the laboratory. Two of them – **Study 4** and **Study 5** which are route-and rate-of degradation studies, were summarised also under the point B.8.1.1.1.1. of this Renewal Assessment Report as **Study 5** and **Study 6** respectively.

Study 1:

Report: Hellpointner E., (1999): “Aerobic Degradation of Flufenacet in Lysimeter Soil Laacherhof AXXa.”; Bayer AG, Institute for Metabolism Research and Residue Analysis, D-513468 Leverkusen, Federal Republic of Germany; study No. M1250988-3, unpublished study Report No. MR-388/99; 23 July 1999; study reference number: M-009592-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guideline for the Official Testing of Plant Protectants, Part IV, 4-1, 1986;
- EC Commission Directive 95/36/EC amending Council Directive 91/414/EEC Annexes I + II, Fate and behaviour in the Environment. 14th July 1995;
- SETAC Procedures for Assessing the Environmental Fate and Ecotoxicity of Pesticides, March 1995;

GLP: Yes;

RMS comments: This is a newly submitted study, provided specifically for purpose of evaluation of Flufenacet for the renewal of its authorisation in the EU. The study was evaluated for its compliance with the following two Guidelines:

- OECD Guideline 307 – Aerobic and Anaerobic transformation in Soil; in the area of the compliance of the analytical protocol with current standards;
- FOCUS (2006) “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp., and “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, versions 1.0 (issued on 23 November 2011) and 1.1 (issued on 18 December 2014); for the compliance of the kinetic analysis of the obtained data with current EU recommendations in the area of kinetic analysis of the data.

It was stated that the study complied with the provisions with OECD 307 Guideline and no deviations from the tow listed above Guidelines were declared/stated. RMS noticed that although the study was performed using the radiolabelled compound, the identification of the degradation products was not performed. Therefore the study cannot be considered as providing the relevant data in the area of elucidating the route of degradation of Flufenacet and may be considered solely as a rate-of-degradation study. It was also determined that the kinetic analysis was not performed in line with the provisions of FOCUS Kinetics Guidance Document. The issue is discussed in detail in the summary of the study provided below.

As a result, the study is acceptable as providing the data for determination of the degradation kinetics of Flufenacet in the test soil used in the experiment. Its summary is given below.

Summary:

The aim of the study was to determine the rate of degradation of Flufenacet and kinetic endpoints for that compound in one soil incubated under aerobic conditions – lysimeter soil Laacherhof AXXa. That soil was used in several lysimeter studies with Flufenacet.

The soil was sampled from the test field – a pasture on which no pesticides were used since 1988, shortly before the study began – on 16th April 1999. It was taken from the top 16-cm layer. The amount of soil taken for the experiment was ~7 kg. Its moisture during sampling was ~16% (MWHC).

The soil was transferred to the test laboratory and there processed about a week before the experiment started, by removing the skeletal parts (stones, plant parts), the gentler air-drying the remaining soil and sieving it through 2-mm sieve. After that the soil was characterised for its properties, and the results of that analysis are presented below in the table B.8.1.1.2.1.1._CA-1.

Table B.8.1.1.2.1.1._CA-1: The characteristic of soil used in the study.

Parameter		Soil:	
Soil origin		<i>Laacherhof AXXa</i>	
Soil type (USDA)		<i>Monheim/ Rheinland/ North Rhine-Westphalia/ Germany</i>	
Particle size distribution		Sandy loam	
	Sand (50 µm – 2 mm) [%]	71.77	
	Silt (2 – 50 µm) [%]	16.47	
	Clay (< 2 µm) [%]	11.76	
pH value in distilled water		7.0	
pH value in 0.01M CaCl ₂		6.1	
Organic carbon content (C _{org}) [%] ¹⁾		1.41	
Organic matter content (OM) [%] ²⁾		2.42	
Cation Exchange Capacity – CEC [mEq/100g]		9.61	
Bulk density [g/cm ³]		2.5	
Water holding capacity	Maximum [g H ₂ O/100 g soil d. w.]	34.4	
	50% MWHC [g H ₂ O/100 g soil d. w.]	17.2	
Soil biomass expressed in mg microbial C/kg soil ³⁾ :	At the beginning of the study – DAT 0	667 (rep. 1)	702 (rep. 2)
	The end of the study – DAT 56	392 (rep. 1)	356 (rep. 2)
Soil biomass expressed as %OC ⁴⁾ :	At the beginning of the study – DAT 0	5.85 (rep. 1)	6.15 (rep. 2)
	The end of the study – DAT 56	3.44 (rep. 1)	3.12 (rep. 2)

Footnotes to the table:

- 1) Measured value;
- 2) Value calculated by the Applicant using the following equation: OM = 1.724*OC;
- 3) Determined using the method by Anderson&Domsch;
- 4) Recalculated by the RMS, using the reported OC = 2.5%;

At the beginning of the experiment the 100-g (d. w.) aliquots of the air-dried test soil were weighed into 300-mL Erlenmeyer flasks, brought to 50% MWHC by addition of the appropriate amount of deionised water (7.14 per flask), weighed and closed with quartz wool stoppers. They were then pre-incubated under the experiment conditions (in the dark at T = 20⁰C) for about 7 days before being treated with the test compound. The stoppers were removed at application. The application rate was set to 480 g Flufenacet /ha – the pre-emergence application rate in maize (corn). It was the same rate as used in two lysimeter studies with Flufenacet.

The test compound used in the experiment was [Phenyl-U-¹⁴C] Flufenacet, having a specific activity of 2.0 MBq/mg and radiochemical purity (determined by radio-HPLC) > 95%. Its structural formula is presented below on the figure B.8.1.1.2.1.1_CA-1.

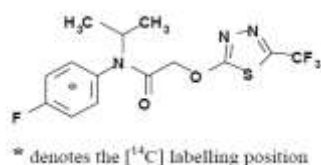

Figure B.8.1.1.2.1.1._CA-1: The structural formula of the radiolabelled Flufenacet used in the experiment (copied from the study report).

It was stored deep-frozen until being used. When used, the whole sample was first dissolved in 5 mL of CH₃CN to obtain the stock solution having a concentration (determined by LSC) of 19 kBq/10µL, corresponding to 0.95 mg Flufenacet/mL, and radiochemical purity > 95%. The stock solution was stored in the dark and under cool conditions until being used to prepare the application solution.

The application solution was prepared by diluting 1.7 mL of the stock solution with the appropriate amount of distilled water to obtain the solution having a target volume of 12.00 mL. That volume was calculated on the basis of the assumption that for treatment of the individual test vessel should be used 70 µL of the stock solution diluted with distilled water to the volume of 500 µL. It was stated that the volume of Application solution was sufficient to treat 24 samples with 500-µL portions.

The concentration of the Application solution was determined to be 14.340 kBq/50 µL, corresponding to 0.1434 mg Flufenacet/mL. Its radiochemical purity, determined using radio-TLC was 96% and the content of organic solvent (acetonitrile) – 14% (v/v).

To obtain the target application rate of 480 g Flufenacet/ha, corresponding to application dose of 0.064 mg Flufenacet/100 g soil d. w. (0.064 mg/kg soil d. w.), or 135 kBq/test vessel (application dose calculated using the standard assumptions – soil bulk density $d = 1.5 \text{ g/cm}^3$ and soil layer $l = 5 \text{ cm}$), 0.475 mL of the application solution was introduced to the test soil in each incubation vessel using microlitre syringe. The organic solvent was allowed to evaporate for 10 minutes, then the soil moisture was brought to designated 50%-level by re-weighing the test vessels and adding the appropriate amount of distilled water. So prepared samples were further called kinetic samples.

The homogeneity and stability of the application solution, as well as the exact amount of the test compound applied to each test vessel, were determined at application by means of LSC and radio-TLC.

Alongside kinetic samples were set the samples for the determination of the soil biomass at the end of the study (on DAT 56). They were prepared in the same way as kinetic samples, with exception that they were treated with blank application solution (not containing the test compound).

All treated incubation vessels were sealed with the traps for volatile compounds, to get the biometer flasks shown below on figure B.8.1.1.2.1.1._CA-2, and placed in the dark in the temperature-controlled room, to be incubated for up to 56 days at constant temperature $T = 20^\circ\text{C}$.

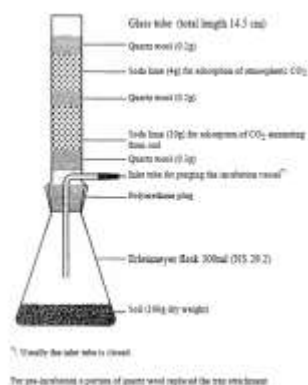

Figure B.8.1.1.2.1.1._CA-2: The biometer flask used in the experiment (copied from the study report).

Samples were taken for processing and analysis at designated time points – on DAT (Days After Treatment) 0, 0.1, 1, 3, 7, 14, 28, 42 and 56. At these time points duplicate samples were taken for analysis. The exception was DAT-0 time point, at which triplicate analysis was performed. Also in case of DAT-0 samples the traps for volatile compounds were not set, as it was assumed that no formation of volatile compounds was not expected then.

The soil moisture content was controlled in 30-days intervals by weighing the biometer flask less the traps and, if necessary, adjusting it by adding the appropriate amount of distilled water.

At designated time points the duplicate samples were removed from the incubation chamber for further processing. First the vessels were purged with humid air for 10 minutes to transfer all volatile compounds to the traps for volatile compounds. Then the traps were removed for further processing and the soil in Erlenmeyer flask immediately extracted. The extraction was performed with 80-mL portions of CH_3CN , in three 50-min. cycles consisting of 30-min. shaking at ambient temperature and 20-min., centrifugation at 9000 G and decantation with filtration of cleared supernatants. The collected supernatants were combined into one organic extract. At the beginning of the first extraction cycle the whole soil portion was quantitatively transferred from the Erlenmeyer flask to centrifuging baker – the extraction vessel, with the 1st 80-mL portion of the extracting agent. The organic extracts were analysed by LSC and HPLC on the day of extraction or the day after.

Each filter paper was pressed into four pellets and analysed, after combustion, for radioactivity content by LSC.

The extracted soil pellets were analysed for radioactivity content, after combustion, by LSC.

The recovered traps for volatile compounds were stored deep frozen until being analysed. Firstly they were dissected into polyurethane plugs (PU) and soda lime fillings. The PU plugs were extracted for 20 min. with 25 mL of CH_3CN on ultrasonic bath. Three 0.5-mL aliquots of so obtained extracts were then analysed for the radioactivity content using LSC. The radioactivity ($^{14}\text{CO}_2$) absorbed by soda lime was liberated with 18% HCl and transferred in the stream of N_2 to three vessels containing LS cocktail (20-mL mixture of Carbosorb E and PremafluorE⁺), using the apparatus presented below on figure B.8.1.1.2.1.1._CA-3.

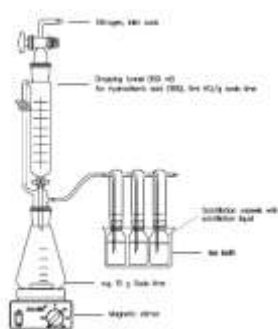

Figure B.8.1.1.2.1.1_CA-3: The apparatus used to liberate $^{14}\text{CO}_2$ from soda lime traps (copied from the study's report).

All samples were analysed for the content of radioactivity using LSC method.

The LSC (Liquid Scintillation Counting) analysis of liquid samples was performed using LS 6500 spectral counter. The radioactivity in all organic extracts was determined in mini-vials, using the sample aliquots of up to 0.5 mL and 2 mL of Quicksafe[®] A solution. The counting time was 10 minutes and the average background 14 cpm. The minimum sensitivity of LSC analysis for these samples was $5.19 \text{ E-}4$ ppm, corresponding to 0.0823% AR. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 28 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 14 cpm. The greatest probable error GPE = 8.10%.

The LSC analysis of radioactivity liberated from soda lime traps was performed on LKB-Wallac 1219 Spectral counter, using whole 20-mL scintillation-cocktail samples. The counting time for these samples was 10 minutes and the average background 28 cpm. The minimum sensitivity of LSC analysis for these samples was $2.85 \text{ E-}6$ ppm, corresponding to 4.52 E-4% AR. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 56 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 28 cpm. The greatest probable error GPE = 5.72%.

The LSC analysis of solid samples was performed using PW 4700 (Philips/Raytest) counter.

The radioactivity retained on paper filters, each weighing ~0.5 g, was determined after their compression to pellets followed by combustion. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxysolve C400. The counting time was 10 min and the average background 21 cpm. The minimum sensitivity of LSC analysis for these samples was $2.19 \text{ E-}6$ ppm, corresponding to 0.0347% AR. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 42 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 21 cpm. The greatest probable error GPE = 6.64%.

The radioactivity in extracted soil pellets was determined using three 1.0-g aliquots of dried and homogenised material, oxidised by combustion. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxysolve C400. The counting time was 10 min and the average background 21 cpm. The minimum sensitivity of LSC analysis for these samples was $6.73 \text{ E-}6$ ppm, corresponding to 1.07 E-3% AR. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 42 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 21 cpm. The greatest probable error GPE = 6.64%.

Liquid samples were also analysed using the following instrumental methods:

- TLC – primary quantitation method for the parent compound and its degradation products;
- HPLC conformatory method for checking the purity of the test compound in the stock solution.

The TLC analysis was carried out directly on the obtained samples, without any enrichment or conditioning step. It was performed at ambient temperature, in saturated chamber, on silica gel 60, F₂₅₄, TLC plates. The solvent system used in the analysis was Chloroform/Ethyl acetate 3:1 (v/v).

Two detectors were used:

- UV cabinet (Camag) detector working at wavelength $\lambda = 254 \text{ nm}$;
- Bio-Imaging Analyser Fujix BAS-2000 for analysis of radioactivity.

The LOD for a single peak was determined to be 1% AR, assuming the instrumental LOD = 0.8 Bq.

The HPLC analysis was performed in a gradient mode using Lichrospher 100 RP 18, 250 * 4 mm, 5 μm , chromatographic column, kept at constant temperature $T = 40^\circ\text{C}$. The chromatograph was coupled with Ramona 92 radioactivity flow-through detector.

The HPLC worked in the following gradient regime:

- **Mobile phase A:** 1% mL CH₃COOH in water;
- **Mobile phase B:** CH₃CN;
- **Gradient mode:** from 10% B on 0 min. to 40% B on 10th min., then to 60% B on 30th min. and finally to 90% B on 35th min.;
- The flow rate was set to 1.0 mL/min.;
- Total run time was 35 minutes.

Results and their discussion:

The monitoring of the experimental conditions demonstrated that the samples were incubated at the mean temperature 20.29^oC, ranging from 20.0^oC to 20.8^oC. These values were in line with the assumed constant temperature T = 20^oC. The soil moisture content was demonstrated to be in line with the assumed value of 50% MWHC and no significant losses were observed throughout the study duration.

The results of the verification of the homogeneity of application showed that it was homogenous – on average the application dose was 135.42 kBq/vessel (with range 134.82 kBq/vessel – 135.94 kBq/vessel; n = 3). That value was set to 100% AR. The purity of the test solution in relation to Flufenacet, determined by TLC, was on average 92.32% (range 92.17% - 92.47%; n = 3). The average application dose calculated on that basis was 62.51 µg Flufenacet/vessel, or 97.67% of the anticipated application dose of 64 µg Flufenacet/vessel.

The determination of the soil microbial activity at the beginning and the end of the study demonstrated that the test soil was biologically viable throughout its duration. For details please refer to the table B.8.1.1.2.1.1._CA-1. The determined decrease in soil microbial activity throughout the incubation period was by 41.23% for Replicate 1 and by 49.29% for replicate 2. The Applicant indicated that the initial soil biomass content was in the usual range expected for agricultural soils. Also the decrease in soil microbial activity was attributed, although that was not explicitly stated, to natural causes. It shall be pointed out however that while the determination of soil biomass content in DAT-0 samples was performed for soil not treated with the blank application solution, at the end of the experiment – in DAT-56 samples, it was done in soil treated with blank application solution. Therefore, in RMS's opinion, the would-be influence of the application solution on the soil biomass cannot be fully ruled out.

Never the less it was demonstrated that the soil microbial biomass was throughout the study duration well above the recommended level of 1% OC, so the conclusion on the biological viability of the test soil during the whole incubation period is fully defensible.

The assessment of the distribution of Applied Radioactivity (AR) was based on the initial value of 135.42 kBq/100 g soil (d. w.), set as 100% AR.

It shall be noted that the mass balance in DAT-0 samples was not determined, because it was assumed that at that time point the whole portion of AR should be extractable. Therefore for that time point the reported values represent the concentration of AR in the application solution. As a result the proper mass balance was performed starting for the samples collected on DAT 0.1 (2 hours after application of the test compound).

The recovery of AR was within the recommended limits, although with tendency to decrease with time, and it was in range of 94.8% AR – 99.5% AR.

The amount of AR extracted decreased in time from 93.6% AR on DAT 0.1 to 20.0% AR on DAT 56. That was correlated with the gradual increase of both NER fraction – from 5.9% AR on DAT 0.1 to 56.7% AR (maximum level) on DAT 42, and mineralisation – from 1.6% AR on DAT 0.1 to 19.5% AR on DAT 56. It shall be also noted that the NER fraction reached its maximum before the termination of the incubation – on DAT 42 (penultimate time point). The level recorded on the last sampling point – DAT 56, was slightly lower – 55.2% AR. That was in line with findings of the study by [Kelley et al.; 1995], summarised under the point B.8.1.1.1.1. as **Study 1**.

The identification of the constituents of the extract was limited solely to the active compound – Flufenacet. The degradation products were quantified under one common name – “Origin”. No further attempts to analyse that fraction qualitatively and quantitatively were made. The same concerns other isolated fractions.

For that reason the study, although performed with radiolabelled material, has limited utility as route-of-degradation study.

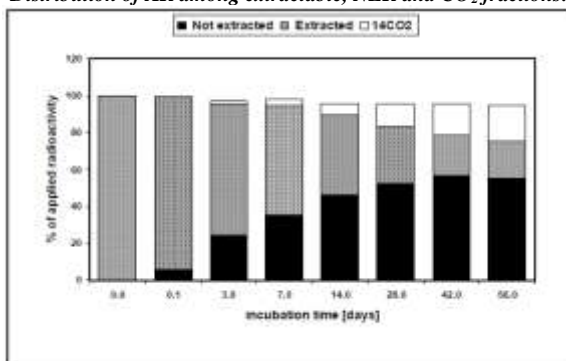

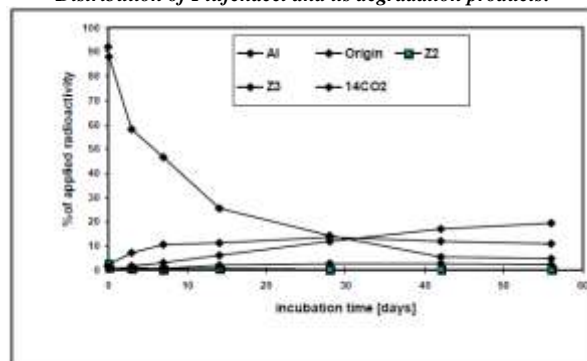

The detailed results are presented below, in numerical form in the table B.8.1.1.2.1.1._CA-2 and in graphical form on figure B.8.1.1.2.1.1._CA-4. The left-hand graph presents the distribution of radioactivity among extracted, not extracted and “mineralised” fractions. On the right-hand graph are presented the concentrations of the constituents of extracts and that of ¹⁴CO₂ (representing the level of mineralisation).

Table B.8.1.2.1.1._CA-4: The detailed results obtained in the study.

% AR		Results obtained for sample collected at DAT ¹⁾ :							
		0 ²⁾	0.1	3	7	14	28	42	56
<i>Extracted as:</i>	Organic extract	100.0	93.6	71.0	59.5	43.3	31.5	21.8	20.0

Footnotes to the table:

- 1) Values presented are the means of the two replicates for each sampling point, with exception of DAT-0 samples (three replicates);
- 2) For that time point the results are those for the application solution;
- 3) "Origin" is sum of all degradation products, detected and quantified in other studies with Flufenacet radiolabelled in phenyl ring;
- 4) Value calculated by adding the results obtained for VOC and those for CO₂
- 5) N. A. = Not Available – fraction by default not analysed at that time point;
- 6) n. a. = not analysed, probably because of the assumption made that at that sampling point neither significant mineralisation nor significant formation of volatile compounds is expected to occur.

Distribution of AR among extractable, NER and CO₂ fractions:*Distribution of Flufenacet and its degradation products:***Figure B.8.1.2.1.1._CA-4:** Graphical presentation of the obtained results (copied from the study report).

The results of the study obtained for Flufenacet were kinetically examined. RMS evaluated that examination and stated that:

- evaluation was performed initially first for 1st order kinetic model using linear regression and MS-Excel tool;
- the refined analysis was performed using Timme&Frehse 2.0 modelling tool for 1st order kinetics and 1.5-order kinetics (best fit).

It does not comply with the current standards of the kinetic analysis set by FOCUS Kinetics Guidance Document (FOCUS, 2006). As such it cannot be considered acceptable. For that reason the RMS decided not to present its results in this summary.

Study 2:

Report: Reinken G., Partsch S., (2014): “Kinetic Evaluation of the Degradation of [phenyl-UL-¹⁴C] flufenacet and its Degradation Products under Aerobic Soil Conditions in Laboratory According to FOCUS Kinetics Using the KinGUI 2 Tool. Flufenacet (FOE 5043); FOE sulfonic acid; FOE oxalate; FOE methylsulfone.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Straße 50, 40789 Monheim, Germany; unpublished Report No. EnSa-12-0575; 2014. 02. 17; study reference number: M-477878-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above. It was stated that the study generally complied with the two evoked Guidance Documents. It was also noted that it was aimed on the derivation of the kinetic endpoints to be used in modelling. For that reason the best fit was not identified and SFO model was generally indicated as returning acceptable fit for parent compound – Flufenacet. As a result when the data for parent and metabolites were kinetically examined only the combination SFO-SFO was tested. RMS summarising the study used the soil names that were provided in the source study reports (in the study report they were slightly altered) to maintain the internal coherence of the document.

Summary:

The aim of the study was to kinetically examine the data obtained in the experiments with [Phenyl-U-¹⁴C] Flufenacet. That was done in order to derive the kinetic parameters suitable for modelling and environmental risk assessment.

The data were taken from three following studies: [Kelley et al.; 1995] (a route-of-degradation study, summarised as **Study 1** under the point B.8.1.1.1.1.), [Pangilinan and Smith; 1994] (a route-of-degradation study, summarised as **Study 2** under the point B.8.1.1.1.1.) and [Hellpointner; 1999] (a rate-of-degradation study, summarised under this point as **Study 1**). The characteristic of the test soils used in each of the experiments is provided below in three following tables: B.8.1.1.2.1.1._CA-5 for the study by [Kelley et al.; 1995], B.8.1.1.2.1.1._CA-6 for the study by [Pangilinan and Smith; 1994] and B.8.1.1.2.1.1._CA-7 for the study by [Hellpointner; 1999]. To maintain the consistency of reporting, only physicochemical properties are reported. The data on soil microbial activity were not given here. To check them please refer to adequate summaries of the source studies.

- 3) Analysis performed by A&L Great Lakes Laboratories Inc. on 29 March 1993;
- 4) Value recalculated by the RMS using the following equation: $pH_{H_2O} = 0.982 pH_{CaCl_2} + 0.648$;
- 5) Value calculated from the corresponding pH in water;
- 6) Value calculated by RMS using the following relationship: OC = OM/1.724.

Table B.8.1.1.2.1.1._CA-7: The characteristic of soil used in the study [Hellpointner; 1999].

Parameter		Soil:
		Laacherhof AXXa
Soil origin		Monheim/ Rheinland/ North Rhine-Westphalia/ Germany
Soil type (USDA)		Sandy loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	71.77
	Silt (2 – 50 µm) [%]	16.47
	Clay (< 2 µm) [%]	11.76
pH value in distilled water		7.0
pH value in 0.01M CaCl ₂		6.1
Organic carbon content (C _{org}) [%] ¹⁾		1.41
Organic matter content (OM) [%] ²⁾		2.42
Cation Exchange Capacity – CEC [mEq/100g]		9.61
Particle density [g/cm ³]		2.5
Water holding capacity	Maximum [g H ₂ O/100 g soil d. w.]	34.4
	50% MWHC [g H ₂ O/100 g soil d. w.]	17.2

Footnotes to the table:

- 1) Measured value;
- 2) Value calculated by the Applicant using the following equation: OM = 1.724*OC;

The incubation conditions used in each experiment are summarised below in the table B.8.1.1.2.1.1._CA-8.

Table B.8.1.1.2.1.1._CA-8: The incubation conditions used in each experiment.

Study	Test soil		Experimental conditions			
	Name	Type (USDA classification)	Incubation temperature T [°C]	Soil moisture		
				In experiment	Reference value	
					MWHC	at ½ bar
Kelley <i>et al.</i> ; 1995	BBA 2.2	Loamy sand	20 ± 1	40% MWHC	53.8%	----
	Laacherhof	Silt loam	20 ± 1	40% MWHC	48.6%	----
	Höfchen im Tal	Silt loam	20 ± 1	40% MWHC	71.6%	----
Pangilinan and Smith; 1994	Howe, Indiana	Sandy loam	21 ± 1	75% of ½ bar	----	13.1%
Hellpointner; 1999	Laacherhof AXXa	Sandy loam	20	50% MWHC	34.4 [g/100 g soil d. w.]	----

The not-processed input data used in the kinetic analysis are presented below, separately for each test soils, in tables B.8.1.1.2.1.1._CA-9 – B.8.1.1.2.1.1._CA-13. In case of the data obtained in two studies – [Pangilinan and Smith; 1994] and [Hellpointner; 1999], only the averages of two replicates are given. For the data from the study by [Kelley et al.; 1995] the results for each replicate are provided only for the parent compound, while for the degradation products they are given as averages. That format of reporting the values was adopted by the authors of this study report.

Table B.8.1.1.2.1.1._CA-9: The non-processed data obtained in **BBA 2.2** Loamy sand soil (study by [Kelley et al.; 1995]) used as input in kinetic analysis.

Time Point – DAT ¹⁾ [days]	Concentration, expressed as [% AR], of:					
	<i>Flufenacet</i>		<i>FOE Sulfonic acid</i>	<i>FOE Oxalate</i>	<i>FOE Methylsulfoxide</i>	<i>FOE Methylsulfone</i>
	Replicate 1	Replicate 2	average	average	average	average
0	97.0	97.7	0.0	0.0	0.0	0.0
7	70.8	75.4	2.4	3.7	0.0	0.0
14	67.2	65.7	3.9	5.4	0.0	0.2
28	45.2	42.0	9.5	6.6	1.1	1.1
56	27.6	27.8	12.3	4.0	1.4	2.8
70	21.5	18.3	17.8	0.6	0.3	2.6

Additionally, in the table B.8.1.1.2.1.1._CA-14 are presented the DAT-0 recoveries, used in processed-data sets as inputs for DAT-0 time points. The averages of two replicates are given, because only these values were provided in source study reports. In the same table are given the LOD values, subsequently used in data-processing procedure.

Table B.8.1.1.2.1.1._CA-14: The DAT-0 recoveries and LOD determined for each experiment.

Study	Test soil		Determined parameter	
	<i>Soil name</i>	<i>Soil type (USDA classification)</i>	<i>DAT-0 recovery [% AR]</i>	<i>LOD [% AR]</i>
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	99.3	0.1
	Laacherhof	Silt loam	93.2	0.1
	Höfchen im Tal	Silt loam	97.3	0.1
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	95.1	0.1
<i>Hellpointner; 1999</i>	Laacherhof AXXa	Sandy loam	100.0	1.0

The data presented in the above tables were subjected to a multistep evaluation procedure performed in line with the recommendations of FOCUS Kinetics Guidelines [FOCUS; 2006]. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using following, 1st order, kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool. That step consisted of the two sub-steps:
 - **Sub-step 1:** kinetic evaluation of the data for parent compound (Flufenacet) only, in order to determine the appropriate kinetic model. At that stage of analysis were tested all three kinetic models listed above;
 - **Sub-step 2:** kinetic evaluation of the data for parent compound (Flufenacet) and its degradation products using for Flufenacet the kinetic model identified as appropriate at previous stage, and SFO model for degradation products;

- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters (not normalised) recommended for modelling.

The raw input data, presented in tables B.8.1.1.2.1.1._CA-9 – B.8.1.1.2.1.1._CA-14, were processes following the recommendations given by FOCUS. In general terms it looked as follows:

- Measured and reported true replicates were taken into account singularly;
- The data sets were checked for their consistency and clear outliers. In case the outliers were found and removed, that was clearly indicated.
- In case of the data from the study by [Pangilinan and Smith; 1994] all data after the time point DAT 28 were removed. That was due to the fact that the collapse of soil microbial activity was observed after that time point. RMS stated that the measure taken by the Applicant was in line with the provisions of FOCUS Kinetics Guidance Document, [FOCUS; 2006].

The particular, measures taken in the processing of the data for the parent compound – Flufenacet, were following:

- The total AR recovery recorded in DAT-0 samples was used as concentration of Flufenacet at that time point, but the M_0 value was allowed to be estimated by the model;
- Values between LOD and LOQ were set to measured values;
- All single values <LOD or the non-detects (n. d.) were set to $\frac{1}{2}$ LOD. The same procedure was applied to the first appearances. However, when the values <LOD/n.d. appeared consecutively for second and next times, the kinetic curve was cut off until the appearance of the first value >LOQ.

The values for degradation products were processed in a following way:

- The initial (DAT-0) concentration was set to 0. That value, unlike the free-fitted M_0 concentration for the parent compound, was a fixed value;
- The values for subsequent time points, if reported as <LOD or non-detects were also set to 0 until the last time point before the first detectable amount was recorded;
- The value reported as <LOD/n.d. appearing just before the first detectable amount was recorded was set to $\frac{1}{2}$ LOD.
- Values between LOD and LOQ were set to measured values;
- In the decline phase the first values <LOD/n.d. were also set $\frac{1}{2}$ LOD. For the consecutive second and next such appearances the kinetic curve was cut off until, eventually, the first value >LOQ appeared.

The processed values used as input data for the kinetic examination are presented below, individually for each test soil, in tables B.8.1.1.2.1.1._CA-15 – B.8.1.1.2.1.1._CA-19. In case of the results obtained in the study by [Kelley et al.; 1995] – in soils **BBA 2.2**, **Laacherhof** and **Höfchen im Tal**, for all compounds the values for two replicates were given. As in case of the degradation products only averages of the two replicates were provided, the measured value was given for the Replicate 1, while for the Replicate 2 it was set to NaN (“Not a Number” – KinGUI default when numbers are not available). In case of the results obtained in two remaining studies – [Pangilinan and Smith; 1994] and [Hellpointner; 1999] the processed values used as input data were the averages of the two replicates, as such were reported in the source study reports.

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure was a two-stage one. The first step, further called **Step 1**, consisted on the determination of the appropriate kinetic model for the parent compound – Flufenacet. At that stage three 1st-order kinetic models were tested: SFO, FOMC and DFOP. During the next stage, further called **Step 2**, the whole data set – data for the Flufenacet and its degradation products, was kinetically examined. In case of Flufenacet the tested kinetic model was that determined as appropriate at **Step 1**, while for the degradation products the SFO model was used.

The conceptual metabolic pathway built in the modelling tool for the most complex data bases – the data from the study by [Kelley et al.; 1995], is presented below on figure B.8.1.1.2.1.1_CA-5. The following abbreviations were used:

- FFA for Flufenacet (parent compound);
- FOESA for FOE Sulfonic acid;
- FOEOX for FOE Oxalate;
- FOEMSX for FOE Methylsulfoxide;
- FOEMS for FOE Methylsulfone.

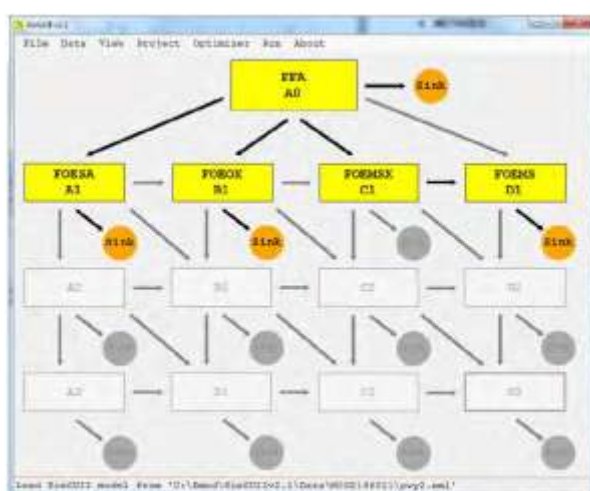

Figure B.8.1.1.2.1.1_CA-5: The conceptual transformation scheme assumed in the modelling tool for the data sets from the study by [Kelley et al.; 1995]
(copied from the study report).

For the data sets from other studies that scheme was adopted, according to the needs, as follows:

- for the data from the study by **[Pangilinan and Smith; 1994]** by removing FOEMSX and FOEMS compartments;
- for the data from the study by **[Hellpointner; 1999]** by removing all compartments representing the degradation products.

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis, comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

Characterising the whole procedure the Applicant stated at the beginning that it is generally preferred to select the simplest kinetic model with a high goodness of fit. That principle was followed when the assessment of the results obtained at the **Step 1** of kinetic analysis of the data was carried out.

Characterising the adopted approach to the visual assessment of the fit, considered to be the first step in the evaluation, the Applicant stated that it focused on the following features:

- the conformity of the fitted decline curve with measured residue concentrations;
- the distribution of the residuals, which should be random and not systematic;
- level of residuals, which should be as small as possible – in such case even if their distribution is rather systematic, the fit may be still qualified as acceptable.

Based on these criteria the fit could be classified as:

- **good fit**, when the conformity of the kinetic curve and measured residues was good, levels of residuals were low, they were randomly scattered and no obvious systematic deviation in residual plot was visible;
- **acceptable fit**, when the conformity of the kinetic curve and measured residues was acceptable, levels of residuals were medium and they were more-or-less randomly scattered, and the absolute level of residuals was low;
- **poor fit**, when the fitted decline curve significantly deviated from the measured residues and did not match the observed pattern, the level of residuals was high and they were clearly not randomly scattered around zero line.

Characterising the next component of the assessment – χ^2 -error statistics, the Applicant indicated that 15% threshold value was not considered to be an absolute cut-off criterion, especially in case of the degradation products. That was indicated to be due to the fact that that threshold value is strictly appropriate for optimal experimental conditions only. It was therefore indicated that in some cases, even though χ^2 -error > 15%, the fit may be acceptable. Additionally, for degradation products it was indicated that for them usually measurements in comparison to the mean of all measurements are low, what strongly influences the χ^2 test.

Finally, characterising the t-test, the Applicant stated that the t-test probability of 0.05 was sufficiently small and should be used as acceptability criterion, in case however of degradation products, or the results of field dissipation studies the *prob* > *t* value of 0.10 or even higher may be still acceptable.

On that basis the following multistep assessment procedure was followed:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in modelling, the SFO kinetic model was tested as first option and if passed the acceptance criteria (visually acceptable, χ^2 -error not exceeding, or not significantly exceeding, 15%, *prob.* > *t* value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the χ^2 -error was significantly greater than 15%, model parameters were fixed and fitting repeated using SFO model;
- **Step 3:** if the **Step-2** fitting failed the χ^2 -error test, bi-phasic models were introduced. These were FOMC, DFOP and, possibly HS. The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved fit, SFO model was selected if visually acceptable. That was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test soil.

- 1) The results of the kinetic analysis of the data obtained in **BBA 2.2** Loamy sand soil (study by [Kelley et al.; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-6 and in numerical form in the table B.8.1.1.2.1.1_CA-20. Additionally the table B.8.1.1.2.1.1_CA-21 provides the kinetic endpoints obtained with each of the kinetic models tested.

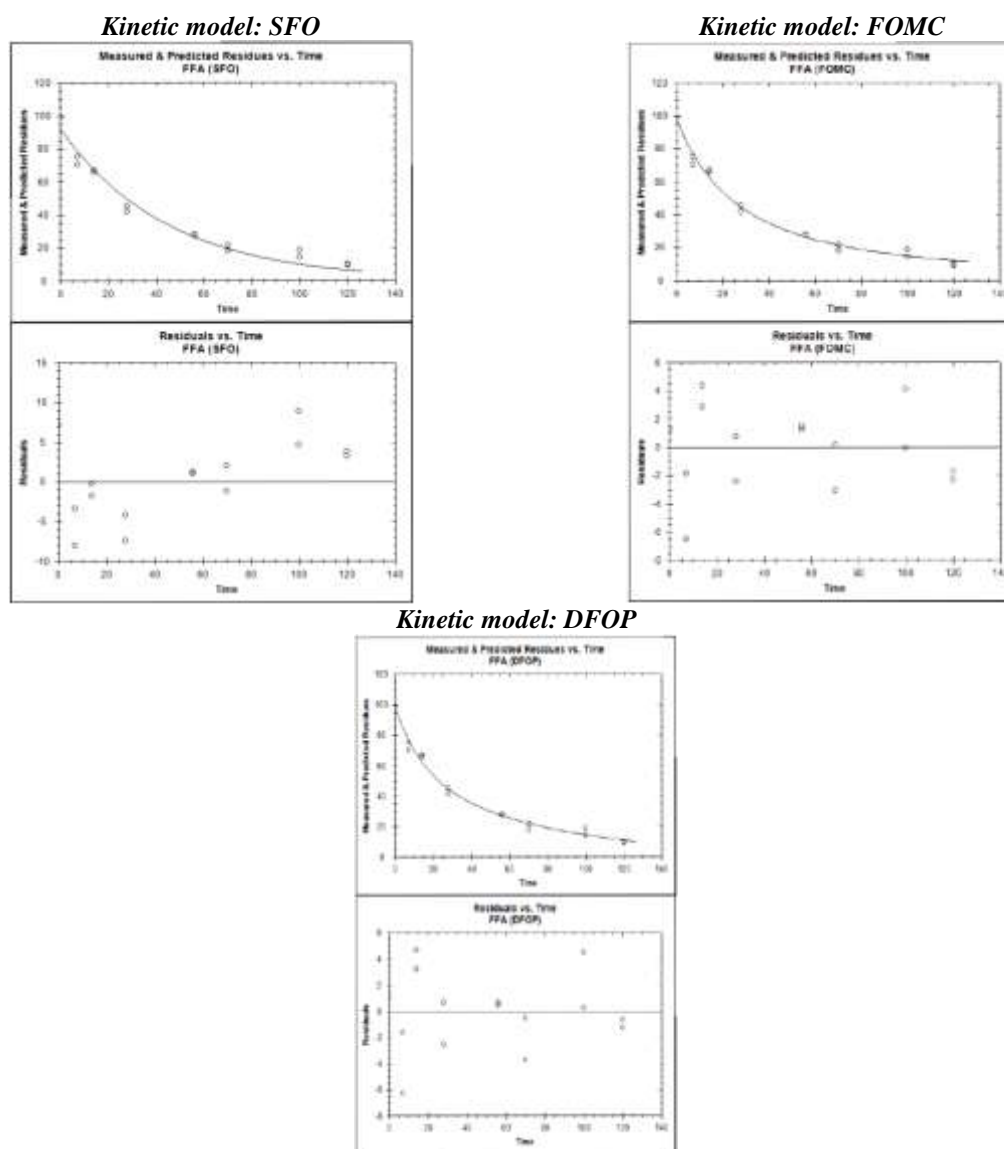

Figure B.8.1.1.2.1.1_CA-6: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-20: The numerical results of the kinetic analysis.

	g	0.4258	0.1580	0.1161	0.735	0.00974		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-21: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	31.16	23.70	23.55
	DT ₉₀ [days]	103.50	142.60	127.90

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable, therefore it was selected as appropriate and used at the next step to kinetically examine the data for Flufenacet and its degradation products. RMS accepted that choice.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-7 and in numerical form in the table B.8.1.1.2.1.1._CA-22. Additionally, in the table B.8.1.1.2.1.1._CA-23 are presented the kinetic endpoints obtained as a result of the evaluation, which were considered reliable by the Applicant.

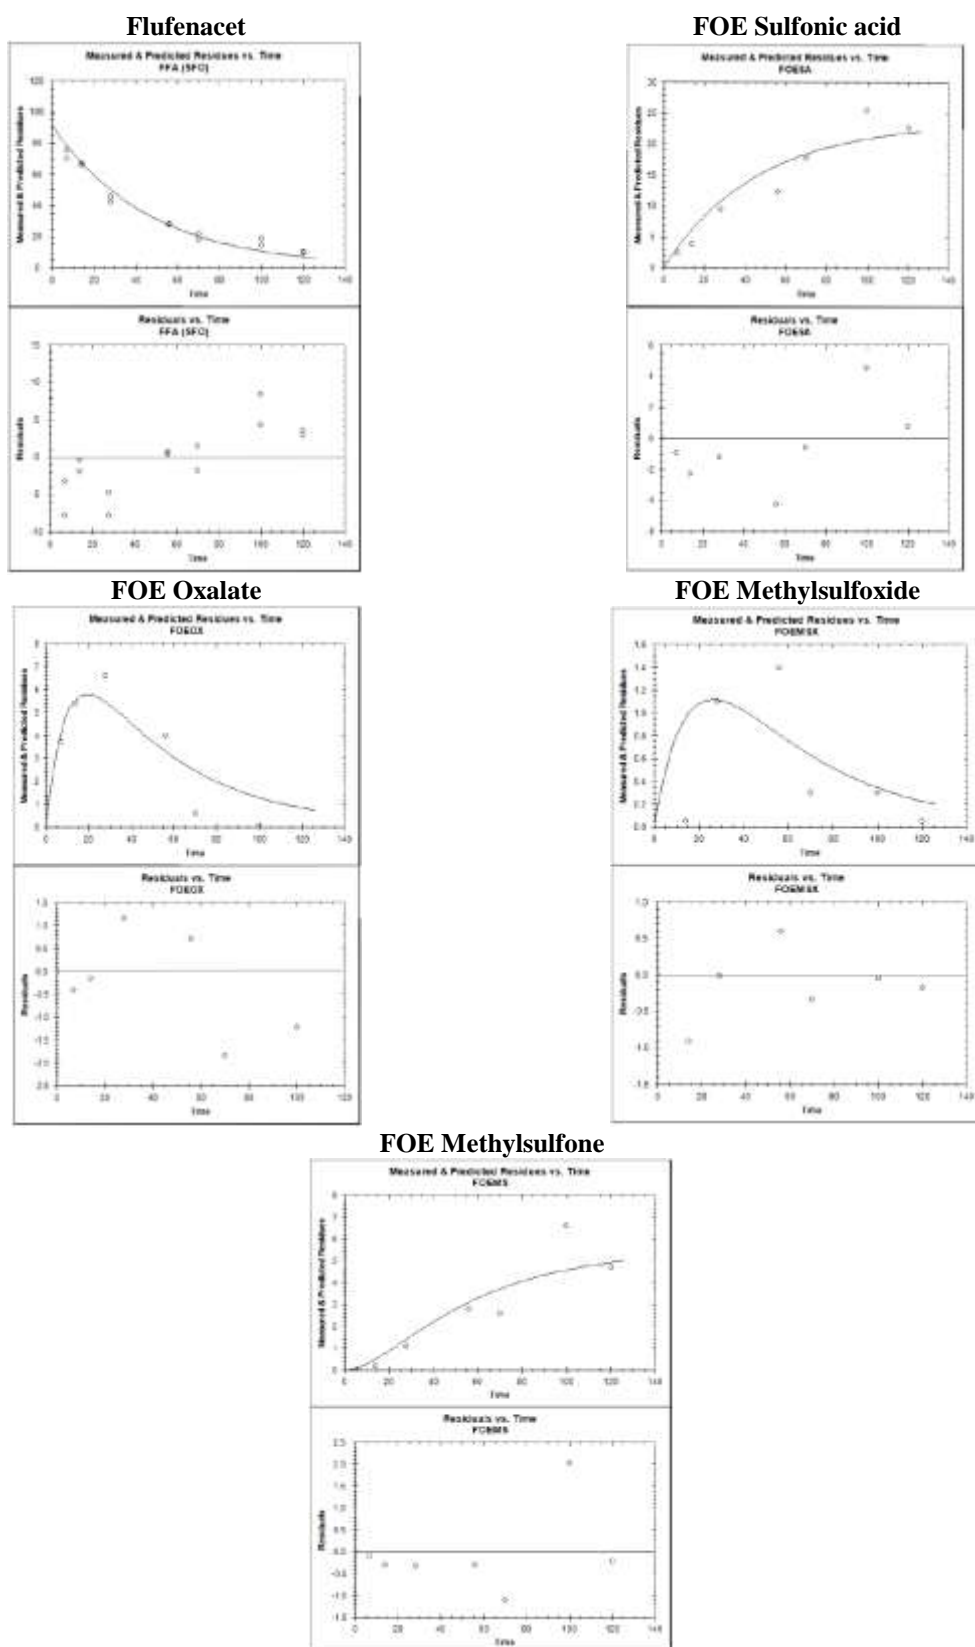

Figure B.8.1.1.2.1.1_CA-7: The graphical results of the kinetic examination of the data for Flufenacet, FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfoxide and FOE Methylsulfone obtained in BBA 2.2 soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-22: The numerical results of the kinetic examination of the data for Flufenacet, FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfoxide and FOE Methylsulfone obtained in BBA 2.2 soil.

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-23: The kinetic endpoints determined in the experiment, as reported by the Applicant.

Determined parameter	Compound			
	Flufenacet	FOE Sulfonic acid	FOE Oxalate	FOE Methylsulfone
DT ₅₀ [days]	31.9	1000	6.9	1000
DT ₉₀ [days]	106.1	> 1000	22.8	> 1000
Kinetic formation fraction ff	Not applicable	0.257 ± 0.021	0.448 ± 0.202	0.061 ± 0.114
Precursor	Not applicable	Flufenacet	Flufenacet	FOE Methylsulfoxide
Kinetic model	SFO	SFO	SFO	SFO

The results of the kinetic fitting for Flufenacet and FOE Sulfonic acid are acceptable. RMS however is of the opinion that while the kinetic formation fraction *ff* calculated for that compound may be considered reliable, the proposed for that compound kinetic endpoints – DT₅₀ and DT₉₀ values bear to high level of uncertainty to be considered such. It was also noticed that the kinetic model did not perform the statistical evaluation of the estimated rate constant *k* for FOE Sulfonic acid. All the may be attributed to the fact that neither well-pronounced decline phase, nor even the would-be maximum, were reached. As a result the proposed DT₅₀ and DT₉₀ values, although included into the definitive set of the endpoints derived from this experiment, will be considered informative only.

Applicant stated that the kinetic endpoints determined for FOE Oxalate are acceptable. In the study report it was stated that the fit, similarly to other fits obtained for all degradation products, showed a good conformity of measured residues and fitted decline curve, demonstrating itself in low χ^2 -error and high correlation coefficients. At the same time the Applicant characterised that fit only as “acceptable”, what stands in contrast with the above statement. RMS analysed the conformity of the fitted curve and measured residues and stated that it was good for the formation phase, but much worse for the decline phase. As a result, the kinetic parameters – DT₅₀ and DT₉₀ values, although statistically reliable according to the results of the t-test, bear some level of uncertainty. RMS also noticed that the distribution of the experimental points on the decline part of the kinetic curve and their number – four, may indicate that the repeated fitting of the data using the top-down approach may result in obtaining more reliable kinetic endpoints. The Applicant’s conclusion with regard to the reliability of the kinetic formation fraction for FOE Oxalate is valid.

In order to verify the assumption about the possible improvement of the fitting results for FOE Oxalate using the top-down approach the RMS performed own kinetic assessment of the data. As a starting point was used the DAT-28 time-point, where the measured concentration of FOE Oxalate in the test soil reached its maximum. The fitting was performed for two data sets – one of them consisting of four points (the DAT-120 was omitted, as it was done by the Applicant), the second one consisting of five data points, including DAT-120, for which the residue value was set to 0. The data used in repeated fitting are presented below in the table B.8.1.1.2.1.1._CA-24.

Table B.8.1.1.2.1.1_CA-24: The input data used in the repeated kinetic assessment for FOE Oxalate performed using the top-down approach.

Variant 1: 4-point data set		Variant 2: 5-point data set	
Time point – DAT [days]	Concentration of FOE Oxalate [%AR]	Time point – DAT [days]	Concentration of FOE Oxalate [%AR]
28	6.6	28	6.6
56	4.0	56	4.0
70	0.6	70	0.6
100	0.05	100	0.05
		120	0.0

The kinetic analysis of the data was performed using CAKE 3.1 modelling tool. IRLS (Iteratively Reweighed Nonlinear Least Squares) was used as optimisation algorithm. Due to the limited amount of the experimental points only SFO model was tested. The results are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-8 and in numerical form in the table B.8.1.1.2.1.1_CA-25.

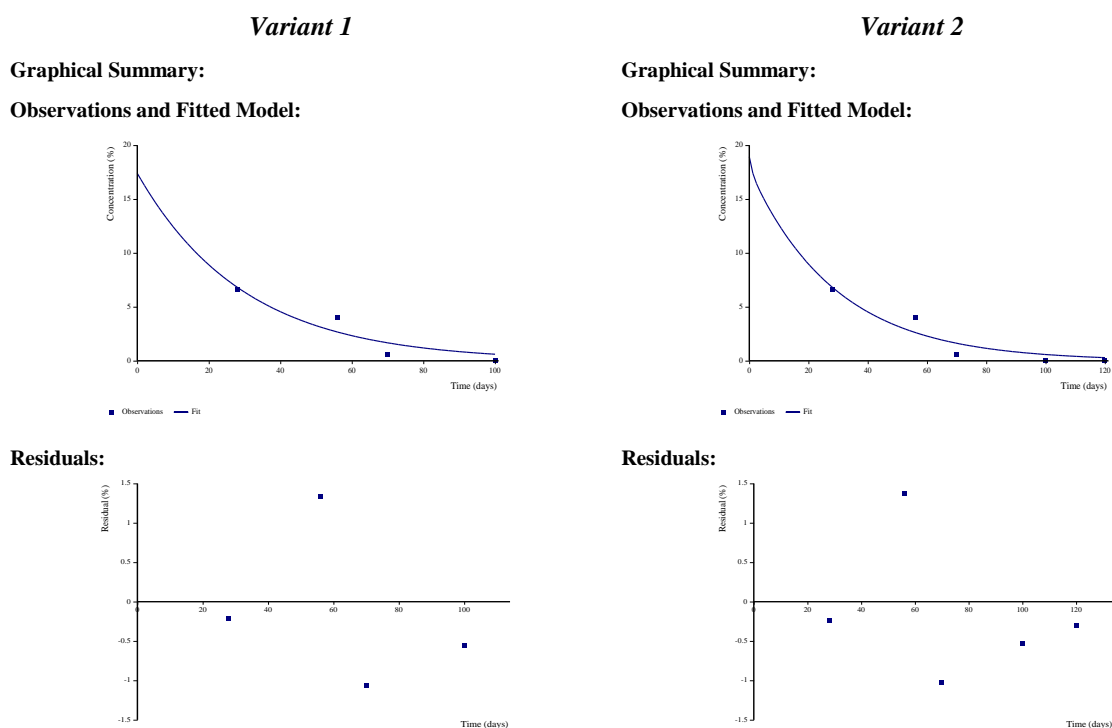

Figure B.8.1.1.2.1.1_CA-8: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1_CA-25: The numerical results of the kinetic examination of the data for FOE Oxalate obtained in BBA 2.2 soil using the top-down approach.

Variant of the experiment	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Variant 1	SFO	M_0	17.39	8.022	-17.12	51.91	-----	26.3	0.890; fit acceptable
		k	0.03349	0.01259	-0.02068	0.088	0.05852		
Variant 2	SFO	M_0	17.73	6.688	-3.551	39.02	-----	29.2	0.909; fit acceptable
		k	0.03411	0.0103	0.001332	0.067	0.02267		

The kinetic re-examination of the data did not resulted in statistical improvement of the fit – the level of the χ^2 -error even increased for both variants. Visually fit improved, but not significantly. The kinetic endpoints

determined for the Variant-1 fitting were not fully reliable – the *prob. > t* was higher than 0.05. In case of the Variant 2 it was possible to obtain reliable kinetic endpoints. RMS noticed that the kinetic endpoints were about three times higher in comparison to those obtained by the Applicant in fitting of the whole data set – for Variant 1 $DT_{50} = 20.7$ days and for Variant 2 $DT_{50} = 20.3$ days.

Additionally, for Variant-2 data set the RMS performed the fitting using two bi-phasic models – FOMC and DFOP. However, as no improvement of the fit was achieved and the reliability of the kinetic parameters was low, RMS decided not to present these results in order not to overburden the report.

In case of FOE Methylsulfone RMS stated that it was not possible to obtain the reliable kinetic fit. That was due to three factors:

- 1) low concentrations of FOE Methylsulfoxide – the precursor of FOE Methylsulfone, what made not possible to obtain the reliable kinetic fit for that compound;
- 2) low concentrations of FOE Methylsulfone itself, what also made impossible to obtain the acceptable fit for this compound;
- 3) the fact that the kinetic curve for FOE Methylsulfone was still in formation phase at the end of the experiment.

As a result, RMS stated that neither kinetic endpoints for FOE Methylsulfone nor the kinetic fraction *ff* reported for that compound by the Applicant may be considered reliable.

Examining the available data set RMS stated that the possible solution, which may lead to some improvement of the results of the fitting, would be to merge the results for FOE Methylsulfoxide and FOE Methylsulfone into one data set, considered as representative for FOE Methylsulfone, and repeat the kinetic analysis.

The data set used in the fitting exercise is presented below in the table B.8.1.1.2.1.1._CA-26. RMS decided for Flufenacet, FOE Sulfonic acid and FOE Oxalate to use the same data as the Applicant. However, as for Flufenacet two replicates were available, while for the metabolites only the averages of the two replicates, the RMS decided to use for all three degradation products, the average values as both Replicate 1 and Replicate 2.

Table B.8.1.1.2.1.1._CA-26: The input data used by the RMS in repeated kinetic evaluation of the results obtained in **BBA 2.2** Loamy sand soil (study [Kelley et al.; 1995]).

Time Point – DAT ¹⁾ [days]	Concentration, expressed as [% AR], of:

Precursor	Not applicable	Flufenacet	Flufenacet	FOE Methylsulfoxide
Kinetic model	SFO	SFO	SFO	SFO

The results of the repeated kinetic analysis returned results comparable to those obtained by the Applicant. No significant improvement was achieved for the corrected data for FOE Methylsulfone.

Final assessment:

The kinetic analysis of the data for Flufenacet and its degradation products – FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfoxide and FOE Methylsulfone resulted in good fitting results for the parent compound and FOE Sulfonic acid. In case of FOE Oxalate the fit was visually acceptable but not statistically, most probably due to the low concentrations of that compound in the test soil. It was noted that in case of FOE Sulfonic acid the decline phase was not reached during the experiment, it is even doubtful whether the kinetic curve reached its maximum point. Therefore the kinetic endpoints for that compound should be considered as indicative. The determined kinetic formation fraction *ff* for that compound may be considered reliable.

For FOE Oxalate it may be stated that despite not very good conformity of the kinetic curve in its decline part with the measurable residues the determined kinetic endpoints may be considered reliable, as demonstrated their statistical evaluation, although they bear some uncertainty. Reliable is also the kinetic formation fraction *ff* determined for that compound. It shall be noted that the repeated kinetic analysis of the data for FOE Oxalate performed by the RMS using the top-down approach did not result in obtaining more reliable fits. That may further indicate that the problems with the fitting are related to low concentrations of FOE Oxalate in the test soil, what in turn indicated its low persistence. Therefore the calculated for the whole kinetic curve DT₅₀ and DT₉₀ values may be considered reliable.

In case of FOE Methylsulfoxide and FOE Methylsulfone it was not possible to obtain fully reliable fit. Hence the kinetic endpoints determined for FOE Methylsulfone should be considered indicative, while kinetic formation fraction *ff* conditionally reliable.

- 2) The results of the kinetic analysis of the data obtained in **Laacherhof** Silt loam soil (study by [Kelley et al.; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-10 and in numerical form in the table B.8.1.1.2.1.1_CA-29. Additionally the table B.8.1.1.2.1.1_CA-30 provides the kinetic endpoints obtained with each of the kinetic models tested.

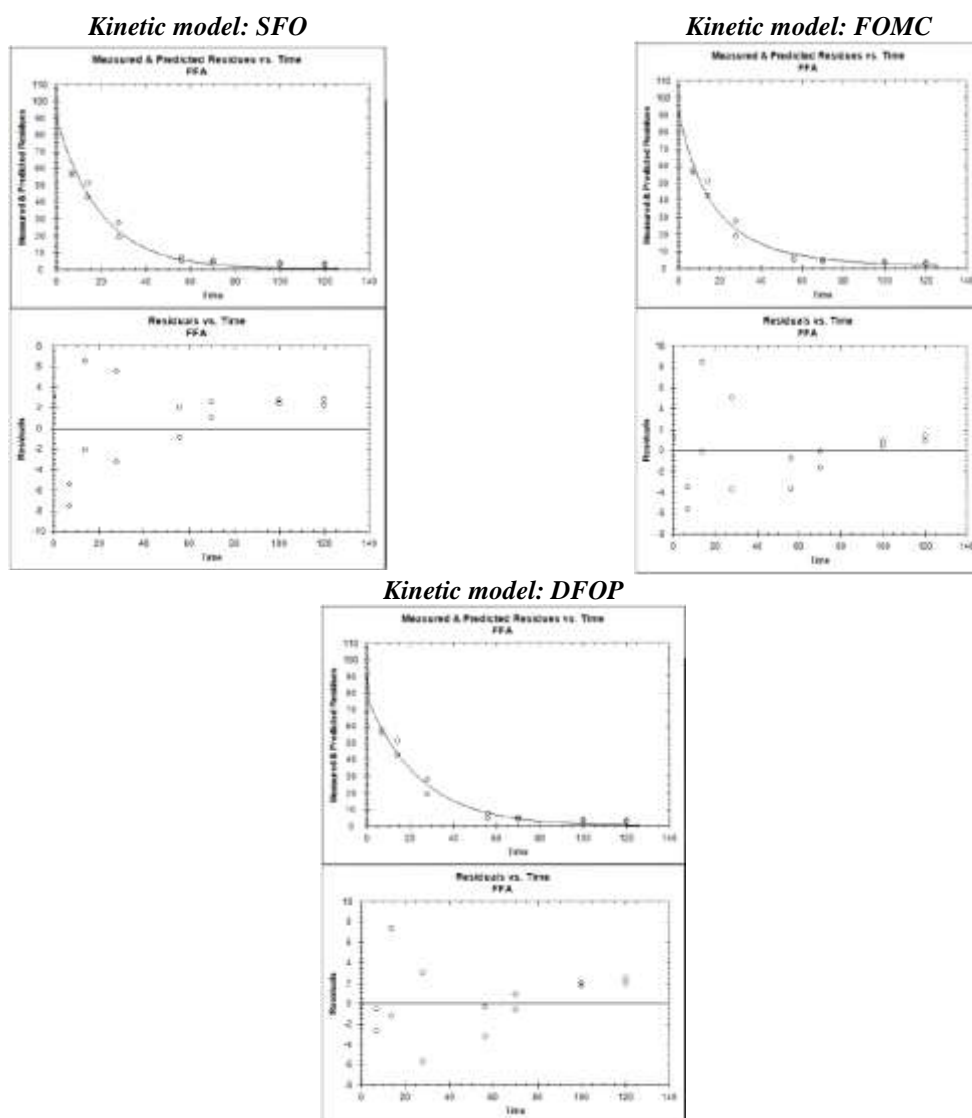

Figure B.8.1.1.2.1.1_CA-10: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-29: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	90.117	2.603	85.015	95.219	2.88 E-15	8.215	0.987; Good fit
	k	0.04965	0.00330	0.04318	0.056	2.43 E-10		
FOMC	M ₀	92.026	2.545	87.038	97.013	9.83 E-15	6.953	0.989; Acceptable fit
	α	3.7022	1.6909	0.3881	7.016	0.0237		
	β	61.4572	33.7177	-4.6283	127.543	0.0457		
DFOP	M ₀	93.200	2.365	88.565	97.835	2.30 E-14	5.496	0.992; Acceptable fit
	k ₁	196.922	n. a. ²⁾	n. a. ²⁾	n. a. ²⁾	n. a. ²⁾		
	k ₂	0.04086	0.00349	0.03402	0.048	3.17 E-8		
	g	0.1610	0.04854	0.06588	0.2562	0.00307		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant;
 2) Value not calculated by the modelling tool.

Table B.8.1.1.2.1.1._CA-30: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	13.96	12.65	12.67
	DT ₉₀ [days]	46.38	53.01	52.05

On the basis of the obtained results the Applicant proposed to consider SFO as returning reliable and acceptable fit. That model was proposed to be used for the parent compound in kinetic examination of the data for parent compound and degradation products. RMS accepted that proposal noticing that neither FOMC nor DFOP returned fully reliable results.

- b) results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-11 and in numerical form in the table B.8.1.1.2.1.1._CA-31. Additionally, in the table B.8.1.1.2.1.1._CA-32 are presented the kinetic endpoints obtained as a result of the evaluation, which the Applicant considered reliable.

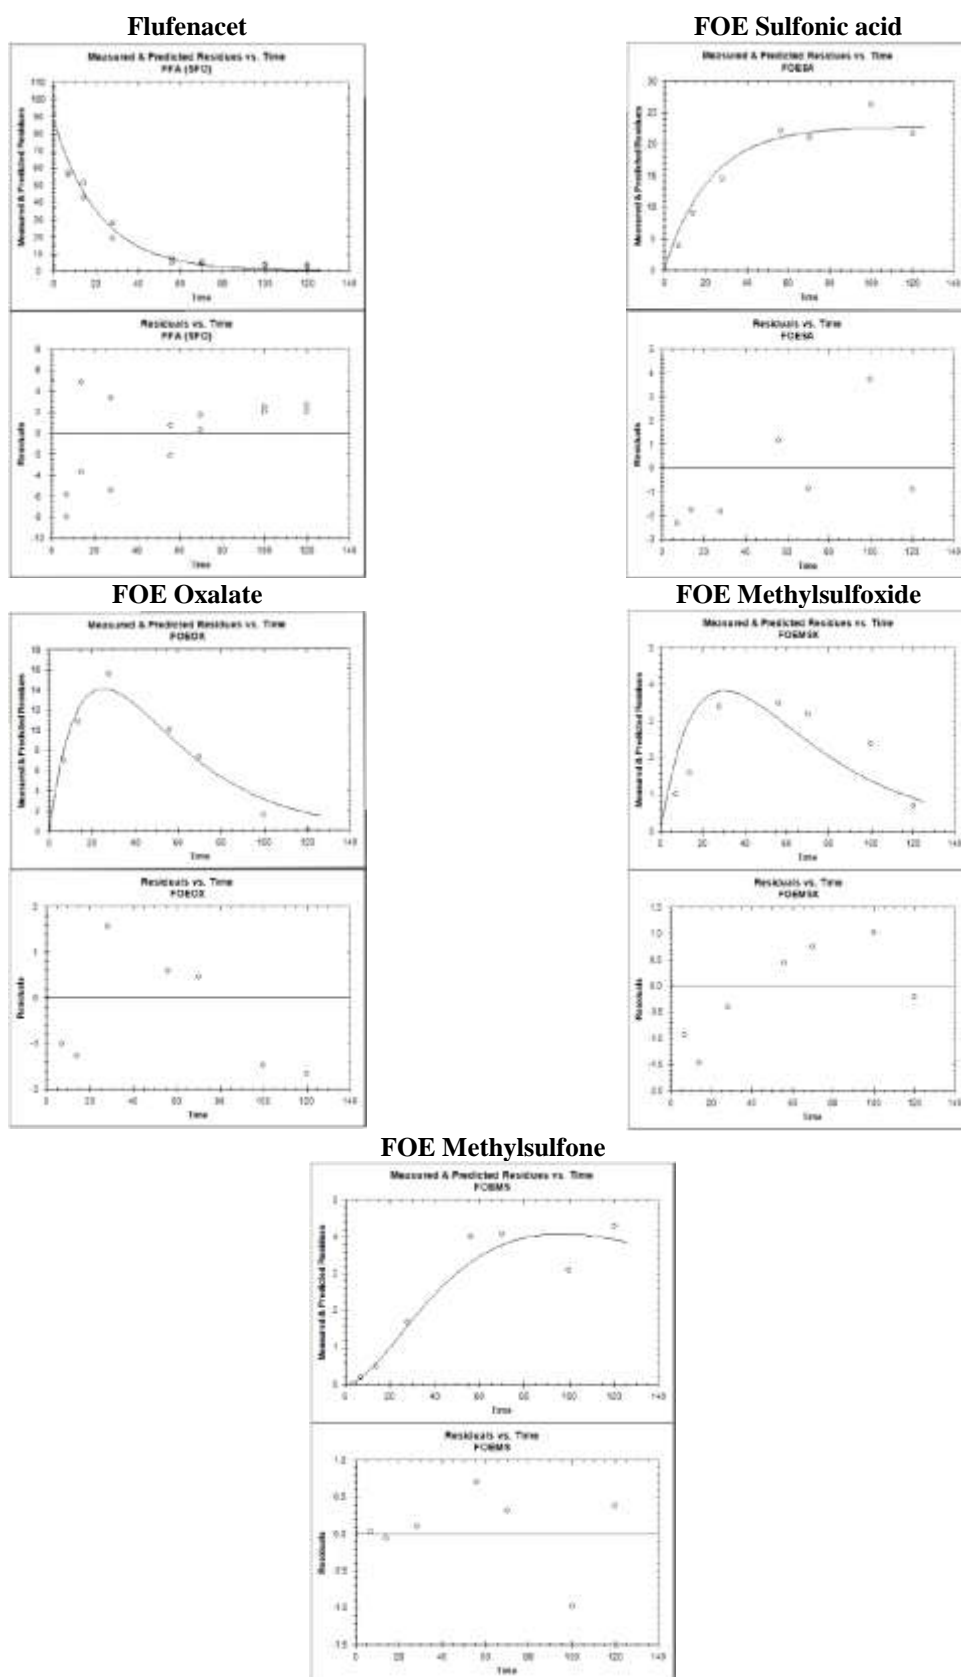

Figure B.8.1.1.2.1.1_CA-11: The graphical results of the kinetic examination of the data for Flufenacet, FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfoxide and FOE Methylsulfone obtained in Laacherhof soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-32: The kinetic endpoints determined in the experiment, as reported by the Applicant.

Determined parameter	Compound			
	Flufenacet	FOE Sulfonic acid	FOE Oxalate	FOE Methylsulfone
DT ₅₀ [days]	15.21	1000	20.70	82.70
DT ₉₀ [days]	50.53	> 1000	68.76	274.74
Kinetic formation fraction ff	Not applicable	0.259 ± 0.029	0.375 ± 0.072	0.087 ± 0.057
Precursor	Not applicable	Flufenacet	Flufenacet	FOE Methylsulfoxide
Kinetic model	SFO	SFO	SFO	SFO

The results of the kinetic fitting for Flufenacet, FOE Sulfonic acid and FOE Oxalate are acceptable.

The kinetic parameters – DT₅₀ and DT₉₀ values for Flufenacet are reliable, therefore acceptable. Also reliable and therefore acceptable are all kinetic parameters – DT₅₀ and DT₉₀ values as well as kinetic formation fraction ff , obtained for FOE Oxalate. Also the statement with regard to the kinetic fit for that compound – it showed a good conformity of measured residues and fitted decline curve, demonstrating itself in low χ^2 -error and high correlation coefficients may be considered correct. RMS noticed that the Applicant classified the fit for FOE Oxalate, on the basis of the results of its visual inspection, as acceptable. RMS however is of the opinion that that fit should be classified as “good”.

In case of FOE Sulfonic acid RMS however is of the opinion that while the kinetic formation fraction ff calculated for that compound may be considered reliable, the proposed kinetic endpoints – DT₅₀ and DT₉₀ values bear to high level of uncertainty to be considered such. It was also noticed that the kinetic model did not estimate rate constant k for FOE Sulfonic acid. All the may be attributed to the fact that the decline phase was not reached. As a result the proposed DT₅₀ and DT₉₀ values, although included into the definitive set of the endpoints derived from this experiment, will be considered informative only.

In case of FOE Methylsulfone the acceptable fit was obtained, but it cannot be considered as reliable due to the lack of reliability of that for its precursor – FOE Methylsulfoxide. The lack of the reliability of the kinetic fit for FOE Methylsulfoxide is caused by low measurable concentrations of that compound used as input data in the kinetic analysis, what in turn is due to the fact that that compound was classified as minor/transient degradation product.

RMS decided to verify whether it was possible to obtain better, reliable fit for FOE Methylsulfone by merging the data for FOE Methylsulfone and FOE Methylsulfoxide into one data set and repeating kinetic analysis. That was done and the resulting data set is presented below in the table B.8.1.1.2.1.1._CA-33. RMS decided to use the data for Flufenacet, FOE Sulfonic acid and FOE Oxalate not modified in comparison to those proposed by the Applicant. However, as for Flufenacet two replicates were available, while for the metabolites only the averages of the two replicates, the RMS decided to use average values as Replicate 1 and Replicate 2. The same approach was adopted in case of FOE Methylsulfone.

Table B.8.1.1.2.1.1_CA-33: The input data used by the RMS in repeated kinetic evaluation of the results obtained in **Laacherhof** Silt loam soil (study [Kelley et al.; 1995]).

1) Value set to ½LOD.

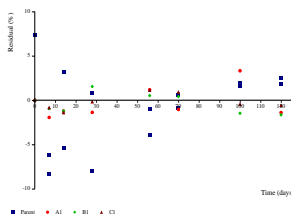

The analysis was carried out using CAKE 3.1 modelling tool, using IRLS (Iteratively Reweighed Nonlinear Least Squares) as optimisation algorithm. To maintain the consistency with the analysis performed by the Applicant RMS decided to perform it only for the SFO model in case of the parent compound. The results of the kinetic analysis performed by the RMS are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-12 and in numerical form in the table B.8.1.1.2.1.1_CA-34. The kinetic endpoints calculated by the model are presented in the table B.8.1.1.2.1.1_CA-35.

Determined parameter	Compound			
	Flufenacet	FOE Sulfonic acid	FOE Oxalate	corr. FOE Methylsulfone
DT ₅₀ [days]	16.9	10000	18.9	174
DT ₉₀ [days]	56	> 10000	62.9	576
Kinetic formation fraction ff	Not applicable	0.272 ± 0.026	0.422 ± 0.052	0.096 ± 0.012
Precursor	Not applicable	Flufenacet	Flufenacet	FOE Methylsulfoxide
Kinetic model	SFO	SFO	SFO	SFO

The results of the repeated kinetic analysis returned results comparable to those obtained by the Applicant. It was noted that for all compounds the calculated ff values increased. Also increased the DT₅₀ and DT₉₀ values for Flufenacet and FOE Methylsulfone. While in case of Flufenacet that increase was not significant, it was substantial for FOE Methylsulfone – the values increased by the factor of two.

In case of FOE Oxalate was observed a slight decrease of both DT₅₀ and DT₉₀ values.

Final assessment:

The kinetic analysis of the data for Flufenacet and its degradation products – FOE Sulfonic acid, FOE Oxalate, and FOE Methylsulfone performed by the Applicant resulted in good fitting results for all examined compounds. In case however of FOE Methylsulfone it cannot be considered fully acceptable, as the not reliable was the kinetic analysis for its immediate precursor – FOE Methylsulfoxide.

RMS repeated the kinetic analysis for the whole data set, correcting the input values for FOE Methylsulfone, obtaining the reliable fits for all evaluated compounds – Flufenacet, FOE Sulfonic acid, FOE Oxalate and FOE Methylsulfone. The obtained results, with exception of those for FOE Methylsulfone, differed slightly from those obtained by the Applicant, so it was possible to keep the Applicant's results at least for Flufenacet, FOE Sulfonic acid and FOE Oxalate. RMS however decided, in order to maintain the internal consistency of the data, to fully rely on the results of the repeated kinetic assessment in the further evaluation.

- 3) The results of the kinetic analysis of the data obtained in **Höfchen im Tal** Silt loam soil (study by [Kelley et al.; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-13 and in numerical form in the table B.8.1.1.2.1.1_CA-36. Additionally the table B.8.1.1.2.1.1_CA-37 provides the kinetic endpoints obtained with each of the kinetic models tested.

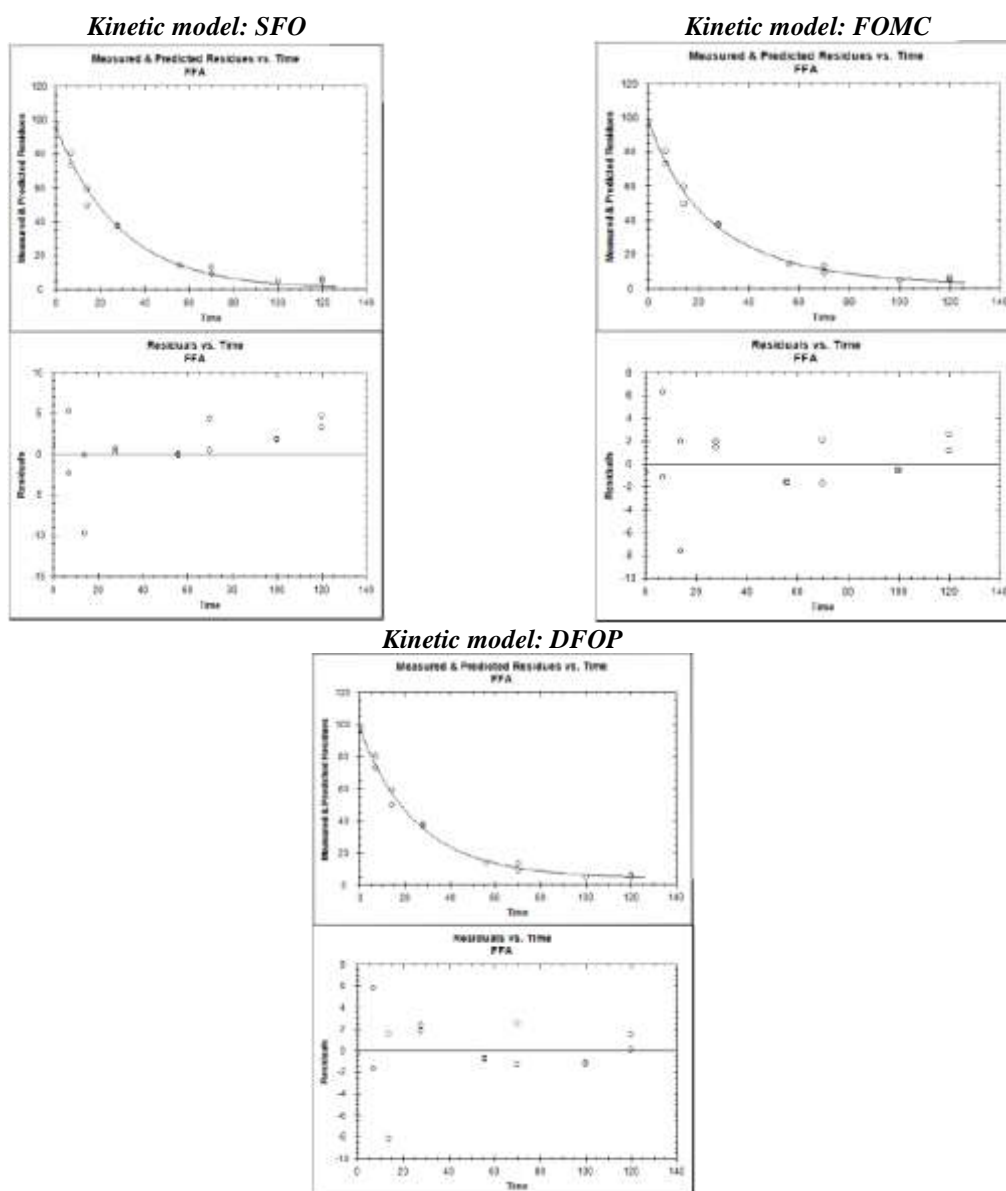

Figure B.8.1.1.2.1.1_CA-13: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-36: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	95.960	2.153	91.740	100.180	<2 E-16	5.459	0.991; Good fit
	k	0.03428	0.00179	0.03077	0.038	9.65 E-12

Table B.8.1.1.2.1.1._CA-39: The kinetic endpoints determined in the experiment, as reported by the Applicant.

Determined parameter	Compound			
	Flufenacet	FOE Sulfonic acid	FOE Oxalate	FOE Methylsulfone
DT ₅₀ [days]	20.44	1000	13.09	1000
DT ₉₀ [days]	67.90	> 1000	43.48	> 1000
Kinetic formation fraction ff	Not applicable	0.143 ± 0.006	0.350 ± 0.045	0.051 ± 0.018
Precursor	Not applicable	Flufenacet	Flufenacet	FOE Methylsulfoxide
Kinetic model	SFO	SFO	SFO	SFO

The results of the kinetic fitting for Flufenacet, FOE Sulfonic acid and FOE Oxalate are acceptable.

The kinetic parameters – DT₅₀ and DT₉₀ values for Flufenacet are reliable, therefore acceptable. Also reliable and therefore acceptable are all kinetic parameters – DT₅₀ and DT₉₀ values as well as kinetic formation fraction ff, obtained for FOE Oxalate. Also the statement with regard to the kinetic fit for that compound – it showed a good conformity of measured residues and fitted decline curve, demonstrating itself in low χ^2 -error and high correlation coefficients may be considered correct.

In case of FOE Sulfonic acid RMS however is of the opinion that while the kinetic formation fraction ff calculated for that compound may be considered reliable, the proposed kinetic endpoints – DT₅₀ and DT₉₀ values bear to high level of uncertainty to be considered such. It was also noticed that the kinetic model although it estimated rate constant k for FOE Sulfonic acid was not able to provide its statistical evaluation. All the may be attributed to the fact that the decline phase was not reached. As a result the proposed DT₅₀ and DT₉₀ values, although included into the definitive set of the endpoints derived from this experiment, will be considered informative only.

In case of FOE Methylsulfone the acceptable fit was obtained, but it cannot be considered reliable due to the lack of reliability of that for its precursor – FOE Methylsulfoxide. The lack of the reliability of the kinetic fit for FOE Methylsulfoxide is caused by low measurable concentrations of that compound used as input data in the kinetic analysis, what in turn is due to the fact that that compound was classified as minor/transient degradation product.

RMS decided to verify whether it was possible to obtain, better, reliable fit for FOE Methylsulfone by merging the data for FOE Methylsulfone and FOE Methylsulfoxide into one data set and repeating kinetic analysis. That was done and the resulting data set is presented below in the table B.8.1.1.2.1.1._CA-40. RMS decided to use the data for Flufenacet, FOE Sulfonic acid and FOE Oxalate not modified in comparison to those proposed by the Applicant. However, as for Flufenacet two replicates were available, while for the metabolites only the averages of the two replicates, the RMS decided to use average values as Replicate 1 and Replicate 2. The same approach was adopted in case of FOE Methylsulfone.

Table B.8.1.1.2.1.1._CA-40: The input data used by the RMS in repeated kinetic evaluation of the results obtained in **Höfchen im Tal** Silt loam soil (study [Kelley et al.; 1995]).

Precursor	Not applicable	Flufenacet	Flufenacet	FOE Methylsulfoxide
Kinetic model	SFO	SFO	SFO	SFO

The results of the repeated kinetic analysis returned results comparable to those obtained by the Applicant, with no significant differences observed.

Final assessment:

The kinetic analysis of the data for Flufenacet and its degradation products – FOE Sulfonic acid, FOE Oxalate, and FOE Methylsulfone resulted in good fitting results for all examined compounds.

It can be therefore stated that:

- the kinetic parameters – DT₅₀ and DT₉₀ values, determined by the Applicant for Flufenacet are reliable and acceptable;
- the kinetic parameters – DT₅₀ and DT₉₀ values as well as kinetic formation fraction ff determined by the Applicant for FOE Oxalate are reliable and acceptable;
- for FOE Sulfonic acid the determined kinetic formation fraction ff may be considered reliable and acceptable, but other kinetic parameters – DT₅₀ and DT₉₀ values should be considered indicative only due to significant level of uncertainty;
- For FOE Methylsulfoxide the determined kinetic formation fraction ff may be considered reliable and acceptable, but other kinetic parameters – DT₅₀ and DT₉₀ values should be considered indicative only due to significant level of uncertainty.

- 4) The results of the kinetic analysis of the data obtained in **Howe, Indiana**, Sandy loam soil (study by [Pangilinan and Smith; 1994]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-16 and in numerical form in the table B.8.1.1.2.1.1_CA-43. Additionally the table B.8.1.1.2.1.1_CA-44 provides the kinetic endpoints obtained with each of the kinetic models tested.

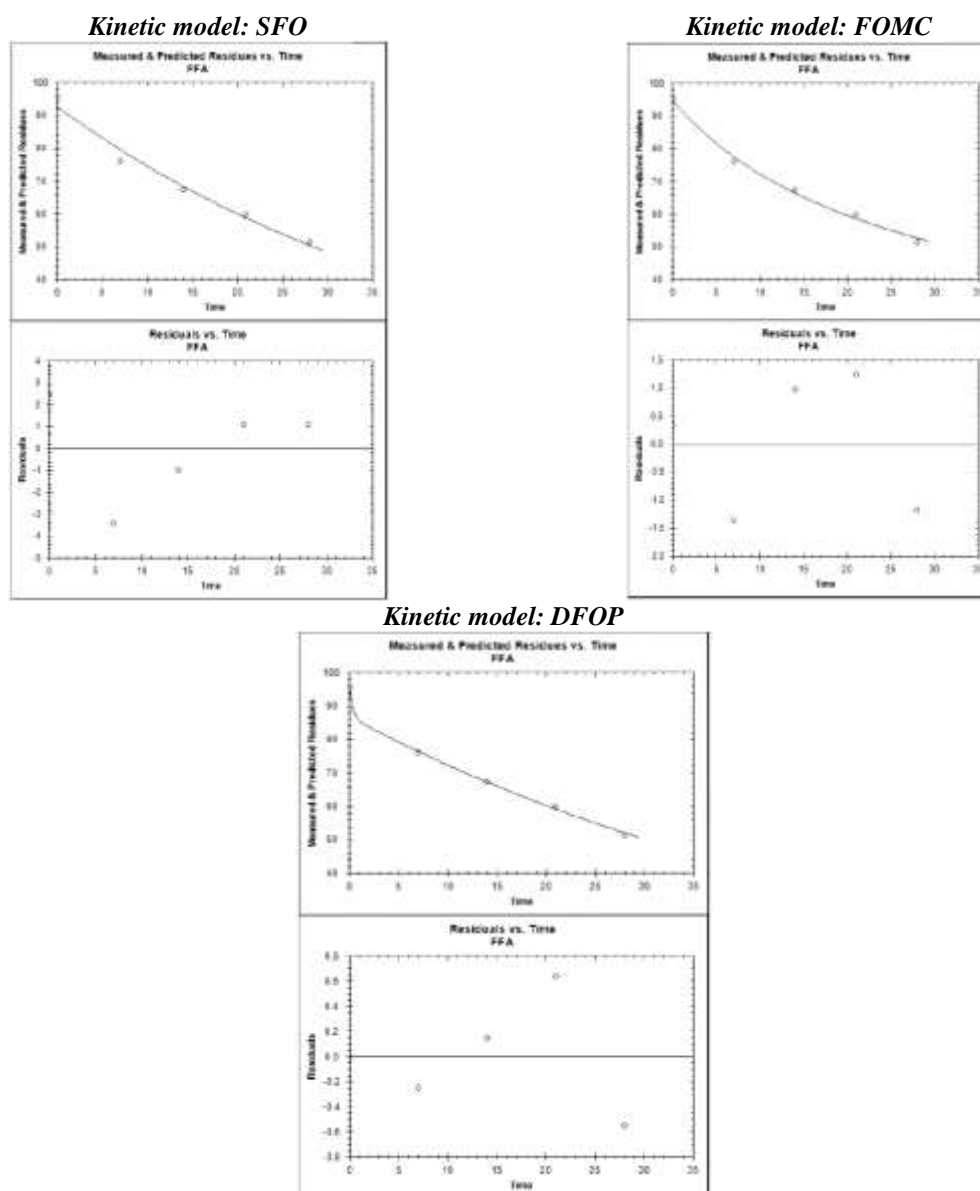

Figure B.8.1.1.2.1.1_CA-16: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-43: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	92.683	2.241	88.291	97.075	1.56 E-5	2.351	0.981; Good fit
	k	0.02182	0.001778	0.01833	0.025	0.000583		
FOMC	M ₀	94.780	1.686	91.474	98.085	1.58 E-4	1.407	0.995; Good fit
	α	0.6735	0.2870	0.1111	1.2360	0.07174		
	β	20.0267	12.1999	-3.8846	43.938	0.1212		
DFOP	M ₀	95.100	0.889	93.360	96.840	0.00298	0.649	0.999; Acceptable fit
	k ₁	2.980	n. a. ²⁾	n. a. ²⁾	n. a. ²⁾	n. a. ²⁾		
	k ₂	0.01834	9.084 E-4	0.01656	0.02	0.01575		
	g	0.08718	0.01654	0.05477	0.120	0.05967		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant;
 2) Value not calculated by the modelling tool.

Table B.8.1.1.2.1.1._CA-44: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	31.77	36.02	32.82
	DT ₉₀ [days]	105.50	591.40	120.60

On the basis of the obtained results the Applicant proposed to consider SFO as returning reliable and acceptable fit. That model was proposed to be used for the parent compound in kinetic examination of the data for parent compound and degradation products. RMS accepted that proposal noticing that neither FOMC nor DFOP returned fully reliable results.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-17 and in numerical form in the table B.8.1.1.2.1.1._CA-45. Additionally, in the table B.8.1.1.2.1.1._CA-46 are presented the kinetic endpoints obtained as a result of the evaluation, which Applicant considered reliable.

DT ₉₀ [days]	107.00	> 1000	64.33
Kinetic formation fraction <i>ff</i>	Not applicable	0.108 ± 0.010	0.484 ± 0.101
Precursor	Not applicable	Flufenacet	Flufenacet
Kinetic model	SFO	SFO	SFO

The results of the kinetic fitting for Flufenacet, FOE Sulfonic acid and FOE Oxalate are acceptable.

The kinetic parameters – DT₅₀ and DT₉₀ values for Flufenacet are reliable, therefore acceptable.

In case of FOE Sulfonic acid RMS is of the opinion that while the kinetic formation fraction *ff* calculated for that compound may be considered reliable, the proposed kinetic endpoints – DT₅₀ and DT₉₀ values bear to high level of uncertainty to be considered such. It was also noticed that the kinetic model, although it estimated rate constant *k* for FOE Sulfonic acid, was not able to provide its statistical evaluation. All the may be attributed to the fact that the decline phase was not reached. As a result the proposed DT₅₀ and DT₉₀ values, although included into the definitive set of the endpoints derived from this experiment, will be considered informative only.

Also for FOE Oxalate RMS stated that while the kinetic formation fraction *ff* calculated for that compound may be considered reliable, the proposed kinetic endpoints – DT₅₀ and DT₉₀ values cannot be considered as such. That conclusion was drawn despite the fact that the model estimated seemingly reliable rate constant *k* for FOE Oxalate and from it calculated the kinetic endpoints – DT₅₀ and DT₉₀. It shall be pointed out however that the decline phase for that compound was not reached. Moreover, careful examination of the full data base, including the later time points cut-off by the Applicant because of the collapse of soil microbial activity, showed that the compound was still forming at the end of the experiment. As a results neither the estimated rate constant *k* nor resulting from it kinetic endpoints – DT₅₀ and DT₉₀ values, may be considered reliable. It is probable that what the modelling tool in fact calculated was the rate constant of the formation of FOE Oxalate in the test soil.

Final assessment:

The kinetic analysis of the data for Flufenacet and its degradation products – FOE Sulfonic acid and FOE Oxalate resulted in good fitting results for all examined compounds.

It can be therefore stated that:

- the kinetic parameters – DT₅₀ and DT₉₀ values, determined by the Applicant for Flufenacet are reliable and acceptable;
- for FOE Sulfonic acid the determined kinetic formation fraction *ff* may be considered reliable and acceptable, but other kinetic parameters – DT₅₀ and DT₉₀ values should be considered indicative only due to significant level of uncertainty;
- For FOE Oxalate the determined kinetic formation fraction *ff* may be considered reliable and acceptable, but other kinetic parameters – DT₅₀ and DT₉₀ values cannot be considered even indicative due to significant level of uncertainty.

- 5) The results of the kinetic analysis of the data obtained in **Laacherhof AXXa** Sandy loam soil (study by [Hellpointner; 1999]):

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-18 and in numerical form in the table B.8.1.1.2.1.1._CA-47. Additionally the table B.8.1.1.2.1.1._CA-48 provides the kinetic endpoints obtained with each of the kinetic models tested.

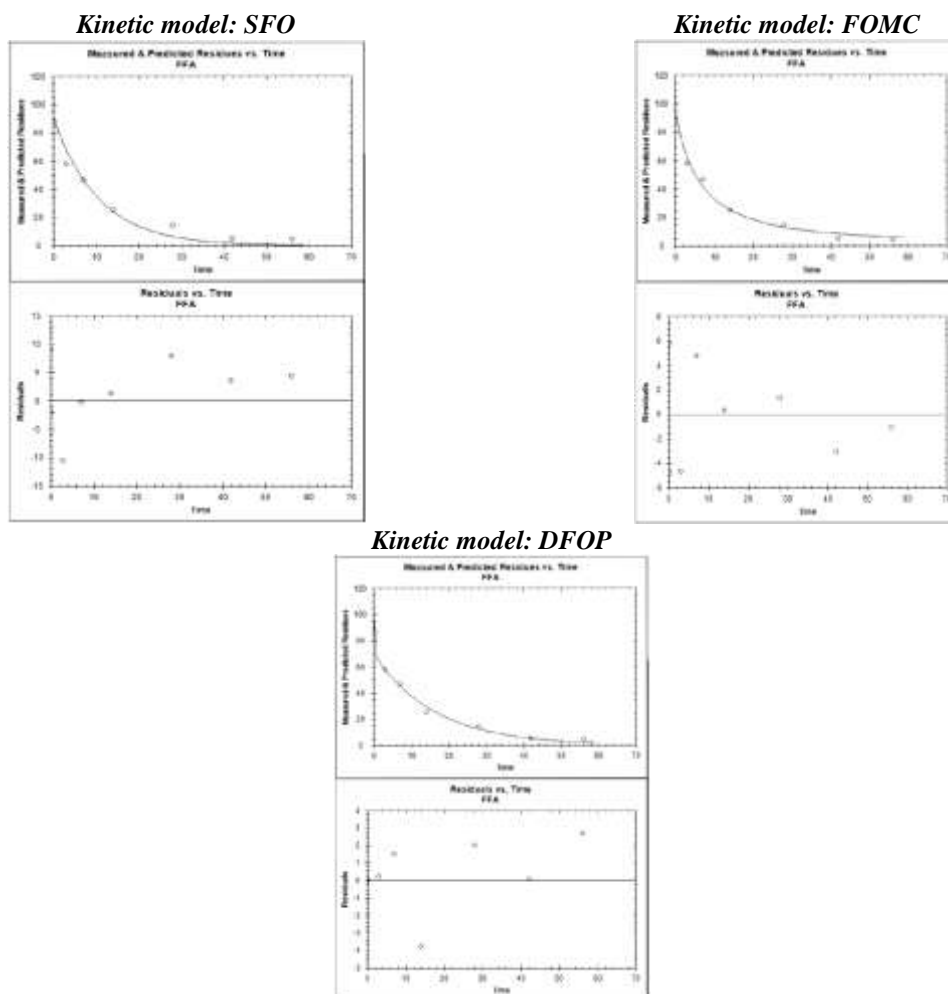

Figure B.8.1.1.2.1.1._CA-18: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-47: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	90.935	4.640	81.840	100.030	5.72 E-7	11.230	0.975; Acceptable fit
	k	0.09431	0.01429	0.06630	0.122	2.91 E-3		
FOMC	M_0	94.236	3.427	87.518	100.953	5.95 E-7	7.457	0.988; Acceptable fit
	α	1.3745	0.5089	0.3770	2.372	0.0214		
	β	8.725	4.942	-0.9619	18.411	0.0689		
DFOP	M_0	100.000	2.635	94.840	105.164	1.44 E-6	3.990	0.997; Good fit
	k_1	4.798	1.784	1.302	8.294	0.02733		
	k_2	0.06166	0.005786	0.05032	0.073	2.20 E-4		
	g	0.3036	0.03943	0.2264	0.381	7.65 E-4		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-48: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>Flufenacet</i>	DT ₅₀ [days]	7.35	5.72	5.37
	DT ₉₀ [days]	24.42	37.86	31.48

On the basis of the obtained results the Applicant proposed to consider SFO as returning reliable and acceptable fit, therefore being appropriate for deriving modelling endpoints for Flufenacet. RMS accepted that proposal, noticing that FOMC did not return fully reliable results. On the other hand the results obtained with DFOP were fully reliable, however the shape of the kinetic curve was unusual, indicating that probably M₀ value was overestimated by the modelling tool.

Conclusions of the study:

On the basis of the performed kinetic analysis, there were identified the kinetic endpoints that may be considered reliable and recommended to be used as persistence and modelling endpoints. It shall be noted however that the DT₅₀ values require normalisation before being used to calculate the geomean values to be used in FOCUS GW and FOCUS SW modelling. All they are presented below in the table B.8.1.1.2.1.1._CA-49.

Table B.8.1.1.2.1.1._CA-49: The final set of reliable kinetic endpoints determined in the study.

Study 3:

Report: Reinken G., Maassen K., (2014): „Trigger evaluation for the Degradation of Flufenacet Degradation Product FOE oxalate under Aerobic Soil Conditions in Laboratory According to FOCUS Kinetics Using the KinGUI 2 Tool. FOE oxalate.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished report No. En-Sa-13-1009; 2014. 02. 18; ; study reference number: M-478440-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above. It was stated that the study generally complied with the two evoked Guidance Documents. The aim of the study was to identify the best-fit kinetic model for Flufenacet and one of its major degradation products – FOE Oxalate. Therefore the study should be considered complementary to the summarised above another study – **Study 2** ([Reinken and Partsch; 2014]), that examined the same data base in order to determine kinetic endpoints for these compounds to be subsequently used in modelling. RMS summarising the study used the soil names as they were provided in the source study reports (in the study report they were slightly altered) to maintain the internal coherence of the Renewal Assessment Report.

Summary:

The aim of the study was to perform the kinetic analysis of the data obtained for Flufenacet and its degradation product FOE Oxalate in two laboratory studies examining degradation of [Phenyl-U-¹⁴C] Flufenacet in aerobic soil – by [Kelley et al.; 1995] and by [Pangilinan and Smith; 1994], both summarised under the point B.8.1.1.1.1. of this report as, respectively, **Study 1** and **Study 2**. It was done in order to identify the best kinetic fit for both compounds in each test soil and derive half-lives for FOE Oxalate (and Flufenacet) suitable for trigger evaluation.

The analysis was performed for the results obtained in four test soils – three EU soils (study by [Kelley et al.; 1995]) and one US soil (study by [Pangilinan and Smith; 1994]). The characteristic of the test soils and the experimental conditions are provided in the summary of the related **Study 2**, in the tables B.8.1.1.2.1.1._CA-6 and B.8.1.1.2.1.1._CA-7 (characterisation of the test soils), and B.8.1.1.2.1.1._CA-8 (characterisation of the experimental conditions). RMS decided not to repeat those data in this summary in order not to overburden the Assessment Report.

The data provided by the source studies are presented below in two separate tables – B.8.1.1.2.1.1._CA-50 for the study by [Kelley et al.; 1995] and B.8.1.1.2.1.1._CA-51 for the study by [Pangilinan and Smith; 1994].

Table B.8.1.1.2.1.1._CA-50: The concentrations of Flufenacet and FOE Oxalate reported in the study by [Kelley et al.; 1995].

180	44.6	14.6
271	38.6	17.0
365	35.2	26.5

The data presented above were subjected to a multistep evaluation procedure, already presented in the summary of the **Study 2**. For convenience it is repeated below.

The kinetic-fitting procedure consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st – order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool. That step consisted of the two sub-steps:
 - **Sub-step 1:** kinetic evaluation of the data for parent compound (Flufenacet) only, in order to determine the appropriate kinetic model. At that stage of analysis all three kinetic models listed above were tested;
 - **Sub-step 2:** kinetic evaluation of the data for parent compound (Flufenacet) and its degradation products using for Flufenacet the kinetic model identified at previous stage as appropriate, and SFO model for degradation products;
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The data-processing to obtain the input values for kinetic analysis (**Step 1**) was identical to the procedure described in the summary of the **Study 2** on page 166. The DAT-0 and LOD values used in this activity are provided below, in the table B.8.1.1.2.1.1._CA-52.

Table B.8.1.1.2.1.1._CA-52: The DAT-0 recoveries and LOD determined for each experiment.

Study	Test soil		Determined parameter	
	<i>Soil name</i>	<i>Soil type (USDA classification)</i>	<i>DAT-0 recovery [% AR]</i>	<i>LOD [% AR]</i>
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	99.3	0.1
	Laacherhof	Silt loam	93.2	0.1
	Höfchen im Tal	Silt loam	97.3	0.1
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	95.1	0.1

The processed data used as input in the kinetic examination are presented below, separately for each source study, in tables B.8.1.1.2.1.1._CA-53 and B.8.1.1.2.1.1._CA-54. In case of the data set originating from the study by [Pangilinan and Smith; 1994], the results obtained after the time point DAT 28 were not included, because at that time point a collapse of soil microbial activity was recorded.

Table B.8.1.1.2.1.1._CA-53: The processed residue data originating from the study by [Kelley et al.; 1995].

21	59.7	10.6
28	51.4	12.2

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure was a two-stage one. The first step, further called **Step 1**, consisted on the determination of the best-fit kinetic model for the parent compound – Flufenacet. At that stage three 1st-order kinetic models were tested: SFO, FOMC and DFOP. During the next stage, further called **Step 2**, the whole data set – data for the Flufenacet and FOE Oxalate, was kinetically examined. In case of Flufenacet the tested kinetic model was that determined as appropriate at **Step 1**, while for the degradation products the SFO model was used.

The conceptual metabolic pathway built in the modelling tool is presented below on figure B.8.1.1.2.1.1._CA-19. The following abbreviations were used:

- FFA for Flufenacet (parent compound);
- FOEOX for FOE Oxalate.

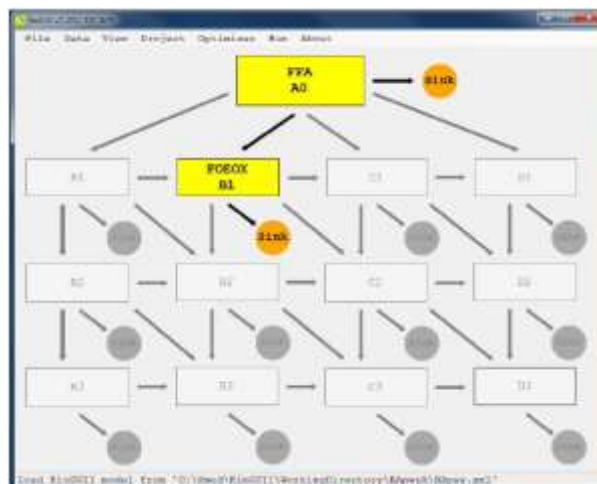

Figure B.8.1.1.2.1.1_CA-19: The conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of that evaluation is provided in the summary of the **Study 2**, on pages 168 – 169.

The whole assessment was carried out as a multistep procedure, similar to that outlined in the presented above summary of the **Study 2**, on page 169. However, as they differed, mainly due to different goals of the kinetic evaluation of the data, the assessment procedure used here is presented below.

It consisted of the following steps:

- **Step 1:** the data for the parent compound were fitted using two kinetic models: SFO and FOMC and verified for passing the acceptance criteria (χ^2 -error and distribution of residuals); in case the SFO fit was found visually acceptable and statistically more appropriate than FOMC, it was selected as the best-fit model;
- **Step 2:** in case the SFO model was found not to be more appropriate than FOMC, it was refined in three-step procedure, by removing the outliers, fixing model parameters and data weighing, until the best fit was achieved;
- **Step 3:** if the **Step-2** fitting for SFO model still failed the χ^2 -error test, and FOMC was demonstrated to be more appropriate, the DFOP model was tested in order to determine if bi-phasic model is acceptable and if so, which one should be selected as returning the best fit;
- **Step 4:** once the best-fit model was identified, the data for the FOE Oxalate were added to the data set and the kinetic analysis repeated using the identified best-fit model for Flufenacet (parent compound) and SFO for FOE Oxalate.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the trigger kinetic endpoints presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test soil.

- 1) The results of the kinetic analysis of the data obtained in **BBA 2.2** Loamy sand soil (study by [Kelley et al.; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-19 and in numerical form in the table B.8.1.1.2.1.1_CA-55. Additionally the table B.8.1.1.2.1.1_CA-56 provides the kinetic endpoints obtained with each of the kinetic models tested.

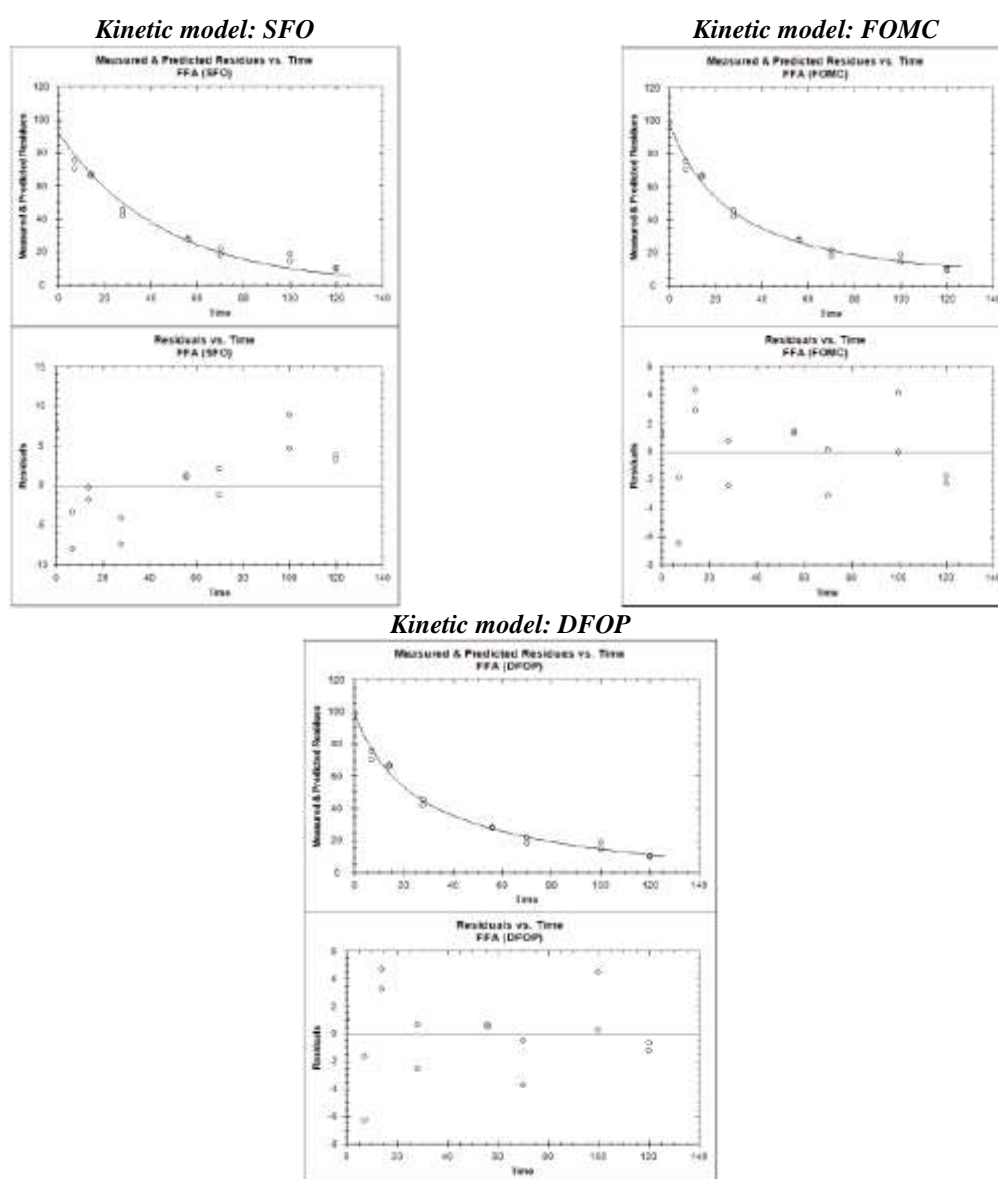

Figure B.8.1.1.2.1.1_CA-19: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.2.1.1._CA-55: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	92.059	2.851	86.472	97.647	7.54 E-15	8.495	0.98; Good fit
	k	0.02224	0.00167	0.01896	0.026	1.24 E-9		
FOMC	M ₀	98.066	2.059	94.030	102.102	2.82 E-16	4.520	0.99; Good fit
	α	1.5659	0.3067	0.9647	2.167	0.00010		
	β	42.5627	12.3870	18.2846	66.841	0.00221

	k ₁	0.06909	0.09018	-0.1077	0.246	0.2292		
	k ₂	0.01367	0.00824	-0.00248	0.030	0.0615		
	g	0.4257	0.4835	-0.5220	1.373	0.1980		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.2.1.1._CA-56: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	31.16	23.70	23.54
	DT ₉₀ [days]	103.50	142.60	127.90

On the basis of the obtained results the Applicant proposed to consider FOMC model as returning the best fit. That model was proposed to be used for the parent compound in kinetic examination of the data for Flufenacet and FOE Oxalate. RMS accepted that proposal.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.2.1.1._CA-20 and in numerical form in the table B.8.1.2.1.1._CA-57.

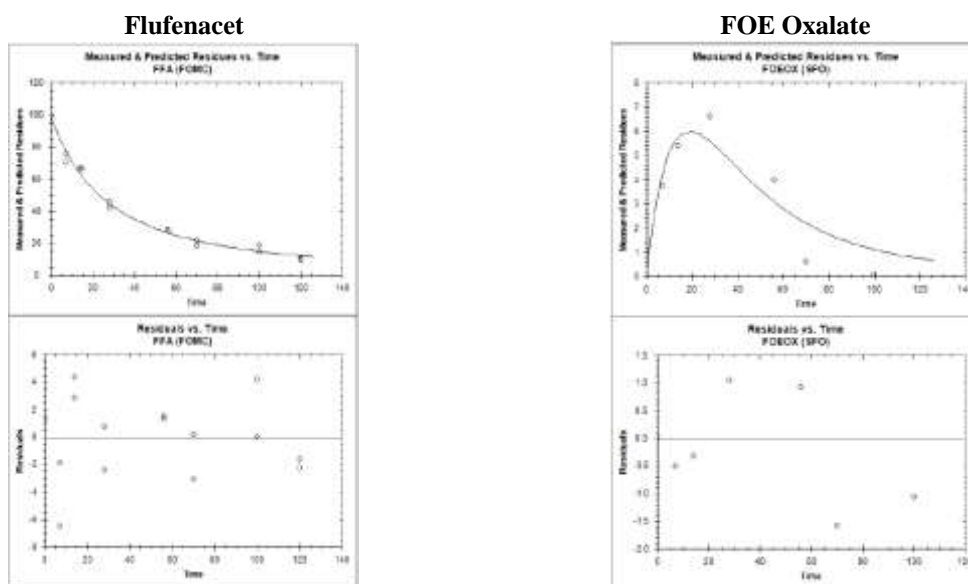

Figure B.8.1.2.1.1._CA-20: The graphical results of the kinetic examination of the data for Flufenacet and FOE Oxalate obtained in BBA 2.2 soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-57: The numerical results of the kinetic examination of the data for Flufenacet and FOE Oxalate obtained in BBA 2.2 soil.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
					Lower	Upper			
Flufenacet	FOMC	M ₀	98.054	2.084	93.969	102.139	<2 E-16	4.52	Not provided

		k	0.0582	0.0144	0.0299	0.086	0.00038		
		ff	0.2496	0.0515	----	----	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.1.1._CA-58.

Table B.8.1.1.2.1.1._CA-58: The kinetic parameters determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Oxalate
DT ₅₀ [days]	23.72	11.91
DT ₉₀ [days]	141.73	39.58
Kinetic formation fraction ff	Not applicable – parent compound	0.250 ± 0.052
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	FOMC	SFO

The results of the kinetic fitting for Flufenacet and FOE Oxalate are acceptable.

Applicant proposed to consider the kinetic parameters for FOE Oxalate resulting from the kinetic examination of the data for that compound and Flufenacet using the combination of kinetic models FOMC-SFO as acceptable. Although that was not explicitly said, the kinetic endpoints determined for Flufenacet in that fitting exercise using FOMC kinetic model should be considered as trigger kinetic endpoints for that compound.

Evaluation of the fitting exercise:

The proposal made by the Applicant to consider the kinetic endpoints obtained for Flufenacet and its metabolite FOE Oxalate in the kinetic examination of the data using the combination FOMC-SFO as reliable trigger endpoints is acceptable.

However, that conclusion is contradictory to the proposal made by the Applicant in the previously summarised study – **Study 2**.

- 2) The results of the kinetic analysis of the data obtained in **Laacherhof** Silt loam soil (study by [Kelley et al.; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-21 and in numerical form in the table B.8.1.1.2.1.1_CA-59. Additionally the table B.8.1.1.2.1.1_CA-60 provides the kinetic endpoints obtained with each of the kinetic models tested.

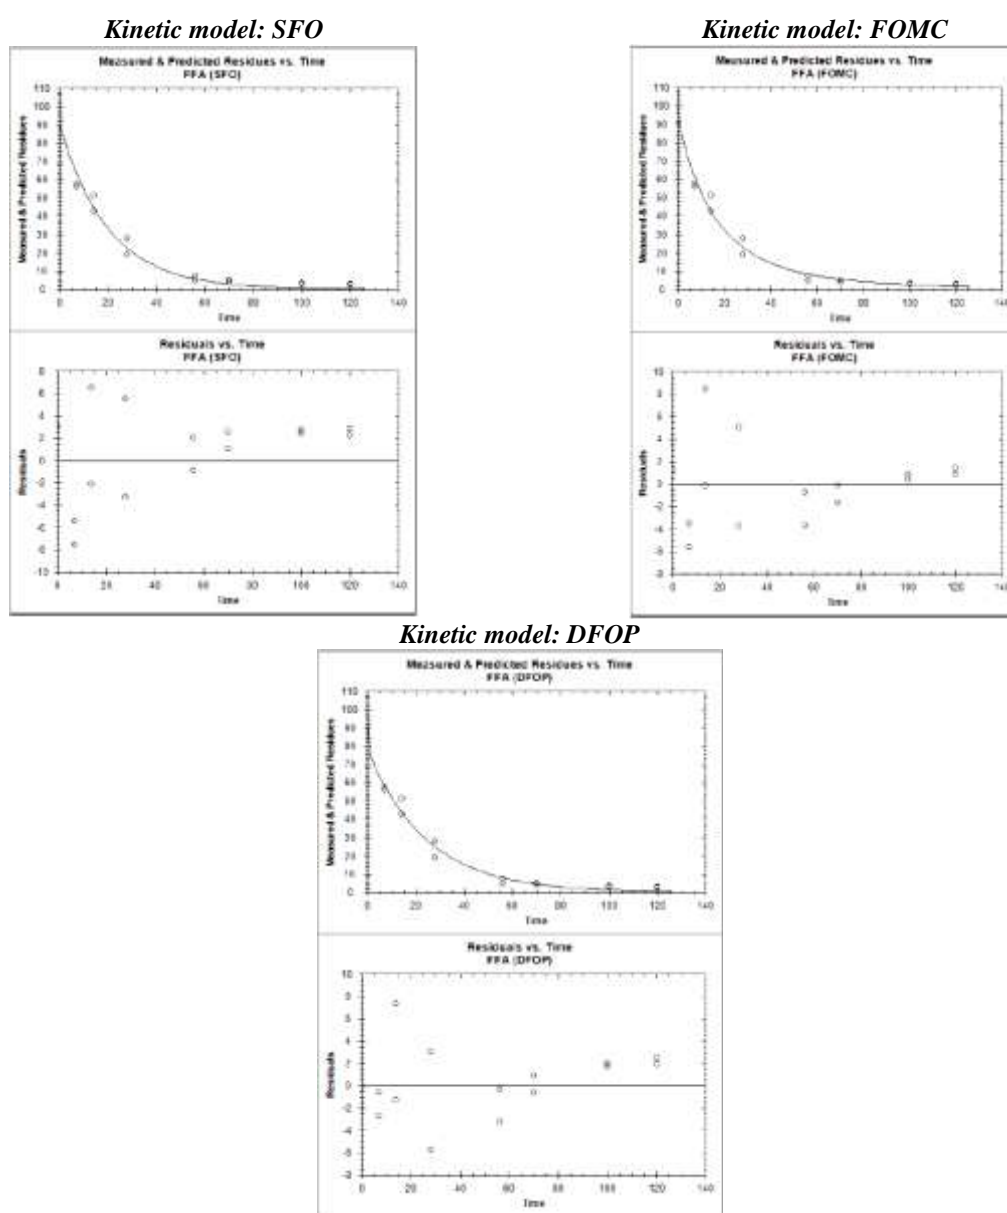

Figure B.8.1.1.2.1.1_CA-21: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.2.1.1._CA-59: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	90.116	2.648	84.927	95.306	3.65 E-15	8.215	0.99; Good fit
	k	0.04964	0.00351	0.04277	0.057	5.50 E-10		
FOMC	M ₀	92.036	2.388	87.356	96.716	4.32 E-15	6.953	0.99; Good fit
	α	3.684	0.326	3.045	4.323	2.14 E-8		
	β	61.095	5.240	50.824	71.365	1.48 E-8		
DFOP	M ₀	93.200	2.100	89.083	97.316	5.58 E-15	5.496	0.99; Poor fit
	k ₁	2.0510	44.8611	-85.8751	89.977	0.4821		
	k ₂	0.04086	0.00353	0.03395	0.048	3.56 E-8		
	g	0.1610	0.0511	0.0609	0.261	0.0042		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.2.1.1._CA-60: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	13.96	12.65	12.67
	DT ₉₀ [days]	46.38	53.04	52.05

On the basis of the obtained results the Applicant proposed to consider FOMC model as returning the best fit. That model was proposed to be used for the parent compound in kinetic examination of the data for Flufenacet and FOE Oxalate. RMS accepted that proposal.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.2.1.1._CA-21 and in numerical form in the table B.8.1.2.1.1._CA-61.

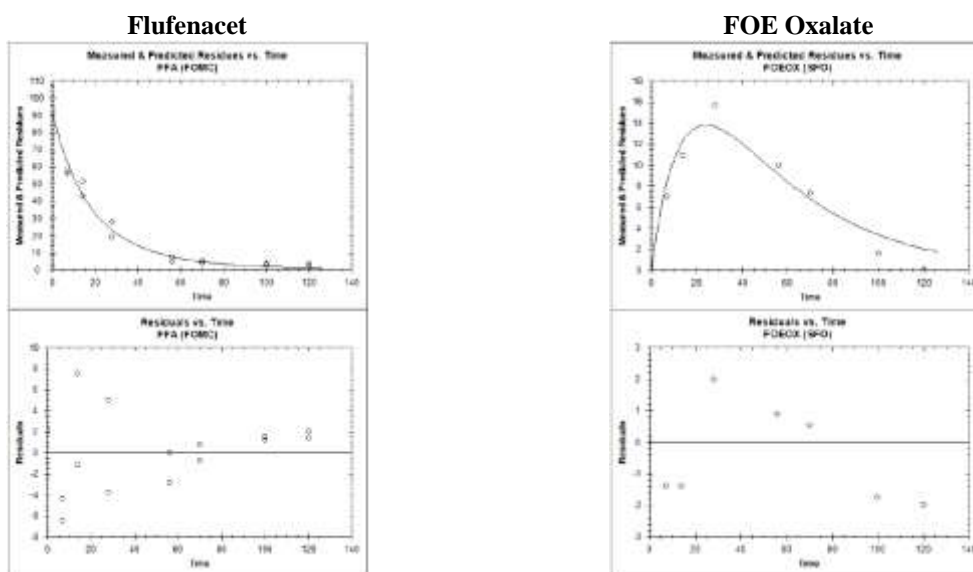

Figure B.8.1.2.1.1._CA-21: The graphical results of the kinetic examination of the data for Flufenacet and FOE Oxalate obtained in Laacherhof soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-61: The numerical results of the kinetic examination of the data for Flufenacet and FOE Oxalate obtained in Laacherhof soil.

		k	0.02962	0.00457	0.02067	0.039	1.63 E-6		
		ff	0.3285	0.0423	----	----	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.1.1._CA-62.

Table B.8.1.1.2.1.1._CA-62: The kinetic parameters determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Oxalate
DT ₅₀ [days]	13.30	23.40
DT ₉₀ [days]	50.86	77.74
Kinetic formation fraction ff	Not applicable – parent compound	0.329 ± 0.042
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	FOMC	SFO

The results of the kinetic fitting for Flufenacet and FOE Oxalate cannot be considered acceptable. That is due to the fact that the estimated kinetic parameters for Flufenacet in FOMC fit are not reliable – for both α and β the CI values contain zero.

Evaluation of the fitting exercise:

The proposal made by the Applicant to consider the kinetic endpoints obtained for Flufenacet and its metabolite FOE Oxalate in the kinetic examination of the data using the combination FOMC-SFO as reliable trigger endpoints cannot be considered acceptable. That is due to the fact that both kinetic parameters estimated for Flufenacet in FOMC fit – α and β are not reliable because their CI values contain zero.

- 3) The results of the kinetic analysis of the data obtained in **Höfchen im Tal** Silt loam soil (study by [Kelley et al.; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-22 and in numerical form in the table B.8.1.1.2.1.1_CA-63. Additionally the table B.8.1.1.2.1.1_CA-64 provides the kinetic endpoints obtained with each of the kinetic models tested.

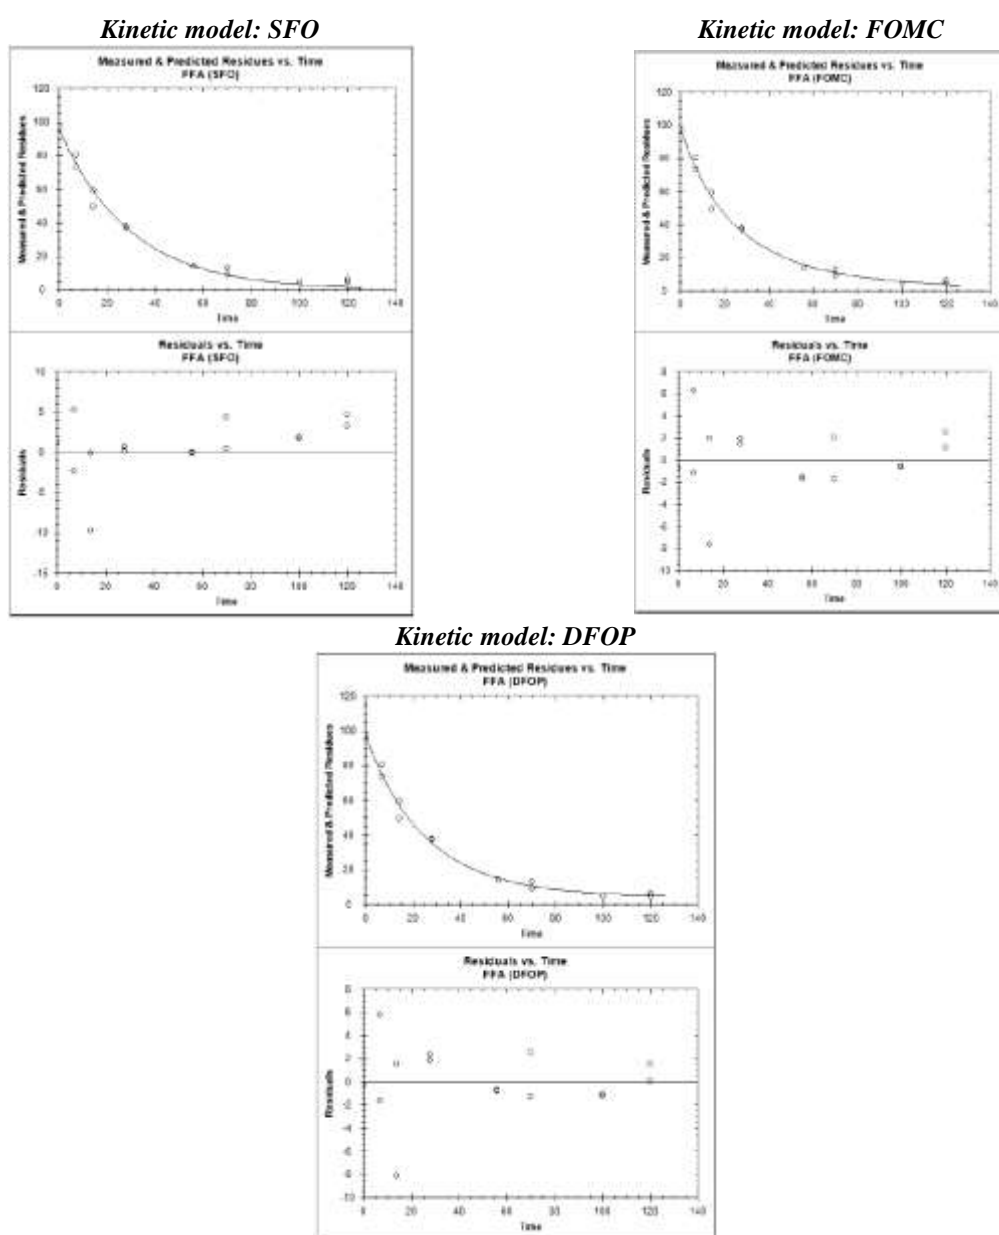

Figure B.8.1.1.2.1.1_CA-22: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.2.1.1._CA-63: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	95.960	2.191	91.665	100.254	< 2 E-16	5.459	0.99; Good fit
	k	0.03428	0.00189	0.03059	0.038	1.94 E-11		
FOMC	M ₀	98.041	1.894	94.330	101.752	< 2 E-16	3.957	0.99; Good fit
	α	4.3348	0.2414	3.8617	4.808	7.36 E-11		
	β	106.2230	4.577	97.252	115.194	2.89 E-12		
DFOP	M ₀	97.580	2.172	93.322	101.838	4.83 E-15	4.072	0.99; Good fit
	k ₁	0.04092	0.00957	0.02216	0.060	0.00054		
	k ₂	0.00492	0.02403	-0.04218	0.052	0.4206		
	g	0.9229	0.2113	0.5087	1.337	0.00046		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.2.1.1._CA-64: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	20.22	18.42	18.68
	DT ₉₀ [days]	67.17	74.46	73.17

On the basis of the obtained results the Applicant proposed to consider SFO model as returning the best fit. That model was proposed to be used for the parent compound in kinetic examination of the data for Flufenacet and FOE Oxalate. RMS accepted that proposal. It shall be noted however that fully reliable and better fit was obtained for FOMC model. For that reason RM is of the opinion that at Step 2 also the combination FOMC-SFO should be tested.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.2.1.1._CA-23 and in numerical form in the table B.8.1.2.1.1._CA-65.

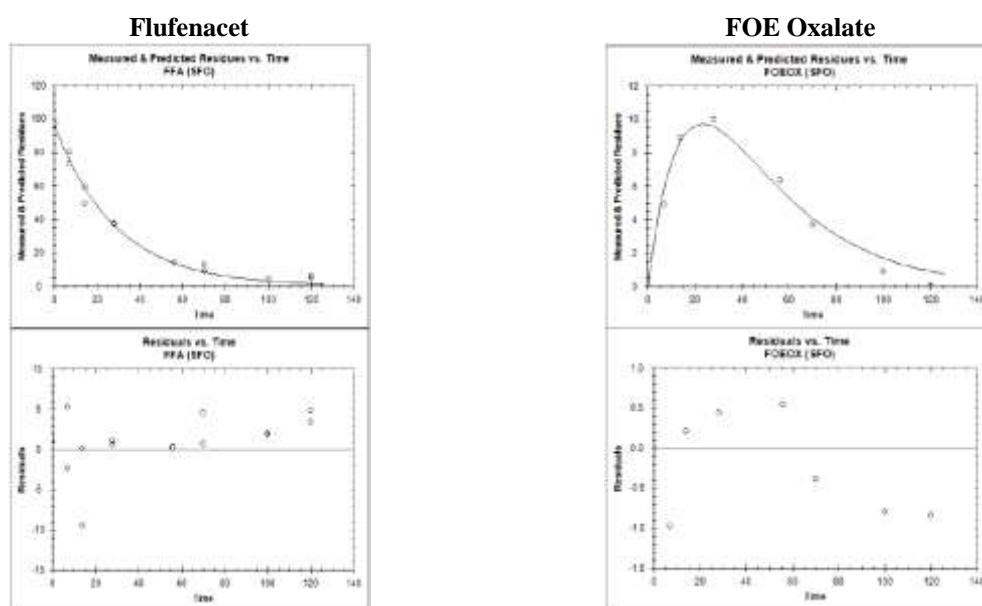

**Figure B.8.1.2.1.1._CA-22:** The graphical results of the kinetic examination of the data for Flufenacet and FOE Oxalate obtained in Höfchen im Tal soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-65: The numerical results of the kinetic examination of the data for Flufenacet and FOE Oxalate obtained in Höfchen im Tal soil.

FOE Oxalate	SFO	M ₀	0.0	----	----	----	----	10.408	0.98; Good fit
		k	0.05179	0.00558	0.03098	0.063	5.47 E-9		
		ff	0.3395	0.0356	----	----	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.1.1._CA-66.

Table B.8.1.1.2.1.1._CA-66: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Oxalate
DT ₅₀ [days]	19.98	13.38
DT ₉₀ [days]	66.36	44.46
Kinetic formation fraction ff	Not applicable – parent compound	0.400 ± 0.036
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The results of the kinetic fitting for Flufenacet and FOE Oxalate are acceptable.

Applicant proposed to consider the kinetic parameters for FOE Oxalate resulting from the kinetic examination of the data for that compound and Flufenacet using the combination of kinetic models SFO-SFO as acceptable. RMS however has to indicate, that thorough analysis of the Step-1 results showed that FOMC returned fit statistically better than that obtained with SFO. Therefore it is possible that the combination FOMC-SFO may return the best fit and hence appropriate trigger endpoints.

Evaluation of the fitting exercise:

The proposal made by RMS to consider the kinetic endpoints obtained for Flufenacet and its metabolite FOE Oxalate in the kinetic examination of the data using the combination SFO-SFO as reliable trigger endpoints is acceptable, although the results indicated that the option FOMC-SFO should have been tested. RMS noticed that they the results do not differ significantly from those obtained in summarised previously similar study – **Study 2**.

Therefore RMS proposes to consider this fitting as conformatory for that presented for full data set in mentioned **Study 2**.

- 4) The results of the kinetic analysis of the data obtained in **Howe, Indiana**, Sandy loam soil (study by [Pangilinan and Smith; 1994]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-23 and in numerical form in the table B.8.1.1.2.1.1_CA-67. Additionally the table B.8.1.1.2.1.1_CA-68 provides the kinetic endpoints obtained with each of the kinetic models tested.

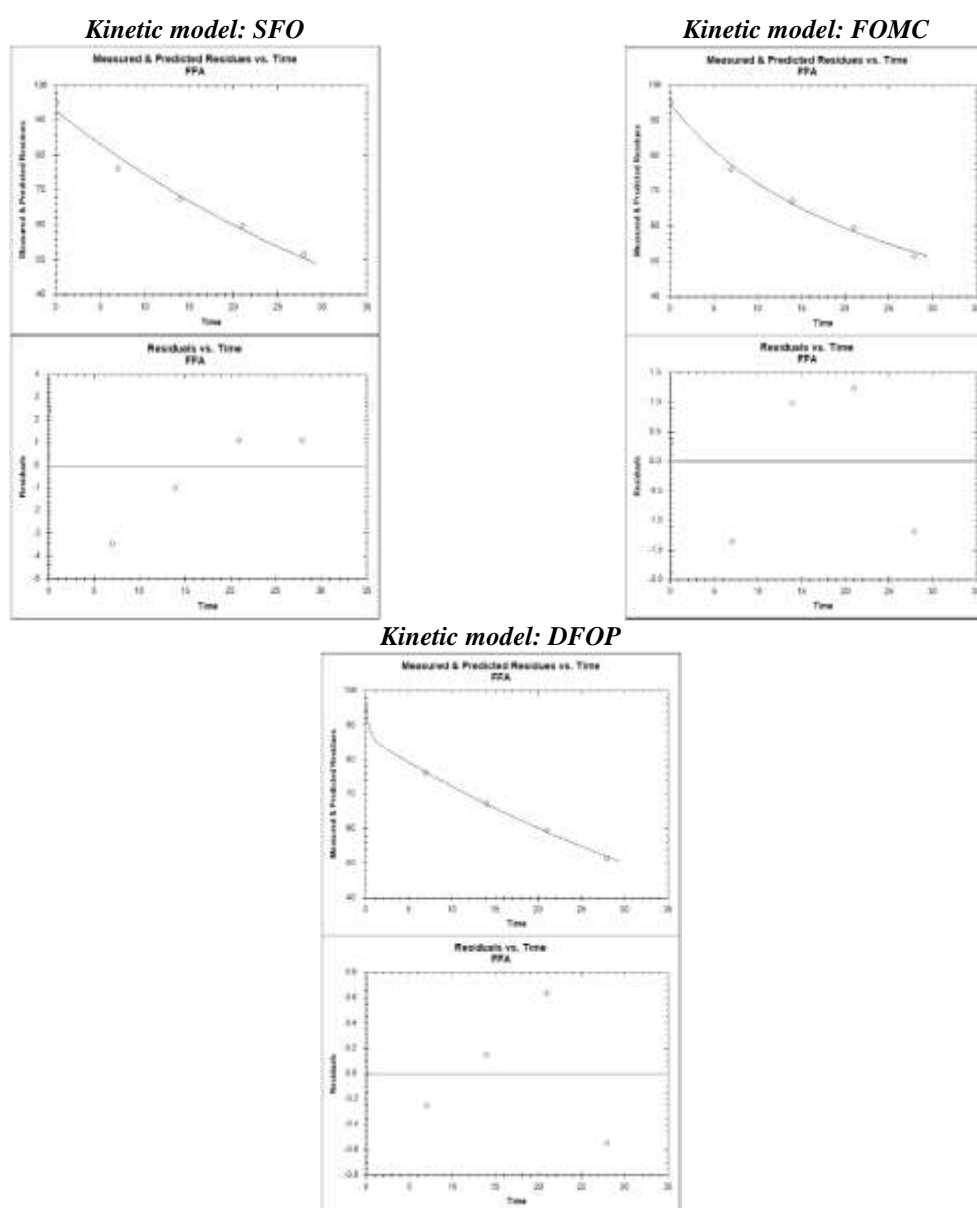

Figure B.8.1.1.2.1.1_CA-23: The graphical results of the kinetic analysis (copied from the study report).

		k	0.02182	0.00180	0.01830	0.025	9.43 E-6		
FOE Oxalate	SFO	M ₀	0.0	----	----	----	----	6.239	0.98; Good fit
		k	0.03543	0.01377	0.00844	0.062	0.0211		
		ff	0.4756	0.0834	----	----	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.1.1._CA-70.

Table B.8.1.1.2.1.1._CA-70: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Oxalate
DT ₅₀ [days]	31.76	19.56
DT ₉₀ [days]	105.52	64.99
Kinetic formation fraction ff	Not applicable – parent compound	0.476 ± 0.083
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The results of the kinetic fitting for Flufenacet and FOE Oxalate are acceptable.

Applicant proposed to consider the kinetic parameters for FOE Oxalate resulting from the kinetic examination of the data for that compound and Flufenacet using the combination of kinetic models SFO-SFO as acceptable.

Evaluation of the fitting exercise:

The proposal made by RMS to consider the kinetic endpoints obtained for Flufenacet and its metabolite FOE Oxalate in the kinetic examination of the data using the combination SFO-SFO as reliable trigger endpoints is acceptable only in case of Flufenacet. It cannot be considered such for FOE Oxalate due to the fact that for that compound the decline phase was not reached. Therefore although the modelling tool was able to calculate the rate constant *k* and resulting from it kinetic endpoints – DT₅₀ and DT₉₀ values, their reliability is very limited. It is possible that the calculated kinetic endpoints, and the rate constant in particular, represent the kinetic rate of the formation of FOE Oxalate in the test soil.

As the results obtained for Flufenacet do not differ significantly from those obtained in summarised previously similar study – **Study 2**, RMS proposes to consider this fitting as conformatory for that presented for full data set in mentioned **Study 2**.

Conclusions of the study:

The kinetic analysis aimed on the determination of the trigger endpoints resulted in reliable kinetic endpoints for both Flufenacet and FOE Oxalate for only two experiments – that on BBA 2.2 soil and on Höfchen im Tal soil. The results obtained for the experiment on Laacherhof soil cannot be considered reliable because the kinetic parameters determined for the parent compound – α and β were not reliable. In case of the fourth experiment – on Howe, Indiana, soil, only the kinetic endpoints for Flufenacet may be considered reliable. The kinetic endpoints for FOE Oxalate determined in that experiment, due to the fact that the decline phase was not reached, bear much too high level of uncertainty to be considered credible, unless it is stated that they represent the rate of formation, not degradation of FOE Oxalate in their test soil.

It was also noted that in case of the experiment with BBA 2.2 soil FOMC was identified as the kinetic model returning the best fit for the parent compound. That makes the results of the fitting contradictory to the conclusions of the previously summarised **Study 2**. Finally, it shall be pointed out that the fitting was performed for partial data base in comparison to what was done in already mentioned **Study 2**. As a result, RMS proposes to consider the results of this study as conformatory for those of the **Study 2**, whenever they display similarity, and not to be used to derive the regulatory endpoints.

Study 4:

Report: Hein E.-M., (2012): “[Thiadiazole-5-¹⁴C] Flufenacet: Aerobic Degradation/Metabolism in One European Soil.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany, Study M1251994-1; unpublished Study Report No. MEF-11/937; 2012. 09. 19, amended (Amendment No 1) 2013. 04. 10; ; study reference number: M-439105-02-1;

Guidelines: The study was performed to comply with the following Guidelines:

- Commission Directive 95/36/EC amending Council Directive 91/414/EEC (Annexes II and III, Fate and Behaviour in the Environment), 1995;
- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

No deviations were stated in the study report.

GLP: Yes

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. Its summary was provided under the point B.8.1.1.1. of this document (**Study 5**). Presently it was verified for compliance, in the area of kinetic analysis, with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

The kinetic analysis provided in the study was found acceptable and its results are presented below.

Summary:

The aim of the study was to investigate the fate – route and rate of degradation, of Flufenacet in aerobic soil incubated under controlled (laboratory) conditions. The experiment was performed using one European soil originating from Germany (Hoefchen am Hohenseh). Its characteristic is provided below in the table B.8.1.1.2.1.1._CA-72. To maintain the consistency of reporting, only physicochemical properties are reported. The data on soil microbial activity were not given here. To check them please refer to adequate summary of the source study.

Table B.8.1.1.2.1.1._CA-72: The characteristic of soil used in the study.

Parameter		Soil:
Soil origin		<i>Hoefchen am Hohenseh 4a</i>
Soil type (USDA)		<i>Burscheid/ North Rhine-Westphalia/ Germany</i>
Particle size distribution		Silt loam
	Sand (50 µm – 2 mm) [%]	29
	Silt (2 – 50 µm) [%]	56
	Clay (< 2 µm) [%]	15
pH value in water (soil:water ratio 1:1)		7.0
pH value in 1N KCl		6.3
pH value in 0.01M CaCl ₂ (soil:solution ratio 1:2)		6.7
Organic carbon content (C _{org}) [%] ¹⁾		2.5
Organic matter content (OM) [%] ²⁾		4.3
Cation Exchange Capacity – CEC [mEq/100g]		12.9
Bulk density (disturbed) [g/cm ³]		1.04
Water holding capacity	Maximum [g H ₂ O/100 g soil d. w.]	61.1
	at ½ bar (pF 2.5) [%]	23.7
	at 0.1 bar (pF 2.0) [%]	29.8

Footnotes to the table:

1) Measured value;

2) Value calculated by the Applicant using the following equation: OM = 1.724*OC;

The summary of the study is provided under the point B.8.1.1.1.1. as **Study 5**. This summary contains only the results the kinetic evaluation of the data obtained for Flufenacet, carried out in line with the provisions of the FOCUS Kinetics Guidance Document [FOCUS; 2006], to identify the best-fit model.

Kinetic analysis was performed using KinGUI 2 software. Three kinetic models were tested: SFO, FOMC and DFOP. Applicant stated that the model input data sets were the residual amounts found in each replicate test system at each sampling interval. It was also declared that, instead of the measured DAT-0 concentrations of Flufenacet, the total AR recovery at that time point was used. Finally, it was stated that the M_0 value was allowed to be estimated by the model.

For the purpose of the kinetic analysis the input values were processed according to the recommendations given by FOCUS. In particular:

- values between LOD and LOQ were set to measured values;
- All single values <LOD or single non-detects (n.d.) were set to 50% LOD determined for HPLC method;
- The consecutive values <LOD or non-detects were not taken into account until the appearance of a value > LOQ.

The raw and processed data for Flufenacet used in kinetic fitting are presented below in the table B.8.1.1.2.1.1._CA-73.

Table B.8.1.1.2.1.1._CA-73: The raw and processed data for Flufenacet used in the kinetic analysis.

The raw data for Flufenacet obtained in the study			The processed data for Flufenacet obtained in the study		
Time point	Concentration of Flufenacet in [%AR]		Time point	Concentration of Flufenacet in [%AR]	
	Replicate 1	Replicate 2		Replicate 1	Replicate 2
DAT 0 – total AR recovered	99.5	100.9	DAT 0	99.5	100.9
DAT 0 – amount of Flufenacet	99.1	100.4

	k	0.04858	1.794 E-3	0.04507	0.052	2.44 E-16		
FOMC	M_0	108.944	2.247	104.540	113.3	<2 E-16	8.349	Good fit
	α	7868.97	4583.33	-1114.19	16852.1	0.0521		
	β	127071.8	74020.9	-18006.5	272150.2	0.05221		
DFOP	M_0	102.52	1.171	100.22	104.82	<2 E-16	3.794	Good fit
	k_1	0.03511	0.00386	0.02754	0.043	5.08 E-8		
	k_2	0.03233	0.00328	0.02591	0.039	1.67 E-8		
	g	4.920	7.459	-9.700	19.541	0.259		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-75: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>Flufenacet</i>	DT ₅₀ [days]	14.27	11.19	14.67
	DT ₉₀ [days]	47.40	37.19	44.74

The obtained results show that all three models returned visually and statistically acceptable fits. The FOMC however was poorest of them and in addition returned statistically unreliable kinetic parameters.

SFO and DFOP returned comparable results, however DFOP was slightly better visually and statistically, so that fit was proposed by the Applicant to be considered as the best fit. RMS however, having analysed the reliability of the kinetic parameters stated that the *g* parameter in DFOP fit was not reliable. For that reason also DFOP model cannot be considered as returning the best fit.

As a result for [Thiadiazole-5-¹⁴C] Flufenacet in Hoefchen am Hohenseh silt loam soil **SFO shall be considered as returning the best fit.**

Study 5:

Report: Hein E.-M., (2012): “[Thiadiazole-5-¹⁴C] Flufenacet: Aerobic Degradation/Metabolism in Three European Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany, Study M1252037-0; unpublished Study Report No. MEF-11/938; 2012. 10. 18, amended (Amendment No 1) 2013. 01. 28; ; study reference number: M-440348-02-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

GLP: Yes

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. Its summary was provided under the point B.8.1.1.1. of this document (**Study 6**). Presently it was verified for compliance, in the area of kinetic analysis of the data, with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

The kinetic analysis provided in the study was found acceptable and its results are presented below.

Summary:

The aim of the study was to investigate the fate – route and rate of degradation, of Flufenacet in aerobic soil incubated under controlled (laboratory) conditions. The experiment was performed using three European soils. Their characteristic is provided below in the table B.8.1.1.2.1.1._CA-76. To maintain the consistency of reporting, only physicochemical properties are reported. The data on soil microbial activity were not given here. To check them please refer to adequate summary of the source study.

Table B.8.1.1.2.1.1._CA-76: The characteristic of soils used in the study.

Parameter	Soil		
	<i>Laacherhof AXx</i> (AX)	<i>Dollendorf II</i> (DD)	<i>Laacherhof Wurmwiess</i> (WW)
Soil origin	Monheim/North Rhine-Westphalia/Germany	Blankenheim/North Rhine-Westphalia/Germany	Monheim/North Rhine-Westphalia/Germany
Soil type (USDA)	Loamy sand	Clay Loam	Loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	75	29
	Silt (2 – 50 µm) [%]	20	38
	Clay (< 2 µm) [%]	5	33
pH value in 0.01M CaCl ₂ (soil/solution ratio 1:2)	6.1	7.2	5.4
pH value in H ₂ O (soil/solution ratio 1:1)	6.4	7.4	5.7
pH value in 1N KCl	5.9	7.0	5.2
Organic carbon content (OC) [%]	2.4	5.3	2.2
Organic matter content (OM) [%] ¹⁾	4.1	9.1	3.8
Cation Exchange Capacity – CEC [mEq/100g]	9.9	20.9	10.8
Water holding capacity	Maximum [g H ₂ O/100 g soil]	49.1	79.8
	at 0.1 bar (pF 2.0) [%]	18.7	46.0
	at ½ bar (pF 2.5) [%]	12.0	35.9
Bulk density (disturbed) [g/cm ³]	1.19	0.95	1.12

Footnotes to the table:

1) Value calculated by the RMS using the following equation: OM = 1.724 * OC;

The summary of the study is provided under the point B.8.1.1.1.1. as **Study 6**. This summary contains only the results the kinetic evaluation of the data obtained for Flufenacet, carried out in line with the provisions of the FOCUS Kinetics Guidance Document [FOCUS; 2006], to identify the best-fit model.

Kinetic analysis was performed using KinGUI 2 software. Three kinetic models were tested: SFO, FOMC and DFOP. Applicant stated that the model input data sets were the residual amounts found in each replicate test system at each sampling interval. It was also declared that, instead of the measured DAT-0 concentrations of Flufenacet, the total AR recovery at that time point was used. Finally, it was stated that the M_0 value was allowed to be estimated by the model.

For the purpose of the kinetic analysis the input values were processed according to the recommendations given by FOCUS. In particular:

- values between LOD and LOQ were set to measured values;
- All single values <LOD or single non-detects (n.d.) were set to 50% LOD determined for HPLC method;
- The consecutive values <LOD or non-detects were not taken into account until the appearance of a value > LOQ.

The input data and results of their kinetic analysis are presented below, individually for each test soil.

- a) Results of the kinetic examination of the data obtained for [Thiadiazole-5-¹⁴C] Flufenacet in **Laacherhof AXXa** Loamy sand soil:

The raw and processed data for Flufenacet used in kinetic fitting are presented below in the table B.8.1.1.2.1.1._CA-77.

	DT ₉₀ [days]	44.76	35.51	42.78

The obtained results show that all three models returned visually and statistically acceptable fits. The FOMC however was poorest of them and in addition returned statistically unreliable kinetic parameters.

SFO and DFOP returned comparable results, SFO being superior to DFOP. RMS also noticed that the g parameter in DFOP fit was not reliable, and that the rate constants k_1 and k_2 were similar.

Applicant proposed to consider SFO as returning the best fit. RMS accepted that proposal.

As a result for [Thiadiazole-5-¹⁴C] Flufenacet in Laacherhof Wurmwiese loam soil **SFO shall be considered as returning the best fit.**

Final conclusion of the study:

The kinetic analysis of the data obtained for [Thiadiazole-5-¹⁴C] Flufenacet in three experimental soils enabled to identify the following kinetic models as returning the best fit:

- in Laacherhof AXXa loamy sand soil: SFO with DT₅₀ = 18.53 days and DT₉₀ = 61.56 days;
- in Dollendorf III clay loam soil: SFO with DT₅₀ = 14.45 days and DT₉₀ = 49.56 days;
- in Laacherhof Wurmwiese loam soil: SFO with DT₅₀ = 13.48 days and DT₉₀ = 44.76 days.

Study 6:

Report: Reinken G., Partsch S., (2014): “Trigger evaluation for the Degradation of Flufenacet Degradation Product FOE 5043 trifluoroethanesulfonic acid under Aerobic Conditions in Laboratory According to FOCUS Kinetics Using the KinGUI 2 Tool. FOE 5043-trifluoroethane sulfonic acid, Trifluoroacetic acid.”; Bayer Crop Science AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished Study Report No. En-Sa-13-1010; 2014. 02. 18; study reference number: M-478444-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above. It was stated that the study generally complied with the two evoked Guidance Documents. The aim of the study was to identify the best-fit kinetic model for Flufenacet and one of its major degradation products – FOE 5043-Trifluoroethanesulfonic acid. The examined data came from two already summarised route-and-rate-of-degradation studies – [Hein; 2012] (Study 5 when summarised under the point B.8.1.1.1.1.) and [Hein; 2012a] (Study 6 when summarised under the point B.8.1.1.1.1.). Their partial kinetic analysis, aimed on the determination of the best kinetic fit for the parent compound – Flufenacet radiolabelled in Thiadiazole-C5 position, was performed and its results were presented above, as Study 4 and Study 5. Never the less for the purpose of this examination it was repeated and RMS decided to present its results as well. It was also noticed that although the study was aimed on the determination of the trigger endpoints for FOE 5043-Trifluoroethanesulfonic acid, the kinetic analysis was performed for the whole data sets. Finally, RMS stated that the soil names used in the study report were slightly altered in comparison to those used in the source study reports. In order to maintain the internal coherence of the Renewal Assessment Report, RMS used the soil names as they were provided in the source study reports.

Summary:

The aim of the study was to perform the kinetic analysis of the data obtained for Flufenacet and its degradation product FOE 5043-Trifluoroethanesulfonic acid in two laboratory studies examining degradation of [Thiadiazole-5-¹⁴C] Flufenacet in aerobic soils – by [Hein; 2012] and by [Hein; 2012a], both summarised under the point B.8.1.1.1.1. of this report as, respectively, Study 5 and Study 6. It was carried out in order to identify the best kinetic fit for both compounds in each test soil and derive half-lives for FOE 5043-Trifluoroethanesulfonic acid (and Flufenacet) suitable for trigger evaluation. The characteristic of the test soils used in each of these experiments was presented above in the summaries of the Study 4 and Study 5, therefore in order to not overburden the Assessment Report, RMS decided not to present it here. The experimental conditions used in each experiment are summarised below in the table B.8.1.1.2.1.1._CA-86.

Table B.8.1.1.2.1.1._CA-86: The experimental conditions used in each experiment.

Study	Test soil		Incubation temperature <i>T</i> [°C]	Experimental conditions		
	Name	Type (USDA classification)		In experiment	Soil moisture	
					Reference value	
<i>Hein; 2012</i>	Hoefchen Am Hohenseh 4a	Silt loam	19.7 ± 0.1	55% MWHC	61.1	29.8
<i>Hein; 2012a</i>	Laaherhof AXXa	Loamy sand	19.9 ± 0.2	55% MWHC	49.1	18.7
	Dollendorf II	Clay loam	19.9 ± 0.2	55% MWHC	79.8	46.0
	Laacherhof Wurmweise	Loam	19.9 ± 0.2	55% MWHC	59.9	23.3

The not processed input data used in the kinetic analysis are presented below in the table B.8.1.1.2.1.1._CA-87. Additionally, in the table B.8.1.1.2.1.1._CA-88 are presented the DAT-0 total recovery and LOD values, subsequently used in data processing.

Table B.8.1.1.2.1.1_CA-87: The not processed data obtained in the test soils used as input in kinetic analysis.

The data presented above were subjected to a multistep evaluation procedure, used with some alterations in all kinetic analyses of the data performed for Flufenacet and its degradation products. RMS stated that it was performed in line with the recommendations of FOCUS Kinetics Guidelines [FOCUS; 2006]. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st – order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool. That step consisted of the two sub-steps:
 - **Sub-step 1:** kinetic evaluation of the data for parent compound (Flufenacet) only, in order to determine the appropriate kinetic model. It was declared that at that stage of analysis all three kinetic models listed above were tested, RMS noticed however, that the analysis was limited only to two – SFO and FOMC;
 - **Sub-step 2:** kinetic evaluation of the data for parent compound (Flufenacet) and its degradation products using for Flufenacet the kinetic model identified at previous stage as appropriate, and SFO model for degradation products;
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The raw input data, presented in table B.8.1.1.2.1.1._CA-87, were processed following the recommendations given by FOCUS. In general terms it looked as follows:

- Measured and reported true replicates were taken into account singularly;
- The data sets were checked for their consistency and clear outliers. In case the outliers were found and removed, that was clearly indicated.

The particular measures taken in the processing of the data for the parent compound – Flufenacet, were following:

- The total AR recovery recorded in DAT-0 samples was used as concentration of Flufenacet at that time point, but the M_0 value was allowed to be estimated by the model; For that purpose the data presented in the table B.8.1.1.2.1.1._CA-88 – “DAT-0 recovery” values, were used;
- Values between LOD and LOQ were set to measured values;
- All single values <LOD or the non-detects (n. d.) were set to $\frac{1}{2}$ LOD. The same procedure was applied to the first appearances. However, when the values <LOD/n.d. appeared consecutively for second and next times, the kinetic curve was cut off until the appearance of the first value >LOQ. For that purpose the data presented in the table B.8.1.1.2.1.1._CA-88 – “LOD” values, were used.

The values for degradation products were processed in a following way:

- The initial, DAT-0, concentration was set to 0. That value, unlike the free-fitted M_0 for the parent compound, was a fixed value;
- The values for subsequent time points, if reported as <LOD or non-detects were also set to 0 until the last time point before the first detectable amount was recorded;
- The value reported as <LOD/n.d. appearing just before the first detectable amount was recorded was set to $\frac{1}{2}$ LOD. For that purpose the data presented in the table B.8.1.1.2.1.1._CA-88 – LOD values, were used.
- Values between LOD and LOQ were set to measured values;
- In the decline phase the first values <LOD/n.d. were also set $\frac{1}{2}$ LOD. For the consecutive second and next such appearances the kinetic curve was cut off until, eventually, the first value >LOQ appeared. For that purpose the data presented in the table B.8.1.1.2.1.1._CA-88 – “LOD” values, were used.

The processed values used as input data for the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-89.

Table B.8.1.1.2.1.1_CA-89: The processed data obtained in the test soils used as input in kinetic analysis.

Footnotes to the table:

- 1) Value set to ½ LOD;
 2) NaN = Not a Number;

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure was a two-stage one. The first step, further called **Step 1**, consisted on the determination of the appropriate kinetic model for the parent compound – Flufenacet. At that stage two 1st-order kinetic models were tested: SFO and FOMC (alteration of the general multistep evaluation procedure characterised above). During the next stage, further called **Step 2**, the whole data set – data for the Flufenacet and its degradation products, was kinetically examined. In case of Flufenacet the tested kinetic model was that determined appropriate at **Step 1**, while for the degradation products the SFO model was used. The conceptual metabolic pathway built in the modelling tool is presented below on figure B.8.1.1.2.1.1._CA-29. The following abbreviations were used:

- FFA for Flufenacet (parent compound);
- THIA for FOE Thiadone;
- TFA for Trifluoroacetic acid (TFA);
- TFESA for FOE 5043-Trifluoroethanesulfonic acid;

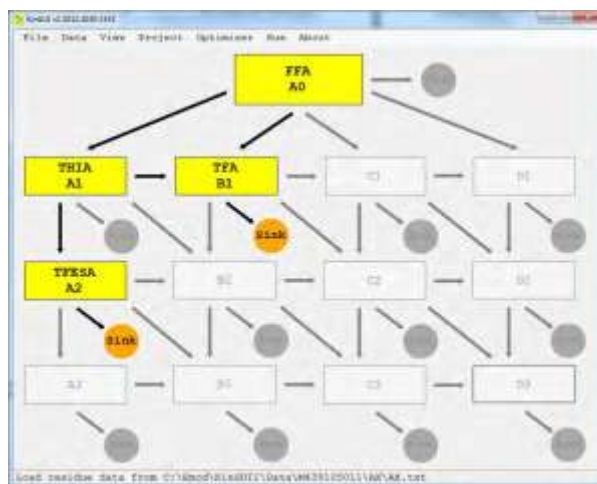

Figure B.8.1.1.2.1.1._CA-29: The conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of that evaluation is provided in the summary of the **Study 2**, on pages 168 – 169.

The whole assessment was carried out as a multistep procedure, similar to that outlined in the presented above summary of the **Study 3**, on page 201. However, as it slightly differed from that scheme, RMS decided to present it in this summary. It consisted of the following steps:

- **Step 1:** the data for the parent compound were fitted using two kinetic models: SFO and FOMC and verified for passing the acceptance criteria (χ^2 -error and distribution of residuals); in case the SFO fit was found visually acceptable and statistically more appropriate than FOMC, it was selected as the best-fit model;
- **Step 2:** in case the SFO model was found not to be more appropriate than FOMC, it was refined in three-step procedure, by removing the outliers, fixing model parameters and data weighing, until the best-fit was achieved;
- **Step 3:** if the **Step-2** fitting for SFO model still failed the χ^2 -error test, and FOMC was demonstrated to be more appropriate, the DFOP model was tested in order to determine if bi-phasic model is acceptable and if so, which one should be selected as returning the best fit;
- **Step 4:** once the best-fit model was determined, the data for the degradation products were added to the data set and the kinetic analysis repeated using the identified best-fit model for Flufenacet (parent compound) and SFO for the metabolites in order to estimate trigger endpoints for them. In case SFO

model was found not acceptable, further analysis was performed using case-to-case approach in line with the recommendations of FOCUS Kinetics [FOCUS; 2006, 2011].

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the trigger kinetic endpoints presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test soil.

- The results of the kinetic analysis of the data obtained in **Hoefchen am Hohenseh 4a** Silt loam soil (study by [Hein; 2012]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-30 and in numerical form in the table B.8.1.1.2.1.1._CA-90.

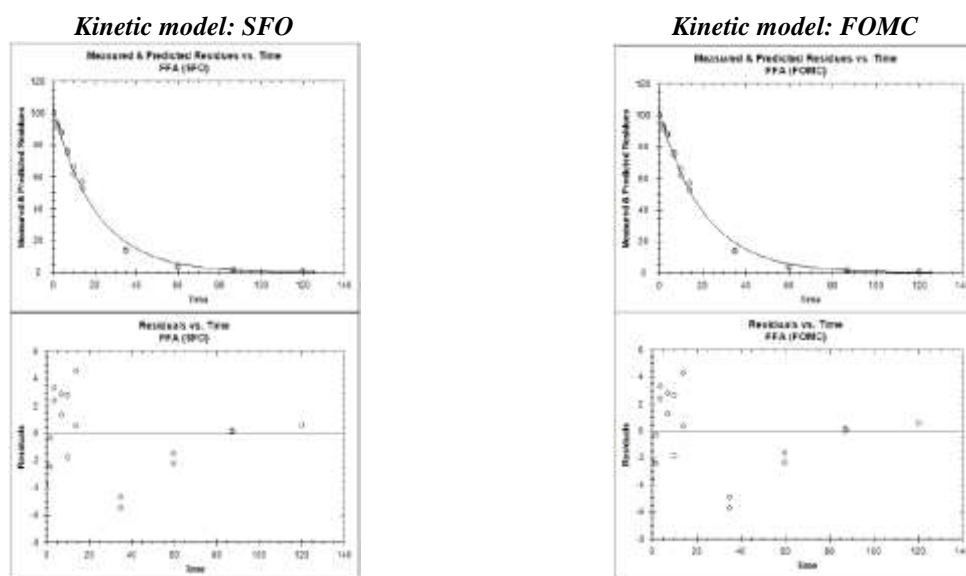

Figure B.8.1.1.2.1.1._CA-30: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-90: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	103.30	1.333	100.60	105.868	< 2 E-16	3.960	1.0; Good fit
	k	0.04858	1.794 E-3	0.04507	0.052	2.44 E-16		
FOMC	M_0	103.099	0.985	101.169	105.00	< 2 E-16	4.179	1.0; Good fit
	α	624.316	659.079	-667.455	1916.10	0.178		
	β	12935.739	13657.756	-13832.971	39704.40	0.178		

Footnotes to the table:

1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable, therefore it was selected as appropriate and used at the next step to kinetically examine the data for Flufenacet and its

degradation products. The analysis using FOMC model did not result in any improvement of the fit and the kinetic parameters were not reliable (the CI values for both α and β passed through zero). As a result, the DFOP model was not tested and SFO was indicated as the best-fit model for Flufenacet in this trial. RMS accepted that choice.

The best-fit kinetic endpoints determined for Flufenacet in this kinetic assessment are following: $DT_{50} = 14.27$ days, $DT_{90} = 47.40$ days, kinetic model: SFO.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-31 and in numerical form in the table B.8.1.1.2.1.1_CA-91.

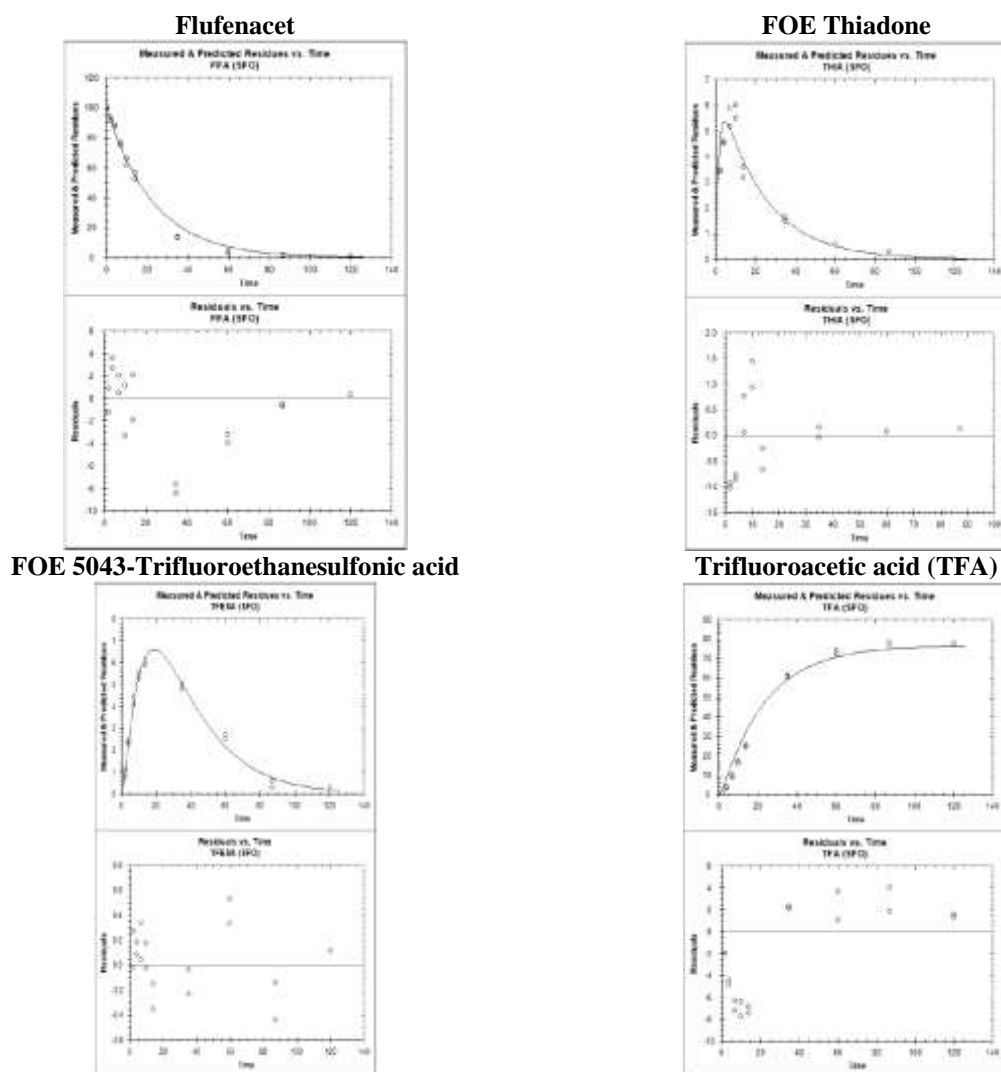

Figure B.8.1.1.2.1.1_CA-31: The graphical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Hoefchen am Hohenseh 4a soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-91: The numerical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Hoefchen am Hohenseh 4a soil.

Trifluoroacetic acid	SFO	M ₀	0.0	----	----	----	----	10.492	Good fit
		k	1.4 E-10	4.85 E-4	-9.51 E-4	0.001	0.500		
		ff ²⁾	0.087	0.044	----	----	----		
		ff ₂ ³⁾	0.736	----	----	----	----		

Footnotes to the table:

- 1) The Applicant provided the R² value and the assessment of the visual fit only for FOE 5043-Trifluoroethanesulfonic acid; for all remaining compounds R² is not reported while the visual assessment is that performed by RMS;
- 2) ff calculated for formation from the parent compound – Flufenacet;
- 3) ff calculated for the formation from FOE Thiadone;

The Applicant stated that in that kinetic analysis it was possible to obtain the reliable trigger kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid. The determined kinetic parameters reported by the Applicant were following: **DT₅₀ = 9.1 days, DT₉₀ = 30.2 days.**

RMS performed own analysis of the obtained results. It led to the following conclusions:

- It was possible to obtain reliable kinetic fits and kinetic parameters for the following compounds: Flufenacet, FOE Thiadone and FOE 5043-Trifluoroethanesulfonic acid;
- In case of Trifluoroacetic acid the fit is reliable, however of the determined kinetic parameters only the kinetic formation fractions – ff, may be considered reliable. The lack of reliability of the degradation rate constant and resulting from it DT₅₀ and DT₉₀ values is due to the fact that the kinetic curve was in its formation phase and even the would-be maximum was not reached.

The final set of the kinetic parameters considered acceptable by the RMS is presented below in the table B.8.1.1.2.1.1._CA-92.

Table B.8.1.1.2.1.1._CA-92: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound			
	Flufenacet	FOE Thiadone	FOE 5043-Trifluoroethane-sulfonic acid	Trifluoroacetic acid
DT ₅₀ [days]	15.84	1.34	9.10	1000
DT ₉₀ [days]	52.61	3.77	30.23	> 1000
Kinetic formation fraction ff	Not applicable	0.913 ± 0.013	0.264	0.087 ± 0.004
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet
Kinetic model	SFO	SFO	SFO	SFO

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound **DT₅₀ = 1000 days and DT₉₀ > 1000 days.**

- 2) The results of the kinetic analysis of the data obtained in **Laacherhof AXXa** Loamy sand soil (study by [Hein; 2012a]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-32 and in numerical form in the table B.8.1.1.2.1.1._CA-93.

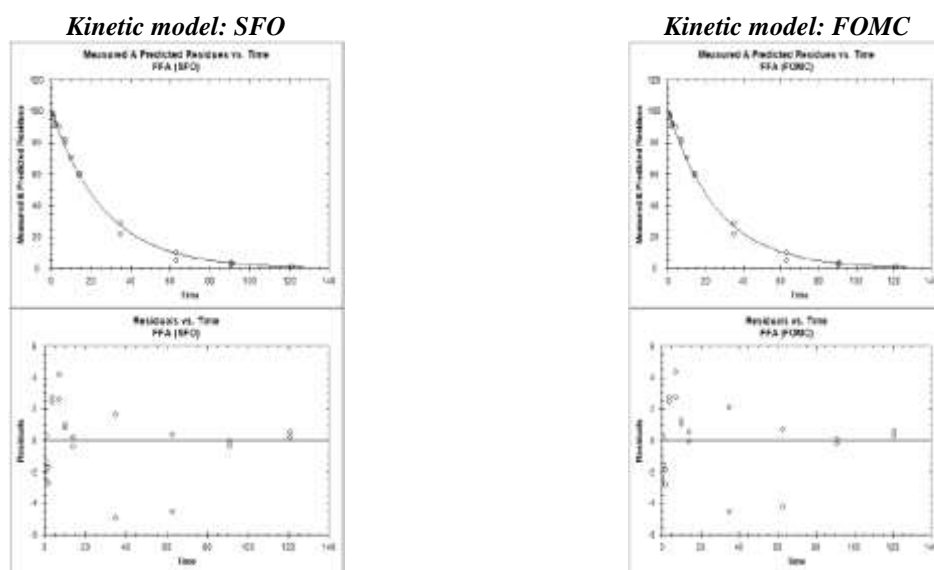

Figure B.8.1.1.2.1.1._CA-32: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-93: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	101.30	0.906	99.54	103.09	< 2 E-16	2.578	1.0; Good fit
	k	0.03741	1.141 E-3	0.03517	0.040	< 2 E-16		
FOMC	M_0	101.60	0.899	99.80	103.30	< 2 E-16	2.724	1.0; Good fit
	α	883.4	809.0	-702.1	2469.0	0.144		
	β	23250	21310	-18520	65027.4	0.144		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable, therefore it was selected as appropriate and used at the next step to kinetically examine the data for Flufenacet and its degradation products. The analysis using FOMC model did not result in any improvement of the fit and the kinetic parameters were not reliable (the CI values for both α and β passed through zero). As a result the DFOP model was not tested and SFO was indicated as the best-fit model for Flufenacet in this trial. RMS accepted that choice.

The best-fit kinetic endpoints determined for Flufenacet in this kinetic assessment are following: **DT₅₀ = 18.53 days, DT₉₀ = 61.56 days, kinetic model: SFO.**

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-33 and in numerical form in the table B.8.1.1.2.1.1._CA-94.

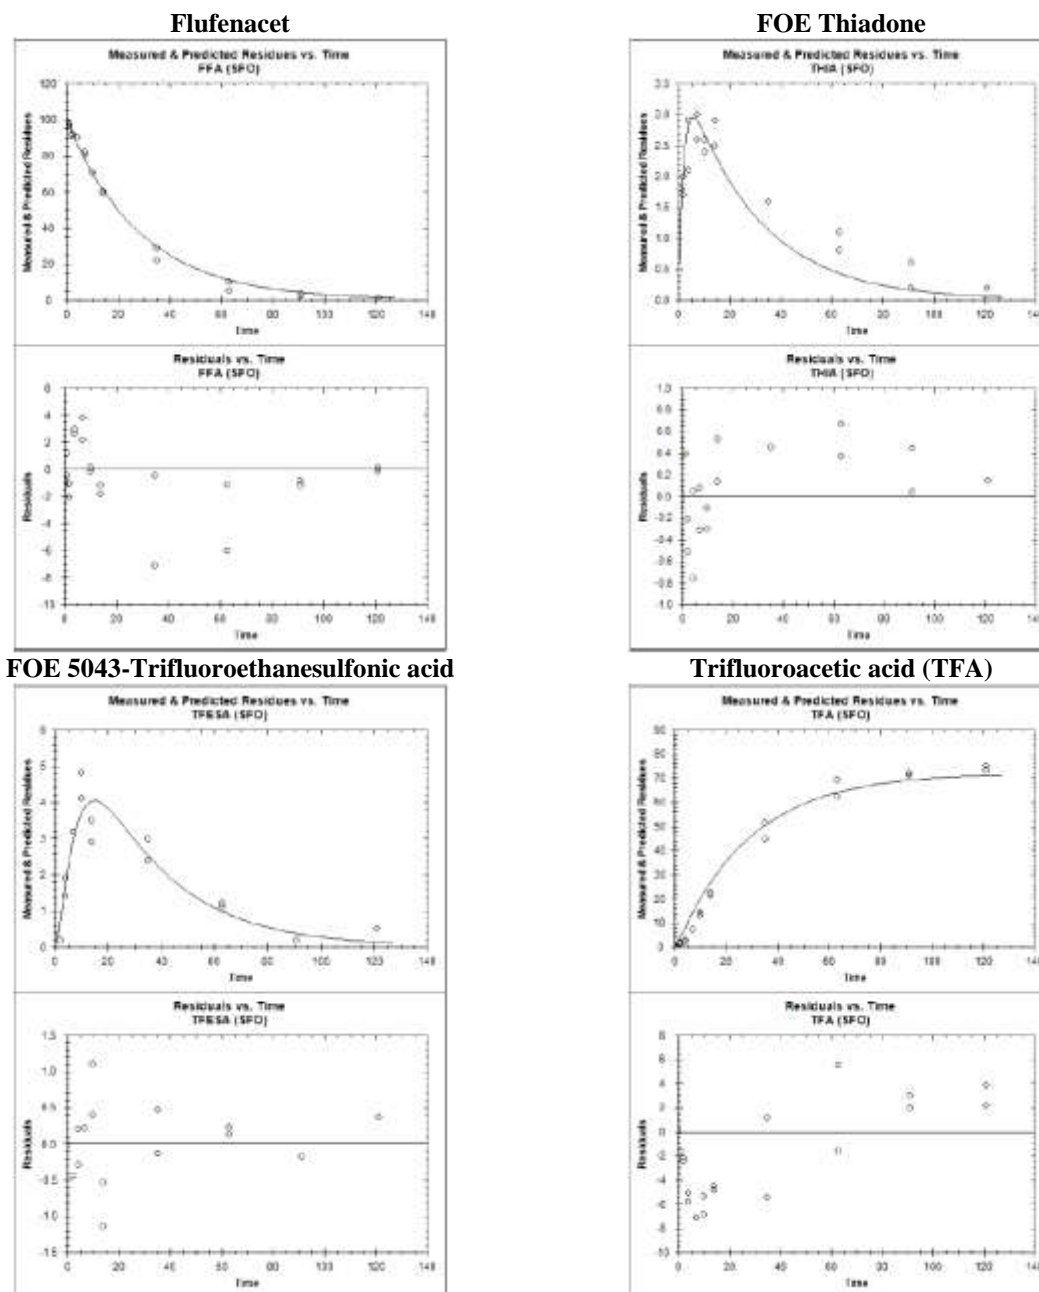

Figure B.8.1.1.2.1.1._CA-33: The graphical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof AXXa soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-94: The numerical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof AXXa soil.

		ff ²⁾	0.562	0.113	----	----	----		
		ff ³⁾	0.578	----	----	----	----		

Footnotes to the table:

- 1) The Applicant provided the R² value and the assessment of the visual fit only for FOE 5043-Trifluoroethanesulfonic acid; for all remaining compounds R² is not reported while the visual assessment is that performed by RMS;
- 2) ff calculated for formation from the parent compound – Flufenacet;
- 3) ff calculated for the formation from FOE Thiadone;

The Applicant stated that using the data from that experiment it was not possible to obtain the reliable trigger kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid. That was due to the fact that the visual fitting was poor and the χ^2 error high, making the whole fit unreliable. RMS confirms the correctness of that conclusion. As a result the Applicant performed an additional fitting for FOE 5043-Trifluoroethanesulfonic acid alone, using the top-down approach. The results of that analysis are presented below under the letter-point c).

RMS performed own analysis of the obtained results. It led to the following conclusions:

- It was possible to obtain reliable kinetic fits and kinetic parameters for the following compounds: Flufenacet and FOE Thiadone;
- In case of Trifluoroacetic acid the fit is reliable, however of the determined kinetic parameters only the kinetic formation fractions – ff, may be considered reliable. The lack of reliability of the degradation rate constant and resulting from it DT₅₀ and DT₉₀ values is due to the fact that the kinetic curve was in its formation phase and even the would-be maximum was not reached;
- In case of FOE 5043-Trifluoroethanesulfonic acid it was not possible to obtain the reliable kinetic fit. Although the visual inspection showed that fit is acceptable – the Applicant classified it as poor, but RMS is of the opinion that the conformity of the determined kinetic curve and experimental data was not bad, what was also conformed by the value of R², but high level of χ^2 error makes it statistically not reliable. As a result, also calculated kinetic endpoints – DT₅₀ and DT₉₀ values cannot be considered reliable in spite of the fact that the calculated rate constant k is reliable according to the results of the t-test (the prob. > t is well below the level of 0.05). RMS noticed that problems with obtaining the reliable kinetic curve were most probably due to the low concentrations of the compound in this experiment. However, the distribution of the data points implied that the acceptable fit may be obtained when these are fitted alone using the top-down approach.

The set of the kinetic parameters considered acceptable by the RMS is presented below in the table B.8.1.1.2.1.1._CA-98. It shall be noted that in case of FOE 5043-Trifluoroethanesulfonic acid the conclusion is provided only for this fitting exercise and not definitive, as it was superseded by the results of the next fitting step.

Table B.8.1.1.2.1.1._CA-98: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound			
	<i>Flufenacet</i>	<i>FOE Thiadone</i>	<i>FOE 5043-Trifluoroethanesulfonic acid</i>	<i>Trifluoroacetic acid</i>
DT ₅₀ [days]	16.30	2.84	Not determined	1000
DT ₉₀ [days]	54.18	9.45	Not determined	> 1000
Kinetic formation fraction <i>ff</i>	Not applicable	0.438 ± 0.066	0.422	0.562 ± 0.113
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet
Kinetic model	SFO	SFO	SFO	SFO

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound **DT₅₀ = 1000 days** and **DT₉₀ > 1000 days**.

- c) Results obtained at **Step 3** for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach:

As the last step of the analysis of the data obtained in the experiment on Dollendorf II soil, the data for FOE 5043-Trifluoroethanesulfonic acid were fitted alone using the top-down approach. To do that the Applicant identified the time point at which the maximum concentration of the compound of concern was recorded. That point was used as a starting point in the analysis. The resulting data set used in the fitting exercise is presented below in the table B.8.1.1.2.1.1._CA-99.

Table B.8.1.1.2.1.1._CA-99: The input data for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach.

Time Point – DAT [days]	Concentration of FOE 5043-Trifluoroethanesulfonic acid expressed as [%AR]	
	Replicate 1	Replicate 2
10	3.8	3.1
14	1.7	1.8
35	1.6	1.6
63	0.5	0.6
91	0.2	0.2
121	NaN	NaN

The fitting was performed using two kinetic models – SFO and FOMC and followed the procedure outlined above. RMS, having examined the data set used in the fitting stated that the number of data points for which measurable values were available – five (DAT 121 was not taken into account), was sufficient for performing the fitting with a bi-phasic model – FOMC (in such cases the current Guidelines recommend that the minimal number of data points should be five).

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-36 and in numerical form in the table B.8.1.1.2.1.1._CA-100.

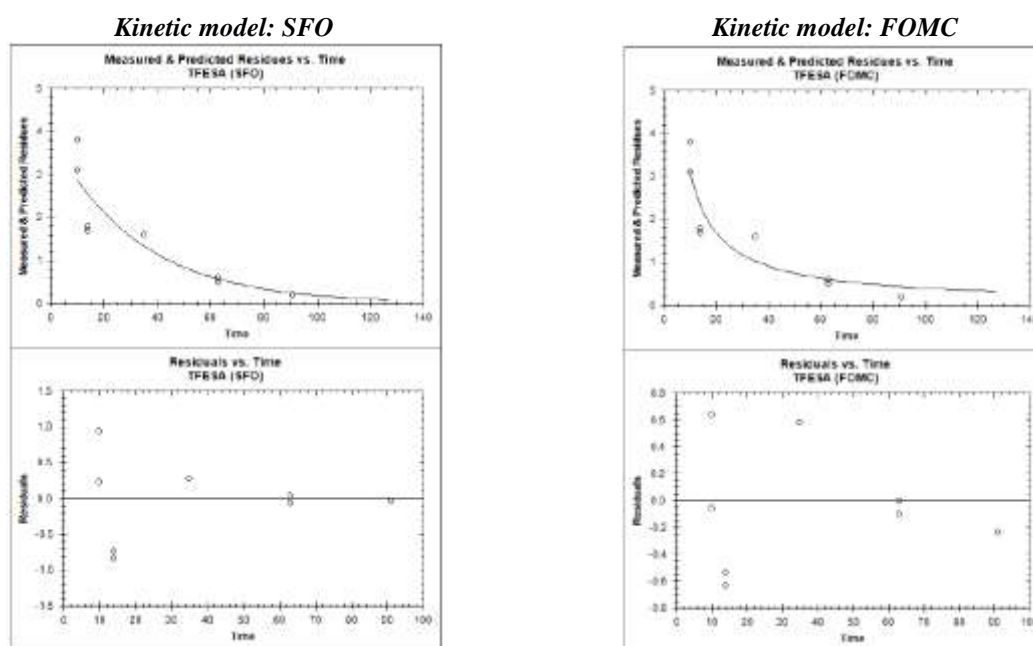

Figure B.8.1.1.2.1.1_CA-36: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1_CA-100: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	3.911	0.633	2.669	5.152	1.33 E-4	24.06	0.82; Good fit
	k	0.03084	0.00876	0.01368	0.048	0.00391		
FOMC	M_0	542.10	2043.0	-3462.0	4546.13	0.3992	24.44	0.86; Acceptable fit
	α	0.9024	0.1560	0.5966	1.208	3.37 E-4		
	β	0.03352	0.1386	-0.2382	0.305	0.4079		

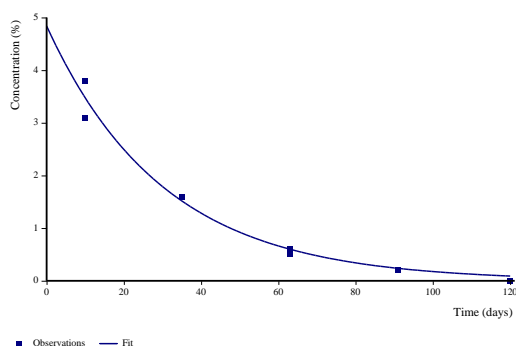

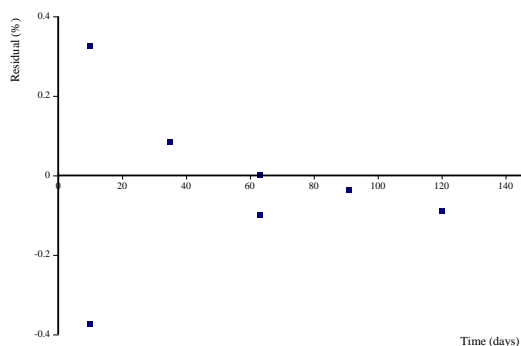

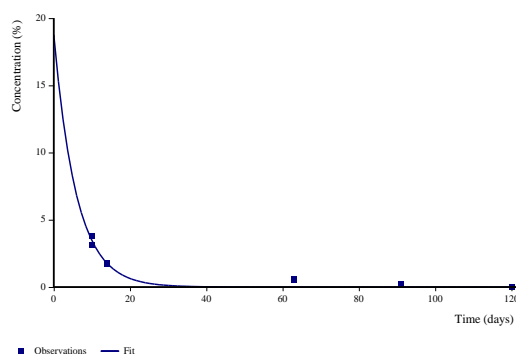

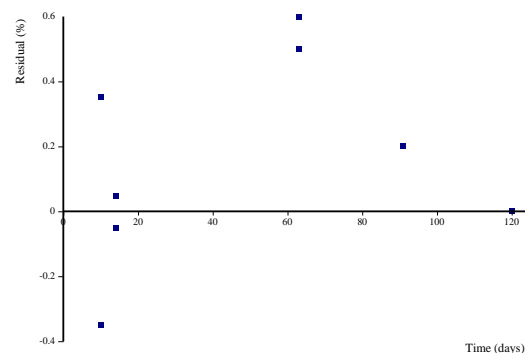

Footnotes to the table:

1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable, therefore it was selected as appropriate to derive the trigger kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid. The analysis using FOMC model did not result in any improvement of the fit and the kinetic parameters were not reliable (the CI values for β passed through zero and the calculated M_0 bore very high level of uncertainty). As a result the DFOP model was not tested and SFO was indicated as the best-fit model for FOE 5043-Trifluoroethanesulfonic acid in this experiment for the fitted-alone data set. RMS accepted that choice noticing however that although the fit was visually acceptable and the determined rate constant was reliable, statistically it bore significant level of uncertainty.

Examining the determined kinetic curve RMS noticed that one of the data point – either DAT-14 or DAT-35 might an outlier, the removal of which could improve the fit visually and statistically. To verify that hypothesis the additional modelling was performed. The modelling tool used in that exercise was CAKE 3.1, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm.

The results of the kinetic analysis performed by the RMS are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-37 and in numerical form in the table B.8.1.1.2.1.1_CA-101.

Kinetic model: SFO, DAT-14 time point omitted**Graphical Summary:****Observations and Fitted Model:****Residuals:****Kinetic model: SFO, DAT-35 time point omitted****Graphical Summary:****Observations and Fitted Model:****Residuals:****Figure B.8.1.2.1.1._CA-37:** The graphical results of the kinetic analysis.**Table B.8.1.2.1.1._CA-101:** The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO, DAT-14 removed	M_0	4.838	0.265	4.228	5.449	----	4.31	0.983; Good fit
	k	0.03315	0.00271	0.0296	0.039	9.28 E-7		
SFO, DAT-35 removed	M_0	18.76	7.959	0.408	37.12	----	17.6	0.965; Good fit
	k	0.1694	0.0388	0.0799	0.259	0.001194		

The calculated kinetic endpoints were following:

- for the fit with DAT-14 time point omitted: $DT_{50} = 20.9$ days, $DT_{90} = 69.5$ days;
- for the fit with DAT-35 time point omitted: $DT_{50} = 4.09$ days, $DT_{90} = 13.6$.

The obtained results of the fitting indicate that the DAT-14 time point may be considered an outlier and as such removed from data set. The results obtained for that variant were much better, in both visual inspection of the fit and statistical term, than those with DAT-35 time point removed from the data set. It was also noted that both estimated parameters, and M_0 in particular, were much more reliable for the data set with DAT-14 data point removed.

Additionally the RMS performed the fitting with the initial time point – DAT-10, omitted. However, that did not result in any significant improvement, on the contrary the obtained fit was worst of the three. RMS decided not to present these results.

On the basis of the evaluation presented above it may be stated that for FOE 5043-Trifluoroethanesulfonic acid it was possible to obtain the reliable kinetic fit using the data set presented in the table

B.8.1.1.2.1.1._CA-99, modified by the removal of the results for the DAT-14 time point identified as an outlier. It is possible that similar results would be obtained for the same compound fitted in the whole data set once that time point had been removed, but that hypothesis was not verified by the RMS.

The resulting set of the trigger endpoints for FOE 5043-trifluoroethanesulfonic acid is therefore following: **DT₅₀ = 20.9 days, DT₉₀ = 69.5 days**, kinetic model: **SFO**.

Final conclusion:

The final set of the trigger kinetic endpoints resulting from that experiment is presented below in the table B.8.1.1.2.1.1._CA-102.

Table B.8.1.1.2.1.1._CA-102: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound				
	<i>Flufenacet</i>	<i>FOE Thiadone</i>	<i>FOE 5043-Trifluoroethane-sulfonic acid</i>	<i>Trifluoroacetic acid</i>	
DT ₅₀ [days]	16.30	2.84	20.9	1000	
DT ₉₀ [days]	54.18	9.45	69.5	> 1000	
Kinetic formation fraction <i>ff</i>	Not applicable	0.438 ± 0.066	0.422	0.562 ± 0.113	0.578
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet	FOE Thiadone
Kinetic model	SFO	SFO	SFO	SFO	

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound **DT₅₀ 1000 days** and **DT₉₀ > 1000 days**.

- 4) The results of the kinetic analysis of the data obtained in **Laacherhof Wurmwiese** Loam soil (study by [Hein; 2012a]):

The analysis for this data-set was a three-step analysis. The additional step added was the kinetic examination of the data for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach. Its results are presented below, individually for each step.

- a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-38 and in numerical form in the table B.8.1.1.2.1.1._CA-103.

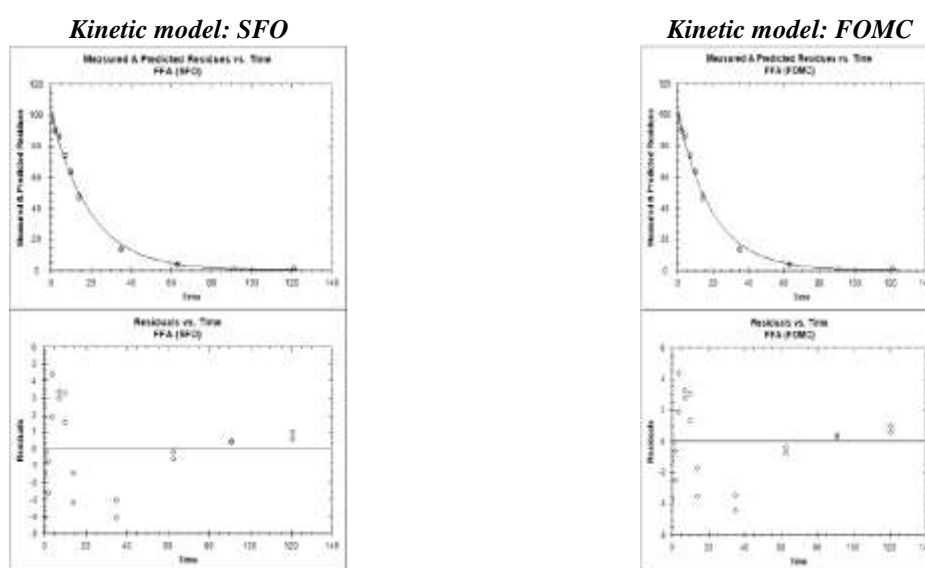

Figure B.8.1.1.2.1.1._CA-38: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-103: The numerical results of the kinetic analysis.

FOMC	M_0	101.886	0.995	99.936	103.8	< 2 E-16	3.612	1.0; Good fit
	α	729.806	893.260	-1020.951	2480.6	0.212		
	β	14354.096	17570.073	-20082.62	48790.80	0.144		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable, therefore it was selected as appropriate and used at the next step to kinetically examine the data for Flufenacet and its degradation products. The analysis using FOMC model did not result in any improvement of the fit and the kinetic parameters were not reliable (the CI values for both α and β passed through zero). As a result the DFOP model was not tested and SFO was indicated as the best-fit model for Flufenacet in this trial. RMS accepted that choice.

The best-fit kinetic endpoints determined for Flufenacet in this kinetic assessment are following: **DT₅₀ = 13.47 days, DT₉₀ = 44.76 days, kinetic model: SFO.**

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-39 and in numerical form in the table B.8.1.1.2.1.1._CA-104.

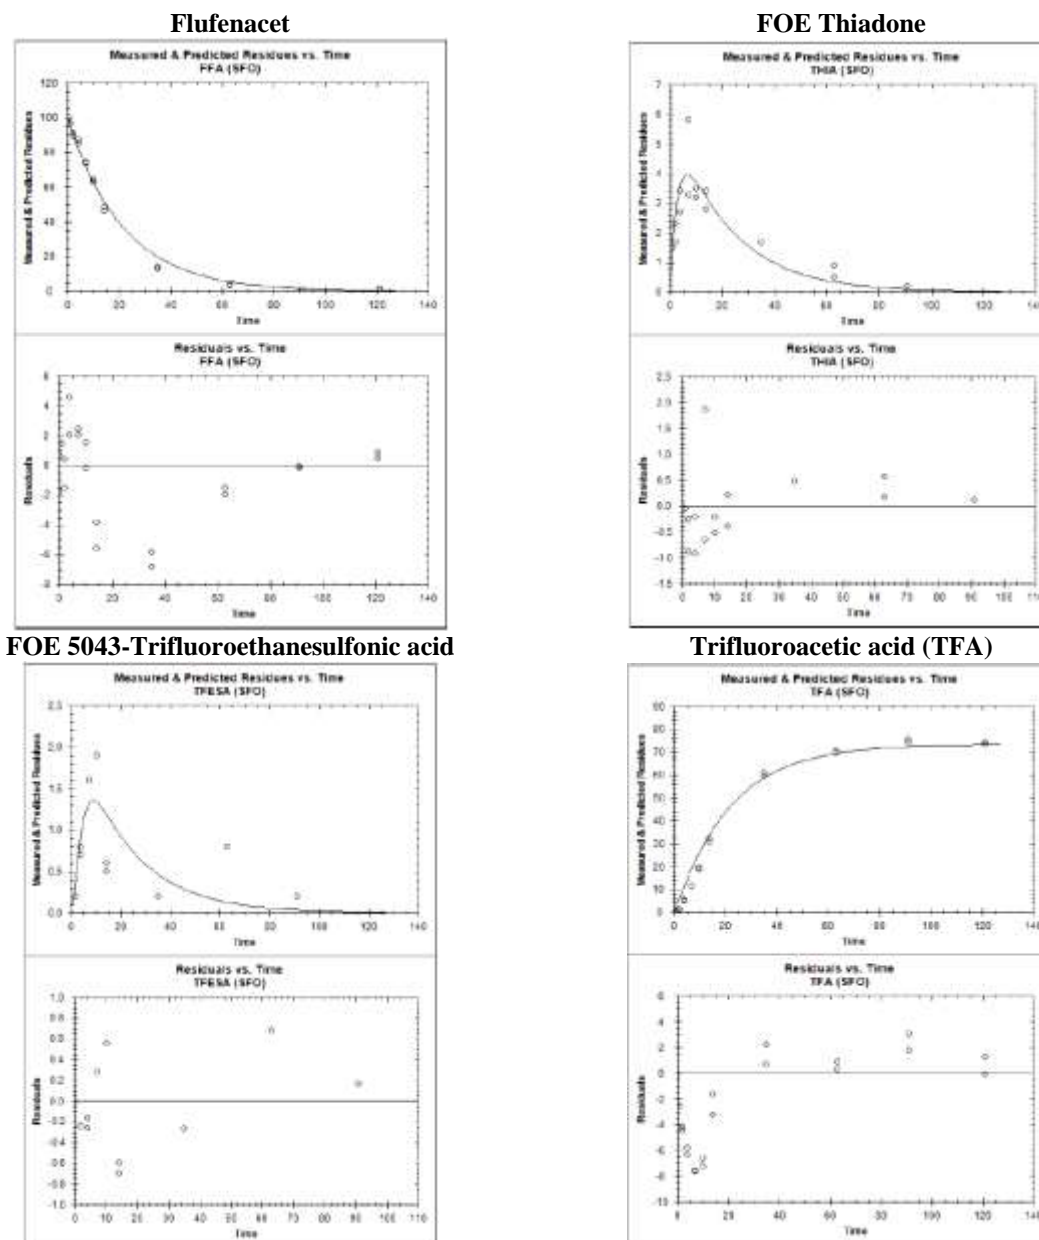

Figure B.8.1.1.2.1.1._CA-39: The graphical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof Wurmwiese soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-104: The numerical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof Wurmwise soil.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M ₀	99.88	1.180	97.57	102.194	< 2 E-16	4.269	Good fit
		k	0.04648	1.67 E-3	0.04321	0.050	< 2 E-16		
FOE Thiadone	SFO	M ₀	0.0	----	----	----	----	14.731	Acceptable fit
		k	0.3490	0.0569	0.2376	0.460	1.96 E-8		
		ff	0.405	0.056	----	----	----		
FOE 5043-Trifluoroethane-sulfonic acid	SFO	M ₀	0.0	----	----	----	----	43.983	0.86; Acceptable fit
		k	0.6478	0.1406	0.3722	0.923	8.48 E-6		
		ff	0.655	----	----	----	----		
Trifluoroacetic acid	SFO	M ₀	0.0	----	----	----	----	9.436	Good fit
		k	4.73 E-9	7.12 E-4	-1.40 E-3	0.001	0.5		
		ff ²⁾	0.596	0.149	----	----	----		
		ff ₂ ³⁾	0.345	----	----	----	----		

Footnotes to the table:

- 1) The Applicant provided the R² value and the assessment of the visual fit only for FOE 5043-Trifluoroethanesulfonic acid; for all remaining compounds R² is not reported while the visual assessment is that performed by RMS;
- 2) ff calculated for formation from the parent compound – Flufenacet;
- 3) ff calculated for the formation from FOE Thiadone;

The Applicant stated that using the data from that experiment it was not possible to obtain the reliable trigger kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid. That was due to the fact that the visual fitting was poor and the χ^2 error high, making the whole fit unreliable. RMS confirms the correctness of that conclusion. As a result the Applicant performed an additional fitting, for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach. The results of that analysis are presented below under the letter-point c).

RMS performed own analysis of the obtained results. It led to the following conclusions:

- It was possible to obtain reliable kinetic fits and kinetic parameters for the following compounds: Flufenacet and FOE Thiadone;
- In case of Trifluoroacetic acid the fit is reliable, however of the determined kinetic parameters only the kinetic formation fractions – ff, may be considered reliable. The lack of reliability of the degradation rate constant and resulting from it DT₅₀ and DT₉₀ values is due to the fact that the kinetic curve was in its formation phase and even the would-be maximum was not reached;
- In case of FOE 5043-Trifluoroethanesulfonic acid it was not possible to obtain the reliable kinetic fit. RMS confirms the Applicant's statement in that area noticing that not only the fit was statistically not acceptable due to the high level of χ^2 error, but also visually – the plotted kinetic curve poorly reproduced the distribution of the experimental points. RMS noticed also that within the decline phase a second local maximum occurred on DAT 63. It is possible that that time point was an outlier. It shall be also noted that the measured value was obtained only for one replicate, while the second was a value < LOD. Therefore that value should probably be removed as an outlier and the last measurable values (½ LOD) should be set for the preceding time point – DAT 35, cutting the subsequent time points off.

RMS did additional kinetic fitting using the modified data set for FOE 5043-Trifluoroethanesulfonic acid to verify the hypothesis presented above. However, even with that modified data set it was not possible to obtain the reliable kinetic fit for that compound, most probably because of the very low concentrations of the compound of concern. RMS decided not to present the results of that fitting in order not to overburden the Report.

The set of the kinetic parameters considered acceptable by the RMS is presented below in the table B.8.1.1.2.1.1._CA-105. It shall be noted that in case of FOE 5043-Trifluoroethanesulfonic acid the conclusion is provided only for this fitting exercise and not definitive, as it was superseded by the results of the next fitting step.

Table B.8.1.1.2.1.1._CA-105: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound			
	<i>Flufenacet</i>	<i>FOE Thiadone</i>	<i>FOE 5043-Trifluoroethanesulfonic acid</i>	<i>Trifluoroacetic acid</i>
DT ₅₀ [days]	14.91	1.99	Not determined	1000
DT ₉₀ [days]	49.54	6.60	Not determined	> 1000
Kinetic formation fraction <i>ff</i>	Not applicable	0.404 ± 0.056	0.655	0.596 ± 0.149 0.345
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet FOE Thiadone
Kinetic model	SFO	SFO	SFO	SFO

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound **DT₅₀ = 1000 days** and **DT₉₀ > 1000 days**.

- c) Results obtained at **Step 3** for FOE 5043 Trifluoroethanesulfonic acid fitted alone using the top-down approach:

As the last step of the analysis of the data obtained in the experiment on Laacherhof Wurmwielse soil, the data for FOE 5043-Trifluoroethanesulfonic acid were fitted alone using the top-down approach. To do that the Applicant identified the time point at which the maximum concentration of the compound of concern was recorded. That point was used as a starting point in the analysis. The resulting data set used in the fitting exercise is presented below in the table B.8.1.1.2.1.1._CA-106.

Table B.8.1.1.2.1.1._CA-106: The input data for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach.

Time Point – DAT [days]	Concentration of FOE 5043-Trifluoroethanesulfonic acid expressed as [%AR]	
	Replicate 1	Replicate 2
10	1.9	1.9
14	0.5	0.6
35	0.2	0.2
63	0.8	NaN
91	0.2	NaN
121	NaN	NaN

The fitting was performed using two kinetic models – SFO and FOMC and followed the procedure outlined above. RMS, having examined the data set used in the fitting stated that the number of data points for which measurable values were available – five (DAT 121 was not taken into account), was sufficient for performing the fitting with a bi-phasic model – FOMC (in such cases the current Guidelines recommend that the minimal number of data points should be five).

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-40 and in numerical form in the table B.8.1.1.2.1.1._CA-109.

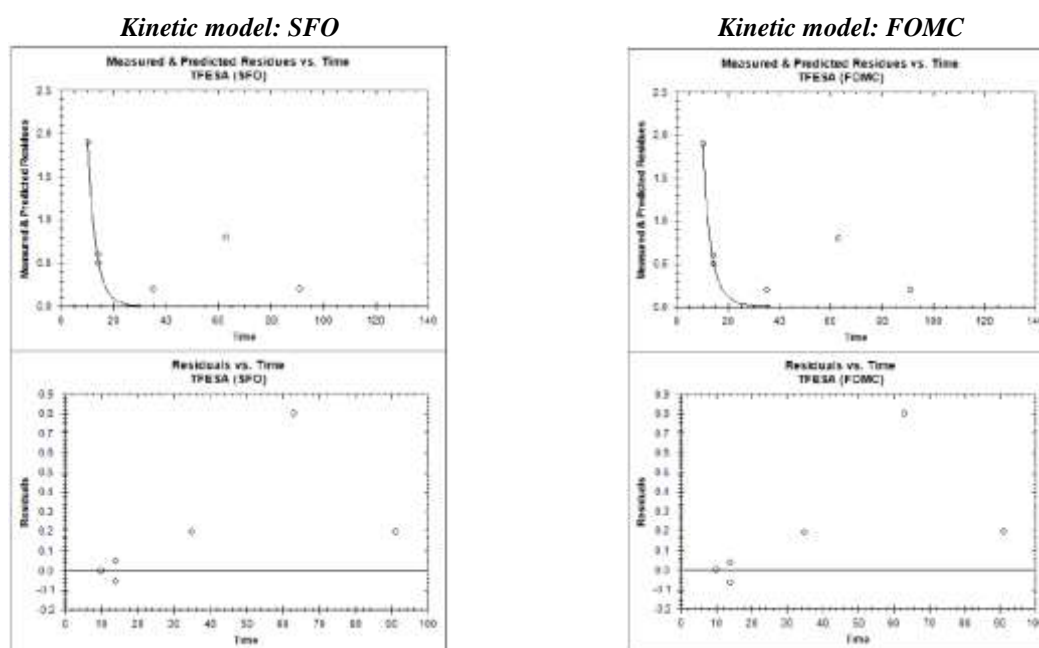

Figure B.8.1.1.2.1.1_CA-40: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1_CA-107: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	41.726	49.146	-54.598	138.050	0.2142	41.57	0.90; Poor fit
	k	0.30895	0.1140	0.08545	0.532	0.0176		
FOMC	M_0	95.473	99.078	-98.717	289.66	0.190	47.42	0.90; Poor fit
	α	9.912	10.381	-10.434	30.26	0.192		
	β	20.624	19.913	-18.405	59.65	0.174		

Footnotes to the table:

1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that neither SFO nor FOMC returned visually and statistically acceptable. As a result it was stated that it was not possible to obtain reliable kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach.

RMS however, analysing the data set for FOE 5043-Trifluoroethanesulfonic acid noticed that the problem was possibly related to the occurrence of the second maximum observed on DAT 63. The measurable concentration was determined at that time point only for one replicate, what may indicate that in fact that value is an outlier. Therefore RMS decided to repeat the fitting removing that value and all subsequent data points. In order to have the minimal required amount of data points – four, RMS decided to use the DAT 63 as the last time point with the concentrations of the compound of concern set to zero. The resulting modified data set used in that fitting is presented below in the table B.8.1.1.2.1.1_CA-108.

Table B.8.1.1.2.1.1_CA-108: The modified input data for FOE 5043-Trifluoroethanesulfonic acid used in the repeated kinetic analysis performed by the RMS using the top-down approach.

Time Point – DAT [days]	Concentration of FOE 5043-Trifluoroethanesulfonic acid expressed as [%AR]	
	Replicate 1	Replicate 2
10	1.9	1.9
14	0.5	0.6
35	0.2	0.2
63	0.0	0.0

The kinetic analysis was performed using CAKE 3.1, developed by Tessella, as a modelling tool. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. Because of the limited number of the data points – only four were available, solely the SFO model was tested.

The results of the kinetic analysis performed by the RMS are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-41 and in numerical form in the table B.8.1.1.2.1.1._CA-109.

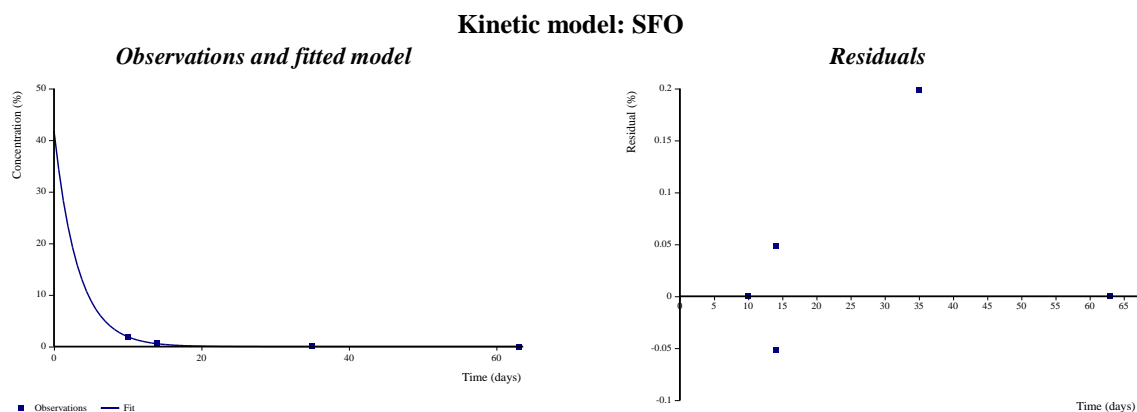

Figure B.8.1.1.2.1.1._CA-41: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-109: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	41.75	17.11	-0.1286	83.62	----	12.3	0.988; Good fit
	k	0.309	0.03954	0.2122	0.406	1.16 E-4		

The calculated kinetic endpoints were following: **DT₅₀ = 2.24 days, DT₉₀ = 7.45 days;**

The obtained results of the fitting indicate that with the elimination of the measurable value for DAT-63 time point it was possible to obtain visually good and statistically reliable fit using the SFO kinetic model. It shall be noted that the kinetic curve bears a considerable level of uncertainty with regard to the estimated M_0 value, but on the other hand that value is close to the determined kinetic formation fraction ff . That taken into account, it may be stated that the kinetic curve may be considered as a good estimation of the kinetic behaviour of FOE 5043-Trifluoroethanesulfonic acid in the test soil, therefore the fit and derived from it kinetic endpoints may be considered reliable.

The resulting set of the trigger endpoints for FOE 5043-Trifluoroethanesulfonic acid is therefore following: **DT₅₀ = 2.24 days, DT₉₀ = 7.45 days, kinetic model: SFO.**

Final conclusion:

The final set of the trigger kinetic endpoints resulting from that experiment is presented below in the table B.8.1.1.2.1.1._CA-110.

Table B.8.1.1.2.1.1._CA-110: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound				
	Flufenacet	FOE Thiadone	FOE 5043-Trifluoroethane-sulfonic acid	Trifluoroacetic acid	
DT ₅₀ [days]	14.91	1.99	2.24	1000	
DT ₉₀ [days]	49.54	6.60	7.45	> 1000	
Kinetic formation fraction <i>ff</i>	Not applicable	0.404 ± 0.056	0.655	0.596 ± 0.149	0.345
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet	FOE Thiadone
Kinetic model	SFO	SFO	SFO	SFO	

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound **DT₅₀ 1000 days** and **DT₉₀ > 1000 days**.

Final conclusion of the study:

On the basis of the results of the kinetic evaluation presented above it was possible to derive the definitive sets of the trigger kinetic endpoints for each evaluated compounds. These are presented below in the table B.8.1.1.2.1.1._CA-111.

Table B.8.1.1.2.1.1._CA-111: The final set of reliable kinetic endpoints determined in the study.

Study	Test soil	Compound	Determined parameter				
			Kinetic model	Rate constant <i>k</i>	DT ₅₀ [days]	DT ₉₀ [days]	Kinetic formation fraction <i>ff</i>

Footnotes to the table:

- 1) The reliable value was not determined – the estimate provided by the model cannot be considered such;
- 2) For formation from parent compound – Flufenacet;
- 3) For formation from FOE Thiadone.

Study 7:

Report: Reinken G., Partsch S., (2014): “Kinetic Evaluation of [thiadiazole-5-¹⁴C] flufenacet and its Degradation Products under Aerobic Conditions in Laboratory According to FOCUS Kinetics Using the KinGUI 2 Tool. Flufenacet (FOE 5043), FOE-thiadone, FOE 5043-trifluoroethane sulfonic acid, Trifluoroacetic acid.”; Bayer Crop Science AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished Study Report No. En-Sa-12-0577; 2014. 02; study reference number: M-477835-01-1;.

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above. It was stated that the study generally complied with the two evoked Guidance Documents. It was also noted that it was aimed on the derivation of the kinetic endpoints to be used in modelling. Therefore the best-fit model for Flufenacet was not identified, also because that was done in the **Study 6** summarised above. Instead the SFO model was generally indicated as returning acceptable fit for parent compound – Flufenacet. Also the first step of the evaluation – verification of the acceptability of SFO fit for Flufenacet fitted alone, was not performed, as that has been done in three previous studies. As a result, when the data for parent and metabolites were kinetically examined only the combination SFO-SFO was tested, unless the top-down approach was used for any of the degradation products. RMS summarising the study used the soil names as they were provided in the source study reports (in the study report they were slightly altered) to maintain the internal coherence of the document.

Summary:

The aim of the study was to kinetically examine the data obtained in the experiments in which [Thiadiazole-5-¹⁴C] Flufenacet was used. That was done in order to derive the kinetic parameters suitable for modelling and environmental risk assessment.

The data were taken from the following studies: [Hein; 2012] – a route- and rate-of-degradation study, summarised under the point B.8.1.1.1.1.as **Study 5** and under this point as **Study 4**, and [Hein; 2012a] – a route- and rate-of-degradation study, summarised under the point B.8.1.1.1.1.as **Study 6** and under this point as **Study 5**. The characteristic of the test soils used in each of these experiments was presented above in the summaries of the **Study 4** and **Study 5**, therefore to not overburden unnecessarily the Assessment Report, RMS decided not to present these data. The experimental conditions used in each experiment are summarised below in the table B.8.1.1.2.1.1._CA-112.

Table B.8.1.1.2.1.1._CA-112: The experimental conditions used in each experiment.

Study	Test soil		Incubation temperature <i>T</i> [°C]	Experimental conditions		
	Name	Type (USDA classification)		Soil moisture		
				In experiment	Reference value	
					MWHC [%]	FC at pF 2.0 [%]
<i>Hein; 2012</i>	Hoefchen Am Hohenseh 4a	Silt loam	19.7 ± 0.1	55% MWHC	61.1	29.8
<i>Hein; 2012a</i>	Laaherhof AXXa	Loamy sand	19.9 ± 0.2	55% MWHC	49.1	18.7
	Dollendorf II	Clay loam	19.9 ± 0.2	55% MWHC	79.8	46.0
	Laacherhof Wurmweise	Loam	19.9 ± 0.2	55% MWHC	59.9	23.3

The not processed input data used in the kinetic analysis are presented below in the table B.8.1.1.2.1.1._CA-113. Additionally, in the table B.8.1.1.2.1.1._CA-114 are presented the DAT-0 total recovery and LOD values, subsequently used in data processing.

Table B.8.1.1.2.1.1_CA-113: The non-processed data obtained in the test soils used as input in kinetic analysis.

Hein; 2012a	Dollendorf II	Clay loam	102.4	99.6	0.4
	Laacherhof Wurmwiese	Loam	98.1	100.6	0.4

The data presented above were subjected to a multistep evaluation procedure performed in line with the recommendations of FOCUS Kinetics Guidelines [FOCUS; 2006]. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st – order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool. That step consisted of the two sub-steps:
 - **Sub-step 1:** kinetic evaluation of the data for parent compound (Flufenacet) only, in order to determine the appropriate kinetic model. At that stage of analysis all three kinetic models listed above were tested;
 - **Sub-step 2:** kinetic evaluation of the data for parent compound (Flufenacet) and its degradation products using for Flufenacet the kinetic model identified as appropriate at previous stage, and SFO model for degradation products;
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The raw input data, presented in table B.8.1.1.2.1.1._CA-113, were processed following the recommendations given by FOCUS. In general terms that looked as follows:

- Measured and reported true replicates were taken into account singularly;
- The data sets were checked for their consistency and clear outliers. In case the outliers were found and removed, that was clearly indicated.

The particular measures taken in the processing of the data for the parent compound – Flufenacet, were following:

- The total AR recovery recorded in DAT-0 samples was used as concentration of Flufenacet at that time point, but the M_0 value was allowed to be estimated by the model; For that purpose the data presented in the table B.8.1.1.2.1.1._CA-114 – DAT-0 recovery values, were used;
- Values between LOD and LOQ were set to measured values;
- All single values <LOD or the non-detects (n. d.) were set to $\frac{1}{2}$ LOD. The same procedure was applied to the first appearances. However, when the values <LOD/n.d. appeared consecutively for second and next times, the kinetic curve was cut off until the appearance of the first value >LOQ. For that purpose the data presented in the table B.8.1.1.2.1.1._CA-114 – “LOD” values, were used.

The values for degradation products were processed in a following way:

- The initial, DAT-0, concentration was set to 0. That value, unlike the free-fitted M_0 concentration for the parent compound, was a fixed value;
- The values for subsequent time points, if reported as <LOD or non-detects were also set to 0 until the last time point before the first detectable amount was recorded;
- The value reported as <LOD/n.d. appearing just before the first detectable amount was recorded was set to $\frac{1}{2}$ LOD. For that purpose the data presented in the table B.8.1.1.2.1.1._CA-88 – “LOD” values, were used.
- Values between LOD and LOQ were set to measured values;
- In the decline phase the first values <LOD/n.d. were also set $\frac{1}{2}$ LOD. For the consecutive second and next such appearances the kinetic curve was cut off until, eventually, the first value >LOQ appeared. For that purpose the data presented in the table B.8.1.1.2.1.1._CA-114 – “LOD” values, were used.

The processed values used as input data for the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-115.

Table B.8.1.1.2.1.1_CA-115: The processed data obtained in the test soils used as input in kinetic analysis.

Footnotes to the table:

- 1) Value set to ½ LOD;
 2) NaN = Not a Number;

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure was a two-stage one. The first step, further called **Step 1**, consisted on the determination of the appropriate kinetic model for the parent compound – Flufenacet. At that stage three 1st-order kinetic models were tested: SFO, FOMC and DFOP. During the next stage, further called **Step 2**, the whole data set – data for the Flufenacet and its degradation products, was kinetically examined. In case of Flufenacet the tested kinetic model was that determined as appropriate at **Step 1**, while for the degradation products the SFO model was used. The conceptual metabolic pathway built in the modelling tool is presented below on figure B.8.1.1.2.1.1_CA-42. The following abbreviations were used:

- FFA for Flufenacet (parent compound);
- THIA for FOE Thiadone;
- TFA for Trifluoroacetic acid (TFA);
- TFESA for FOE 5043-Trifluoroethanesulfonic acid;

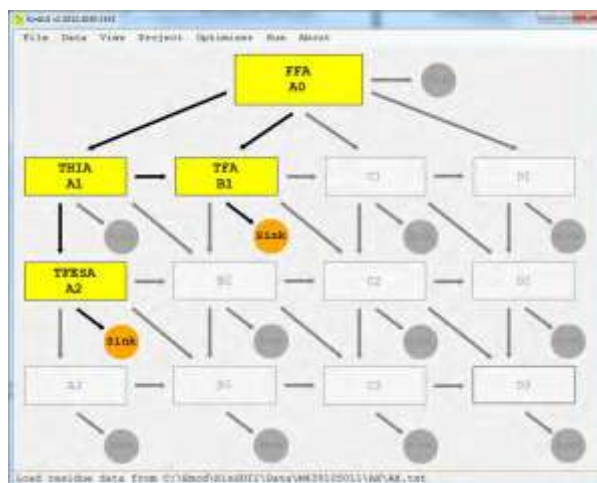

Figure B.8.1.1.2.1.1_CA-42: The conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of that evaluation is provided in the presented above summary of the **Study 2**, on pages 168 – 169.

On that basis the following multistep assessment procedure was developed. It was presented in the summary of the **Study 2** above, on page 169. RMS decided, for clarity, to repeat it below. It consisted of the following steps:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in modelling, the SFO kinetic model was tested as first option and if passed the acceptance criteria (visually acceptable, χ^2 -error not exceeding or not significantly exceeding 15%, *prob.* > *t* value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the χ^2 -error was significantly greater than 15%, model parameters were fixed and fitting repeated using SFO model;
- **Step 3:** if the **Step-2** fitting failed the χ^2 -error test, bi-phasic models were included. These were FOMC, DFOP and, possibly HS. The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved fit, SFO model was selected if visually acceptable; that was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic examination of the data and their evaluation are provided below, individually for each test soil.

- 1) The results of the kinetic analysis of the data obtained in **Hoefchen am Hohenseh 4a** Silt loam soil (study by [Hein; 2012]):

The analysis for this data-set was a single-step analysis in which the data for the parent compound and metabolites were kinetically examined together. The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-43 and in numerical form in the table B.8.1.1.2.1.1_CA-115.

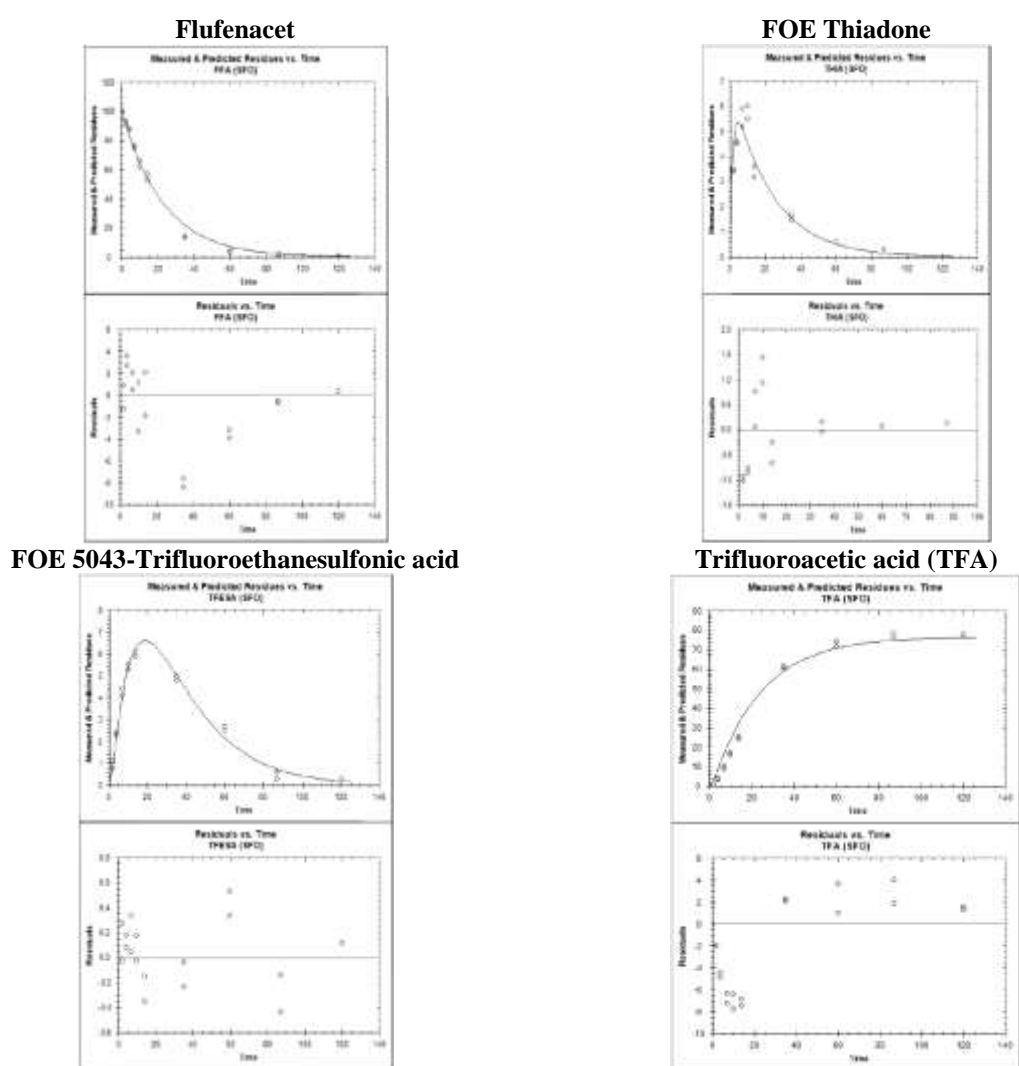

Figure B.8.1.1.2.1.1_CA-43: The graphical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Hoefchen am Hohenseh 4a soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-115: The numerical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Hoefchen am Hohenseh 4a soil.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M ₀	100.90	1.174	98.58	103.186	< 2 E-16	4.882	0.995; Good fit
		k	0.04377	1.20 E-3	0.04142	0.046	< 2 E-16		
FOE Thiadone	SFO	M ₀	0.0	----	----	----	----	16.421	0.913; Good fit
		k	0.6110	0.08962	0.4354	0.787	1.34 E-9		
		ff	0.913	0.126	----	----	----		
FOE 5043-Trifluoroethane-sulfonic acid	SFO	M ₀	0.0	----	----	----	----	5.845	0.988; Good fit
		k	0.07617	4.53 E-3	0.0673	0.085	< 2 E-16		
		ff	0.264	----	----	----	----		
Trifluoroacetic acid	SFO	M ₀	0.0	----	----	----	----	10.492	0.991; Good fit
		k	7.1 E-10	4.85 E-4	-9.51 E-4	0.001	0.500		
		ff ²⁾	0.087	0.044	----	----	----		
		ff ₂ ³⁾	0.736	----	----	----	----		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant;
- 2) ff calculated for formation from the parent compound – Flufenacet;
- 3) ff calculated for the formation from FOE Thiadone;

RMS performed own analysis of the obtained results. It led to the following conclusions:

- It was possible to obtain reliable kinetic fits and kinetic parameters for the following compounds: Flufenacet, FOE Thiadone and FOE 5043-Trifluoroethanesulfonic acid;
- In case of Trifluoroacetic acid the fit is reliable, however of the determined kinetic parameters only the kinetic formation fractions – ff, may be considered reliable. The lack of reliability of the degradation rate constant and resulting from it DT₅₀ and DT₉₀ values is due to the fact that the kinetic curve was in its formation phase and even the would-be maximum was not reached.

The final set of the kinetic parameters considered acceptable by the RMS is presented below in the table B.8.1.1.2.1.1._CA-116.

Table B.8.1.1.2.1.1._CA-116: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound			
	Flufenacet	FOE Thiadone	FOE 5043-Trifluoroethane-sulfonic acid	Trifluoroacetic acid
DT ₅₀ [days]	15.84	1.13	9.10	1000
DT ₉₀ [days]	52.61	3.77	30.23	> 1000
Kinetic formation fraction ff	Not applicable	0.913 ± 0.013	0.264	0.087 ± 0.004 0.736
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet FOE Thiadone
Kinetic model	SFO	SFO	SFO	SFO

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound DT₅₀ = 1000 days and DT₉₀ > 1000 days.

- 2) The results of the kinetic analysis of the data obtained in **Laacherhof AXXa** Loamy sand soil (study by [Hein; 2012a]):

The analysis for this data-set was a single-step analysis in which the data for the parent compound and metabolites were kinetically examined together. The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-44 and in numerical form in the table B.8.1.1.2.1.1._CA-117.

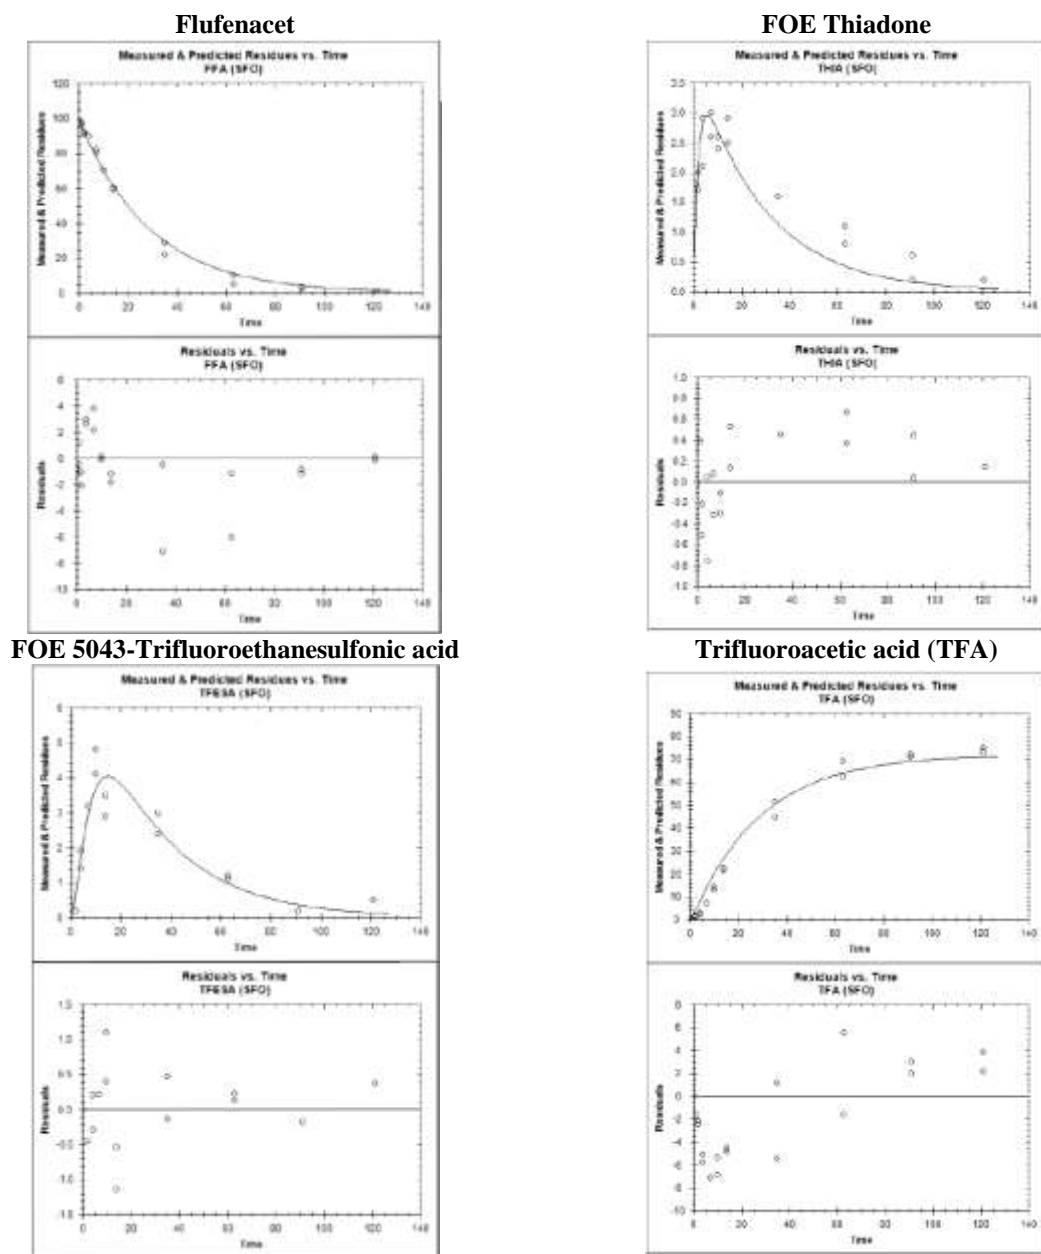

Figure B.8.1.1.2.1.1._CA-44: The graphical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof AXXa soil (copied from the study report).

		ff	0.438	0.066	----	----	----		
FOE 5043-Trifluoroethane-sulfonic acid	SFO	M ₀	0.0	----	----	----	----	35.241	0.741; Good fit
		k	0.1727	0.0441	0.08624	0.259	9.97 E-5		
		ff	0.422	----	----	----	----		
Trifluoroacetic acid	SFO	M ₀	0.0	----	----	----	----	9.451	0.991; Good fit
		k	2.33 E-9	5.95 E-4	-1.17 E-3	0.001	0.4999		
		ff ²⁾	0.562	0.113	----	----	----		
		ff ₂ ³⁾	0.578	----	----	----	----		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant;
- 2) ff calculated for formation from the parent compound – Flufenacet;
- 3) ff calculated for the formation from FOE Thiadone;

The Applicant stated that for FOE 5043-Trifluoroethanesulfonic acid the kinetic fit was not fully reliable due to the high χ^2 error. For that reason the Applicant performed an additional fitting, for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach. The results of that analysis are presented further down this point.

RMS performed own analysis of the obtained results. It led to the following conclusions:

- It was possible to obtain reliable kinetic fits and kinetic parameters for the following compounds: Flufenacet and FOE Thiadone;
- In case of Trifluoroacetic acid the fit is reliable, however of the determined kinetic parameters only the kinetic formation fractions – ff, may be considered reliable. The lack of reliability of the degradation rate constant and resulting from it DT₅₀ and DT₉₀ values is due to the fact that the kinetic curve was in its formation phase and even the would-be maximum was not reached;
- In case of FOE 5043-Trifluoroethanesulfonic acid it was not possible to obtain the reliable kinetic fit. Although the visual inspection showed that fit is acceptable high level of χ^2 error makes it statistically not reliable. As a result, also calculated kinetic endpoints – DT₅₀ and DT₉₀ values, cannot be considered reliable in spite of the fact that the calculated rate constant k is reliable according to the results of the t-test (the prob. > t is well below the level of 0.05). RMS noticed that problems with obtaining the reliable kinetic curve were most probably due to the low concentrations of the compound in this experiment. However, the distribution of the data points implied that the acceptable fit may be obtained when these are fitted alone using the top-down approach.

As the final step of the analysis of the data obtained in the experiment on Dollendorf II soil, the data for FOE 5043-Trifluoroethanesulfonic acid were fitted alone using the top-down approach. To do that the Applicant identified the time point at which the maximum concentration of the compound of concern was recorded. That point was used as a starting point in the analysis. The resulting data set used in the fitting exercise is presented below in the table B.8.1.1.2.1.1_CA-120.

Table B.8.1.1.2.1.1._CA-120: The input data for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach.

Time Point – DAT [days]	Concentration of FOE 5043-Trifluoroethanesulfonic acid expressed as [%AR]	
	Replicate 1	Replicate 2
10	3.8	3.1
14	1.7	1.8
35	1.6	1.6
63	0.5	0.6
91	0.2	0.2
121	NaN	NaN

The fitting was performed using SFO model and followed the procedure outlined above. The results of that kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-46 and in numerical form in the table B.8.1.1.2.1.1._CA-121.

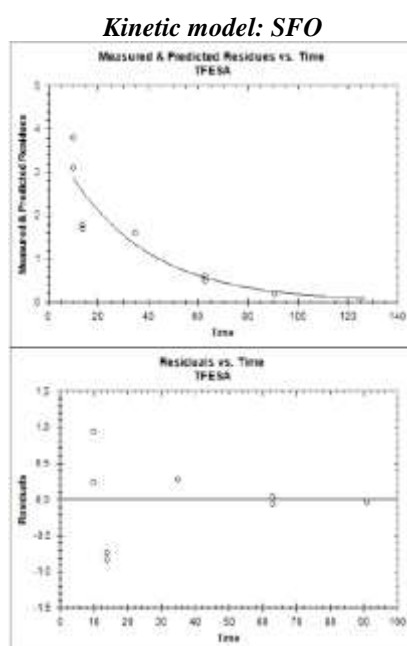

Figure B.8.1.1.2.1.1._CA-46: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-121: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	3.911	0.609	2.716	5.105	1.33 E-4	24.06	0.824; Good fit
	k	0.03084	0.00858	0.01403	0.048	0.00351		

Footnotes to the table:

1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable.

Examining the determined kinetic curve RMS noticed that one of the data points – DAT-14 was an outlier, the removal of which may improve the fit visually and statistically. That hypothesis was verified and the results of that verification are presented in the summary of the **Study 6** above, on pages 245 – 247.

Therefore RMS repeated the kinetic analysis of the data set modified by the elimination of the values for DAT-14 time point. The modelling was performed using CAKE 3.1 modelling tool, developed by Tessella, and IRLS (Iteratively Reweighted Nonlinear Least Squares) algorithm as optimisation method.

The results of the kinetic analysis performed by the RMS are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-47 and in numerical form in the table B.8.1.1.2.1.1._CA-122.

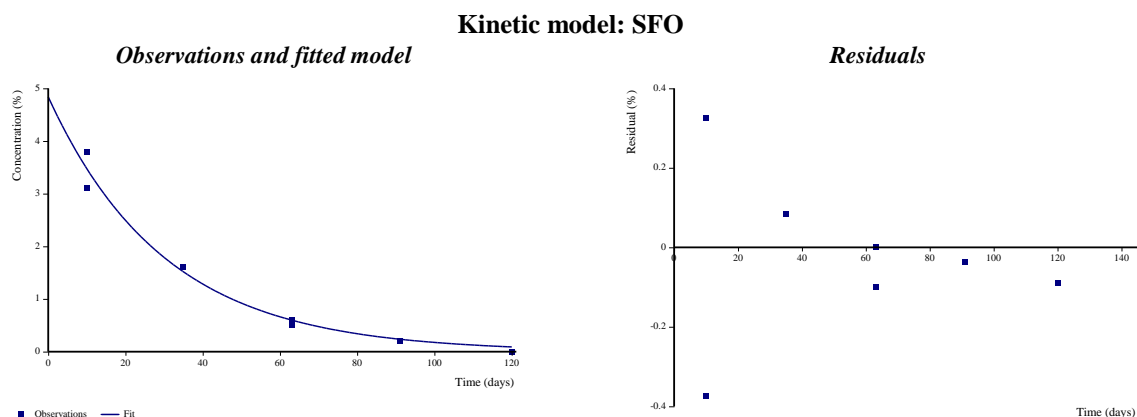

Figure B.8.1.1.2.1.1._CA-47: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-122: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO, DAT-14 removed	M_0	4.838	0.265	4.228	5.449	----	4.31	0.983; Good fit
	k	0.03315	0.00271	0.0296	0.039	9.28 E-7		

The calculated kinetic endpoints were following: **DT₅₀ = 20.9 days, DT₉₀ = 69.5 days;**

On the basis of the evaluation presented above it may be stated that for FOE 5043-Trifluoroethanesulfonic acid it was possible to obtain the reliable kinetic fit using the data set presented in the table B.8.1.1.2.1.1._CA-120, modified by the removal of the results for the DAT-14 time point identified as an outlier.

Additionally RMS checked the possibility that similar results could be obtained for the same compound fitted in the whole data set once that time point had been removed. The kinetic analysis was performed using CAKE 3.1 modelling tool, developed by Tessella, and IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm as optimisation method. No significant improvement was achieved, so RMS decided not to present the results of that kinetic analysis in order not to overburden the Renewal Assessment Report.

The final set of the trigger kinetic endpoints resulting from that experiment is presented below in the table B.8.1.1.2.1.1._CA-123.

Table B.8.1.1.2.1.1._CA-123: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound			
	Flufenacet	FOE Thiadone	FOE 5043-Trifluoroethanesulfonic acid	Trifluoroacetic acid
DT ₅₀ [days]	16.30	2.84	20.9	1000
DT ₉₀ [days]	54.18	9.45	69.5	> 1000
Kinetic formation fraction <i>ff</i>	Not applicable	0.438 ± 0.066	0.422	0.562 ± 0.113
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet
Kinetic model	SFO	SFO	SFO	SFO

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound **DT₅₀ = 1000 days and DT₉₀ > 1000 days.**

- 4) The results of the kinetic analysis of the data obtained in **Laacherhof Wurmwiese** Loam soil (study by [Hein; 2012a]):

The analysis for this data-set was a single-step analysis in which the data for the parent compound and metabolites were kinetically examined together. The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-48 and in numerical form in the table B.8.1.1.2.1.1._CA-124.

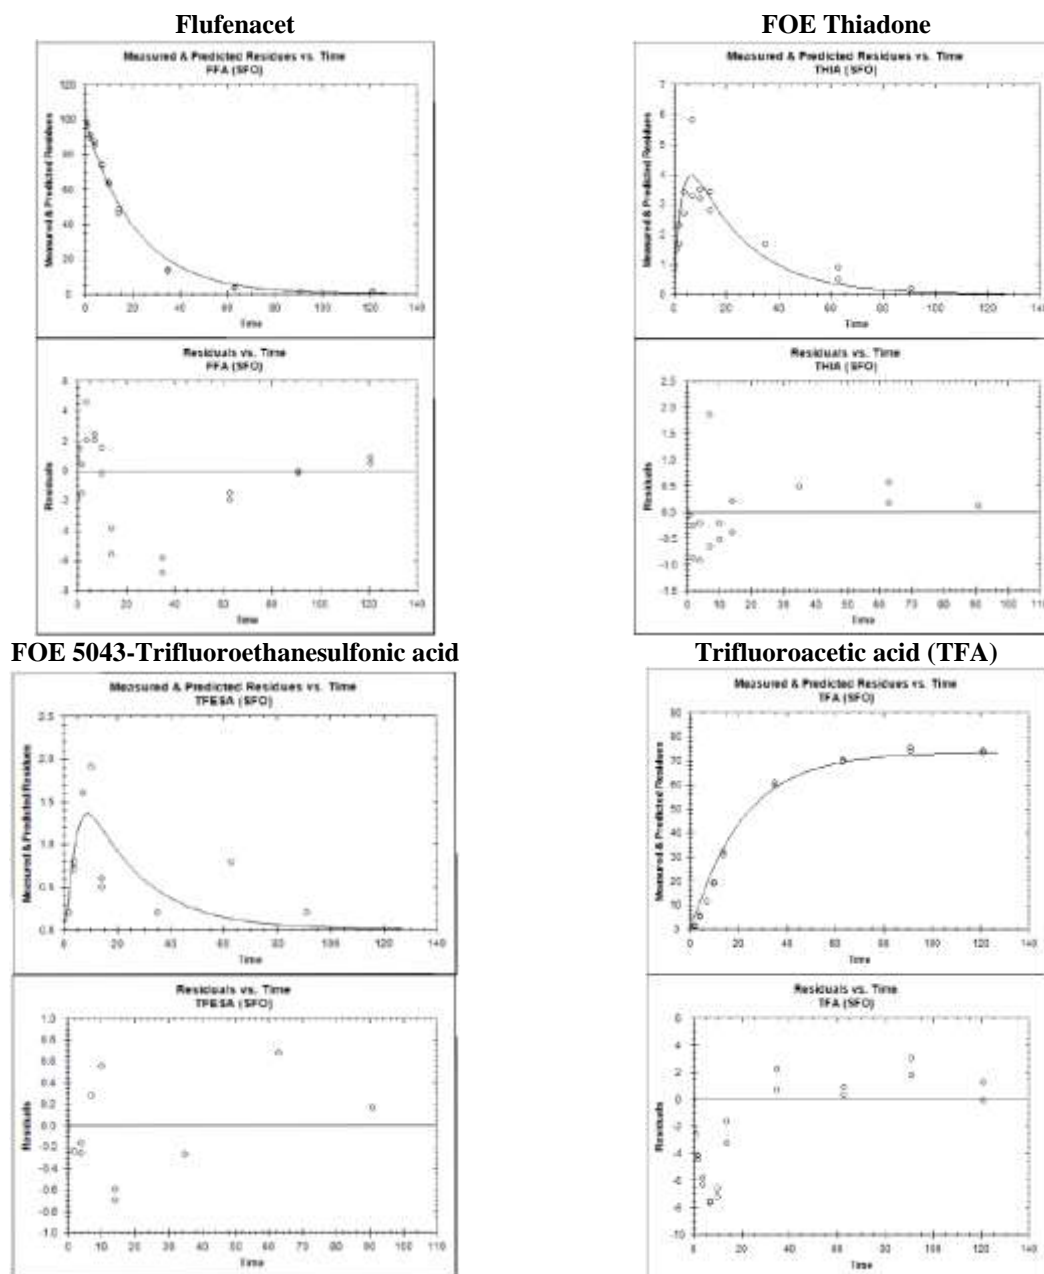

Figure B.8.1.1.2.1.1._CA-48: The graphical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof Wurmwiese soil (copied from the study report).

Table B.8.1.1.2.1.1._CA-124: The numerical results of the kinetic examination of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid obtained in Laacherhof Wurmwise soil.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M ₀	99.88	1.180	97.57	102.194	< 2 E-16	4.270	0.995; Good fit
		k	0.04648	1.67 E-3	0.04321	0.050	< 2 E-16		
FOE Thiadone	SFO	M ₀	0.0	----	----	----	----	14.730	0.850; Good fit
		k	0.3490	0.0569	0.2376	0.460	1.97 E-8		
		ff	0.405	0.056	----	----	----		
FOE 5043-Trifluoroethane-sulfonic acid	SFO	M ₀	0.0	----	----	----	----	43.983	0.640; Acceptable fit
		k	0.6478	0.1406	0.3722	0.923	8.50 E-6		
		ff	0.655	----	----	----	----		
Trifluoroacetic acid	SFO	M ₀	0.0	----	----	----	----	9.435	0.993; Good fit
		k	2.2 E-10	7.12 E-4	-1.40 E-3	0.001	0.5		
		ff ²⁾	0.596	0.149	----	----	----		
		ff ₂ ³⁾	0.345	----	----	----	----		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as reported by the Applicant;
- 2) ff calculated for formation from the parent compound – Flufenacet;
- 3) ff calculated for the formation from FOE Thiadone;

The Applicant stated, that using the data from that experiment it was not possible to obtain the reliable kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid. That was due to the fact that the visual fitting was poor and the χ^2 error high, making the whole fit unreliable. RMS conforms the correctness of that conclusion. As a result the Applicant performed an additional fitting for FOE 5043-Trifluoroethanesulfonic acid fitted alone, using the top-down approach.

RMS performed own analysis of the obtained results. It led to the following conclusions:

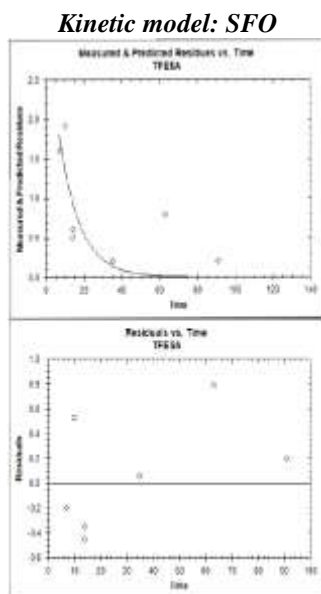

- It was possible to obtain reliable kinetic fits and kinetic parameters for the following compounds: Flufenacet and FOE Thiadone;
- In case of Trifluoroacetic acid the fit is reliable, however of the determined kinetic parameters only the kinetic formation fractions – ff, may be considered reliable. The lack of reliability of the degradation rate constant and resulting from it DT₅₀ and DT₉₀ values is due to the fact that the kinetic curve was in its formation phase and even the would-be maximum was not reached;
- In case of FOE 5043-Trifluoroethanesulfonic acid it was not possible to obtain the reliable kinetic fit. RMS conforms the Applicant's statement in that area noticing that not only the fit was statistically not acceptable due to the high level of χ^2 error, but also visually – the plotted kinetic curve poorly reproduced the distribution of the experimental points. RMS noticed also that within the decline phase a second local maximum occurred on DAT 63. It is possible that that time point was an outlier.

RMS did additional kinetic fitting using the modified data set for FOE 5043-Trifluoroethanesulfonic acid to verify the hypothesis presented above. However, even with that modified data set it was not possible to obtain the reliable kinetic fit for that compound, most probably because of the very low concentrations of the compound of concern. RMS decided not to present the results of that fitting in order not to overburden the Report.

The results of the kinetic examination of the data for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach, performed by the Applicant, are presented below in graphical form on figure B.8.1.1.2.1.1._CA-49 and in numerical form in the table B.8.1.1.2.1.1._CA-126. They are preceded by the table B.8.1.1.2.1.1._CA-125, containing the data set used in the fitting exercise. The fitting was performed using one kinetic model – SFO, and followed the procedure outlined above.

Table B.8.1.1.2.1.1._CA-125: The input data for FOE 5043-Trifluoroethanesulfonic acid fitted alone using the top-down approach.

Time Point – DAT [days]	Concentration of FOE 5043-Trifluoroethanesulfonic acid expressed as [%AR]	
	Replicate 1	Replicate 2
10	1.9	1.9
14	0.5	0.6
35	0.2	0.2
63	0.8	NaN
91	0.2	NaN
121	NaN	NaN

**Figure B.8.1.1.2.1.1._CA-49:** The graphical results of the kinetic analysis (copied from the study report).**Table B.8.1.1.2.1.1._CA-126:** The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter				Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error
				Lower	Upper		
SFO	M ₀	3.407	1.439	0.588	6.227	0.0227	39.76
	k	0.09120	0.0460	9.46 E-3	0.181	0.0415	
							R ² and visual assessment ¹⁾
							0.701; Acceptable fit

Footnotes to the table:

1) Visual assessment of the kinetic curve as reported by the Applicant.

The Applicant stated that the fit was of a sufficient quality to determine the reliable kinetic endpoints to be used as input to derive the modelling endpoints. That statement however stands in clear contrast to the conclusion made in the previous study – for the experiment on that soil it was not possible to determine the reliable kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid. RMS is also of the opinion that the quality of the fit is not sufficient to derive reliable kinetic endpoints that could be subsequently used to calculate the average values used in modelling.

However, analysing the data set for FOE 5043-Trifluoroethanesulfonic acid RMS stated that the problem was related to the occurrence of the second maximum observed on DAT 63. There are several indicators for that time point being an outlier:

- measurable concentration was determined at that time point only for one replicate,
- for both preceding and following time point in both replicates the compound was not detected and the proposed measurable values are resulting from the processing of the data set according to the principles set by FOCUS,
- for the last time point with measurable concentrations of FOE 5043-Trifluoroethanesulfonic acid – DAT 14, these were lower than the measured DAT-63 concentration.

RMS thinks that all that indicate that the DAT-63 concentration of FOE 5043-Trifluoroethanesulfonic acid of 0.8% is in fact an analytical artefact that should be removed from the data set during the data-processing. Therefore RMS decided to repeat the fitting, removing that value and all subsequent data points. In order to have the minimal required amount of data points – four, RMS decided to use the DAT-63 time point as the last time point with the concentrations of the compound of concern set to zero. The resulting modified data set used in that fitting is presented below in the table B.8.1.1.2.1.1._CA-127.

Table B.8.1.1.2.1.1._CA-127: The modified input data for FOE 5043-Trifluoroethanesulfonic acid used in the repeated kinetic analysis performed by the RMS using the top-down approach.

Time Point – DAT [days]	Concentration of FOE 5043-Trifluoroethanesulfonic acid expressed as [%AR]	
	Replicate 1	Replicate 2
10	1.9	1.9
14	0.5	0.6
35	0.2	0.2
63	0.0	0.0

The kinetic analysis was performed using CAKE 3.1, developed by Tessella, as a modelling tool. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. Because of the limited number of the data points – only four were available, solely the SFO model was tested.

The results of the kinetic analysis performed by the RMS are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-50 and in numerical form in the table B.8.1.1.2.1.1._CA-128.

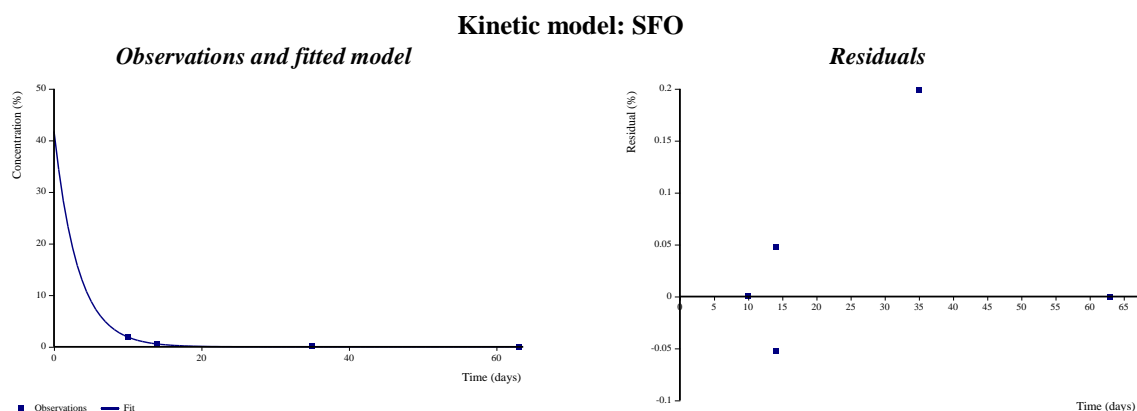

Figure B.8.1.1.2.1.1._CA-50: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-128: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	41.75	17.11	-0.1286	83.62	----	12.3	0.988; Good fit
	k	0.309	0.03954	0.2122	0.406	1.16 E-4		

The calculated kinetic endpoints were following: $DT_{50} = 2.24$ days, $DT_{90} = 7.45$ days;

The obtained results of the fitting indicate that with the elimination of the measurable value for DAT-63 time point it was possible to obtain visually good and statistically reliable fit using the SFO kinetic model. It shall be noted that the kinetic curve bears a considerable level of uncertainty with regard to the estimated M_0 value, but on the other hand that value is close to the determined kinetic formation fraction ff . That taken into account, it may be stated that the kinetic curve may be considered as a good estimation of the kinetic behaviour of FOE 5043-Trifluoroethanesulfonic acid in the test soil, therefore the fit and derived from it kinetic parameters may be considered reliable.

The final set of the kinetic parameters resulting from that experiment and considered acceptable by the RMS is presented below in the table B.8.1.1.2.1.1._CA-129.

Table B.8.1.1.2.1.1._CA-129: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound			
	Flufenacet	FOE Thiadone	FOE 5043-Trifluoroethane-sulfonic acid	Trifluoroacetic acid
DT ₅₀ [days]	14.91	1.99	2.24	1000
DT ₉₀ [days]	49.54	6.60	7.45	> 1000
Kinetic formation fraction <i>ff</i>	Not applicable	0.404 ± 0.056	0.655	0.596 ± 0.149
Precursor	Not applicable	Flufenacet	FOE Thiadone	Flufenacet
Kinetic model	SFO	SFO	SFO	SFO

As the decline phase was not reached for Trifluoroacetic acid, RMS proposed as estimated kinetic endpoints for that compound DT₅₀ = 1000 days and DT₉₀ > 1000 days.

Final conclusion of the study:

On the basis of the results of the kinetic evaluation presented above it was possible to derive the definitive sets of the kinetic endpoints for each evaluated compounds. These are presented below in the table B.8.1.1.2.1.1._CA-130. It shall be noted that they are identical to the results obtained in previously summarised **Study 8**. It shall be also indicated that these values are not-normalised values, requiring normalisation before being used to calculate the averaged kinetic endpoint to be used in GW and SW modelling. That will be done separately further down the Report.

Table B.8.1.1.2.1.1._CA-130: The final set of reliable kinetic endpoints determined in the study.

Study	Test soil	Compound	Determined parameter

Footnotes to the table:

- 1) The reliable value was not determined – the estimate provided by the model cannot be considered such;
- 2) For formation from parent compound – Flufenacet;
- 3) For formation from FOE Thiadone.

Study 8:

Report: Reinken G., Partsch S., (2014): „Kinetic Evaluation of the Degradation of [thiadiazole-2-¹⁴C] flufenacet and its Degradation Product under Aerobic Soil Conditions in Laboratory According to FOCUS Kinetics using the KinGUI 2 Tool. Flufenacet (FOE 5043); FOE-thiadone.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished Study Report No. EnSa-12-0576; 2014. 02.17; study reference number: M-477885-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above.

It was stated that the study generally compiled with the two evoked Guidance Documents. It was also noted that it was aimed on the derivation of the kinetic endpoints to be used in modelling. For that reason the best fit was not identified and SFO model was generally indicated as returning acceptable fit for parent compound – Flufenacet. For that reason when the data for parent and metabolites were kinetically examined only the combination SFO-SFO was tested.

Summary:

The aim of the study was to kinetically examine the data obtained in the experiments in which [Thiadiazole-2-¹⁴C] Flufenacet was used. That was done in order to derive the kinetic parameters suitable for modelling and environmental risk assessment.

The data were taken from the study by [Pangilinan and Smith; 1994a] – a route-of-degradation study, summarised as **Study 4** under the point B.8.1.1.1.1. The characteristic of the test soil used in the experiment with [Thiadiazole-2-¹⁴C] Flufenacet is provided below in the table B.8.1.1.2.1.1._CA-131. To maintain the consistency of reporting, only physicochemical properties are reported. The data on soil microbial activity were not given here. To check them please refer to adequate summaries of the source studies.

Table B.8.1.1.21.1._CA-131: The characteristic of soil used in the study.

Parameter		Soil:			
		395			
Soil origin		Howe, Indiana, USA			
Batch analysed		A ¹⁾	B ²⁾	C ³⁾	Average
Soil type (USDA)		Sandy loam	Sandy loam	Sandy loam	Sandy loam
Particle size distribution	Sand [%]	72.5	77.5	70.4	73.5
	Silt [%]	20.0	17.2	20.0	19.1

Footnotes to the table:

1) DAT stands for “Days After Treatment”;

The data presented above were subjected to a multistep evaluation procedure performed in line with the recommendations of FOCUS Kinetics Guideline [FOCUS; 2006]. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st – order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool. That step consisted of the two sub-steps:
 - **Sub-step 1:** kinetic evaluation of the data for parent compound (Flufenacet) only, in order to determine the appropriate kinetic model. At that stage of analysis all three kinetic models listed above were tested;
 - **Sub-step 2:** kinetic evaluation of the data for parent compound (Flufenacet) and its degradation products using for Flufenacet the kinetic model identified at previous stage as appropriate, and SFO model for degradation products;
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The raw input data, presented in the table B.8.1.1.2.1.1._CA-133, were processed following the recommendations given by FOCUS. In general terms that looked as follows:

- Measured and reported true replicates were taken into account singularly;
- The data sets were checked for their consistency and clear outliers. In case the outliers were found and removed, that was clearly indicated.
- All data after the time point DAT 32 were removed. That was due to the fact that the collapse of soil microbial activity was observed after that time point. RMS stated that the measure taken by the Applicant was in line with the provisions of FOCUS Kinetics Guidance Document, [FOCUS; 2006].

The particular measures taken in the processing of the data for the parent compound – Flufenacet, were following:

- The total AR recovery recorded in DAT-0 sample – 102.7% AR, was used as concentration of Flufenacet at that time point, but the M_0 value was allowed to be estimated by the model;
- Values between LOD and LOQ were set to measured values;

- All single values <LOD or the non-detects (n. d.) were set to $\frac{1}{2}$ LOD. The same procedure was applied to the first appearances. However, when the values <LOD/n.d. appeared consecutively for second and next times, the kinetic curve was cut off until the appearance of the first value >LOQ.

The values for degradation product – FOE Thiadone, were processed in a following way:

- The initial, DAT-0, concentration was set to 0. That value, unlike the free-fitted M_0 concentration for the parent compound, was a fixed value;
- The values for subsequent time points, if reported as <LOD or non-detects, were also set to 0 until the last time point before the first detectable amount was recorded;
- The value reported as <LOD/n.d. appearing just before the first detectable amount was recorded was set to $\frac{1}{2}$ LOD.
- Values between LOD and LOQ were set to measured values;
- In the decline phase the first values <LOD/n.d. were also set $\frac{1}{2}$ LOD. For the consecutive second and next such appearances the kinetic curve was cut off until, eventually, the first value >LOQ appeared.

RMS noted that the presented above procedure of data-processing is a general procedure used by the Applicant for all experiments that underwent kinetic examination of the data.

In this particular case however, as there were no values below LOQ or LOD, as well as the “non-detects” were not reported, these elements were not performed as a part of data-processing.

The processed values used as input data for the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-134.

Table B.8.1.1.2.1.1._CA-134: The processed residue data for **Howe, Indiana**, Sandy loam soil (study [Pangilinan and Smith; 1994]).

Time Point – DAT ¹⁾ [days]	Concentration, expressed as [% AR], of:	
	<i>Flufenacet</i>	<i>FOE Thiadone</i>
0	102.7	0.0
7	87.7	3.9
14	81.6	2.6
32	69.7	1.4

Footnotes to the table:

1) DAT stands for “Days After Treatment”;

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure was two-stage one. The first step, further called **Step 1**, consisted on the determination of the appropriate kinetic model for the parent compound – Flufenacet. At that stage three 1st-order kinetic models were tested: SFO, FOMC and DFOP. During the next stage, further called **Step 2**, the whole data set – data for the Flufenacet and its degradation products, was kinetically examined. In case of Flufenacet the tested kinetic model was that determined as appropriate at **Step 1**, while for the degradation products the SFO model was used.

The conceptual metabolic pathway built in the modelling tool was based on the transformation pathway which, in form of simplified scheme, is presented below on figure B.8.1.1.2.1.1._CA-51.

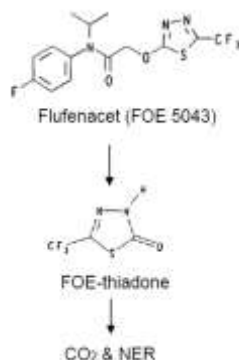

Figure B.8.1.1.2.1.1._CA-51: The simplified transformation pathway used to create conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of the evaluation procedure was presented in the summary of the **Study 2** on pages 168 – 169. RMS decided not to repeat it here in order to not overburden the Renewal Assessment Report.

On that basis the following multistep assessment procedure was followed:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in modelling, the SFO kinetic model was tested as first option and if passed the acceptance criteria (visually acceptable, χ^2 -error not exceeding or not significantly exceeding 15%, *prob.* > *t* value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the χ^2 -error was significantly greater than 15%, model parameters were fixed and fitting repeated using SFO model;
- **Step 3:** if the **Step-2** fitting failed the χ^2 -error test, bi-phasic models were included. These were FOMC, DFOP and, possibly, HS. The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved fit, SFO model was selected if visually acceptable; that was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006]. RMS also noticed that the data set used in kinetic analysis consisted of four experimental points only. Therefore, although the Applicant performed the kinetic analysis using two bi-phasic fits – FOMC and DFOP, but in RMS's opinion the data set consisting of only four data points may be too small to obtain reliable kinetic parameters for bi-phasic kinetic models, even if the results of the fitting (visual fit and its statistical evaluation as well as statistically determined reliability of the estimated parameters) are good.

The analysis for the data-set was a two-step analysis. At **Step 1** the appropriate kinetic model for the parent – Flufenacet, was identified. At **Step 2** the data for the degradation product – FOE Thiadone were added and the kinetic analysis repeated using the identified appropriate kinetic model for Flufenacet and SFO model for the degradation product. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-52 and in numerical form in the table B.8.1.1.2.1.1._CA-135. Additionally the table B.8.1.1.2.1.1._CA-136 provides the kinetic endpoints obtained with each of the kinetic models tested.

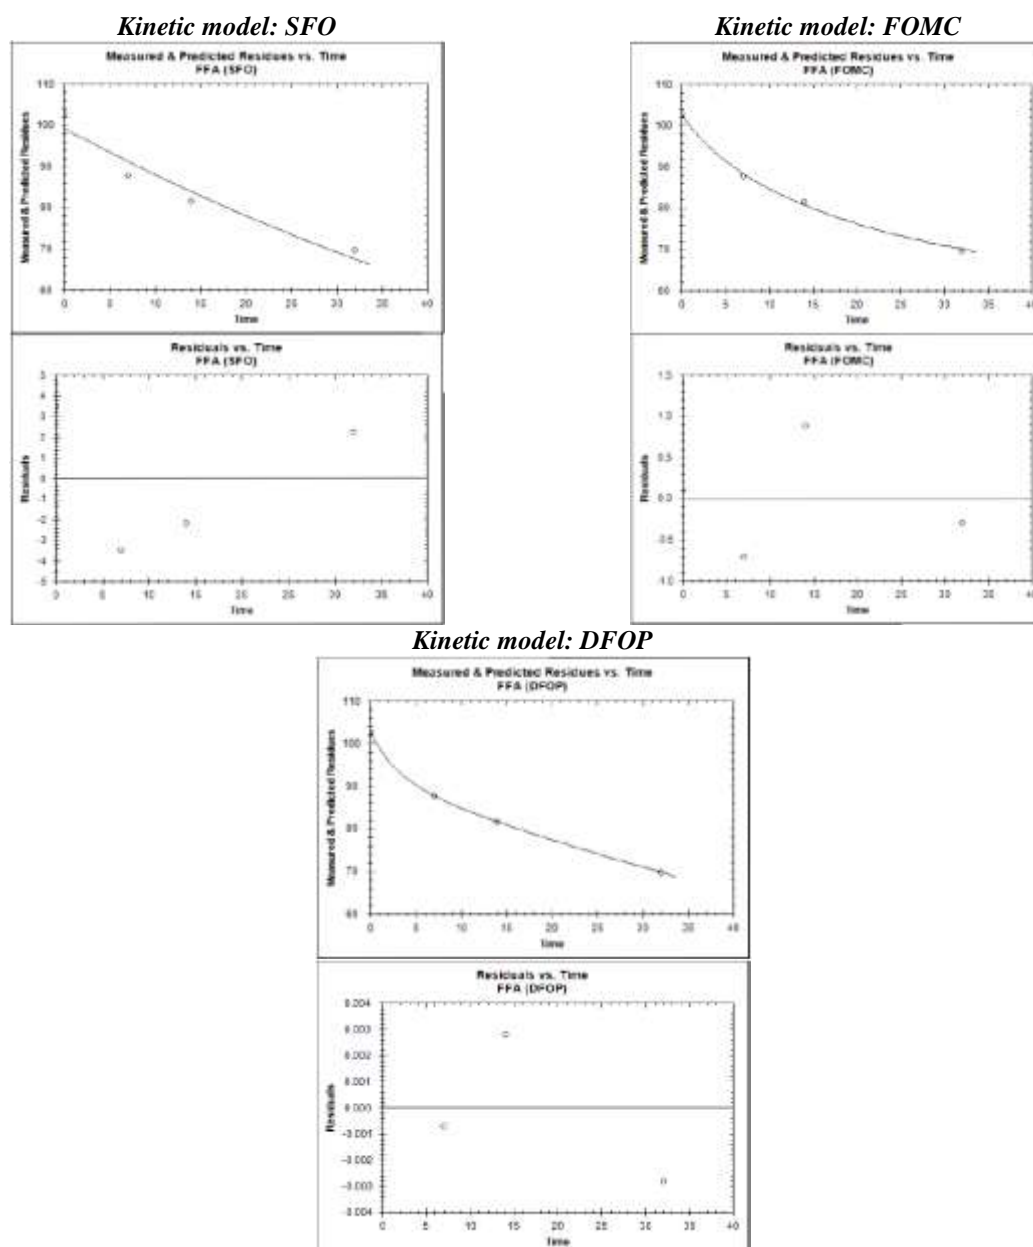

Figure B.8.1.1.2.1.1_CA-52: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1_CA-135: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	99.169	3.316	92.669	105.668	5.58 E-4	2.796	0.94; Acceptable fit
	k	0.0120	0.00229	0.00755	0.0170	0.0171		
FOMC	M_0	102.590	1.151	100.333	104.846	0.00357	0.703	1.00; Good fit
	α	0.2391	0.05425	0.1328	0.345	0.0710		
	β	8.1089	3.3796	1.4850	14.733	0.1257		
DFOP	M_0	102.70	∞	$-\infty$	$+\infty$	Not determined	∞	1.00; Good fit
	k_1	0.3223	∞	$-\infty$	$+\infty$	Not determined		
	k_2	0.008673	∞	$-\infty$	$+\infty$	Not determined		
	g	0.1042	∞	$-\infty$	$+\infty$	Not determined		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1_CA-136: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>Flufenacet</i>	DT ₅₀ [days]	57.63	139.05	67.231
	DT ₉₀ [days]	191.42	123215	252.79

The Applicant stated that the fit returned by the SFO model was visually and statistically acceptable, therefore it was selected as appropriate and used at the next step to kinetically examine the data for Flufenacet and its degradation products. RMS accepted that choice. It shall be noted that although FOMC returned the fit visually and statistically superior to that obtained with SFO and for which estimated parameters were reliable, it cannot be taken into account as the concentration recorded at the last time point was significantly higher than 10%. Also DFOP returned the fit that was visually better than that obtained with SFO. It was however statistically not reliable.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-53 and in numerical form in the table B.8.1.1.2.1.1_CA-137.

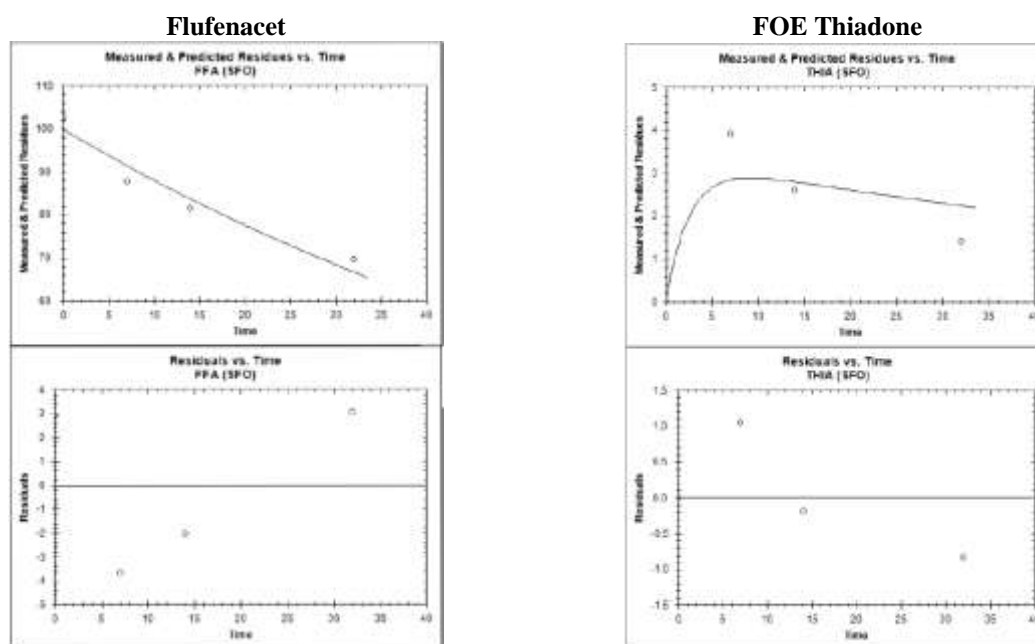

Figure B.8.1.1.2.1.1_CA-53: The graphical results of the kinetic examination of the data for Flufenacet and FOE Thiadone (copied from the study report).

Table B.8.1.1.2.1.1._CA-137: The numerical results of the kinetic examination of the data for Flufenacet and FOE Thiadone.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M ₀	99.789	3.327	93.269	106.309	3.68 E-5	2.841	0.94; fit acceptable
		k	0.0126	0.00229	0.00813	0.0170	0.00264		
FOE Thiadone	SFO	M ₀	0.0	----	----	----	----	26.352	0.78; poor fit
		k	0.3885	0.2769	-0.1542	0.931	0.1166		
		ff	1.00	----	----	----	----		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Applicant stated that reliable kinetic endpoints from that kinetic fitting could be derived only for the parent compound – Flufenacet. The fit for FOE Thiadone was visually poor and statistically unreliable, therefore it was not possible to derive kinetic endpoints or even the kinetic formation fraction *ff*.

The reliable kinetic endpoints determined for Flufenacet were following: **DT₅₀ = 54.96 days** and **DT₉₀ = 182.56 days**.

RMS noticed however that the distribution of the data points for FOE Thiadone at would-be decline phase suggested that it was possible to obtain the acceptable fitting results in that experiment for that compound fitted alone using the top-down approach.

Such analysis was performed by the RMS using CAKE 3.1 modelling tool. IRLS (Iteratively Reweighed Nonlinear Least Squares) was used as optimisation algorithm. Due to very limited amount of the experimental points – only three were available, SFO model was solely tested. The data set used in that fitting is presented below in the table B.8.1.1.2.1.1._CA-138.

Table B.8.1.1.2.1.1._CA-138: The input data for FOE Thiadone used in the repeated kinetic analysis performed by the RMS.

Time Point – DAT [days]	Concentration of FOE Thiadone, expressed as [%AR]
7	3.9
14	2.6
32	1.4

The results are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-54 and in numerical form in the table B.8.1.1.2.1.1._CA-139.

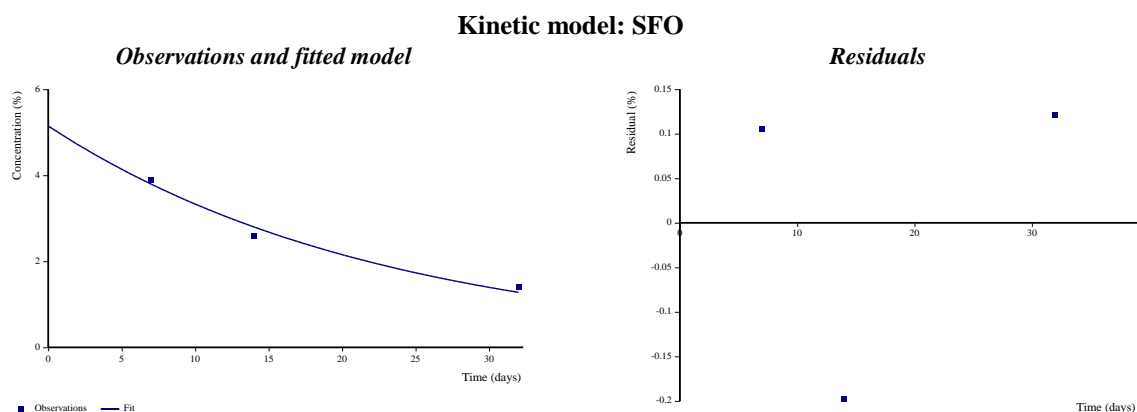

**Figure B.8.1.1.2.1.1._CA-54:** The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-139: The numerical results of the kinetic examination of the data for FOE Thiadone using the top-down approach.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
FOE Thiadone	SFO	M ₀	5.146	0.526	-1.540	11.830	----	4.95	0.980; good fit
		k	0.04352	0.00798	-0.05794	0.1450	0.05776		

The kinetic re-examination of the data showed that it was possible to obtain the reliable fit for FOE Thiadone fitted alone using the top-down approach.

The calculated rate constant did not pass the t-test – the *prob. > t* was slightly above the threshold value of 0.05, but that may be related to the limited data base. Therefore the obtained kinetic endpoints presented below should be considered with care.

The model returned following kinetic endpoints: **DT₅₀ = 15.9 days** and **DT₉₀ = 52.9 days**. RMS noticed that these values were much higher than those determined for the same compound in **Study 7**. They were also higher than the kinetic endpoints obtained for FOE Thiadone in another study, summarised below as **Study 18**, in which FOE Thiadone was applied as a parent compound.

The final set of the kinetic parameters considered acceptable by the RMS is presented below in the table B.8.1.1.2.1.1._CA-140. It shall be also indicated that these values are not-normalised values, requiring normalisation before being used to calculate the averaged kinetic endpoint to be used in GW and SW modelling. That will be done separately further down the Report.

Finally, it shall be also pointed out that because at **Step 2** of the kinetic analysis it was not possible to obtain the robust kinetic fit for FOE Thiadone, RMS decided not to use the proposed by the Applicant default value of the kinetic formation fraction – *ff* = 1 as reliable endpoint in further assessment. Also, because of the lack of reliability of the fit for FOE Thiadone at Step 2, it was not justifiable to use in the further assessment the results of the fitting for Flufenacet obtained at that step. Therefore RMS decided to consider reliable for the further assessment the results for Flufenacet obtained at **Step 1**.

Table B.8.1.1.2.1.1._CA-140: The reliable set of the kinetic parameters determined in the experiment

Determined parameter	Compound	
	Flufenacet	FOE Thiadone
DT ₅₀ [days]	57.63	15.9
DT ₉₀ [days]	191.42	52.9
Kinetic formation fraction <i>ff</i>	Not applicable	Not determined
Precursor	Not applicable	-----
Kinetic model	SFO	SFO – top-down approach

Next fourteen studies, summarised below, are examining the rate of degradation of four degradation products of Flufenacet – FOE Sulfonic acid, FOE Methylsulfone, FOE Thiadone and Trifluoroacetic acid, for which it was either not possible to obtain reliable kinetic endpoints examining the data coming from the route studies, or the obtained results were not sufficient to calculate the reliable kinetic endpoints to be used in modelling. Applicant submitted flowing studies:

- for FOE Sulfonic acid seven studies were submitted, of which three were “old studies” and three new/newly submitted ones; two of them were found by the RMS to be not relevant for the current evaluation;
- for FOE Methylsulfone three studies were submitted, all identified as new/newly submitted studies;
- for FOE Thiadone two studies were submitted, both new/newly submitted studies;
- for Trifluoroacetic acid two studies, both new/newly submitted studies, were submitted.

Study 9:

Report: Hellpointner E., (1996): “Degradation of [Phenyl-UL-¹⁴C]FOE 5043-Sulfonic Acid in Three Soils.”; Bayer AG, Crop Protection Business Group, Crop-Protection Development, Agrochemicals Division, Development, Institute for Metabolism Research and Residue Analysis, D51368 Leverkusen; Germany for Bayer Corporation, Agriculture Division, P. O. Box 4913, Hawthorne Road, Kansas City, MO 64120-0013, USA; unpublished Report No. PF 4110 (Bayer Report Number 107515); 8 January 1996; ; study reference number: M-004098-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guidelines for the Official Testing of Plant Protectants, Part IV, 4-1 (1986);
- SETAC-Europe Procedures for Assessing the Environmental Fate and Ecotoxicology of Pesticides (*ed.* Mark Lynch), March 1995;
- US. EPA Guideline 162-1 Aerobic Soil Metabolism (supplemental);

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by its inclusion into the Annex I of the Directive 91/414/EEC. Its summary can be found under the point B.7.1.2.1.1.2.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. The study was evaluated for its compliance with OECD Guideline 307 – Aerobic and Anaerobic Transformation in Soil. RMS stated that the study complied with the provisions of the reference Guideline, therefore it can be considered acceptable for the present assessment. It is summarised below.

Summary:

The aim of the study was to examine the degradation of FOE 5043-Sulfonic acid (FOE Sulfonic acid) – the major degradation product of Flufenacet, in soil under aerobic conditions in order to determine its rate of degradation. The experiment was performed on three European (German) soils. Their characteristic is given below in the table B.8.1.1.2.1.1._CA-141. In the study report it was stated that the test soils had been used in several other studies and met the requirements of the registration authorities; the statement provided most probably as a justification of their selection.

The test soils BBA 2.1 and BBA 2.2 were stored prior to the experiment in a wooden boxes, havingh the dimensions of 70 cm x 80 cm x 40 cm (length/width/depth) and wodden bottom plate permeable for water, outdoors during vegetation period and in a greenhouse at T = 16⁰C in winter. Each box was filled with approx. 35-cm layer of soil. Grass was used as crop cover. Third test soil – Laacherhof, was freshly sampled from the nearby field.

Table B.8.1.1.2.1.1._CA-141: The characteristic of soils used in the study.

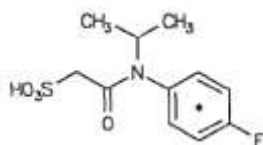

Parameter			Soil		
Soil origin			<i>BBA 2.1</i>	<i>BBA 2.2</i>	<i>Laacherhof</i>
Soil type (in the DAR)			Germany; EU	Germany; EU	Germany; EU
Soil type (USDA; reported in the study)			Sand	Loamy sand	Silt Loam
Particle size distribution	Sand [%]		89.4	80.5	36.9
	Silt [%]		10.5	12.3	51.1
	Clay [%]		0.1	7.2	12.0
pH value in H ₂ O			5.9	Not determined	8.1
pH value in CaCl ₂			5.3	6.3	7.3
Organic carbon content (C _{org}) [%]			0.57	2.48	0.9
Cation Exchange Capacity – CEC [mEq/100g]			5	10	8
Soil moisture at 40% MWHC [g H ₂ O/100 g soil d. w.]			9.0	17.9	14.0
Soil moisture at 75% of ½ bar [g H ₂ O/100 g soil d. w.]			9.2	16.1	15.5
Soil density [mg/cm ³]			2.59	2.45	2.40
Soil biomass expressed in mg microbial C/kg soil ¹⁾	Control (no test compound)	DAT 0	111	390	780
		DAT 100	n. m. ⁴⁾	115	188
	Treated with test compound ³⁾	DAT 0	90	381	812
		DAT 100	n. m. ⁴⁾	138	145
Soil biomass expressed as %OC ²⁾	Control (no test compound)	DAT 0	1.95	1.57	3.25
		DAT 100	----	0.46	0.49
	Treated with test compound ³⁾	DAT 0	1.58	1.56	3.38
		DAT 100	----	0.56	0.60

Footnotes to the table:

- 1) The soil microbial biomass was determined in soil samples using Anderson and Domsch method;
- 2) Values calculated by the RMS using the OC content reported in the study report for each test soil;
- 3) Samples were treated with 375-μL aliquots of application solution containing solely non-radiolabelled test compound; the amount of the test substance introduced was 40 μg/sample;
- 4) Not measurable, Applicant stated that most probably due to the extreme dryness of soil.

The test soils were gently air-dried about 1 week before the experiment began, sieved through 2-mm sieve and analysed for their moisture content. Then 100-g aliquots of each test soil were weighed into 300-mL Erlenmeyer flasks and adjusted to soil moisture level of 75% of ½ bar, roughly corresponding to about 40% MWHC, with the appropriate amount of demineralised water. So prepared test vessels were once again weighed, closed with cotton-wool plug and pre-incubated for 7 days in the dark at T = 20°C. The number of so prepared test vessels was such to obtain for each test soil duplicate samples per each sampling point and samples for determination of soil biomass (further called **Control samples**) at the beginning and the end of the incubation period (lasting 100 days).

The test substance used in the experiment was the ¹⁴C-FOE Sulfonic acid, in form of ammonium (NH₄⁺) salt, radiolabelled uniformly in phenyl ring, as shown below on figure B.8.1.1.2.1.1._CA-55 (RMS noticed that the structure presented on in the study report was that for acid, not its ammonium salt).

**Figure B.8.1.1.2.1.1._CA-55:** The structural formula of the radiolabelled FOE Sulfonic acid used in the experiment (copied from the study report).

The specific activity of the test compound was 2.846 MBq/mg, corresponding to 22.4 mCi/mmol and its radiochemical purity, determined by TLC, was 99.3%.

Also the non-radiolabelled test compound was used, having chemical purity of 93.6% (with 5.79% of water).

The whole delivered amount of radiolabelled test compound was dissolved in 10 mL of the H₂O/CH₃CN 9:1 (v/v) to obtain the stock solution. The concentration of the test compound in that solution, determined by LCS in three 50-μL aliquots, was 92.48 kBq/mL, corresponding to ~0.032 mg/mL. That solution will be further called **Stock solution 1**.

Also the stock solution of the non-radiolabelled test compound was prepared, having the nominal concentration of 1.8 mg/mL. That was done by dissolving 19.23 mg of the technical non-radiolabelled test compound (corresponding to 18.0 mg of the pure compound, assuming the purity of the test compound 93.6%) in 100 mL of the H₂O/CH₃CN 9:1 (v/v). That solution will be further called **Stock solution 2**.

Next the total amount of the **Stock solution 1** was mixed with 10 mL of the **Stock solution 2** to obtain the **Application solution**. The total volume of the **Application solution** was 19.85 mL, and its concentration was 40 µg of FOE Sulfonic acid/375 µL. The specific radioactivity of the test compound in the **Application solution** was 0.4297 kBq/ µg and solution's radiochemical purity – 97.2% when determined by HPLC and 95.4% when determined by TLC.

The characterised above **Application solution** was used to treat test soils in each test vessel. The assumed application dose was 40 µg test compound/100 g of the test soil (d. w.), corresponding to the application rate of 300 g test compound/ha, assuming soil density of 1.5 g/cm³ and the depth of soil layer of 5 cm (standard assumptions). The application rate was calculated assuming the maximum recommended application rate for Flufenacet of 750 g/ha and 40%-conversion of that compound to FOE Sulfonic acid. To obtain the target application dose, to each test vessel 375-µL aliquots of the **Application solution** were introduced by pipetting it in small droplets onto the soil surface. The exact application dose was subsequently verified. It was determined to be 36.8 µg FOE Sulfonic acid/100 g of the test soil (d. w.).

After application the test vessels were closed with tower traps for volatile compounds. The so obtained incubation vessels looked as presented below on the figure B.8.1.1.2.1.1._CA-56.

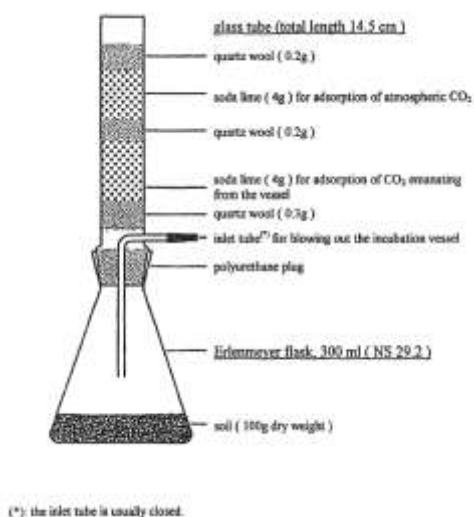

Figure B.8.1.1.2.1.1._CA-56: The example incubation vessel used in the experiment (scheme copied from the study report).

So prepared incubation vessels were placed in the dark, in a temperature-controlled incubation chamber and incubated at $T = 20 \pm 2^{\circ}\text{C}$ for up to 100 days. The temperature in the incubation chamber was recorded continuously with circular charts changed on every 7th day. Treated samples were removed for the analysis at DAT (Days After Treatment) 0, 0.08 (after 2 hours), 3, 7, 14, 30, 63, 80 and 100.

At these time points also soil moisture was adjusted. That was done in all samples not taken to the analysis in a following way: all test vessels were ventilated for 10 minutes with air, introduced for the first 5 minutes at rate 1 mL/s. and then at rate 10 mL/s., to transfer all volatile compounds present in the headspace above the soil surface to the traps for volatile compounds. Then they were dissected the Erlenmayer flasks containing test soil samples weighed to determine the loss of water and replenishing it adequately. Then the tower traps were set and the incubation vessels returned to the incubation chamber.

For each test soil the **Control samples** were set. They were prepared in two variants – as samples not treated with the test compound (Bio-) and treated with the test compound (Bio+) samples. The “BIO+” samples were treated in a way identical to described above for the test samples, with exception that the treatment solution contained solely non-radiolabelled test compound. Two sets of the **Control samples** were prepared – DAT-0 samples analysed at the beginning of the experiment and DAT-100 samples incubated for 100 days as all other samples and analysed for the soil microbial activity at the end of the whole incubation period. The DAT-100 samples were prepared and maintained as all remaining samples, with exception that their soil moisture content was not controlled and corrected during incubation period.

The test vessels removed for analysis were also ventilated for 10 minutes with air, introduced for the first 5 minutes at rate 1 mL/s. and then at rate 10 mL/s., to transfer all volatile compounds present in the headspace above the soil surface to the traps for volatile compounds. Then the test vessels were dissected and the content of volatile traps analysed for the radioactivity content.

Soil samples from the Erlenmeyer flasks were then entirely transferred to the centrifuging beakers and extracted using three-step procedure, looking as follows:

- Step 1: extraction by shaking for 60 minutes at room temperature with 50 mL of water, followed by centrifugation at ~10,000 g for ~15 minutes; clear supernatants were decanted by filtering through paper filters to collect suspended particles (**Filter 1**), their volumes measured and three 100- μ L aliquots analysed by LSC while the remaining extracts stored for further analysis by TLC;
- Step 2: extraction by shaking for 60 minutes at room temperature with 50 mL of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ solution, followed by centrifugation at ~10,000 g for ~15 minutes; clear supernatants were decanted by filtering through the same paper filters as used at Step 1 to collect suspended particles (**Filter 1**), their volumes measured and three 100- μ L aliquots analysed by LSC while the remaining extracts stored for further analysis by TLC;
- Step 3: extraction by shaking for 60 minutes at room temperature with 50 mL of 0.01N HCl_{aq} in CH_3CN solution, followed by centrifugation at ~10,000 g for ~15 minutes; clear supernatants were decanted by filtering through paper filters to collect suspended particles (**Filter 2**), their volumes measured and three 100- μ L aliquots analysed by LSC while the remaining extracts stored for further analysis by TLC.

The **Filter 1** and **Filter 2** together with retained particles were pressed to pills, combusted and resulting $^{14}\text{CO}_2$ quantified. Also the radioactivity remaining in extracted soil pellets was quantified. That was done by combusting three 1-g aliquots of dried and homogenised soil pellets, and measuring the amount of formed $^{14}\text{CO}_2$ by LSC.

The radioactivity measured for each sample in both **Filters** and extracted soil pellet was subsequently considered to form the NER fraction.

The volatile traps were dissected into polyurethane plugs, which were not further processed (it was stated that they contained no substantial amount of radioactivity), and soda lime filling, processed to determine the amount of captured $^{14}\text{CO}_2$ formed during incubation. That was done by dissolving soda lime in 60 mL of 18% HCl_{aq} in an apparatus presented below on figure B.8.1.1.2.1.1._CA-57. Liberated $^{14}\text{CO}_2$ was absorbed in a suitable scintillation cocktail and analysed by LSC.

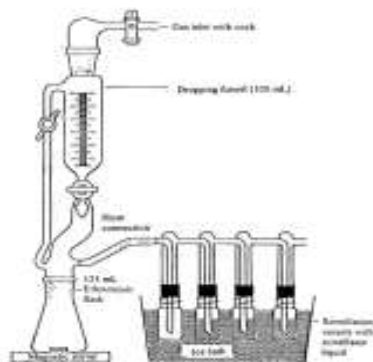

Figure B.8.1.1.2.1.1._CA-57: The apparatus used for the liberation of $^{14}\text{CO}_2$ (scheme copied from the study report).

All liquid samples were analysed for their radioactivity content using LS6000LL (Beckmann 6500) liquid scintillation counter. The scintillation cocktail declared to be used was Instant Scint Gel[®].

In case of the aqueous soil extracts – water extracts and $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ extracts, the volume of analysed sample was 2 mL, the counting time was 10 minutes and the average background (BKGD) – 19 cpm. The minimum sensitivity of LSC analysis for these samples was 2.01 E-4 ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 943 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 924 cpm. The greatest probable error GPE = 2.1%. Limit of sensitivity was set to 2*BKGD – 38 cpm.

In case of organic soil extracts – 0.01N $\text{HCl}_{\text{aq}}/\text{CH}_3\text{CN}$ extracts, the volume of analysed sample was 2 mL, the counting time was 10 minutes and the average background (BKGD) – 19 cpm. The minimum sensitivity of LSC analysis for these samples was 1.24 E-5 ppm. When expressed as Lowest Acceptable Gross Count Rate (LAGC)

it was 76 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 57 cpm. The greatest probable error GPE = 9.5%. Limit of sensitivity was set to $2 \times \text{BKGD}$ – 38 cpm.

The $^{14}\text{CO}_2$ generated during the combustion of extracted soil pellets was absorbed in Oxisolve C 400 (Zinsser Analytic) scintillation cocktail and quantified using PW4700 (Raytest Co) LS Counter or LKB 1219 (Wallac Oy.) LS Counter.

The initial amount of the analysed sample was 1.0 g, the counting time was 10 minutes and the average background (BKGD) – 24 cpm. The minimum sensitivity of LSC analysis for these samples was 1.05 E-4 ppm . When expressed as Lowest Acceptable Gross Count Rate (LAGC) it was 236 cpm, while as Lowest Acceptable Net Count Rate (LANC) – 212 cpm. The greatest probable error GPE = 4.1%. Limit of sensitivity was set to $2 \times \text{BKGD}$ – 48 cpm.

Similar parameters were recorded in case of LSC analysis for paper filters. The only difference consisted on initial amount of analysed sample – it was <500 mg.

All extracts were analysed qualitatively and quantitatively – for identification and quantitation of FOE Sulfonic acid, using TLC.

The TLC analysis was performed on silica gel 60 plates coated by F-254 (Merck, Co.) developed in glass chamber with following solvent system: $\text{CH}_3\text{CN}/\text{CH}_3\text{CHOHCH}_3/\text{CH}_3\text{COOC}_2\text{H}_5/\text{H}_2\text{O}$ 60:9:6:3 (v/v/v/v) solution ($\text{CH}_3\text{CHOHCH}_3$ stands for 2-propanol and $\text{CH}_3\text{COOC}_2\text{H}_5$ for ethyl acetate).

The identification of the test compound was performed by means of the comparison of the R_f values for the analysed sample with those of the known standards.

The quantitative analysis – radioactivity counting, was performed using BIO imaging analyser (Fuji Co.). The LOD (determination limit) for a single peak was <0.5% AR.

Results and their discussion:

The results of the determination of soil moisture, soil pH and soil microbial activity in each test soil are presented below in the table B.8.1.1.2.1.1._CA-142. In the study report it was indicated that in samples incubated for 100 days the soil moisture content was not checked and corrected during the incubation period, what resulted in observed decrease in microbial activity. Therefore the results of the soil biomass determination obtained for the DAT-100 samples should be considered with care when used to decide on the validity of the study, as they may not represent the situation in the test samples, adjusted for the soil moisture at each sampling point.

Table B.8.1.1.2.1.1._CA-142: The results of the determination of the soil microbial activity, soil moisture content and soil pH in the **Control samples**.

Test soil	Type of sample	Results obtained for DAT-0 samples				Results obtained for DAT-100 samples			
		Determination of soil biomass		Soil moisture content [%]	Soil pH in KCl	Determination of soil biomass		Soil moisture content [%]	Soil pH in KCl
		[mg microbial C/kg soil]	%OC			[mg microbial C/kg soil]	%OC

Footnotes to the table:

- 1) Samples not treated with the test compound;
- 2) Samples treated with the non-radiolabelled test compound in amount (nominal) 40 µg/sample;
- 3) Not measurable; in the study report this was attributed to the extreme dryness of the test soil.

The level and uniformity of the application dose was checked at application by LSC in 100-µL aliquots of the **Application solution**. The results are presented below in the table B.8.1.1.2.1.1._CA-143.

Table B.8.1.1.2.1.1._CA-143: The results of the determination of the level and uniformity of application dose.

Parameter determined in/as:	Measured values

Footnotes to the table:

- 1) Application solution sampled prior to the first application;
- 2) Application solution sampled after treatment of the half of the test vessels;
- 3) Application solution sampled after all test vessels were treated with the test compound;

The presented above results conformed the uniformity of the application for each test vessel. It was also stated that the level of applied radioactivity was 16.55 kBq/vessel – the value defined as 100% AR. When the radiochemical purity of the test compound was taken into account the treatment level was determined to be 15.79 kBq/vessel, corresponding to 36.8 μ g FOE Sulfonic acid/test vessel.

The value of 16.55 kBq/vessel, determined to be 100% AR was subsequently used in reporting the results as DAT-0 value for all test soils. Other data for DAT-0 samples (e. g. amount of AR extracted from soil) were not reported.

The obtained results showed good recovery of AR, within the limits recommended by the relevant Guidelines (OECD 307). It looked as follows:

- in BBA 2.1 soil the total recovery was in range 91.7% – 103% (mean values); the lowest values were observed for DAT-0.1 samples and were attributed to the fact that the filters were combusted without oxygen, therefore the radioactivity was not released as $^{14}\text{CO}_2$;
- in BBA 2.2 soil the total recovery was in range 96.9 – 102.7% (mean values);
- in Laacherhof soil the total recovery was in range 96.7 – 100.0% (mean values).

It was stated that in none of the test soil the time-dependent tendency was observed.

The level of mineralisation, measured by the amount of $^{14}\text{CO}_2$ formed, was not very high, reaching at the end of the study (DAT 100) 10% in BBA 2.1 soil, 11% in BBA 2.2 soil and 14% in Laacherhof soil.

The amount of NER formed was following:

- in BBA 2.1 soil at the end of the study (DAT 100) – ~15% AR;
- in BBA 2.2 soil at the end of the study (DAT 100) – ~19% AR;
- in Laacherhof soil – ~31% AR.

The values were given as a sum of the radioactivity in extracted soil pellets and that retained on filters. It was stated that while in BBA 2.1 and BBA 2.2 soils NER fraction steadily increased with time, no such tendency was observed in Laacherhof soil.

The Applied Radioactivity was recovered mainly in extracts. In case of the two soils – BBA 2.1 and BBA 2.2, the amount of radioactivity extracted decreased with time to reach at the end of incubation period the level of 75.4% AR in BBA 2.1 soil and 66.5% AR in BBA 2.2 soil. In case of Laacherhof soil the situation was more complex, because on DAT 30 and DAT 63 time points the amount of radioactivity in extracts was higher than recorded in preceding and succeeding time points. RMS having analysed the whole data set came to conclusion that these two points may be analytical artifacts, but that should be verified during the kinetic analysis of the data.

It was also noted that in BBA 2.1 and BBA 2.2 soils the extracted radioactivity was predominantly found in water- and water/acetonitrile- extracts, while in case of Laacherhof soil it was more evenly distributed between the three fractions.

The only identified constituent of extracts was FOE Sulfonic acid, decreasing steadily with time to reach at the end of the study (DAT 100) the level of 62.3% AR in both BBA 2.1 and BBA 2.2 soils. More complex picture, with local maximum on DAT 30 and DAT 63, was observed in Laacherhof soil, the phenomenon identical to that observed in that soil for radioactivity extracted.

The detailed results are presented below, separately for each test soil, in numerical and graphical form. All values were rounded to one digit after the decimal point. RMS noticed that there were several discrepancies between the averages, what may be the result of the applied rounding procedure.

The results obtained in BBA 2.1 (Sand) soil are presented below in numerical form in the table B.8.1.1.2.1.1._CA-144 and in numerical form on figure B.8.1.1.2.1.1._CA-58.

Table B.8.1.1.2.1.1._CA-144: The numerical results of the experiment performed on BBA 2.1 soil.

Figure B.8.1.1.2.1.1._CA-60: The graphical results of the determination of the distribution of radioactivity in the test soil Laacherhof (scheme copied from the study report).

The results obtained for FOE Sulfonic acid presented in the tables above were kinetically examined to derive the kinetic endpoints. The kinetic analysis was performed using the linear regression method. As it did not comply with principles set by FOCUS Kinetics Guidance Document, its results will not be presented here.

Additionally the results were kinetically examined by Schäfer in two separate reports – MR-1085/95 and MR-037/98, summarised briefly further down this Renewal Assessment Report as **Study 21** and **Study 22** respectively. Finally, the results of this study were kinetically examined in compliance with provisions of FOCUS Kinetics Guidelines [FOCUS; 2006, 2011]. The results of that exercise are presented further down in the **Study 13**.

Study 10:

Report: Hellpointner E., (2003): “Time-Dependent Sorption of FOE5043-Sulfonic Acid in Soil.”; Bayer Crop Science AG, Development – Global Regulatory Affairs, D-40789 Monheim, Germany; unpublished study Report No. MEF-229/03; 2003-10-13; study reference number: M-111445-01-1;

Guidelines: Due to the aims of the study – examination of the time-dependent sorption of FOE Sulfonic acid, it was declared to be performed in such way, to comply with the following Guidelines:

- examination of soil sorption of the test compound: OECD Guideline for Testing of Chemicals No. 106, Adsorption and Desorption;
- in the area of incubation of the test flasks – ageing and processing of test soils:
 - BBA Guidelines for the Official Testing of Plant Protectants, Part IV, 4-1 (1986);
 - SETAC-Europe Procedures for Assessing the Environmental Fate and Ecotoxicology of Pesticides (*ed.* Mark Lynch), March 1995;
 - US. EPA Guideline 162-1 Aerobic Soil Metabolism (supplemental);

GLP: Yes

RMS comments: This is a newly submitted study. Its was to examine the time-dependent sorption of FOE Sulfonic acid in soil. Although the examination of the degradation kinetics was not its main task, the rate of degradation of the test compound in the test soils had also to be determined as a necessary component of the experiment. Therefore RMS decided to evaluate the study for its compliance with the following Guidelines examining the degradation in soil:

- OECD Guideline 307 – Aerobic and Anaerobic Transformation in Soil for the experimental protocol;
- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp (main GD) and FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 issued on 23 November 2011.(supplementary GD) in the area of the kinetic evaluation of the data.

It was verified by the RMS and found acceptable in the area of the examination of the degradation kinetics of FOE Sulfonic acid in soil. It is summarised below. The summary is given only for the part of the study examining the degradation of the test compound in soil.

Summary:

The aim of the study was to examine the phenomenon of the time-dependent sorption, i.e. increase with time of the K_{OC} value, of FOE Sulfonic acid onto soil. That was done in order to clarify the reasons for the observed discrepancies of the results of different studies, namely:

- high mobility and leaching potential of FOE Sulfonic acid in soil demonstrated by the results of the batch equilibrium sorption studies – average K_{OC} = 12.5 mL/g, and modelling GW exposure assessment, with PEC_{GW} for cereals in range of 3.1 – 9.2 µg/L;
- moderate concentrations of the compound in lysimeter studies – up to 1.69 µg/L in the average 1st year leachates when the compound was applied twice in the same year;
- the fact stated in the regulatory study by Hellpointner [1999], examining the degradation of FOE Sulfonic acid in soil (summarised above as **Study 9**), that the compound was not as easily extracted from soil, especially at later time points, as it might be suggested by its K_{OC} value.

The experiment was performed using the [Phenyl-U-¹⁴C] FOE Sulfonic acid in form of ammonium salt. Its structural formula is presented below on figure B.8.1.1.2.1.1._CA-61. The specific activity of the test compound was 2.66 MBq/mg (21.0 mCi/mMole) and its radiochemical purity was 98%.

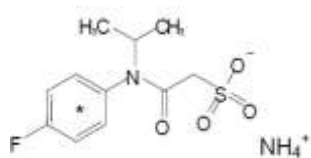

Figure B.8.1.1.2.1.1._CA-61: The structural formula of the test compound (copied from the study report).

The test compound was used to prepare the **Stock solution**, subsequently used in the experiment to treat the test soil. That solution was prepared by dissolving the whole delivered amount of radiolabelled FOE Sulfonic acid in 1 mL of CH₃CN and 19 mL of H₂O. Next the concentration of the test compound in the solution was determined. For that purpose five 50- μ L aliquots of the **Stock solution** were radioassayed. The concentration of the test compound, expressed as radioactivity, was determined to be 9706.3 kBq/20 mL (9.7063 MBq/20 mL), corresponding to 0.1824 mg FOE Sulfonic acid/mL. The radiochemical purity of the solution, determined by TLC, was ~98%. The **Stock solution** was used directly to treat the test soils.

Two test soils were used in the study. The soils were freshly sampled, shortly before the beginning of the experiment, from the 0-20 cm layer. Their characteristics are presented below in the table B.8.1.1.2.1.1._CA-147.

Table B.8.1.1.2.1.1._CA-147: The characteristics of soils used in the study.

Parameter		Soil	
		<i>Laacherhof AXXa</i>	<i>Laacherhof AIII</i>
Soil origin		Monheim, Germany	Monheim, Germany
Soil type (USDA)		Sandy loam	Silt loam
Particle size distribution	Sand (50 μ m – 2 mm) [%]	72.4	36.9
	Silt (2 – 50 μ m) [%]	22.6	51.1
	Clay (< 2 μ m) [%]	5.0	12.0
pH value in CaCl ₂		6.3	6.8
pH value in H ₂ O		6.9	7.6
pH value in KCl		6.3	7.2
Organic carbon content (OC) [%]		1.47	0.88
Organic matter content (OM) [%]		2.53	1.51
Cation Exchange Capacity – CEC [mEq/100g]		10.3	9.8
Water holding capacity	Max. [g H ₂ O/100 g soil]	34.42	36.40
	In air-dried and sieved soil [%]	8.62	7.22
Bulk density [g/cm ³]		2.5	2.55
Soil microbial biomass [mg microbial C/kg soil]	At start of incubation period – DAT 0	242	275
	At the end of incubation period – DAT 100	209	195
Soil microbial biomass [% OC] ¹⁾	At start of incubation period – DAT 0	1.65	3.13
	At the end of incubation period – DAT 100	1.42	2.22

Footnotes to the table:

1) Value calculated by the RMS.

In the laboratory the test soils were air-dried and sieved to a particle size ≤ 2 mm. Then the soil moisture content was measured in sieved soil by drying it at 105°C and determining the loss of weight.

Next 100-g (d.w.) portions of air-dried and sieved test soils (109.43 g in case of Laacherhof AXXa soil and 107.78 g in case of Laacherhof AIII soil) were weighed into 1000-mL centrifuge tubes and brought to 40% MWHC by the addition of the appropriate amount of distilled water – 4.33 g/vessel for Laacherhof AXXa soil and 6.78 g/vessel for Laacherhof AIII. The test vessels were then closed with cotton-wool plugs and pre-incubated for about one week in the darkness and at constant T = 20°C.

At the beginning of the whole experiment the soils in the test vessels were treated with the test compound applied as already described **Stock Solution** in amount 73 μ L/vessel, using a 100- μ L Eppendorf pipette. That gave the treatment dose of 35.5 kBq/vessel when expressed in terms of radioactivity, corresponding to the application dose of 13 μ g FOE Sulfonic acid/100 g soil. It was declared in the study report that such application dose corresponded to the lowest concentration of the test compound – 0.13 μ g/g soil, used in the study examining adsorption of FOE Sulfonic acid onto soil.

RMS recalculated that application dose to obtain the theoretic application rate expressed in g/ha. Standard assumptions were used: soil density $d = 1.5$ g/cm³ and the depth of the soil layer $l = 5$ cm. The resulting

application rate was **A = 99.70 g FOE Sulfonic acid/ha**. It corresponds to ~41% highest application rate of Flufenacet proposed in the current EU-representative GAP – 240 g/ha.

When the experimentally determined soil bulk density values were used, the calculated theoretic application rates were as follows:

- in Laacherhof AXXa soil (bulk density $d = 2.5 \text{ g/cm}^3$) application rate **A = 162.50 g FOE Sulfonic acid/ha**;
- in Laacherhof AIII soil (bulk density $d = 2.55 \text{ g/cm}^3$) application rate **A = 165.75 g FOE Sulfonic acid/ha**.

After treatment of the test soils with the test compound several test were performed, aimed on the determination of adsorption parameters. All they were performed in the same way as typical batch sorption tests described in OECD 106 Guidance document. The main test was performed with treated soil aged for the determined amount of days before the adsorption was examined. All test are briefly characterised, in form of a table copied from the study report, on figure B.8.1.1.2.1.1._CA-62.

Table 2 Applications with each approx. 35.5 kBq of test item

Test	Tubes/soil	Investigations
a) DAT-0: Soil treated prior to shaking	1	Samples taken after 1, 3, 7 and 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant
b) DAT-0: Solution treated prior to shaking	1	Samples taken after 1, 3, 7 and 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant
c) DAT-0: Reference solution: soil not treated during shaking	1	Processing after 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution, then treatment of decanted aqueous 0.01 M CaCl_2 filled into a new empty tube and shaking for 24 hrs, LSC and TLC of solution and LSC of tube extract ^{*)}
d) DAT-0: soil treated prior to shaking	1	Processing after 24 hrs of shaking with 333 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant and soil extract combustion of soil solids
e) DAT-0: Control without soil Solution treated prior to shaking	1	Samples taken after 1, 3, 7 and 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution LSC and TLC of supernatant and LSC of tube extract ^{*)}
Main Test: DAT-X: soil treated then aged prior to shaking	14	Processing after 24 hrs of shaking with 100 mL of 0.01 M CaCl_2 solution, LSC and TLC of supernatant and soil extract, combustion of soil solids

^{*)}: In order to get information on the sorption of radioactivity onto the walls of the testing tubes. The tube was washed (extracted) as it is described for test a or d.

Figure B.8.1.1.2.1.1._CA-62: The table listing and briefly characterising tests performed in the experiment (copied from the study report).

The data possible to be used in the determination of the degradation kinetics of Flufenacet in the test soils were obtained in the main test, so only that stage will be characterised in this summary.

For each test soil 14 pre-incubated test vessels treated with the test compound applied to the soil surface as **Stock solution** in amount 73 $\mu\text{L}/\text{vessel}$, to obtain the application dose of 0.13 mg/kg, corresponding to the theoretic application rate **A = 99.7 g/ha**. Then the test vessels were closed with cotton-wool plugs and all, except DAT-0 samples placed in the darkness in the temperature-controlled room and incubated for up to 100 days at $T = 20^\circ\text{C}$.

For each test soil duplicate samples were removed for further processing at the following time points: DAT 0, DAT 3, DAT 7 DAT 14, DAT 28, DAT 56 and DAT 100. The samples removed from the incubation room were further processed following their procedure presented below on figure B.8.1.1.2.1.1._CA-63.

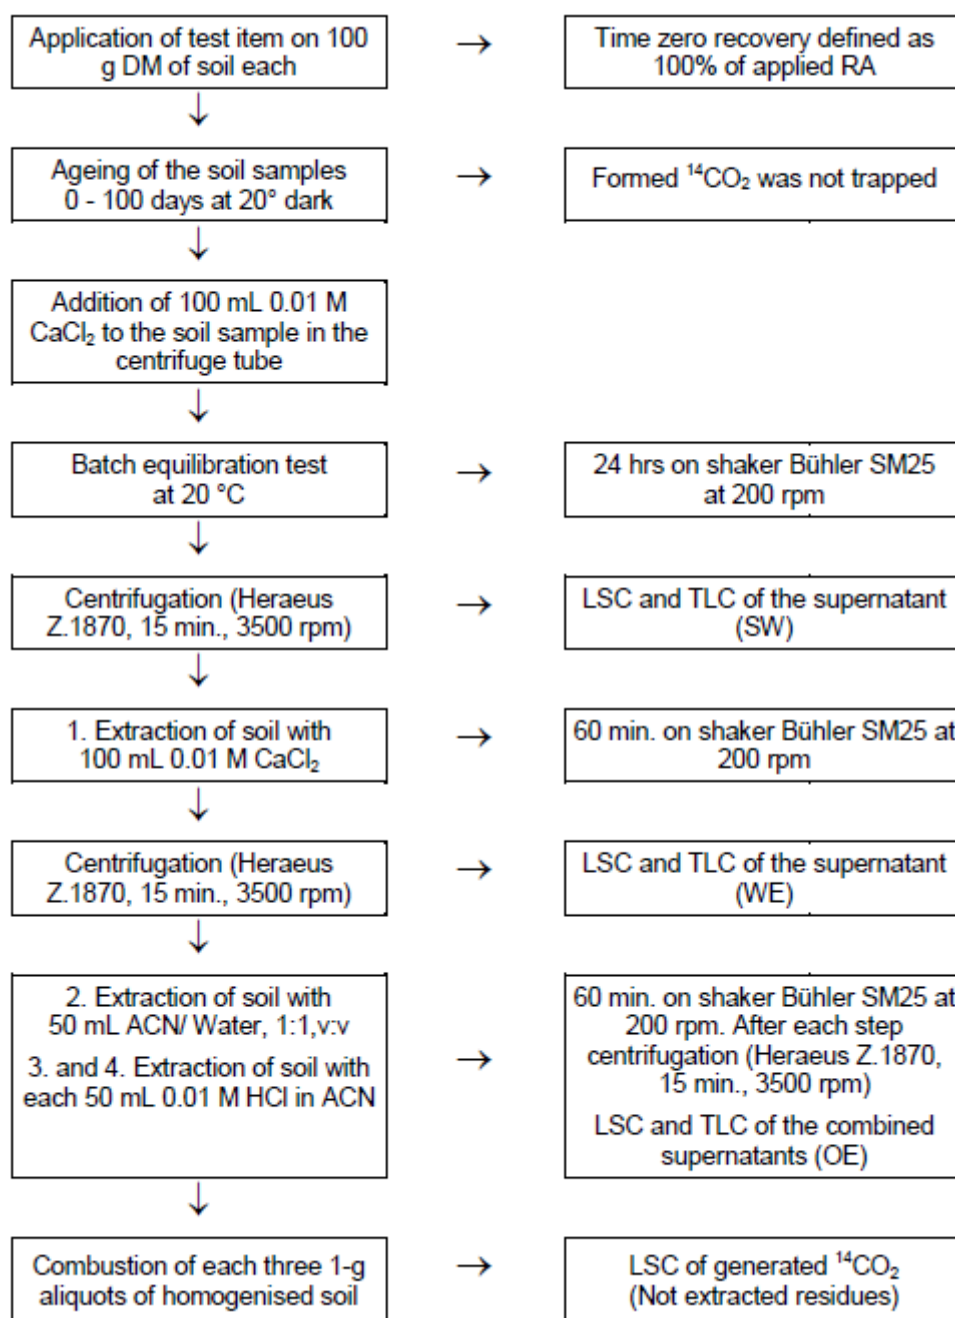

Figure B.8.1.1.2.1.1._CA-63: The flow chart of the processing of samples during the main test of the experiment (copied from the study report).

The 0.01M CaCl_2 solution used at the first stage of extraction, named on the flow chart “batch equilibration test”, was prepared by dissolving 2.94 g of $\text{CaCl}_2 \times \text{H}_2\text{O}$ in 2 L of deionised (Milli-Q) water. Three such solutions were prepared for the purpose of the experiment, having a pH ranging from 5.5 to 6.2. The same solution was also used at 1st step of extraction.

The clear supernatants obtained at each step after centrifugation were collected and their volume determined by weighing. The acetonitrile extracts ($\text{CH}_3\text{CN}/\text{H}_2\text{O}$ and 0.01N $\text{HCl}_{\text{aq}}/\text{CH}_3\text{CN}$ extracts) were combined.

The supernatant obtained during batch equilibration test was further called **Supernatant**, that obtained after extraction with 100 mL of 0.01 M CaCl_2 – **water extract**, while combined supernatants obtained after extraction with solutions containing CH_3CN – **organic extract**.

The extracts were not further processed but their three 200- μ L aliquots analysed for radioactivity content using LSC.

The extracts were also analysed using radio-TLC. For that purpose the following amounts of each fraction were used:

- in case of **Supernatant** one 100- μ L aliquot;
- in case of **Water extract** one 200- μ L aliquot;
- in case of **Organic extract** one 500- μ L aliquot

The extracted soil pellets were air-dried, homogenised and analysed for the content of NER fraction. For that purpose their three 1-g aliquots were combusted in oxidiser and generated $^{14}\text{CO}_2$ quantified using LSC.

The LSC analysis of the liquid samples (200- μ L aliquots) was performed in 2-mL Quicksafe-A scintillation liquid containing 5% of water. The measurements were done on LS 6500 or LS 6000LL counters. Sample counting time was 10 minutes, average counting efficiency ~91% and the background 14-16 cpm.

The $^{14}\text{CO}_2$ generated during the oxidative combustion of the extracted soil pellets was absorbed in Oxysolve C-400 scintillation cocktail and analysed by LSC.

The TLC analysis was performed on crude solutions of each extract in order to determine the concentration of the test compound in each of the fractions. The analysed samples were not enriched or preconditioned prior to the analysis.

The TLC analysis was performed on 200 x 200 mm silica gel Si60 TLC plates. Chromatograms were developed in glass chamber using the following solvent system: $\text{CH}_3\text{CN}/\text{CH}_3\text{CHOHCH}_3/\text{CH}_3\text{COOC}_2\text{H}_5/\text{H}_2\text{O}$ 60:9:6:3 (v/v/v/v) solution ($\text{CH}_3\text{CHOHCH}_3$ stands for 2-propanol and $\text{CH}_3\text{COOC}_2\text{H}_5$ for ethyl acetate).

The identification of the test compound was performed by means of the comparison of the R_f – values for the analysed sample with those of the known standards.

The quantitative analysis – radioactivity counting, was performed using BIO imaging analyser (Fuji Co.). The LOD (determination limit) for a single peak was 0.5% AR. That value however significantly depended on the volume of sample introduced on the plate.

Results and their discussion:

Below are presented the results obtained during the main test. RMS decided to present only the results relevant for the determination of the degradation kinetics of FOE Sulfonic acid in the test soils.

The total recoveries of Applied radioactivity in DAT-0 samples were as follows:

- for Laacherhof AXXa soil: **34.152 kBq**, subsequently used as a reference 100% AR value; it corresponded to 12.23 μg FOE Sulfonic acid/100 g soil;
- for Laacherhof AIII soil: **34.840 kBq**, subsequently used as a reference 100% AR value; it corresponded to 12.40 μg FOE Sulfonic acid/100 g soil.

The temperature in incubation chamber was demonstrated to be constant during the whole incubation period, and maintained at the designated level $T = 20 \pm 1^\circ\text{C}$. The mean temperature during incubation was $T = 19.9^\circ\text{C}$ ranging from 19.8°C to 20.35°C .

The graphical presentation of the changes of incubation temperature are presented below on figure B.8.1.1.2.1.1._CA-56.

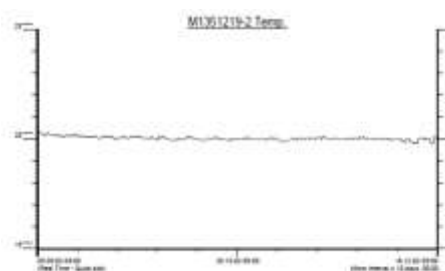

Figure B.8.1.1.2.1.1._CA-56: Temperature recorded in incubation chamber during the experiment (copied from the study report).

In the study report it was stated that both soils were microbiologically viable and that the microbial biomass was within the usual range expected for soils sampled from agricultural fields.

RMS stated that the microbial biomass was above the minimal level recommended by OECD 307 Guideline – 1% OC throughout the whole study duration. It was also noted that, as expected, higher decrease in microbial biomass was observed in soil having lower OC content, but that parameter at the end of the study was still on such level that the test soil may be considered fully viable.

The results of the qualitative and quantitative analysis of the radioactivity in both test systems are presented below. Because of the design of the incubation vessels – the traps for the volatile compounds were not set, it was not possible to determine the level of mineralisation and hence it was also not possible to determine the mass balance.

RMS also noticed that the way the results were reported in the study report made them not fully transparent with regard to their further use in kinetic analysis. In particular, the results of the determination of radioactivity in each fraction was given in [Bq] for individual replicates. When transformed to % AR the values were given as averages of the two replicates.

The concentrations of FOE Sulfonic acid in different fractions at each time point determined by TLC, were expressed as % radioactivity in analysed sample. Only for extracts obtained in Laacherhof AIII soil were given the values for %AR in given fraction, enabling the calculation of the concentration of FOE Sulfonic acid expressed as % AR.

As a result, RMS decided to recalculate all the results provided in the study report in order to:

- a) obtain the results of the quantitation of radioactivity in each fraction, on each time point and for each replicate, expressed as %AR;
- b) obtain the concentrations of FOE Sulfonic acid in each replicate at each time point expressed as %AR.

The repeated calculations were carried out using the raw results presented in the study report. These are shown below, as tables copied from the study report, on figures B.8.1.1.2.1.1._CA-64 and B.8.1.1.2.1.1._CA-65. On figure B.8.1.1.2.1.1._CA-64 are reproduced the results of the determination of radioactivity in each fraction. For calculations were used the values marked bold – amount of radioactivity in the whole sample expressed in [Bq]. The reference value, defined as 100% AR, was “Avg. DAT-0” value reported at the bottom of each table.

On the next figure – B.8.1.1.2.1.1._CA-65 are presented the raw results of the analysis of each fraction by TLC. The following abbreviations were used by the Applicant in the reproduced tables to characterise fractions:

- SW for **Supernatant**;
- WE for **Water extract**;
- OE for **Organic extract**.

The numerical, re-formatted results of the experiment are given in two tables – B.8.1.1.2.1.1._CA-148 for Laacherhof AXXa soil and B.8.1.1.2.1.1._CA-149 for Laacherhof AIII soil. Presenting them the RMS decided to provide the average values for concentration of radioactivity in fractions at each sampling point as they were given in the study report. Also the concentrations of the test compound – FOE Sulfonic acid, expressed in [$\mu\text{g}/100\text{ g soil}$] are taken from the study report.

To maintain the coherence of the reported results RMS decided to present all results in form of a single digit after the decimal coma. The only exception was made when the average concentrations of FOE Sulfonic acid in [$\mu\text{g}/100\text{ g soil}$], reproduced from the study report, were reported – the format used in the study report was kept. Such approach may possibly result in small discrepancies between the averages reported by the Applicant and would –be averages calculated by the RMS, but such differences are estimated to be negligible.

In addition to numerical results RMS presented the graphical results of the determination of the distribution of radioactivity between extractable and non-extractable phases, reproduced from the study report (figures B.8.1.1.2.1.1._CA-66 and B.8.1.1.2.1.1._CA-67).

Finally RMS decided to provide the estimates of the mineralisation level. That was done assuming the theoretical total recovery level of AR at each time point and for each replicate equal to 100% and subtracting from that value the experimentally determined total radioactivity recovered. The resulting value was considered to represent the approximate level of mineralisation. RMS noticed that the obtained values were in line with those obtained in the previously summarised study by [Hellpointner; 1999] (**Study 9**).

Footnotes to the table:

- 1) The theoretical level of mineralisation calculated by the RMS by subtracting the appropriate value representing the “Total radioactivity recovered” from the theoretical level of applied radioactivity – 100%. For DAT-0 samples that value was set to 0, as for that time point no mineralisation was expected to occur. In cases when the amount of radioactivity recovered at the given time point was higher than 100% the level of would-be mineralisation was also set to zero.

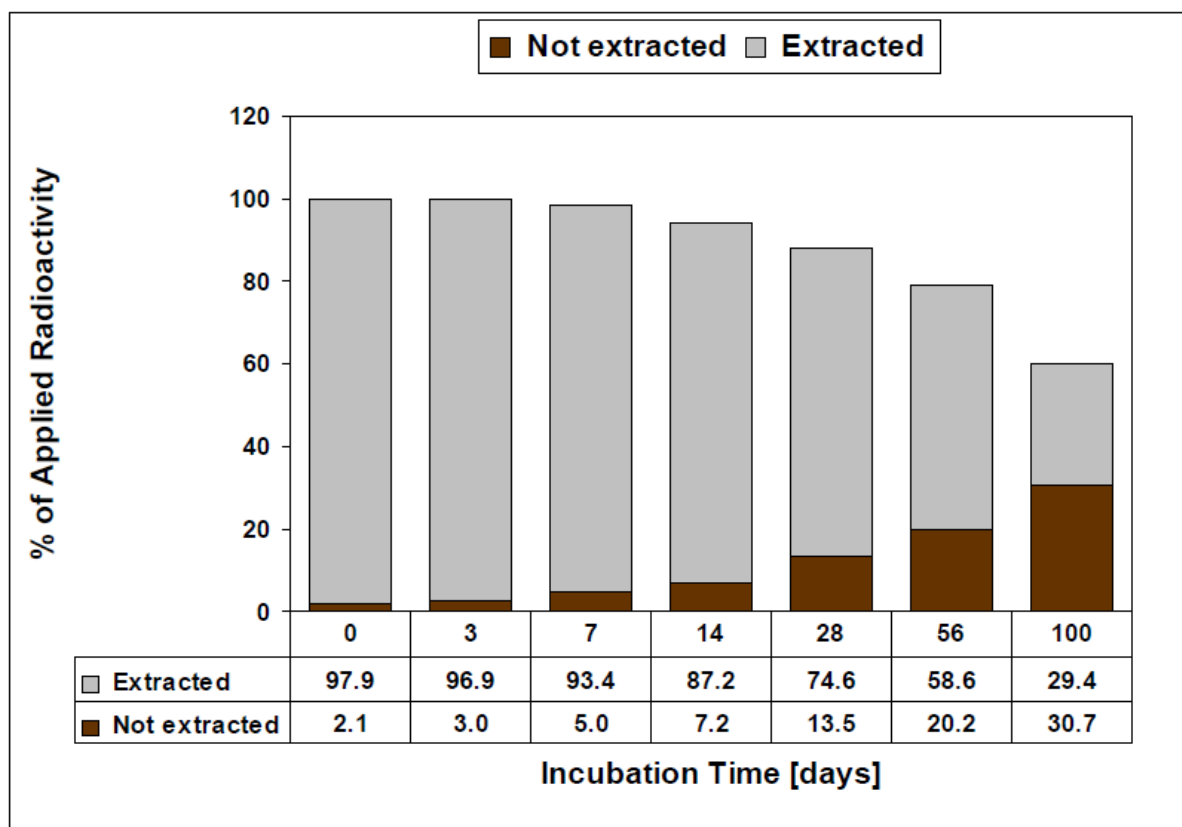

Figure B.8.1.1.2.1.1._CA-66: The graphical results of the determination of the distribution of radioactivity in the test soil Laacherhof AXXa (scheme copied from the study report).

The results obtained in Laacherhof AIII (Silt loam) soil are presented below in numerical form in the table B.8.1.1.2.1.1._CA-149 and in graphical form on figure B.8.1.1.2.1.1._CA-67.

Footnotes to the table:

- 1) The theoretical level of mineralisation calculated by the RMS by subtracting the appropriate value representing the “Total radioactivity recovered” from the theoretical level of applied radioactivity – 100%. For DAT-0 samples that value was set to 0, as for that time point no mineralisation was expected to occur. In cases when the amount of radioactivity recovered at the given time point was higher than 100% the level of would-be mineralisation was also set to zero.

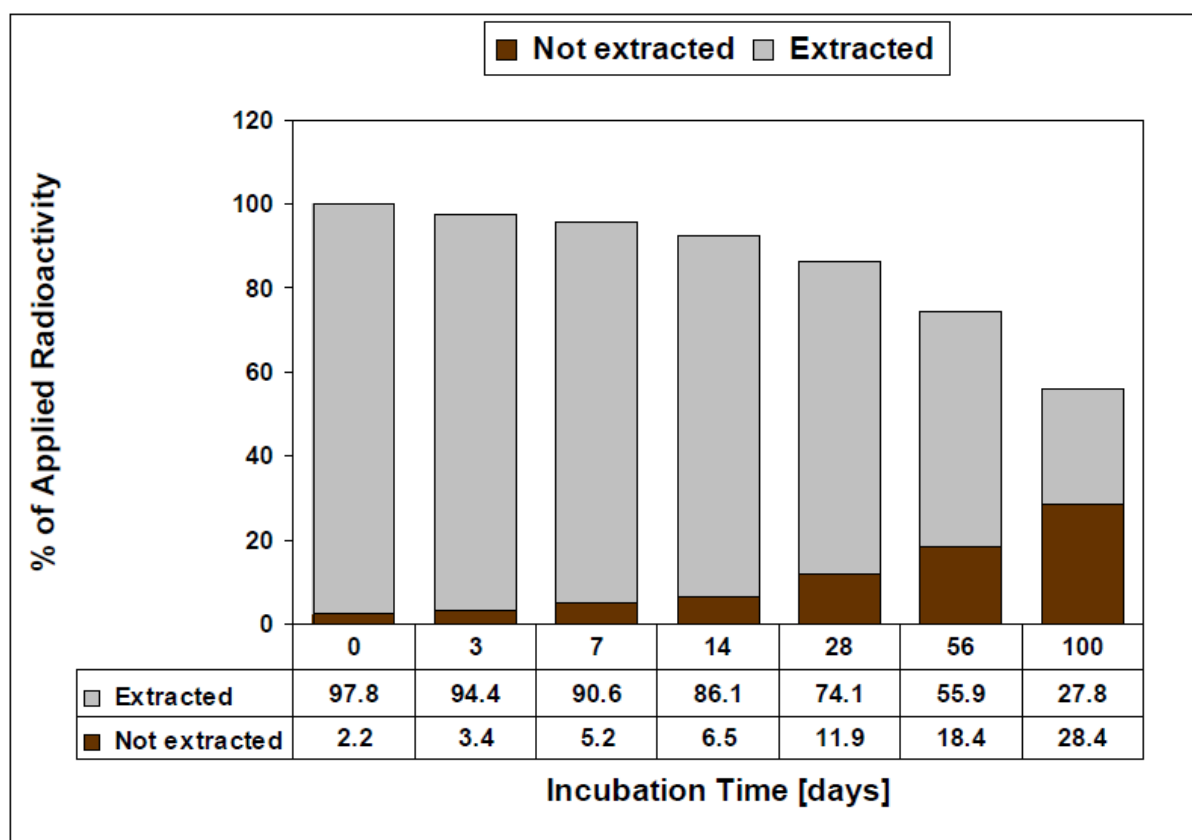

Figure B.8.1.1.2.1.1. CA-67: The graphical results of the determination of the distribution of radioactivity in the test soil Laacherhof AIII (scheme copied from the study report).

The data obtained for FOE Sulfonic acid were kinetically examined in order to obtain the kinetic endpoints – DT_{50} and DT_{90} values, in each of the test soils. The kinetic examination of the data was performed only for SFO model. The data used in the fitting were the average concentrations of FOE Sulfonic acid expressed in [$\mu\text{g}/100 \text{ g soil}$]. RMS stated that the kinetic analysis of the results did not comply with the recommendations of the FOCUS Kinetics Guideline. Therefore, and also because the same data sets were kinetically re-examined fully in line with FOCUS Kinetics recommendations in another study – **Study 13** below, RMS decided not to present them.

Study 11:

Report: Hein E. M., (2013): “FOE sulfonic acid: Aerobic Degradation in Four European Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany; unpublished Study Report No. EnSa-13-0442; 2013. 08. 05, updated by the Amendment No. 1 (Hein E. M. (2013): “Amendment No. 1 to: FOE Sulfonic Acid: Aerobic Degradation in Four European Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany;) issued on 2013. 08. 22; study reference number: M-461413-02-1;

Guidelines: The study was declared to be performed in line with the provisions of the OECD Guideline for the Testing of Chemicals No. 307 – Aerobic and Anaerobic Transformation in Soil. The Applicant stated that there was no deviations from the declared Guideline. Additionally, as the data obtained in their study were kinetically evaluated and the results presented in the study report, it was declared that the following Guideline was used:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;

In this case also no deviations from the Guideline referred to were stated.

GLP: Yes;

RMS comments: This is a new study, submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to determine the rate of degradation FOE Sulfonic acid in aerobic soil incubated under laboratory conditions. The experiment was performed on four test soils taken from the agriculturally used areas, representing different geographical origin and different soil properties, in line with the requirement of the relevant Guideline. The characteristic of the test soils is provided below in the table B.8.1.1.2.1.1._CA-150.

Table B.8.1.2.1.1.CA-150: The characteristic of soils used in the study.

Parameter			Soil			
			<i>Laacherhof AXa (AX)</i>	<i>Dollendorf II (DD)</i>	<i>Höfchen am Hohenseh 4a (HH)</i>	<i>Wurmweise (WW)</i>
Soil origin			Monheim/ North Rhine-Westphalia /Germany	Blankenheim/ North Rhine-Westphalia /Germany	Burscheid/ North Rhine-Westphalia /Germany	Monheim/ North Rhine-Westphalia /Germany
Soil type (USDA)			Loamy sand	Loam	Silt loam	Sandy loam

		BIO+ ⁵⁾	2.35	----	2.55	2.01

Footnotes to the table:

- 1) Value calculated from experimentally determined OC content, using the following equation: $OM = 1.724 \text{ OC}$;
- 2) Determined using the SIR method developed by Anderson & Domsch [1978];
- 3) Values recalculated by the RMS using the OC content reported in the table for each test soil;
- 4) Determined in samples not treated with blank application solution – 0.4 mL of 1:1 MeOH/H₂O;
- 5) Determined in samples treated with blank application solution – 0.4 mL of 1:1 CH₃OH/H₂O;
- 6) The second value is given for repeated DAT-0 sample; analysis was performed as it has become necessary to introduce two additional sampling points – DAT 1 and DAT 3;
- 7) Analysis not performed as in this soil, due to the rapid degradation of the test compound, the incubation was terminated on DAT 37.

The test soils were sampled shortly before being used (17 days before the experiment began) with shovel from 0-20 cm layer of grassland plot. No Plant Protection Products were used on the sampling field for 5 years preceding sampling. Sampled test soils were transported to the test facility in plastic bags. There they were sieved through 2-mm sieve and stored in the darkness at either $T = 5^{\circ}\text{C}$ or $T = 20^{\circ}\text{C}$ until being used. The whole soil sampling-and-handling procedure was declared to be performed in accordance with ISO 10381-6.

The experiment was performed using 300-mL Erlenmeyer flasks into which 100-g (d. w.) portions of sieved test soils were weighed. Next the soil moisture content of each sample was adjusted to $55 \pm 5\%$ MWHC by addition of the appropriate amount of deionised water. So prepared incubation flask were then capped with PU plugs to allow free air exchange. The example incubation vessel is presented below on figure B.8.1.1.2.1.1._CA-68. After adjustment of the soil moisture the incubation vessels were pre-conditioned for 3 days in the dark, in a temperature-controlled walk-in climatic chamber at $T = 20 \pm 2^{\circ}\text{C}$, until being treated with the test compound. The number of incubation vessels prepared for each test soils was such to grant at least to have duplicate treated samples at each sampling point and those for the determination of soil biomass in soil samples not treated and treated with blank application solution.

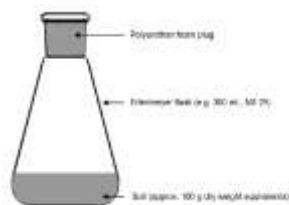

Figure B.8.1.1.2.1.1._CA-68: The example incubation vessel (copied from the study report).

The test compound was a non-radiolabelled FOE Sulfonic acid in form of Na^+ salt, having the chemical purity, determined by ^{19}F -NMR, of 86% (RMS noticed that the chemical purity of the test compound was 9-% lower than recommended minimum, but that had no impact on the validity of the study, as that factor was taken into account in all calculations). Its structural formula is shown below on figure B.8.1.1.2.1.1._CA-69.

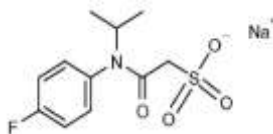

Figure B.8.1.1.2.1.1._CA-69: The structural formula of the test compound used in the experiment (copied from the study report).

It was delivered as a solid sample, in form of a white powder, weighing 16.48 mg. That sample was used entirely to prepare first a **Stock solution** and next **Application solutions**.

The **Stock solution** was prepared by dissolving the whole delivered sample of FOE Sulfonic acid Na^+ salt in 14.44 mL of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ (1:1 v/v), to obtain a solution having a nominal concentration 1.0 mg FOE Sulfonic acid/mL, taking into account the chemical purity of the test compound being 86%. The so prepared **Stock solution**, labelled **Ja66 SS**, was stored in the darkness at $T < 8^{\circ}\text{C}$ until being used.

Three diluted solutions were prepared from the **Stock Solution**:

- **Dilution solution 1**, labelled **Ja66 SS D1**, by transferring 0.43 mL of the **Stock solution Ja66 SS** into 50-mL volumetric flask and bringing it to a volume with the appropriate amount of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ (1:1 v/v). The so prepared solution had a nominal concentration 8600 ng/mL and was used to prepare the series of calibration solutions;

- **Dilution solution 2**, labelled **Ja66 SS D2**, by transferring 5 mL mL of the **Ja 66 SS D1** solution into 50-mL volumetric flask and bringing it to a volume with the appropriate amount of CH₃CN/H₂O (1:1 v/v). The so prepared solution had a nominal concentration 860 ng/mL and was used to prepare the series of calibration solutions;
- **Dilution solution 3**, labelled **Ja66 SS D3**, by transferring 0.5 mL mL of the **Ja 66 SS D1** solution into 50-mL volumetric flask and bringing it to a volume with the appropriate amount of CH₃CN/H₂O (1:1 v/v). The so prepared solution had a nominal concentration 86 ng/mL.

Next two following application solutions were prepared:

- **Application solution Ja66 AS AR**, to treat samples used in validation of the analytical procedure, concurrent recovery samples and the degradation samples;
- **Application solution Ja66 AS LOQ**, to treat concurrent recovery samples and those used in the determination of LOQ.

The application solution **Ja66 AS AR** was prepared by transferring 8.6 mL of the **Stock solution Ja66 SS** into 100-mL volumetric flask and evaporating it to dryness under the constant stream of N₂. The residue was reconstituted and brought to volume with the appropriate amount of 1:1 (v/v) CH₃OH/H₂O. The nominal concentration of so prepared application solution was 0.086 mg FOE Sulfonic acid/mL.

The application solution **Ja66 AS LOQ** was prepared by transferring 0.43 mL of the **Stock solution Ja66 SS** into 100-mL volumetric flask and evaporating it to dryness under the constant stream of N₂. The residue was reconstituted and brought to volume with the appropriate amount of 1:1 (v/v) CH₃OH/H₂O. The nominal concentration of so prepared application solution was 0.0043 mg FOE Sulfonic acid/mL.

The **Ja66 AS AR** solution was used to treat degradation samples. To do that 0.4 mL of it was applied dropwise onto soil surface in each incubation vessel to obtain the application dose of 34.4 µg FOE Sulfonic acid/100 g soil (d. w.). That application dose – equal to 0.344 mg/kg soil was determined using the following assumptions:

- field application rate of Flufenacet (parent compound, precursor of FOE Sulfonic acid): 600 g/ha;
- maximum occurrence of FOE Sulfonic acid in aerobic soil (determined in the laboratory studies): 26.3%;
- molar weight of Flufenacet M = 363.3 g/mol;
- molar weight of FOE Sulfonic acid M' = 297.3 g/mol;
- soil bulk density: 1.5 g/cm³;
- thickness of the soil layer: 2.5 cm.

RMS analysing the calculations noticed that the assumed soil layer was ½ of that routinely used to calculate field application rate (in [g/ha]) from that expressed in mg/kg soil. Therefore the RMS back calculated the would-be field application rate for FOE Sulfonic acid using the standard assumptions:

- soil bulk density: 1.5 g/cm³;
- thickness of the soil layer: 5 cm.

The so calculated field application rate **A = 258.0 g FOE Sulfonic acid/ha**.

Using the measured soil bulk density of each test soil used in the experiment that value would be:

- for Laacherhof AXXa soil: **A = 204.68 g/ha**;
- for Dollendorf II soil: **A = 177.16 g/ha**;
- for Höfchen am Hohenseh 4a soil: **A = 187.48 g/ha**;
- for Wurmwielse soil: **A = 201.24 g/ha**

The verification of application rate and homogeneity of application was performed using **Ja66 AS AR** solution at the beginning and at the end of the whole application cycle. That was done by transferring of 0.4-mL portions of the application solution into 500-mL graduated cylinders. Next the solution was brought to the volume of 400 mL using 1:1 (v/v) CH₃OH/H₂O solution and analysed using HPLC-MS/MS.

The same solution was used to treat the Concurrent Recovery Samples. The application dose was the same as for degradation samples – 0.4 mL/100 g soil, resulting in fortification level of 0.344 mg/kg soil. The samples were freshly prepared at each sampling point using Laacherhof AXXa soil.

Application solution **Ja66 AS LOQ** was used to treat another set of Concurrent Recovery Samples, in amount 0.4 mL/100 g soil (d.w.), what resulted in application rate 1.72 µg/100 g soil (0.072 mg/kg soil) – 5% of the nominal application rate. The samples were freshly prepared at each sampling point using Laacherhof AXXa soil.

The verification of application rate and homogeneity of application in Concurrent Recovery Samples was performed in the same manner as for degradation samples.

Immediately after treatment the incubation vessels designated as degradation samples were closed with PU plugs to grant free access of air, placed in the darkness in temperature-controlled walk-in climatic chamber and incubated for up to 120 days under aerobic conditions at $T = 20 \pm 2^{\circ}\text{C}$. Duplicate samples were removed from incubation chamber at following time-points (DAT stands for “Days After Treatment”):

- for Laacherhof AXXa soil: DAT 0, DAT 7, DAT 14, DAT 21, DAT 37, DAT 58, DAT 86 and DAT 120;
- for Dollendorf II soil: DAT 0, DAT 1, DAT 3, DAT 7, DAT 14, DAT 21, DAT 37;
- for Höfchen am Hohenseh 4a soil: DAT 0, DAT 1, DAT 3, DAT 7, DAT 14, DAT 21, DAT 37, DAT 58, DAT 86 and DAT 120;
- for Wurmwielse soil: DAT 0, DAT 7, DAT 14, DAT 21, DAT 37, DAT 58, DAT 86 and DAT 120;

The soil moisture content in incubation vessels was controlled by weighing them at designated time points and replenishing lost water with adequate amount of deionised water. That was done 3 days before application and on the following time points: DAT 0, DAT 7, DAT 14, DAT 21, DAT 37, DAT 51, DAT 58, DAT 65, DAT 79, DAT 86, DAT 93, DAT 102, DAT 112 and DAT 120 for all test vessels remaining in the incubation chamber.

Samples removed from the incubation chamber were processed and analysed immediately after sampling. That was done using the entire portions of the test soil recovered at each sampling point, using the procedure presented below on figure B.8.1.1.2.1.1_CA-70. The same procedure was applied to Concurrent Recovery Samples.

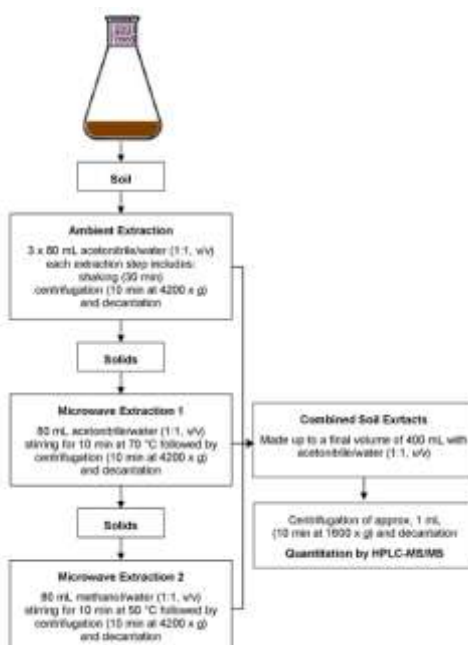

Figure B.8.1.1.2.1.1_CA-70: The sample-processing procedure used in the experiment (scheme copied from the study report, slightly modified by the RMS to increase its transparency).

The samples for the determination of soil biomass were set alongside the degradation samples. The soil biomass was determined in pre-conditioned test soil samples sampled on DAT 0 (beginning of the incubation period), DAT 60 (middle of the incubation period) and DAT 120 (end of incubation period). The experiment was performed in two variants:

- “BIO-” samples, not treated with blank application solution; these samples were taken for the analysis on DAT 0, DAT 60 and DAT 120;
- “BIO+” samples, treated with 0.4 mL of blank application solution ($\text{CH}_3\text{OH}/\text{H}_2\text{O}$ 1:1 v/v); these samples were taken for the analysis on DAT 60 and DAT 120.

The quantitative and qualitative analysis of combined soil extracts and other liquid samples was performed by means of HPLC-MS/MS. The analysis was performed using HP1200 chromatography workstation equipped with UV absorption detector and Finnigan TSQ Vantage (Thermo Electron Corporation, San Jose, CA, USA) MS detector. The chromatographic separation was performed on Nucleodur Gravity C8 50*2 mm * 5 μm

chromatographic column working in a gradient mode. The column was maintained at constant temperature $T = 40^{\circ}\text{C}$. The gradient elution programme is presented below in the table B.8.1.1.2.1.1._CA-151.

Table B.8.1.1.2.1.1._CA-151: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% HCOOH</i>	<i>Solvent B – Acetonitrile + 0.1% HCOOH</i>
0	95	5
1	95	5
2	50	50
5	40	60
6	5	95

The elution lasted for 6 minutes and the flow rate of the mobile phase was 0.3 mL/min.

The identification of the test compound was performed by means of MS analysis using the following MS signals: $m/z = 276.1$ as parent ion and $m/z = 234.1$ as product ion (quantifier). Additional identification parameter for FOE Sulfonic acid was the retention time $R_t = 3.4$ min. (approx.).

The quantitative analysis was performed using the external calibration curve constructed with a series of calibration solutions having concentrations: 1% SAR (0.86 μg FOE Sulfonic acid/L), 5% SAR (4.3 μg FOE Sulfonic acid/L), 10% SAR (8.6 μg FOE Sulfonic acid/L), 50% SAR (43 μg FOE Sulfonic acid/L), 100% SAR (86 μg FOE Sulfonic acid/L) and 150% SAR (129 μg FOE Sulfonic acid/L), where SAR stands for Standard Application Rate defined as 34.4 μg test compound/400 mL of extract. Two types of calibration curves were constructed:

- in CH_3CN ;
- in respective blank soil matrix for each test soil.

The calibration curves in blank soil matrices were prepared in the following way:

- to obtain blank soil matrix solutions 100-g (d.w.) portions of each test soil were weighed into 1-L centrifuge beakers and extracted in a way identical to that presented on figure B.8.1.1.2.1.1._CA-70; in that way the following blank soil matrix solutions were prepared: AX (Laacherhof AXXa soil), DD (Dollendorf II soil), HH (Höfchen am Hohenseh 4a soil) and WW (Wurmweise soil);
- next, each of listed above calibration solutions was prepared by:
 - pipetting 0.375 mL of the **Ja 66 SS D1** solution into 25-mL volumetric flask and bringing it to volume with the adequate amount of the given blank soil matrix solution to obtain 150% SAR calibration solution,
 - pipetting 0.25 mL of the **Ja 66 SS D1** solution into 25-mL volumetric flask and bringing it to volume with the adequate amount of the given blank soil matrix solution to obtain 100% SAR calibration solution,
 - pipetting 1.25 mL of the **Ja 66 SS D2** solution into 25-mL volumetric flask and bringing it to volume with the adequate amount of the given blank soil matrix solution to obtain 50% SAR calibration solution,
 - pipetting 0.25 mL of the **Ja 66 SS D2** solution into 25-mL volumetric flask and bringing it to volume with the adequate amount of the given blank soil matrix solution to obtain 10% SAR calibration solution
 - pipetting 0.5 mL of the **Ja 66 SS D2** solution into 100-mL volumetric flask and bringing it to volume with the adequate amount of the given blank soil matrix solution to obtain 5% SAR calibration solution,
 - pipetting 0.1 mL of the **Ja 66 SS D2** solution into 100-mL volumetric flask and bringing it to volume with the adequate amount of the given blank soil matrix solution to obtain 1% SAR calibration solution.

That resulted in four calibration curves, one for extracts from each test soil – AX calibration curve, DD calibration curve, HH calibration curve and WW calibration curve.

Additionally the calibration curve in CH_3CN – ACN calibration curve, was prepared in the same way as described above, with exception that the appropriate amounts of the solutions containing the test compound were diluted with CH_3CN instead of the appropriate blank soil matrix solution. That calibration curve was used in the quantitative analysis aimed on the verification of application rate and homogeneity of application.

The obtained results – concentrations of FOE Sulfonic acid in each test soil at each time point, were subjected to the kinetic analysis in order to identify the best-fit kinetic model and determine persistence and modelling kinetic endpoints for FOE Sulfonic acid in each test soil.

The kinetic analysis was performed in line with the recommendations of the FOCUS Kinetics Guidance Document [FOCUS; 2006], using KinGUI 2 modelling tool. It followed the procedure used in several already summarised studies, in particular **Study 4** and **Study 5**. Three kinetic models were used in the assessment –

SFO, FOMC and DFOP. The obtained fits were evaluated using the same principles as presented in the summaries of **Studies 2 – 8**.

The results of the study are presented below.

Results and their discussion:

The results of the determination of soil physicochemical properties and soil microbial activity in each test soil are presented in the table B.8.1.1.2.1.1._CA-150 at the beginning of this summary. On their basis it can be stated that the soils were appropriately selected, in line with the recommendations of OECD 307 Guideline, and were biologically viable throughout the experiment.

The results of the monitoring of the incubation temperature are presented below on figure B.8.1.1.2.1.1._CA-71. In the study report it was stated that the main incubation temperature was 19.6°C and it ranged from 18.9°C to 20.3°C.

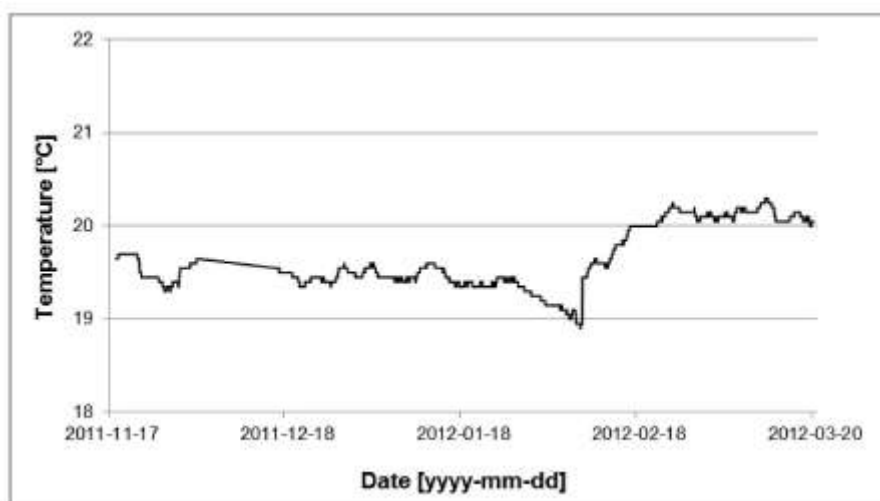

Figure B.8.1.1.2.1.1._CA-71: The temperature recorded during soil pre-conditioning and samples incubation period (copied from the study report).

The results of the monitoring of soil moisture during the experiment are presented below, in the table B.8.1.1.2.1.1._CA-152. On their basis it may be stated that this parameter was maintained on the assumed level during the whole experiment.

Table B.8.1.1.2.1.1._CA-152: The results of the determination of soil moisture content

Test soil	Soil moisture content [g H ₂ O/100 g soil]			Soil moisture during incubation [% MWHC]		
	MWHC	55% MWHC	Actual – in sieved soil	mean	min.	max.
Laacherhof AXXa	48.9	26.7	15.6	55.0	50.5	59.4
Dollendorf II	79.1	43.5	21.9	54.9	52.2	58.3
Höfchen am Hohenseh 4a	54.8	30.1	18.7	54.5	50.5	58.2
Wurmweise	56.3	31.0	18.5	55.2	50.6	59.9

The results of the determination of application rate and the homogeneity of application for DAT 0 – DAT 120 samples were following:

- the amount of the test compound applied per test system at the beginning of application cycle was 34.06 µg (99.0% Standard Application Rate);
- the amount of the test compound applied per test system in the middle of application cycle was 35.26 µg (102.5% Standard Application Rate);
- the amount of the test compound applied per test system at the end of application cycle was 35.00 µg (101.7% Standard Application Rate);

- the mean amount of the test compound applied per test system was 34.77 µg (101.1% Standard Application Rate) with RSD = 1.5%.

In case of additional DAT-1 samples it was 34.54 µg (100.4% Standard Application Rate) with RSD = 1.3% and for DAT-3 samples – 33.15 µg (96.4% Standard Application Rate) with RSD = 1.0%.

On that basis it was stated that the application was homogenous and in good agreement with assumed theoretical application rate of 34.4 µg/100 g soil (d. w.).

The LOQ – limit of quantification, was defined as 5% of nominal study application rate of 344 µg/kg soil, and was equal to 17.2 µg/kg soil. The corresponding LOD was set to $\frac{1}{5}$ LOQ – 1% of the nominal study application rate of 344 µg/kg soil, and was equal to 3.44 µg/kg soil. The values were determined experimentally by examining the linearity of the response of MS/MS detector to the calibration curve built on Blank Soil Matrix AX (Laacherhof AXXa soil). Only the curve based on that Blank Soil Matrix was used because it was stated that the matrix effects were of the same order of magnitude for all investigated soils. The numerical results of that examination are presented below in the table B.8.1.1.2.1.1._CA-153. In the study report it was stated that the excellent correlation between the concentration of the test item and the detector's response was achieved, with $R^2 = 0.9999$. As the graphical presentation of the results caused some problems with its interpretation, RMS repeated the analysis using the CurveExpert Professional 1 tool. The results are presented in graphical form below on figure B.8.1.1.2.1.1._CA-72, conforming the excellent linearity of the detector's response and hence the correctness of the determined LOQ and LOD values.

Table B.8.1.1.2.1.1._CA-153: The numerical results of the determination of the linearity of the response of MS/MS detector.

Calibration sample No.	Nominal concentration		Peak area [a.u.]			RSD [%]
	[% AA]	[ng/mL]	Replicate 1	Replicate 2	Mean	
1	1	0.86	654731	661032	657882	0.5
2	5	4.3	3275334	3237584	3256459	0.6
3	10	8.6	6581627	6467002	6524315	0.9
4	50	43.0	31740125	32235509	31987817	0.8
5	100	86.0	63011508	63058516	63035012	0.0
6	150	129.0	90028439	91279930	90654185	0.7

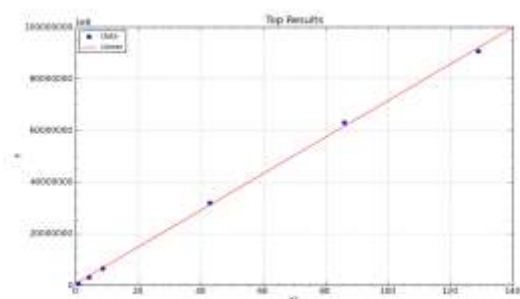

Table B.8.1.1.2.1.1._CA-72: The graphical results of the determination of the linearity of the response of MS/MS detector – calibration curve.

The determination of the accuracy and precision of the method, assessed on the basis of the recovery rates at LOQ level (5% SAR) and application level (100% SAR), looked as follows:

- for Laacherhof AXXa soil mean recovery at LOQ and AR level was 99.3% (96.4 – 102.9%) with RSD = 1.9%;
- for Dollendorf II soil mean recovery at LOQ and AR level was 99.3% (97.6 – 101.1%) with RSD = 1.2%;
- for Höfchen am Hohenseh 4a soil mean recovery at LOQ and AR level was 100.7% (96.6 – 104.0%) with RSD = 2.4%;
- for Wurmwielse soil mean recovery at LOQ and AR level was 98.1% (95.5 – 101.9%) with RSD = 1.9%;
- the mean recovery at LOQ and AR level was 99.4% with RSD = 2.1%.

The results of the experiment – concentrations of FOE Sulfonic acid in soil in function of time, are presented below in the table B.8.1.1.2.1.1._CA-154. For each test soil the concentrations of the test compound are reported

as % of applied amount – [% AA] and in [µg/kg soil]. The values expressed as [%AA] were calculated using the following assumptions:

- for all samples, except DAT-1 and DAT-3 samples, the application rate was determined to be 347.7 µg/kg soil and that value was set to 100% AA (Applied Amount);
- for DAT-1 samples the application rate was determined to be 345.3 µg/kg soil and that value was set to 100% AA (Applied Amount);
- for DAT-3 samples the application rate was determined to be 331.5 µg/kg soil and that value was set to 100% AA (Applied Amount).

The graphic presentation of the results is given on figure B.8.1.1.2.1.1._CA-73.

Table B.8.1.1.2.1.1._CA-154: Concentration of FOE Sulfonic acid in test soils in function of time.

Figure B.8.1.1.2.1.1._CA-73: The graphic presentation of the obtained results (copied from the study report).

The data presented in the table B.8.1.1.2.1.1._CA-1543 were subjected to the kinetic analysis aimed on the determination of the best kinetic fit and derivation of the kinetic endpoints representing persistence of the test compound and suitable for modelling. For that purpose the values obtained for replicates, expressed as [%AA] were used. The values were inserted to the model as they are given in the table above. The results of the kinetic analysis are presented below, separately for each test soil.

- 1) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Laacherhof AXXa soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-74 and in numerical form in the table B.8.1.1.2.1.1._CA-155. Additionally the table B.8.1.1.2.1.1._CA-156 provides the kinetic endpoints obtained with each of the kinetic models tested.

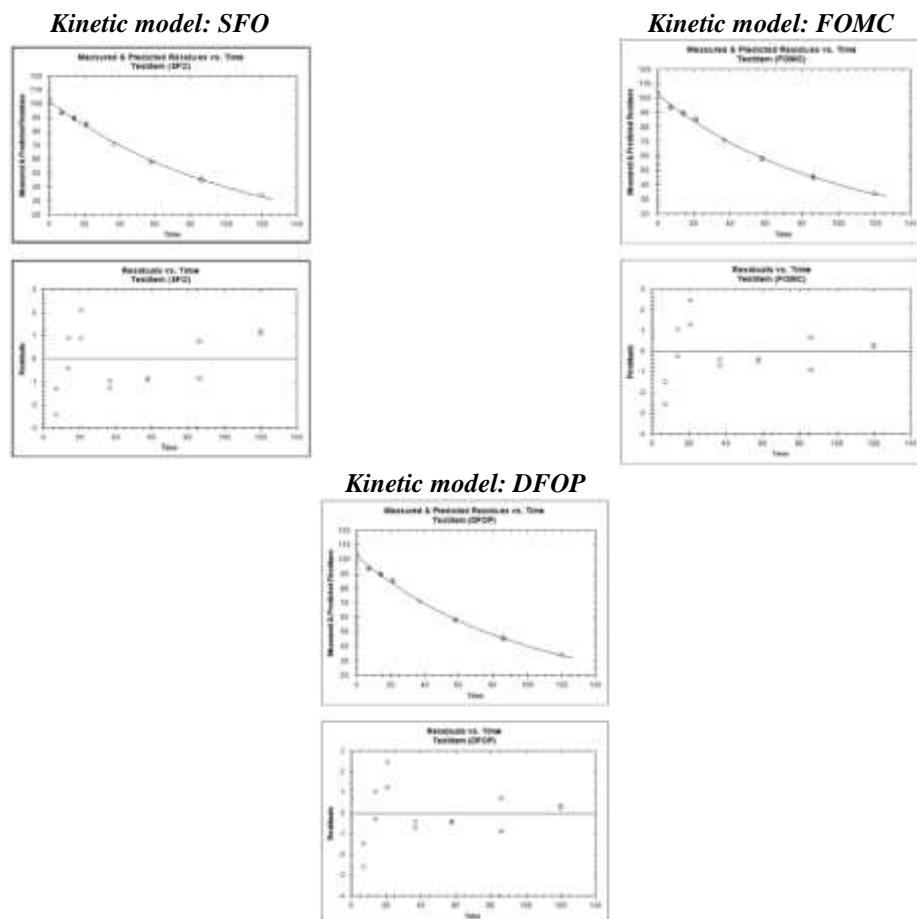

Figure B.8.1.1.2.1.1._CA-74: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-155: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	101.9	0.586	100.8	103.09	< 2 E-16	1.275	Good fit
	k	0.009446	1.678 E-4	0.009117	0.017	< 2 E-16		
FOMC	M_0	102.555	0.695	101.193	103.92	< 2 E-16	1.232	Good fit
	α	6.6259	4.61635	-2.4218	15.67	0.0874		
	β	655.8761	4876.5089	-299.624	1611.38	0.1008		
DFOP	M_0	102.511	0.752	101.037	103.985	< 2 E-16	1.325	Good fit
	k_1	0.01227	0.00510	0.00228	0.022	0.01654		
	k_2	0.004977	0.00372	-0.00233	0.012	0.1034		
	g	0.6916	0.5529	-0.3921	1.775	0.1174		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-156: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Sulfonic acid</i>	DT ₅₀ [days]	73.38	72.33	72.31
	DT ₉₀ [days]	243.77	272.55	278.41

Conclusion:

All three models returned visually and statistically good fits. In terms of χ^2 error the best fit was obtained using FOMC model, although it shall be pointed out that the value of that parameter was very close for all three models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. In case of DFOP not fully reliable were k_2 and g – for both of them *prob. > t* was higher than 0.1. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Laacherhof AXXa soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 2) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Dollendorf II soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-75 and in numerical form in the table B.8.1.1.2.1.1._CA-157. Additionally the table B.8.1.1.2.1.1._CA-158 provides the kinetic endpoints obtained with each of the kinetic models tested.

	k_2	0.08274	0.02501	0.03373	0.132	0.00395		
	g	0.2460	0.3295	-0.3999	0.892	0.2363		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1_CA-158: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Sulfonic acid</i>	DT ₅₀ [days]	6.71	6.23	6.15
	DT ₉₀ [days]	22.30	24.55	24.46

Conclusion:

All three models returned visually and statistically good fits. In terms of χ^2 error the best fit was obtained using FOMC model, although it shall be pointed out that the value of that parameter was very close for all three models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. In case of DFOP not fully reliable were k_I and g – for both of them *prob. > t* was higher than 0.1. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Dollendorf II soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 3) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Höfchen am Hohenseh 4a soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-76 and in numerical form in the table B.8.1.1.2.1.1._CA-159. Additionally the table B.8.1.1.2.1.1._CA-160 provides the kinetic endpoints obtained with each of the kinetic models tested.

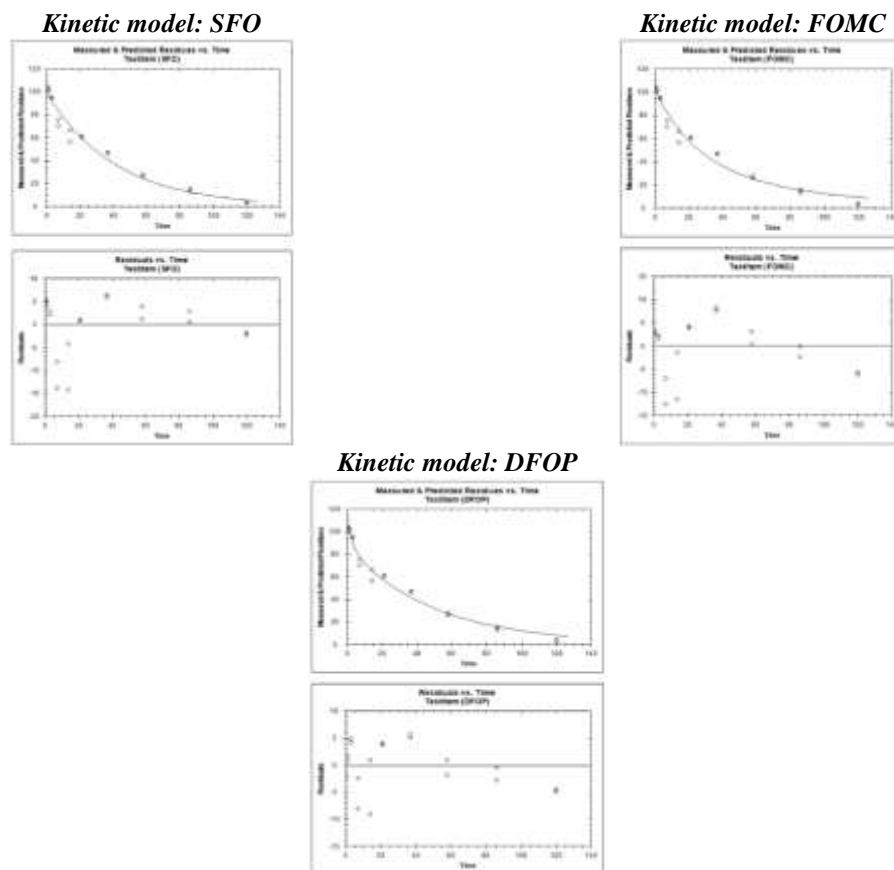

Figure B.8.1.1.2.1.1._CA-76: The graphical results of the kinetic analysis (copied from the study report).

	k ₂	0.019673	1.704 E-3	0.01633	0.023	1.81 E-9		
	g	0.1985	0.04972	0.1011	0.296	5.24 E-4		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-160: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Sulfonic acid</i>	DT ₅₀ [days]	28.58	25.25	24.03
	DT ₉₀ [days]	94.95	113.44	105.82

Conclusion:

All three models returned visually and statistically good fits. In terms of χ^2 error the best fit was obtained using DFOP model, which also returned, as it was in case of SFO model, fully reliable kinetic parameters. It was noted that both tested bi-phasic models returned the fits that were statistically superior to SFO fit. At the same time in case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Applicant identified DFOP as the model returning the best fit, fully reliable in terms of determined kinetic parameters for FOE Sulfonic acid in Höfchen am Hohenseh 4a soil.

RMS, agreeing in principle with that proposal, noticed that SFO returned fit that was visually and statistically good. The χ^2 error was well below the threshold value of 15%, the distribution of experimental points well correlated with the decline curve (it was comparable to what was obtained using DFOP model), and the residuals on the similar level to that determined for DFOP fit, with also comparable distribution.

All that taken into account, RMS is of the opinion that SFO fit may be considered appropriate as returning persistence and modelling kinetic endpoints. Such selection may be also supported by recommendation given by the relevant Guidelines that whenever it is possible SFO should be selected as first choice, also in order to avoid overparametrisation during the model exposure assessment.

Therefore the final conclusion from that fitting is following: the SFO is of the sufficient quality to be considered as fully appropriate to derive persistence and modelling endpoints for FOE Sulfonic acid in Höfchen am Hohenseh 4a soil.

- 4) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Wurmwiese soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-77 and in numerical form in the table B.8.1.1.2.1.1._CA-161. Additionally the table B.8.1.1.2.1.1._CA-162 provides the kinetic endpoints obtained with each of the kinetic models tested.

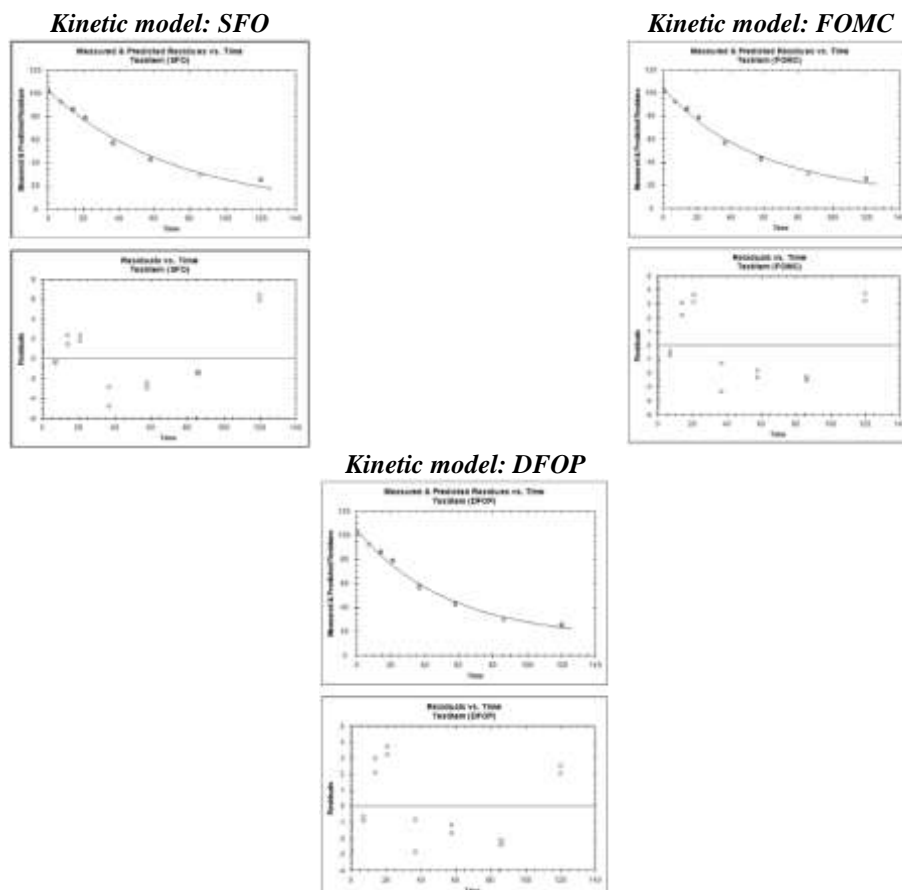

Figure B.8.1.1.2.1.1._CA-77: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-161: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	102.2	1.521	99.20	105.161	< 2 E-16	3.662	Good fit
	k	0.01393	5.539 E-4	0.01284	0.015	2.36 E-13		
FOMC	M_0	103.992	1.604	100.847	107.136	< 2 E-16	3.304	Good fit
	α	3.5269	1.63475	0.3228	6.731	0.0251		
	β	215.7837	115.7458	-11.0739	442.641	0.0425		
DFOP	M_0	104.20	1.399	101.4	106.917	< 2 E-16	3.164	Moderate fit
	k_1	0.01852	4.373 E-3	9.946 E-3	0.027	5.79 E-4		
	k_2	2.402 E-9	0.01392	-0.02729	0.027	0.500		
	g	0.8733	0.2748	0.3347	1.412	3.977 E-3		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-161: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Sulfonic acid</i>	DT ₅₀ [days]	49.77	46.86	45.90
	DT ₉₀ [days]	165.32	198.75	Not determined

Conclusion:

All three models returned visually and statistically good fits, although DFOP fit was classified in the study report as moderate. However, in RMS's opinion it visually did not significantly differ from other two fits, classified as "good". In terms of χ^2 error the best fit was obtained using DFOP model, although it shall be pointed out that the value of that parameter was very close for all three models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated β was not reliable because CI for it passed through zero. In case of DFOP not fully reliable was k_2 – for that parameter the *prob. > t* was much higher than 0.1, reaching the level of 0.5. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Wurmwiese soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-163.

Table B.8.1.1.2.1.1._CA-163: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
Soil name	Soil type (USDA)	OC [%]	pH ¹⁾			χ^2 error	Visual fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]

2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

Study 12:

Report: Ströch K., Junge T., (2013): „FOE sulfonic acid: Degradation in Four Aerobic Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany; unpublished Study Report No. EnSa-13-0618; 2013. 10. 24; ; study reference number: M-467862-01-1;

Guidelines: The study was declared to be performed in line with the provisions of the OECD Guideline for the Testing of Chemicals No. 307 – Aerobic and Anaerobic Transformation in Soil. The Applicant stated that there was no deviations from that Guideline. Additionally, as the data obtained in the study were kinetically evaluated and the results presented in the study report, it was declared that the following Guideline was used:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;

In this case also no deviations from the Guideline referred to were stated.

GLP: Yes;

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to determine the kinetic degradation rate of FOE Sulfonic acid in aerobic soil incubated under laboratory conditions. The experiment was performed on four test soils taken from the agriculturally used areas representing different geographical origin and different soil properties, in line with the requirements of the relevant Guideline. Their characteristic is provided in the table B.8.1.2.1.1._CA-164.

Table B.8.1.2.1.1.CA-164: The characteristic of soils used in the study.

Parameter		Soil

- 1) Value calculated from experimentally determined OC content, using the following equation: OM = 1.724 OC;
- 2) Determined using the SIR method developed by Anderson & Domsch [1978];
- 3) Values recalculated by the RMS using the OC content reported in the table for each test soil;
- 4) Determined in samples not treated with blank application solution – 0.4 mL of 1:1 CH₃OH/H₂O; instead 0.2 mL of distilled water was added;
- 5) Determined in samples treated with blank application solution – 0.4 mL of 1:1 CH₃OH/H₂O;

The test soils were sampled shortly before being used (14 days before the experiment began) with shovel from 0-20 cm layer of grassland plot. No Plant Protection Products were used on the sampling fields for 5 years preceding sampling. The sampled test soils were transported to the test facility in plastic bags. There they were sieved through 2-mm sieve and stored in the darkness at either $T < 8^{\circ}\text{C}$ or $T = 20^{\circ}\text{C}$ until being used. The whole soil sampling-and-handling procedure was declared to be performed in accordance with ISO 10381-6.

The experiment was performed using 300-mL Erlenmeyer flasks into which 100-g (d. w.) portions of sieved test soils were weighed. Next the soil moisture content of each sample was adjusted to $55 \pm 5\%$ MWHC by addition of the appropriate amount of deionised water. So prepared incubation flasks were capped with PU plugs to allow free air exchange. The example incubation vessel is presented below on figure B.8.1.1.2.1.1._CA-78. After adjustment of the soil moisture the incubation vessels were pre-conditioned for 3 days in the dark, in a temperature-controlled walk-in climatic chamber at $T = 20 \pm 2^{\circ}\text{C}$, until being treated with the test compound. The number of incubation vessels prepared for each test soils was such to grant at least to have duplicate treated samples at each sampling point and those for the determination of soil biomass in soil samples not treated and treated with blank application solution.

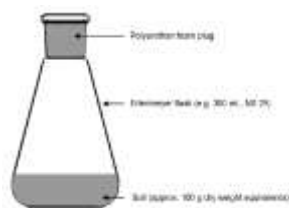

Figure B.8.1.1.2.1.1._CA-78: The example incubation vessel (copied from the study report).

The test compound was non-radiolabelled FOE Sulfonic acid in form of Na^+ salt, having the chemical purity (determined by ^{19}F -NMR) of 87.6%. Its structural formula is shown below on figure B.8.1.1.2.1.1._CA-79.

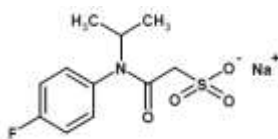

Figure B.8.1.1.2.1.1._CA-79: The structural formula of the test compound used in the experiment (copied from the study report).

It was delivered as a solid sample, in form of a white powder. The whole delivered amount of the test compound was used to prepare first a **Stock solution** and then **Application solutions**.

The **Stock solution** was prepared by dissolving the whole delivered sample of FOE Sulfonic acid Na^+ salt in 2.0 mL of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ (1:1 v/v) sonicated for 10 minutes, to obtain a solution having a nominal concentration 8.8 mg FOE Sulfonic acid/mL. The so prepared **Stock solution**, labelled **TM109_SS**, was stored in the darkness at $T \leq -18^{\circ}\text{C}$ until being used.

The **Stock solution TM109_SS** was subsequently used to prepare the Application solution of Test Item at Application Rate Level, labelled **TM109_AS_AR**, further called **Application solution TM 109_AS_AR**. The **Application solution TM 109_AS_AR** was in turn used to prepare the Application solution of Test Item at LOQ Level, labelled **TM109_AS_LOQ**, further called **Application solution TM 109_AS_LOQ**.

The **Application solution TM 109_AS_AR** was used to treat degradation samples and method validation samples, and to create the calibration curve used in quantitative HPLC-MS/MS analysis. The **Application solution TM 109_AS_LOQ** was used for treatment of concurrent recovery samples at LOQ and for method validation.

The **Application solution TM 109_AS_AR** was prepared by transferring 0.982 mL of the **Stock solution TM109_SS** into 100-mL volumetric flask and evaporating it to dryness under the constant gentle stream of N_2 . The residue was redissolved in 100 mL of $\text{CH}_3\text{OH}/\text{H}_2\text{O}$ 1:1 (v/v) and sonicated for 10 minutes. The obtained solution had a nominal concentration 86.4 $\mu\text{g}/\text{mL}$. The identity of the test compound in so prepared solution was conformed by HPLC-MS/MS. The **Application solution TM 109_AS_AR** was stored in the dark at $T \leq 8^{\circ}\text{C}$.

The **Application solution TM 109_AS_LOQ** was prepared from **Application solution TM 109_AS_AR** by diluting it. That was done in the following way: 2.5 mL of the **Application solution TM 109_AS_AR** was transferred to the 50-mL volumetric flask, brought to volume with the adequate amount of $\text{CH}_3\text{OH}/\text{H}_2\text{O}$ 1:1 (v/v)

and sonicated for 10 minutes. The obtained solution had a nominal concentration 4.3 µg/mL. That solution was also stored in the dark at $T \leq 8^{\circ}\text{C}$.

Additionally the stable-labelled test compound was used in the experiment. The labelling was performed in isopropyl group and consisted on replacing ^1H (*protium*) atoms with ^2H (*deuterium*; marked with symbol D) atoms. Its structural formula is presented below on figure B.8.1.1.2.1.1._CA-80. The compound's chemical purity was 84.8%. It was used as an internal standard in quantitative analysis of FOE Sulfonic acid performed using HPLC-MS/MS method.

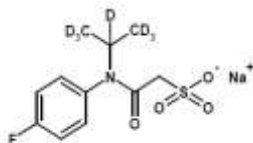

Figure B.8.1.1.2.1.1._CA-80: The structural formula of the deuterised test compound (internal standard) used in the experiment (copied from the study report).

It was delivered as a solid sample, in form of a white powder. The whole delivered amount of the test compound was used to prepare first a **Stock solution** and then a set of **Internal standard solutions**.

The **Stock solution** was prepared by dissolving the whole delivered sample of ^2H - FOE Sulfonic acid Na^+ salt in 5.0 mL of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ (1:1 v/v) sonicated for 10 minutes, to obtain a solution having a nominal concentration 0.848 mg ^2H - FOE Sulfonic acid /mL. The so prepared **Stock solution**, labelled **TM109IS_SS**, was stored in the dark at $T \leq -18^{\circ}\text{C}$ until being used.

The prepared from **TM109IS_SS** solution **Internal standard solutions** were following:

- **Internal standard solution TM109IS_AR**, prepared by transferring 2.028 mL of the **Stock solution TM109IS_SS** into 50-mL volumetric flask, bringing it to the volume with the appropriate amount of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 1:1 (v/v) and sonicating it for 10 minutes; the nominal concentration of so prepared solution was 0.0344mg/mL;
- **Internal standard solution TM109IS_D1**, prepared by transferring 0.203 mL of the **Stock solution TM109IS_SS** into 20-mL volumetric flask, bringing it to the volume with the appropriate amount of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 1:1 (v/v) and sonicating it for 10 minutes; the nominal concentration of so prepared solution was 0.0086mg/mL;
- **Internal standard solution TM109IS_D2**, prepared by transferring 5 mL of the **Internal standard solution TM109IS_D1** into 50-mL volumetric flask, bringing it to the volume with the appropriate amount of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 1:1 (v/v) and sonicating it for 10 minutes; the nominal concentration of so prepared solution was 0.0022mg/mL;

All listed above **Internal standard solutions** were stored in the darkness at $T \leq -18^{\circ}\text{C}$. **Internal standard solution TM109IS_AR** was added to soil extracts and was used in the verification of application rate and homogeneity of application. The **Internal standard solution TM109IS_D2** was added to the standard solutions used to construct calibration curve.

The **Application solution TM 109_AS_AR** was used to treat degradation samples. To do that 0.4 mL of it was applied dropwise onto soil surface in each incubation vessel to obtain the target application dose of 34.4 µg FOE Sulfonic acid/100 g soil (d. w.). That application dose – equal to 0.344 mg/kg soil was determined using the following assumptions:

- field application rate of Flufenacet (parent compound, precursor of FOE Sulfonic acid): 600 g/ha;
- maximum occurrence of FOE Sulfonic acid in aerobic soil (determined in the laboratory studies): 26.3%;
- molar weight of Flufenacet $M = 363.3$ g/mol;
- molar weight of FOE Sulfonic acid $M' = 297.3$ g/mol;
- soil bulk density: 1.5 g/cm^3 ;
- thickness of the soil layer: 2.5 cm.

RMS analysing the calculations noticed that the assumed soil layer was $\frac{1}{2}$ of that routinely used to calculate field application rate (in [g/ha]) from that expressed in mg/kg soil. Therefore the RMS back calculated the would-be field application rate for FOE Sulfonic acid using the standard assumptions:

- soil bulk density: 1.5 g/cm^3 ;
- thickness of the soil layer: 5 cm.

The so calculated theoretic field application rate **A = 258.0 g FOE Sulfonic acid/ha**.

Using the measured soil bulk density of each test soil used in the experiment that value would be:

- for Hanscheider Hof soil: **A = 178.88 g/ha**;
- for Frankfirst soil: **A = 197.80 g/ha**;
- for LUFA 2.3 soil: **A = 220.16 g/ha**;
- for LUFA 6S soil: **A = 209.84 g/ha**

The verification of application rate and homogeneity of application was performed using **Application solution TM 109_AS_AR**, at the beginning of application procedure and after treatment of each test soil. That was done by transferring of 0.4-mL portions of the **Application solution TM 109_AS_AR** into 250-mL volumetric flasks, to which 0.1-mL portions of the **Internal standard solution TM109IS_AR** were added next. The solutions were then brought to volume with the appropriate amount of CH₃OH/H₂O 1:1 (v/v) and mixed thoroughly.

The same **Application solution** and the **Application solution TM 109_AS_LOQ** were used to treat the Concurrent Recovery Samples. The dosing of each application solution was the same as for degradation samples – 0.4 mL/100 g soil. That resulted in fortification level of 0.344 mg/kg soil for samples treated with **Application solution TM 109_AS_AR** and 1.72 µg/100 g/soil (0.072 mg/kg soil) – 5% of the nominal application rate, for samples treated with **Application solution TM 109_AS_LOQ**. The samples were freshly prepared at each sampling point using LUFA 2.3 soil.

The verification of application rate and homogeneity of application was performed in the same way as for degradation samples.

Immediately after treatment the incubation vessels designated as degradation samples were closed with PU plugs to grant free access of air, placed in the darkness in temperature-controlled walk-in climatic chamber and incubated for up to 120 days under aerobic conditions at $T = 20 \pm 2^{\circ}\text{C}$. Duplicate samples were removed from incubation chamber at following time-points (DAT stands for “Days After Treatment”): DAT 0, DAT 2, DAT 4, DAT 7, DAT 14, DAT 30, DAT 58, DAT 91 and DAT 120 (last time point was set only for LUFA 2.3 and LUFA 6S soils).

The soil moisture content in incubation vessels was controlled by weighing them at designated time points: DAT 0, DAT 2, DAT 4, DAT 7, DAT 11, DAT 14, DAT 23, DAT 30, DAT 38, DAT 45, DAT 52, DAT 58, DAT 67, DAT 79, DAT 91, DAT 107 and DAT 120. Soil moisture in the test vessels was adjusted to the designated level, by addition of appropriate amount of deionised water at following time-points: DAT 4, DAT 14, DAT 23, DAT 30, DAT 38, DAT 45, DAT 52, DAT 67, DAT 79 and DAT 107.

The samples for the determination of soil biomass were set alongside the degradation samples. The soil biomass was determined in pre-conditioned test soil samples sampled on DAT 0 (beginning of the incubation period), DAT 58 (middle of the incubation period) and DAT 121 (end of incubation period). The experiment was performed in two variants:

- “BIO-” samples, not treated with blank application solution (instead, 0.2 mL of distilled water was added to each test vessel) ; these samples were taken for the analysis on DAT 0, DAT 58 and DAT 121;
- “BIO+” samples, treated with 0.4 mL of blank application solution (CH₃OH/H₂O 1:1 v/v); these samples were taken for the analysis on DAT 58 and DAT 121.

Samples removed from the incubation chamber were processed and analysed immediately after sampling. That was done using the entire portions of the test soil recovered at each sampling point, using the procedure presented below on figure B.8.1.1.2.1.1._CA-81. The same procedure was applied to Concurrent Recovery Samples.

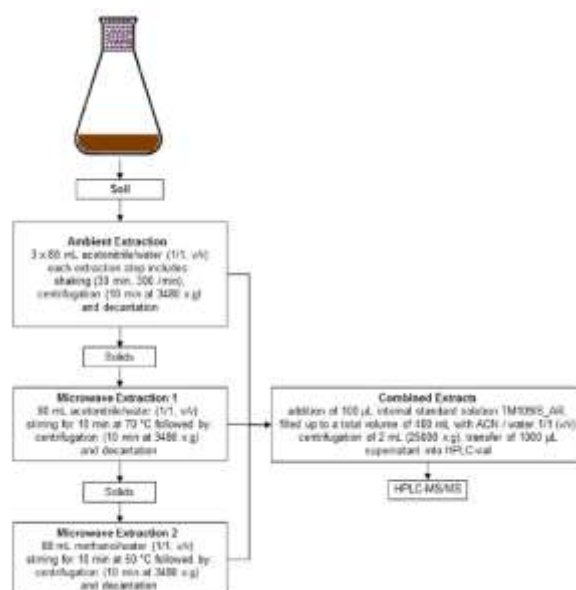

Figure B.8.1.1.2.1.1_CA-81: The sample-processing procedure used in the experiment (scheme copied from the study report, slightly modified by the RMS to increase its transparency).

The quantitative and qualitative analysis of combined soil extracts and other liquid samples was performed by means of HPLC-MS/MS. The analysis was performed using HP1200 chromatography workstation equipped with UV absorption detector and Finnigan TSQ Vantage (Thermo Electron Corporation, San Jose, CA, USA) MS detector. The chromatographic separation was performed on Nucleodur Gravity C8 50*2 mm * 5 µm chromatographic column working in a gradient mode. The column was maintained at constant temperature $T = 40^{\circ}\text{C}$. The gradient elution programme is presented below in the table B.8.1.1.2.1.1_CA-165.

Table B.8.1.1.2.1.1_CA-165: The HPLC gradient modes used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% HCOOH</i>	<i>Solvent B – Acetonitrile + 0.1% HCOOH</i>
0	95	5
1	95	5
2	50	50
5	40	60
6	5	95

The elution lasted for 6 minutes and the flow rate of the mobile phase was 0.3 mL/min.

The identification of the test compound was performed by means of MS analysis using the following MS signals:

- for non-labelled test item: $m/z = 276.1$ as parent ion and $m/z = 234.1$ as product ion (quantifier);
- for ^2H -labelled internal standard: $m/z = 283.1$ as parent ion and $m/z = 2354.1$ as product ion (quantifier).

Additional identification parameter for FOE Sulfonic acid was the retention time $R_t = 3.5$ min. (approx.).

The quantitative analysis was performed using the external calibration curve constructed using the calibration solutions having concentration: 1% SAR (0.86 µg FOE Sulfonic acid/L), 5% SAR (4.3 µg FOE Sulfonic acid/L), 10% SAR (8.6 µg FOE Sulfonic acid/L), 50% SAR (43 µg FOE Sulfonic acid/L), 100% SAR (86 µg FOE Sulfonic acid/L) and 150% SAR (129 µg FOE Sulfonic acid/L), where SAR stands for Standard Application Rate, defined as 34.4 µg test compound in 400 mL of extract. The calibration curve was constructed using $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 1:1 (v/v) as a solvent.

The procedure of the preparation of calibration curve is described below.

Firstly the **Standard solution TM109_SS_D1** was prepared by transferring 2 mL of the **Application solution TM 109_AS_AR** to 20-mL volumetric flask, filling it to the volume with the appropriate amount of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 1:1 (v/v) and sonicating for 10 minutes. The nominal concentration of so obtained solution was 8.6 µg/mL. That solution was used to prepare next dilute – **Standard solution TM109_SS_D2**. That was done by

transferring 2 mL of the **Standard solution TM109_SS_D1** to 20-mL volumetric flask, filling it to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicating for 10 minutes. The nominal concentration of so obtained solution was 0.86 µg/mL. These two **Standard solutions** were stored in the dark at T ≤ -18°C until being used.

The solutions used to build calibration curve were freshly prepared on the day of measurements in the following way:

- 0.375 mL of the **Standard solution TM109_SS_D1** and 0.1 mL of the **Internal standard solution TM109IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 150% SAR calibration solution,
- 0.25 mL of the **Standard solution TM109_SS_D1** and 0.1 mL of the **Internal standard solution TM109IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 100% SAR calibration solution,
- 0.125 mL of the **Standard solution TM109_SS_D1** and 0.1 mL of the **Internal standard solution TM109IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 50% SAR calibration solution,
- 0.25 mL of the **Standard solution TM109_SS_D2** and 0.1 mL of the **Internal standard solution TM109IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 10% SAR calibration solution
- 0.125 mL of the **Standard solution TM109_SS_D2** and 0.1 mL of the **Internal standard solution TM109IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 5% SAR calibration solution,
- 0.025 mL of the **Standard solution TM109_SS_D2** and 0.1 mL of the **Internal standard solution TM109IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 1% SAR calibration solution.

The obtained results – concentrations of FOE Sulfonic acid in each test soil at each time point, were subjected to the kinetic analysis in order to identify the best-fit kinetic model and determine persistence and modelling kinetic endpoints for FOE Sulfonic acid in each test soil.

The kinetic analysis was performed in line with the recommendations of the FOCUS Kinetics Guidance Document [FOCUS; 2006], using KinGUI 2 modelling tool. It followed the procedure used in several already summarised studies, in particular **Study 4** and **Study 5**. Two kinetic models were used in the assessment – SFO and FOMC. The obtained fit were evaluated using the same principles as presented in the summaries of **Studies 2 – 8**.

The results of the study are presented below.

Results and their discussion:

The results of the determination of soil physicochemical properties and soil microbial activity in each test soil are presented in the table B.8.1.1.2.1.1._CA-164 at the beginning of this summary. On their basis it can be stated that the soils were appropriately selected, in line with the recommendations of OECD 307 Guideline, and were biologically viable throughout the experiment.

The results of the monitoring of the incubation temperature are presented below on figure B.8.1.1.2.1.1._CA-82. In the study report it was stated that the main incubation temperature was 19.9°C and it ranged from 19.4°C to 20.7°C.

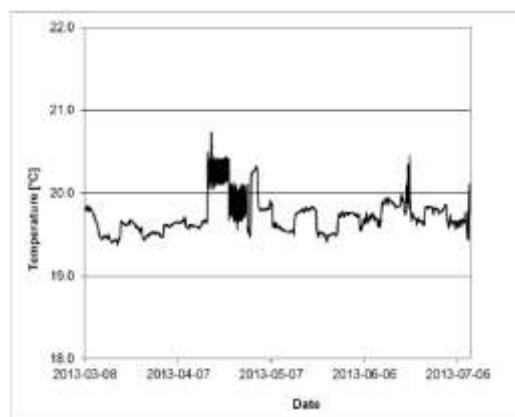

Figure B.8.1.1.2.1.1_CA-82: The temperature recorded during soil pre-conditioning and samples incubation period (copied from the study report).

The results of the monitoring of soil moisture content during the experiment are presented below, in the table B.8.1.1.2.1.1_CA-166. On their basis it may be stated that this parameter was maintained on the assumed level during the whole experiment.

Table B.8.1.1.2.1.1_CA-166: The results of the determination of soil moisture content

Test soil	Soil moisture content [g H ₂ O/100 g soil]			Soil moisture during incubation [% MWHC]		
	MWHC	55% MWHC	Actual – in sieved soil	mean	min.	max.
Herscheider Hof	64.4	35.4	27.6	55.4	51.8	58.0
Frankenforst	56.7	31.2	17.1	55.2	52.2	58.1
LUFA 2.3	39.3	21.6	8.0	54.5	50.2	58.1
LUFA 6S	48.3	26.6	8.5	54.9	51.0	58.0

The results of the determination of application rate and the homogeneity of application for DAT 0 – DAT 120 samples were following:

- the application rate at the beginning of the process was determined to be 422.4 µg/kg;
- the application rate at the end of the 1st series was determined to be 420.4 µg/kg;
- the application rate at the end of the 2nd series was determined to be 418.3 µg/kg;
- the application rate at the end of the 3rd series was determined to be 415.6 µg/kg;
- the application rate at the end of the 4th series was determined to be 420.4 µg/kg;
- the mean application rate was determined to be 419.4 µg/kg with RSD = 0.6%.

On that basis it was stated that the application was homogenous and in good agreement with assumed theoretical application rate.

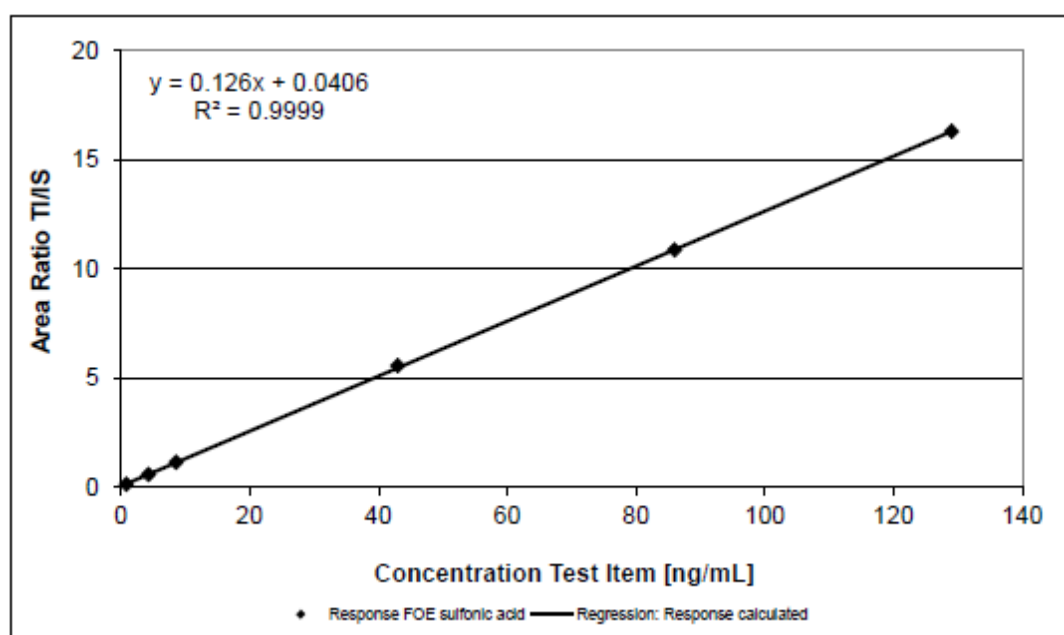

The LOQ – limit of quantification, was defined as 5% of nominal study application rate of 344 µg/kg soil, and was equal to 17.2 µg/kg soil. The corresponding LOD was set to $\frac{1}{5}$ LOQ – 1% of the nominal study application rate of 344 µg/kg soil, and was equal to 3.44 µg/kg soil. The values were determined experimentally by examining the linearity of the response of MS/MS detector to the calibration curve. The numerical results of this examination presented below in the table B.8.1.1.2.1.1_CA-167 and in the graphical form on figure B.8.1.1.2.1.1_CA-83. They conform the good linearity of the detector's response and hence the correctness of the determined LOQ and LOD values.

Table B.8.1.1.2.1.1._CA-167: The numerical results of the determination of the linearity of the response of MS/MS detector.

Calibration sample No.	Nominal concentration		Peak area ratio TI ¹⁾ /IS ²⁾				RSD [%]
	[% AA]	[ng/mL]	Replicate 1	Replicate 2	Replicate 3	Mean	
1	1	0.86	0.1078	0.1085	0.1147	0.1104	2.8
2	5	4.3	0.5582	0.5570	0.5764	0.5639	1.6
3	10	8.6	1.0982	1.1375	1.1465	1.1274	1.9
4	50	43.0	5.4422	5.4795	5.7470	5.5562	2.4
5	100	86.0	10.6867	10.7507	11.1143	10.8503	1.7
6	150	129.0	16.3284	16.1822	16.3563	16.2890	0.5

Footnotes to the table:

- 1) TI – Test Item,
- 2) IS – Internal standard; its amount is always 10% of the nominal study application rate

**Table B.8.1.1.2.1.1._CA-83:** The graphical results of the determination of the linearity of the response of MS/MS detector – calibration curve (copied from the study report).

The determination of the accuracy and precision of the method, assessed on the basis of the recovery rates at LOQ level (5% SAR) and application level (100% SAR), looked as follows:

- for Hanscheider Hof soil mean recovery at LOQ and AR level was 97.4% (93.6 – 100.0%) with RSD = 2.1%;
- for Frankenforst soil mean recovery at LOQ and AR level was 97.9% (95.3 – 102.5%) with RSD = 2.4%;
- for LUFA 2.3 soil mean recovery at LOQ and AR level was 103.9% (97.4 – 103.9%) with RSD = 4.7%;
- for LUFA 6S soil mean recovery at LOQ and AR level was 100.7% (95.9 – 108.3%) with RSD = 4.2%;
- the mean recovery at LOQ and AR level was 100.0% (93.6 – 112.1%) with RSD = 2.1%.

The results of the experiment – concentrations of FOE Sulfonic acid in soil in function of time, are presented below in the table B.8.1.1.2.1.1._CA-168. For each test soil the concentrations of the test compound are reported as % of applied amount – [% AA] and in [µg/kg soil]. The values expressed as [%AA] were calculated using the following assumptions:

- for all samples the application rate was determined to be 41.9 µg/ test system, corresponding to 419 µg/kg soil, and that value was set to 100% AA (Applied Amount);

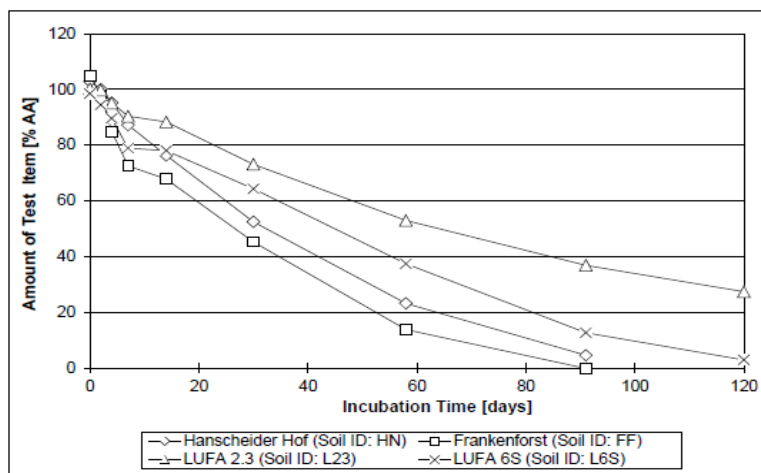

The graphic presentation of the results is given on figure B.8.1.1.2.1.1._CA-84.

Table B.8.1.1.2.1.1._CA-168: Concentration of FOE Sulfonic acid in tets soils in function of time.

- 2) Not available – not calculated;
- 3) LOD – Limit of Detection – 1% AA;
- 4) LOD – Limit of Detection – 3.44 µg/kg soil

**Figure B.8.1.1.2.1.1._CA-84:** The graphic presentation of the obtained results (copied from the study report).

The data presented in the table B.8.1.1.2.1.1._CA-168 were subjected to the kinetic analysis aimed on the determination of the best kinetic fit and derivation of the kinetic endpoints representing persistence of the test compound and suitable for modelling. For that purpose the values obtained for replicates, expressed as [% AA], were used. The values were inserted to the model as they are presented in the table above. The results of the kinetic analysis are presented below, separately for each test soil.

- 1) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Hanscheider Hof soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-85 and in numerical form in the table B.8.1.1.2.1.1._CA-169. Additionally the table B.8.1.1.2.1.1._CA-170 provides the kinetic endpoints obtained with each of the kinetic models tested.

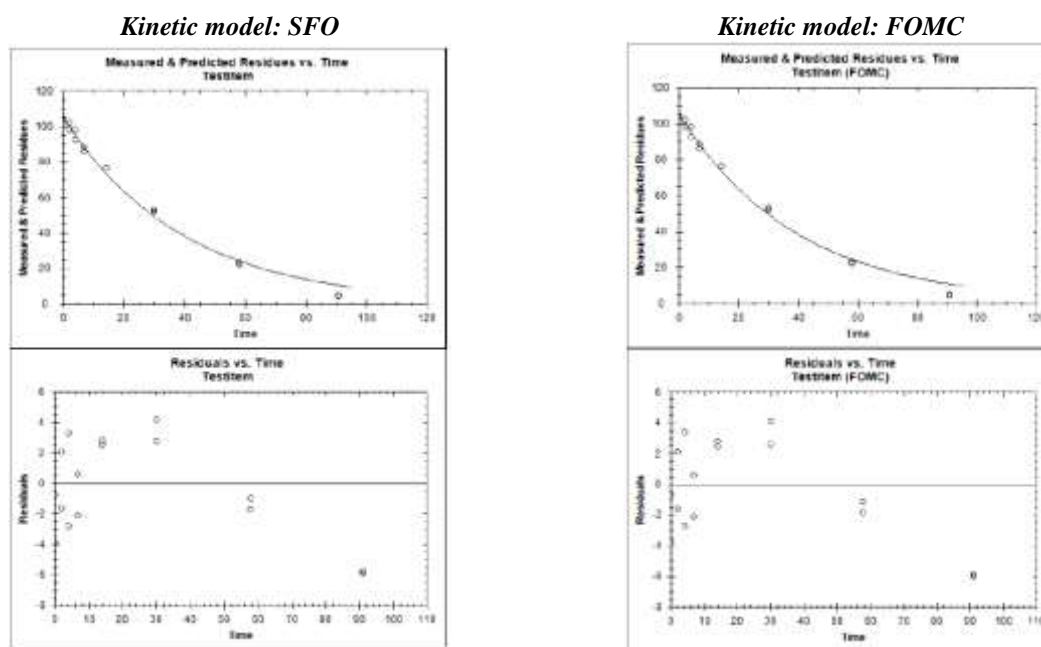

Figure B.8.1.1.2.1.1._CA-85: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-169: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	105.2	1.363	102.5	107.833	< 2 E-16	3.247	Good fit
	k	0.025396	1.049 E-3	0.02333	0.027	3.99 E-13		
FOMC	M_0	105.101	1.184	102.780	107.400	< 2 E-16	3.475	Good fit
	α	732.652	632.078	-506.198	1971.5	0.134		
	β	28946.583	25008.052	-20068.298	77961.5	0.134		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-170: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Sulfonic acid	DT ₅₀ [days]	27.30	27.40
	DT ₉₀ [days]	90.70	91.12

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very close for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Hanscheider Hof soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 2) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Frankenforst soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-86 and in numerical form in the table B.8.1.1.2.1.1._CA-171. Additionally the table B.8.1.1.2.1.1._CA-172 provides the kinetic endpoints obtained with each of the kinetic models tested.

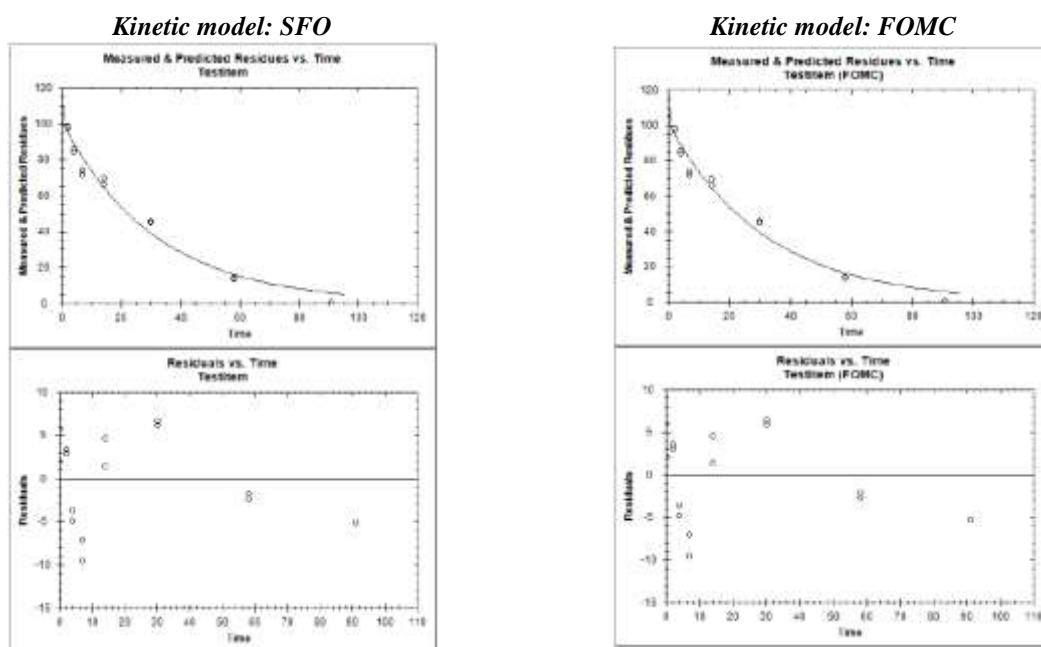

Figure B.8.1.1.2.1.1._CA-86: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-171: The numerical results of the kinetic analysis.

	k	0.03181	2.328 E-3	0.02724	0.036	8.69 E-10		
FOMC	M_0	100.969	2.155	96.745	105.2	3.48 E-16	6.849	Good fit
	α	471.952	1395.635	-2263.443	3207.3	0.370		
	β	14979.798	44387.211	-72017.538	101977.1	0.371		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-172: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Sulfonic acid	DT ₅₀ [days]	21.79	22.02
	DT ₉₀ [days]	72.39	73.26

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very close for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Frankenforst soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

3) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in LUFA 2.3 soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-87 and in numerical form in the table B.8.1.1.2.1.1._CA-173. Additionally the table B.8.1.1.2.1.1._CA-174 provides the kinetic endpoints obtained with each of the kinetic models tested.

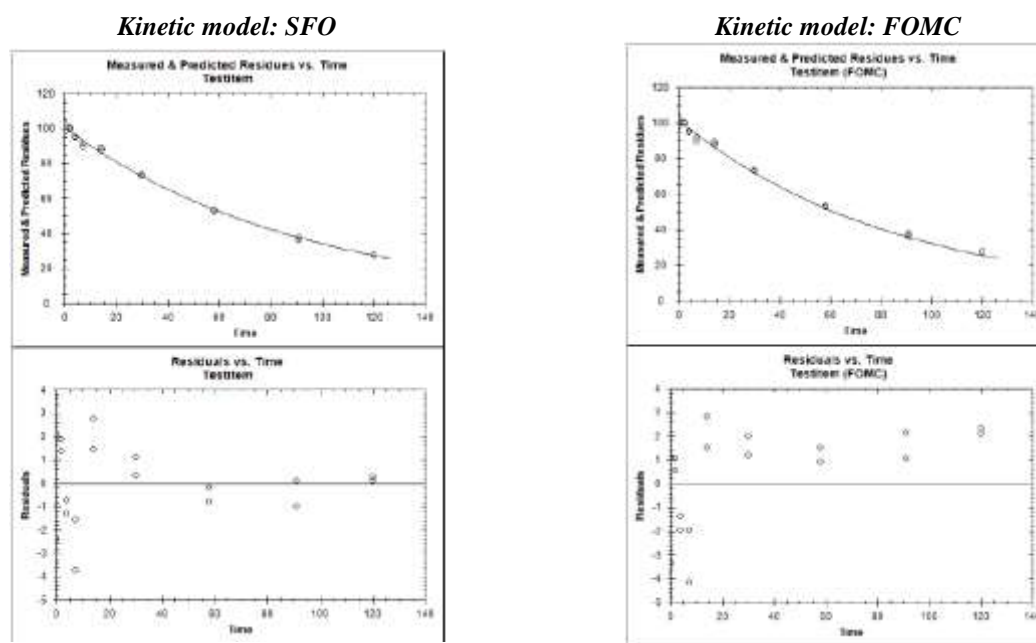

Figure B.8.1.1.2.1.1._CA-87: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-173: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	100.4	0.604	99.20	101.567	< 2 E-16	1.450	Good fit
	k	0.01085	2.28 E-4	0.01041	0.011	< 2 E-16		
FOMC	M_0	101.4	0.643	100.1	102.6	< 2 E-16	2.099	Good fit
	α	362.5	62.63	239.7	485.2	1.79 E-5		
	β	3.127 E4	5.411 E3	2.066 E4	41873.0	1.82 E-5		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-174: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Sulfonic acid	DT ₅₀ [days]	63.87	59.85
	DT ₉₀ [days]	212.16	199.27

Conclusion:

Both models returned visually and statistically good fits, although residuals for SFO were more randomly distributed (in case of FOMC the distribution was systematic). In terms of χ^2 error better fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very close for both models tested. Both models returned full reliable kinetic parameters. As a result, the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in in LUFA 2.3 soil, hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 4) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in LUFA 6S soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-88 and in numerical form in the table B.8.1.1.2.1.1._CA-175. Additionally the table B.8.1.1.2.1.1._CA-176 provides the kinetic endpoints obtained with each of the kinetic models tested.

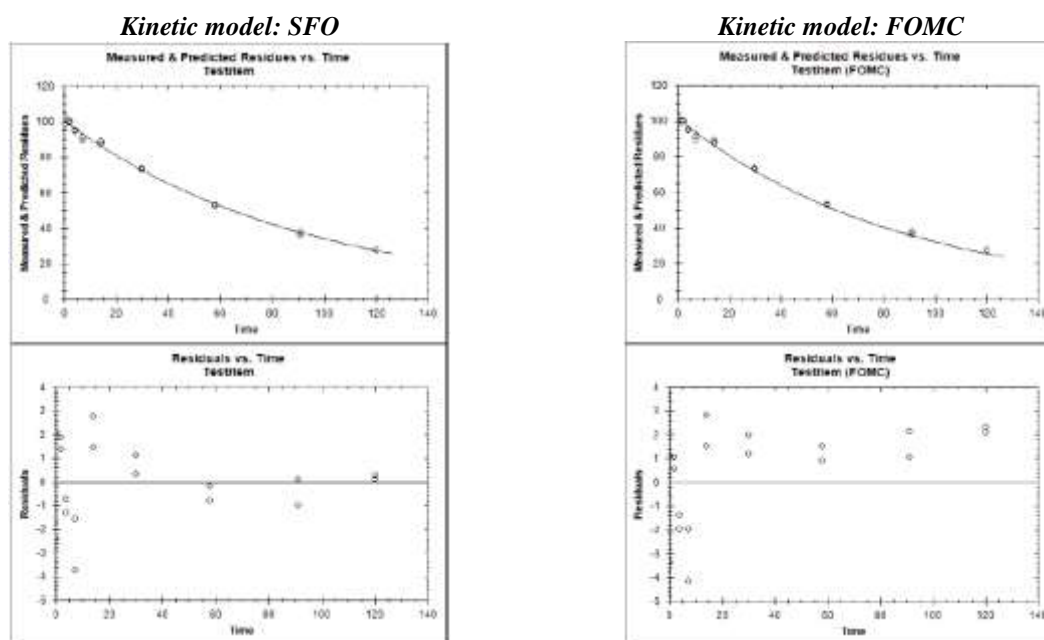

Figure B.8.1.1.2.1.1._CA-88: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-175: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	97.664	2.103	93.542	101.786	< 2 E-16	6.49	Good fit
	k	0.01838	0.00122	0.01599	0.0021	3.42 E-11		
FOMC	M_0	98.75	10.16	78.83	118.7	3.64 E-8	7.123	Good fit
	α	1566.39	1671.79	-1710.26	4843.0	0.182		
	β	79448.94	84831.76	-86818.25	245716.1	0.182		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-176: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Sulfonic acid	DT ₅₀ [days]	37.71	35.17
	DT ₉₀ [days]	125.28	116.88

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very similar for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in LUFA 6S soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-177.

Table B.8.1.1.2.1.1._CA-177: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
Soil name	Soil type (USDA)	OC [%]	pH ¹⁾			χ^2 error	Visual fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]
<i>Hanscheider Hof</i>	Loam	2.8	5.6	19.9°C/ 55% MWHC	SFO	3.247	G	<i>k</i>	0.02540	27.30	90.70
<i>Frankenforst</i>	Silt loam	1.8	6.8	19.9°C/ 55% MWHC	SFO	6.412	G	<i>k</i>	0.03181	21.79	72.39
<i>LUFA 2.3</i>	Sandy loam	1.1	6.8	19.9°C/ 55% MWHC	SFO	1.450	G	<i>k</i>	0.01085	63.87	212.16
<i>LUFA 6Se</i>	Clay	1.9	7.0	19.9°C/ 55% MWHC	SFO	6.49	G	<i>k</i>	0.01838	37.71	125.28

Footnotes to the table:

1) Measured in 0.01M CaCl₂.

2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

Study 13:

Report: Reinken G., Partsch S., (2014): “Kinetic Evaluation of the Degradation of Flufenacet Degradation Product FOE sulfonic acid under Aerobic Soil conditions in Laboratory according to FOCUS Kinetics Using the KinGUI 2 Tool. FOE sulfonic acid.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished Study Report No. EnSa-12-580; 2014. 02. 17; ; study reference number: M-477844-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above.

It was stated that the study generally complied with the two evoked Guidance Documents. The study was aimed on the derivation of the modelling kinetic endpoints for FOE Sulfonic acid. It followed modelling approach outlined already in other studies summarised above – **Study 2**, **Study 7** and **Study 8**. The analysis was performed for the results of the two summarised above studies – by [Hellpointner; 1999] (**Study 9**) and by [Hellpointner; 2003] (**Study 10**). Analysing the data sets declared to be derived from the above source studies and subsequently used in the kinetic analysis RMS noticed that in case of the input data coming from the source **Study 9** the concentrations were given in %. It was also noticed that these values were different from those reported in the tables B.8.1.1.2.1.1._CA-148 for Laacherhof AXXa soil and B.8.1.1.2.1.1._CA-149 for Laacherhof AIII as total radioactivity in extracts identified by TLC as the test compound (values calculated from the raw results by the RMS). In the study report it was not explained how these values were obtained. However, the thorough comparative analysis of the results presented in the source study and this one, enabled to identify the way the input values for Laacherhof AXXa and Laacherhof AIII were derived. That will be explained in details in the summary below. RMS stated that the approach adopted by the authors of the study may be considered acceptable, hence the kinetic analysis presented in the study report did not require to be repeated using different data sets. In general, the study was found to be acceptable and is summarised below.

Summary:

The aim of the study was to kinetically examine the data for FOE Sulfonic acid obtained in two studies summarised above - **Study 9** [Hellpointner; 1999] and **Study 10** [Hellpointner; 2003] in order to derive the kinetic endpoints suitable for use in modelling exposure assessment.

In these two studies the degradation of FOE Sulfonic acid in aerobic soil was examined in five soils – three in **Study 9** and two in **Study 10**. The characteristic of test soils used in these experiments is provided in the table B.8.1.1.2.1.1._CA-141 for **Study 9** and table B.8.1.1.2.1.1._CA-147 for **Study 10**. As their summaries immediately precede the summary of this study, RMS decided not to reproduce these tables in order to not overburden the Assessment Report. However, in the table B.8.1.1.2.1.1._CA-178 are presented key soil properties of each test soil, relevant for the reporting of the results of the kinetic analysis. The experimental conditions used in each experiment are summarised further down, in the table B.8.1.1.2.1.1._CA-179.

Table B.8.1.1.2.1.1._CA-178: The brief characteristic of the test soils.

Study	Soil name	Soil type (USDA classification)	Soil properties			
			pH in CaCl ₂	OC [%]	Soil microbial biomass at the beginning of the study	
					mg microbial C/kg soil	% OC
<i>Hellpointner; 1996</i>	BBA 2.1	Sand	5.3	0.57	111	1.95
	BBA 2.2	Loamy sand	6.3	2.48	390	1.57
	Laacherhof AIII	Silt loam	7.3	0.9	780	3.25
<i>Hellpointner; 2003</i>	Laacherhof AXXa	Sandy loam	6.3	1.47	242	1.65
	Laacherhof AIII	Silt loam	6.8	0.88	275	3.13

Table B.8.1.1.2.1.1._CA-179: The experimental conditions used in each experiment.

Study	Test soil		Incubation temperature $T [^{\circ}\text{C}]$	Experimental conditions		
	Name	Type (USDA classification)		In experiment [% MWHC]	Soil moisture	
					Reference value [g/100g soil]	
Hellpointner; 1999	BBA 2.1	Sand	20 ± 2	31	----	9.2
	BBA 2.2	Loamy sand	20 ± 2	29	----	16.1
	Laacherhof AIII	Silt loam	20 ± 2	44	----	15.1
Hellpointner; 2003	Laacherhof AXXa	Sandy loam	20 ± 2	40	34.42	----
	Laacherhof AIII	Silt loam	20 ± 2	40	36.40	----

The not-processed input data used in the kinetic analysis are presented below in the table B.8.1.1.2.1.1._CA-180. In case of the data derived from the study by [Hellpointner; 2003] the values were transformed to be expressed as [% of the initial dose]. That was done using the results reported in the tables B.8.1.1.2.1.1._CA-148 for Laacherhof AXXa soil and B.8.1.1.2.1.1._CA-149 for Laacherhof AIII as “FOE Sulfonic acid recovered [$\mu\text{g}/100 \text{ g soil}$]”. The data were processed in a following way:

- the DAT-0 average value was defined as 100%;
- the values for each replicate at each time point were recalculated into % initial by dividing them by the DAT-0 average value; the resulting value was multiplied by a factor of 100 to obtain the value expressed in %.

RMS checked the correctness of the calculations and accepted them. It was noted that the values differed from those calculated by the RMS as results of the TLC quantification of the test compound in extracts. However, as the values proposed in the study report were higher, what resulted in longer $\text{DT}_{50}/\text{DT}_{90}$ values, the proposed approach was accepted by the RMS.

Table B.8.1.1.2.1.1._CA-180: The non-processed data obtained in the test soils used as input in kinetic analysis.

The data presented above were subjected to a multistep evaluation procedure, almost identical to that already presented in the summary of the **Study 2**, for convenience repeated below. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool, in order to determine the appropriate kinetic model.
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The data-processing to obtain the input values for kinetic analysis (**Step 1**) was identical to the procedure described in the summary of the **Study 2**, on page 166. The processed data used as input in the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-181.

Table B.8.1.1.2.1.1._CA-181: The processed residue data used in the kinetic analysis.

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure consisted on the determination of the appropriate kinetic model for FOE Sulfonic acid.

The conceptual metabolic pathway built in the modelling tool was based on the transformation pathway which, in form of simplified scheme, is presented below on figure B.8.1.1.2.1.1._CA-89.

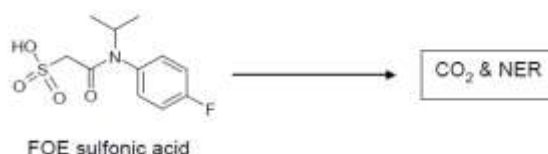

Figure B.8.1.1.2.1.1._CA-89: The simplified transformation pathway used to create conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of the evaluation procedure was presented in the summary of the **Study 2** on pages 168 – 169. RMS decided not to repeat it here in order to not overburden the Renewal Assessment Report.

On that basis the following multistep assessment procedure was followed:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in modelling, the SFO kinetic model was tested as first option and if passed the acceptance criteria (visually acceptable, χ^2 -error not exceeding or not significantly exceeding 15%, *prob. > t* value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the χ^2 -error was significantly greater than 15%, model parameters were fixed and fitting repeated using SFO model;
- **Step 3:** if the **Step-2** fitting failed the χ^2 -error test, bi-phasic models were included. These were FOMC, DFOP and, possibly HS. The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved fit, SFO model was selected if visually acceptable; that was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic analysis are presented below, individually for each test soil.

- 1) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in BBA 2.1 soil (study by [Hellpointner; 1999]):

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-90 and in numerical form in the table B.8.1.1.2.1.1._CA-182. Additionally the table B.8.1.1.2.1.1._CA-183 provides the kinetic endpoints obtained with each of the kinetic models tested.

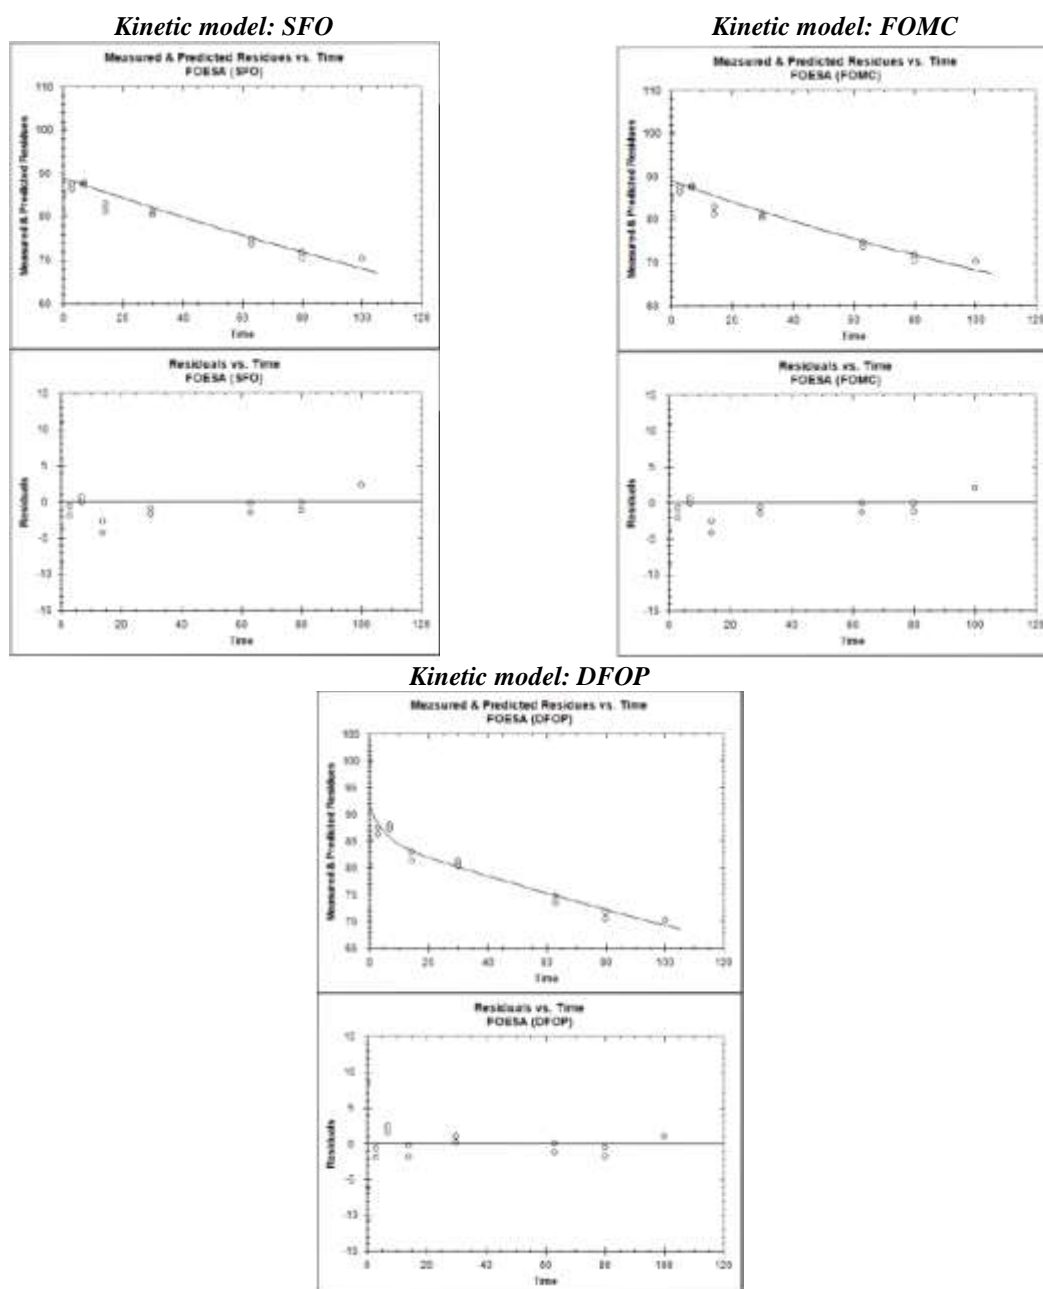

Figure B.8.1.1.2.1.1._CA-90: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-182: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	88.954	1.589	85.840	92.069	< 2 E-16	4.377	0.73; Good fit
	k	2.682 E-3	4.22 E-4	1.855 E-3	0.004	4.77 E -6		
FOMC	M ₀	89.108	1.638	85.899	92.318	< 2 E-16	4.577	0.77; Good fit
	α	1.4819	0.2446	1.0024	1.961	1.1 E-5		
	β	506.8549	9.1175	488.985	524.725	< 2 E-16		
DFOP	M ₀	91.449	2.233	87.072	95.8267	2.81 E-16	4.561	0.74; Good fit
	k ₁	0.1937	0.4986	-0.7834	1.171	0.3517		
	k ₂	2.084 E-3	9.771 E-4	1.689 E-4	0.004	0.0256		
	g	0.06756	0.06248	-0.05490	0.190	0.1489		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-183: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	258.44	302.29	299.05
	DT ₉₀ [days]	858.51	1890.3	Not determined

Conclusion:

All three models returned visually and statistically good fits. In terms of χ^2 error the best fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very close for all three models tested. Two models – SFO and FOMC, returned fully reliable kinetic parameters. In case of DFOP not fully reliable were k_2 and g – for these parameterers the *prob. > t* was higher than 0.1.

The Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in BBA 2.1. soil and hence appropriate to derive persistence and modelling endpoints for that trial. RMS consider that proposal acceptable.

At the same time RMS noticed that there was a significant difference in concentration of the test item between the DAT-0 and DAT-0.08 samples, what might have influenced the shape of the kinetic curve in its initial phase, especially in case of bi-phasic models (FOMC and DFOP). Thorough analysis of the data showed that true DAT-0 samples were not processed and analysed. Instead for that tim point the 100% level, based on the results of verification of the level and homogeneity of application, was set. on. The concentrations in DAT 0.08 samples are therefore first truly measured concentrations of FOE Sulfonic acid in soil. As a result, because the two time points are located very close to each other, RMS decided to repeat the kinetic analysis removing the values for DAT-0 time point from the data set. That was done in order to verify would such action improve the fitting results. The outcome is presented further down the report under the point 6).

- 2) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in BBA 2.2 soil Study by [Hellpointner; 1999]:

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-91 and in numerical form in the table B.8.1.1.2.1.1._CA-184. Additionally the table B.8.1.1.2.1.1._CA-185 provides the kinetic endpoints obtained with each of the kinetic models tested.

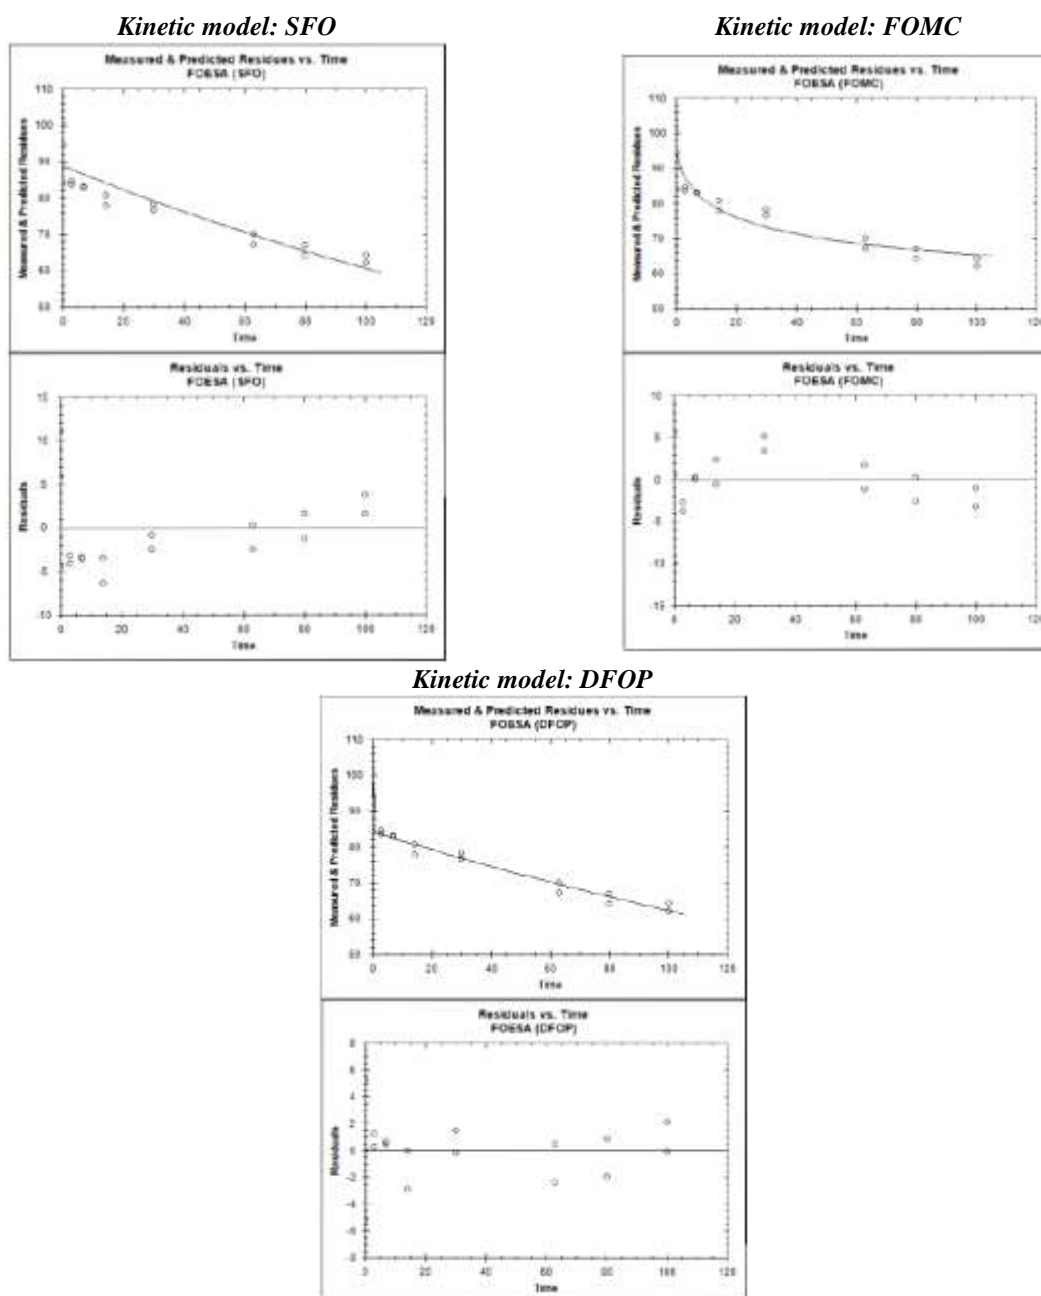

Figure B.8.1.1.2.1.1._CA-91: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-184: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	88.73	1.757	85.29	92.175	< 2 E-16	4.638	0.81; Acceptable fit
	k	3.833 E-3	5.037 E-4	2.846 E-3	0.005	5.26 E-7		
FOMC	M ₀	94.418	2.267	89.975	98.862	< 2 E-16	3.363	0.94; Acceptable fit
	α	0.09969	0.02777	0.045526	0.154	0.00134		
	β	2.5286	2.5026	-2.3764	7.433	0.1642		
DFOP	M ₀	100.0	1.581	96.90	103.098	< 2 E-16	0.905	0.97; Good fit
	k ₁	13.73	4.381	5.140	22.314	0.00367		
	k ₂	3.028 E-3	2.616 E-4	2.515 E-3	0.004	7.44 E-9		
	g	0.1587	0.01736	0.1247	0.193	1.40 E-7		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-185: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	180.82	2643.3	171.85
	DT ₉₀ [days]	600.67	27168313490	703.43

Conclusion:

Of the three tested models DFOP returned visually and statistically good fit, while the fits obtained using FOMC and SFO were, according to the Applicant, statistically good, but visually only acceptable. RMS noticed that in case of FOMC model the visual fit may also be considered good. Of all three models tested DFOP returned the superior fit, while that for SFO was the poorest. In terms of the reliability of kinetic parameters, SFO and DFOP may be considered fully reliable, while in case of FOMC the calculated β was not reliable because CI for it passed through zero. It was also noticed that the kinetic endpoints returned by the modelling tool for FOMC were unrealistically long.

The Applicant stated that despite displayed deficiencies, the fit obtained with SFO was robust enough to be considered appropriate to derive persistence and modelling endpoints for FOE Sulfonic acid in BBA 2.2. soil. RMS is of the opinion that the proposal is acceptable.

At the same time RMS noticed that there was a significant difference in concentration of the test item between the DAT-0 and DAT-0.08 samples, what might have influenced the shape of the kinetic curve in its initial phase, especially in case of bi-phasic models (FOMC and DFOP). Thorough analysis of the data showed that true DAT-0 samples were not processed and analysed. Instead for that time point the 100% level, based on the results of verification of the level and homogeneity of application, was set. on. The concentrations in DAT 0.08 samples are therefore first truly measured concentrations of FOE Sulfonic acid in soil. As a result, because the two time points are located very close to each other, RMS decided to repeat the kinetic analysis removing the values for DAT-0 time point from the data set. That was done in order to verify would such action improve the fitting results. The outcome is presented further down the report under the point 7).

- 3) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Laacherhof soil (study by [Hellpointner; 1999]):

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-92 and in numerical form in the table B.8.1.1.2.1.1._CA-186. Additionally the table B.8.1.1.2.1.1._CA-187 provides the kinetic endpoints obtained with each of the kinetic models tested.

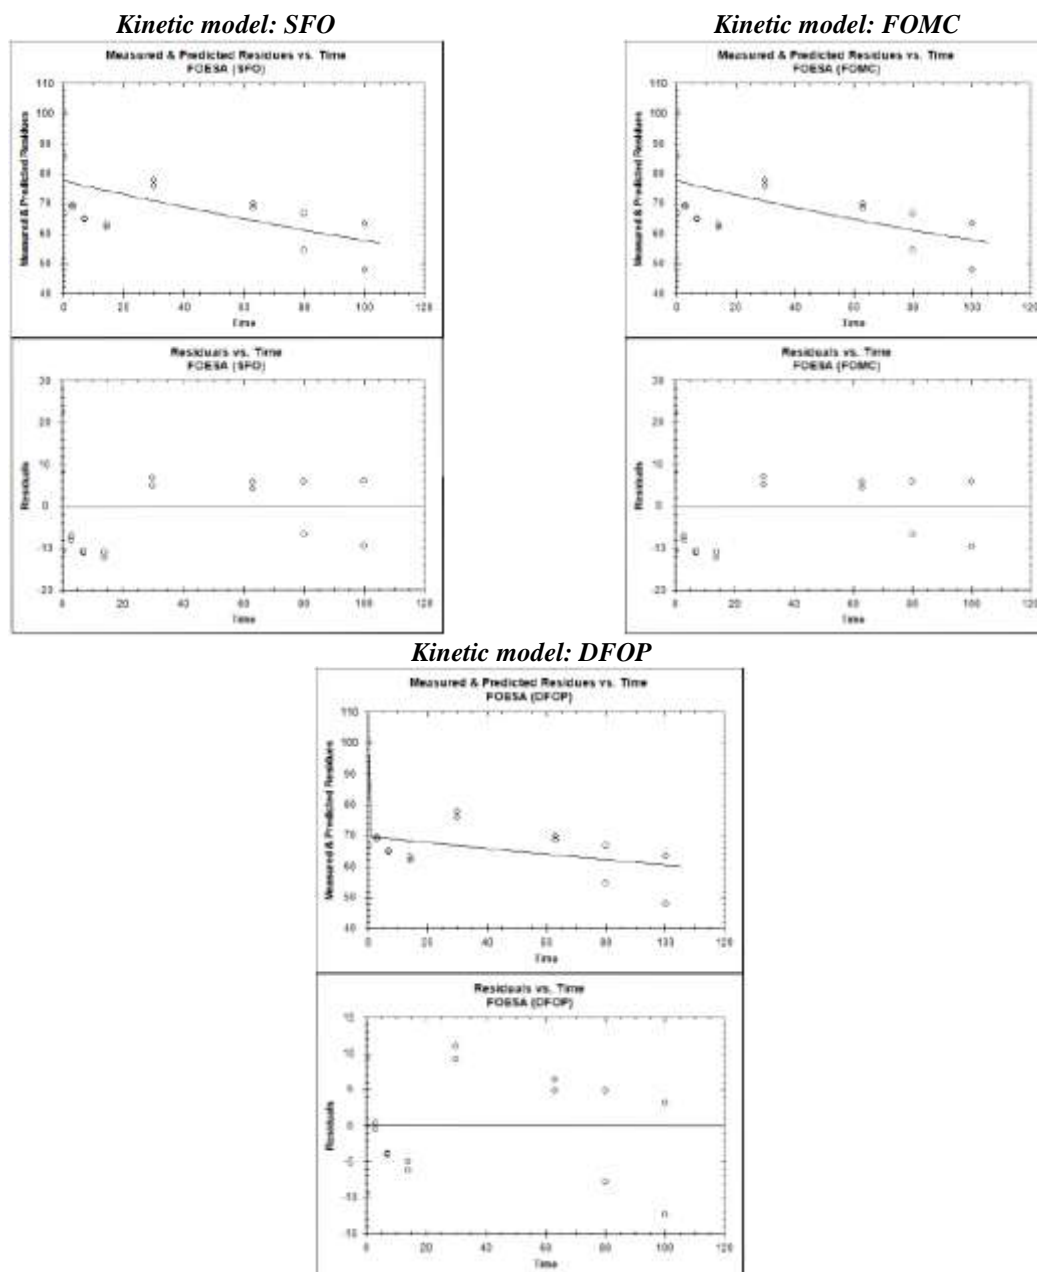

Figure B.8.1.1.2.1.1._CA-92: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-186: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	77.37	3.812	69.90	84.84	3.81 E-13	11.24	0.30; Acceptable fit
	k	2.95 E-3	1.177 E-3	6.432 E-4	0.005	0.0117		
FOMC	M ₀	77.454	3.953	69.706	85.201	2.12 E-12	11.88	0.30; Acceptable fit
	α	2.5601	1.0448	0.5123	4.608	0.0135		
	β	822.5645	43.1441	738.0035	907.125	3.15 E-12

	k ₁	19.11	11.01	-2.460	40.678	0.0522		
	k ₂	1.417 E-3	7.778 E-4	-1.074 E-4	0.003	0.0449		
	g	0.3044	0.04429	0.2176	0.391	3.82 E-63		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-187: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	234.92	255.78	232.98
	DT ₉₀ [days]	780.40	1199.4	Not determined

Conclusion:

All three models returned fits acceptable visually and statistically fits, with DFOP the best of the three. Also the determined kinetic parameters were reliable for all three models.

The Applicant proposed to consider SFO model to return the fit robust enough to be appropriate to derive from it persistence and modelling endpoints for FOE Sulfonic acid in Laacherhof soil.

RMS however stated that none of the fits is adequate and for two reasons.

Reason 1: RMS noticed that there was a significant difference in concentration of the test item between the DAT-0 and DAT-0.08 samples, what might have influenced the shape of the kinetic curve in its initial phase, especially in case of bi-phasic models (FOMC and DFOP). Thorough analysis of the data showed that true DAT-0 samples were not processed and analysed. Instead for that time point the 100% level, based on the results of verification of the level and homogeneity of application, was set. on. The concentrations in DAT 0.08 samples are therefore first truly measured concentrations of FOE Sulfonic acid in soil. Elimination of the theoretical DAT 0 values may result in change of the curve's shape in its initial part, eliminating the alleged breakpoint at DAT 0.08.

Reason 2: The concentrations at DAT 30 and DAT 63 time points were unusually high in comparison to preceding time points, indicating problems with sample processing at earlier some points, or some problems with DAT-30 and DAT-63 samples, not necessarily related to sample processing. Evaluating the source study (please refer to the summary of the **Study 9** above) RMS postulated that these two time points may be outliers, not to be used in kinetic analysis.

Reason 3: For the samples recovered at last two sampling points – DAT 80 and DAT 100, a substantial difference between the concentrations of FOE Sulfonic acid in replicates was observed, what also possibly influenced the results of the fitting. In this case however the situation seems not to be as clear as it was for the samples collected on DAT-30 and DAT-63, and it may be difficult to indicate which values are outliers.

As a result RMS decided to repeat the kinetic analysis with modified data set: DAT-0, DAT-30 and DAT-63 samples were removed from it. The results are presented further down the report, under the point 8).

- 4) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Laacherhof AXXa soil (study by [Hellpointner; 2003]):

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-93 and in numerical form in the table B.8.1.1.2.1.1._CA-188. Additionally the table B.8.1.1.2.1.1._CA-189 provides the kinetic endpoints obtained with each of the kinetic models tested.

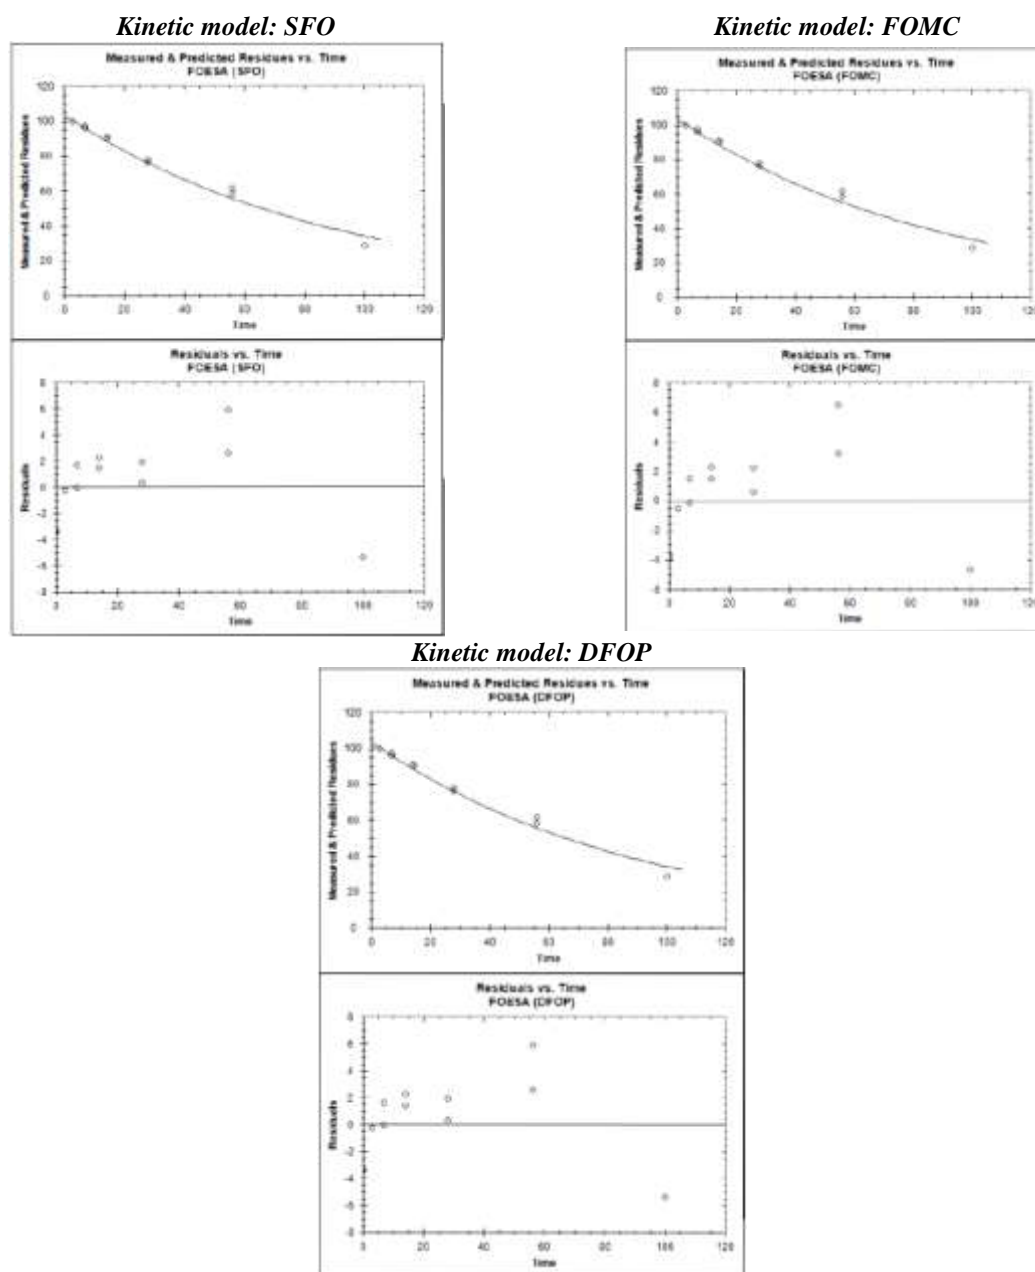

Figure B.8.1.1.2.1.1._CA-93: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-188: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	103.4	1.357	100.7	106.071	< 2 E-16	3.046	0.98; Good fit
	k	0.01112	5.343 E-4	0.01008	0.012	4.36 E-11		
FOMC	M ₀	103.7	1.424	101.0	106.5	< 2 E-16	3.327	0.98; Good fit
	α	451.4	818.0	-1152	2054.7	0.296		
	β	39660	71980	-101400	180746.4	0.296		
DFOP	M ₀	103.411	5.972	91.707	115.116	4.37 E-9	3.625	0.98; Good fit
	k ₁	0.01113	0.01027	-0.00901	0.031	0.1521		
	k ₂	0.01112	0.00255	0.00612	0.016	7.13 E-4		
	g	0.2489	5.4513	-10.4354	10.933	0.4822		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-189: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	62.31	60.96	62.31
	DT ₉₀ [days]	206.99	202.86	206.98

Conclusion:

All three models returned visually and statistically good fits. In terms of χ^2 error the best fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very close for all three models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC both α and β were not reliable because CI passed through zero. In case of DFOP not fully reliable were k_2 and g – for those parameters the *prob. > t* was higher than 0.1, being close to the level of 0.5 for g . Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Laacherhof AXXa soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 5) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Laacherhof AIII soil (study by [Hellpointner; 2003]):

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-94 and in numerical form in the table B.8.1.1.2.1.1._CA-190. Additionally the table B.8.1.1.2.1.1._CA-191 provides the kinetic endpoints obtained with each of the kinetic models tested.

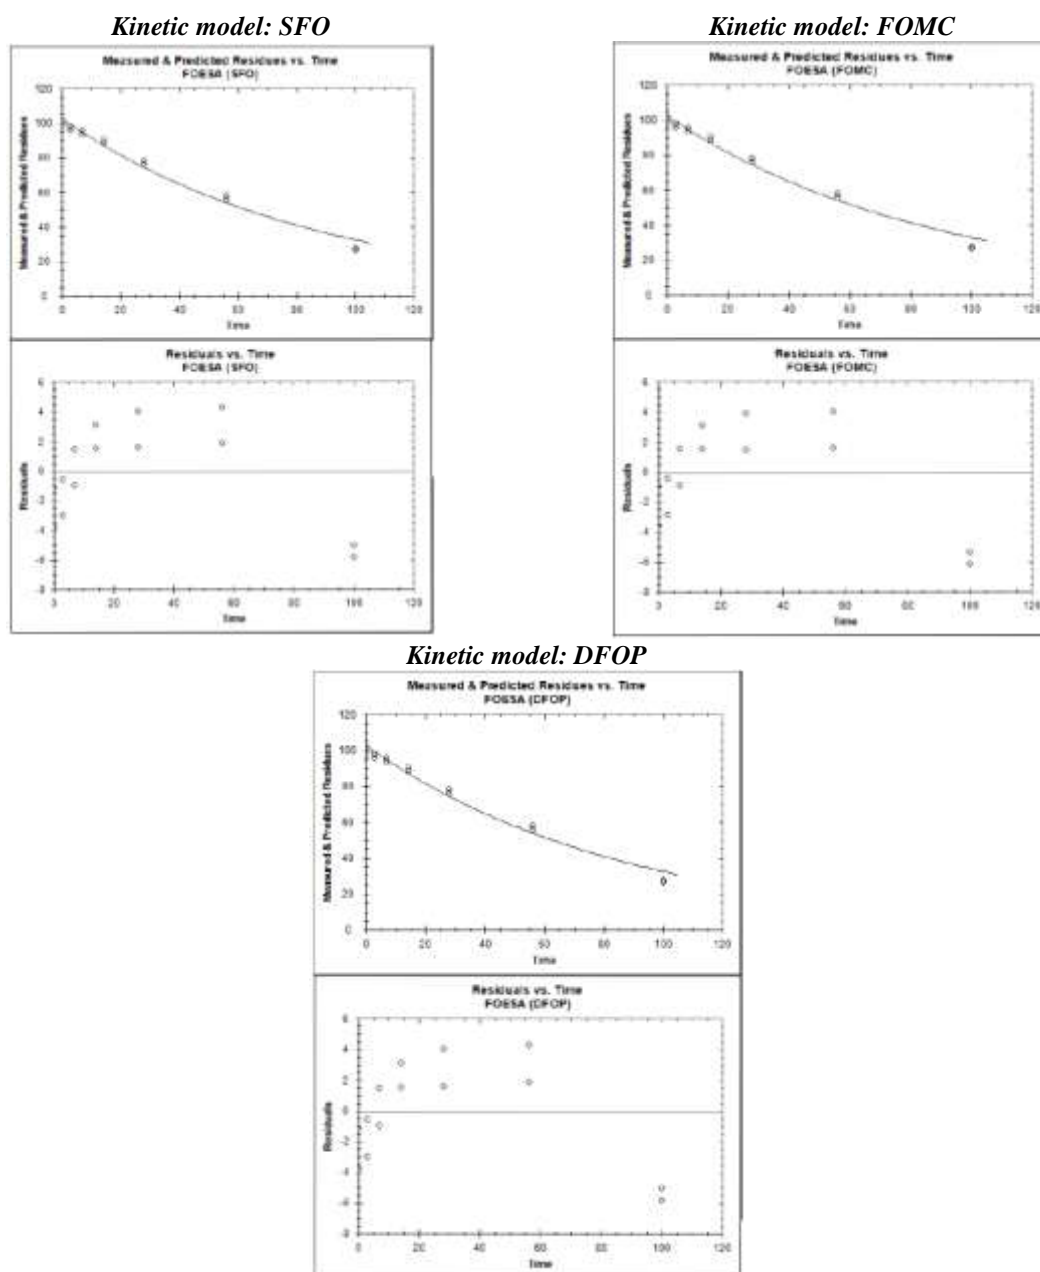

Figure B.8.1.1.2.1.1._CA-94: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-190: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit

	k ₁	0.0115	4.848 E-3	2.002 E-3	0.021	0.0195		
	k ₂	0.0115	1.707 E-3	8.156 E-3	0.015	2.56 E-5		
	g	0.2447	2.477	-4.6101	5.100	0.4616		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-191: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	60.26	60.88	60.26
	DT ₉₀ [days]	200.18	202.71	200.18

Conclusion:

All three models returned visually and statistically good fits. In terms of χ^2 error the best fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very close for all three models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC both α and β were not reliable because CI passed through zero. In case of DFOP not fully reliable was g – for that parameter the $prob. > t$ was significantly higher than 0.1, being close to the level of 0.5. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Sulfonic acid in Laacherhof AXXa soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

Additional kinetic analysis performed by the RMS

The data used as input in the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-192. The values not used in the fitting are marked italics.

Table B.8.1.1.2.1.1._CA-192: The processed residue data used in the kinetic analysis.

The data obtained in the study by [Hellpointner; 1999]								
Soil: BBA 2.1			Soil: BBA 2.2			Soil: Laacherhof		
Time Point – DAT [days]	Concentration [%] of FOE Sulfonic acid		Time Point – DAT [days]	Concentration [%] of FOE Sulfonic acid		Time Point – DAT [days]	Concentration [%] of FOE Sulfonic acid	
	Replic. 1	Replic. 2		Replic. 1	Replic. 2		Replic. 1	Replic. 2
0	100.0	100.0	0	100.0	100.0	0	100.0	100.0
0.08	80.6	85.2	0.08	84.2	94.6	0.08	85.6	66.7
3	86.3	87.6	3	83.6	84.6	3	69.6	68.8
7	87.3	88.0	7	82.8	83.0	7	64.9	65.0

63	73.6	74.9	63	70.0	67.2	63	70.0	68.4
80	70.5	71.7	80	64.1	66.9	80	66.9	54.3
100	70.3	70.3	100	64.3	62.1	100	48.0	63.5

The processed data were kinetically examined using CAKE ver. 3.1 modelling tool, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The settings of the optimiser were the defaults of the tool:

- maximum iterations: 100,
- maximum reweighing: 10,
- SANN maximum iterations: 10000,
- convergence tolerance: 1 E-5,
- error variance tolerance: 1 E-5,
- extra solver: yes, if required.

To reproduce as closely as possible the evaluation performed by the Applicant the RMS used all three kinetic models – SFO, FOMC and DFOP. The initial parameters were the same as presented in the study report.

The conceptual metabolic pathway built in the modelling tool was based on the transformation pathway which, in form of simplified scheme, is presented below on figure B.8.1.1.2.1.1._CA-95.

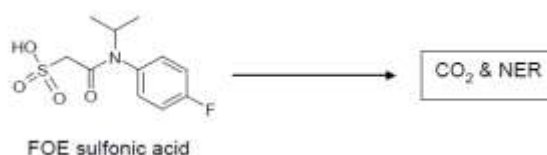

Figure B.8.1.1.2.1.1._CA-95 (-89): The simplified transformation pathway used to create conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The results of the fitting are presented below, individually for each test soil. RMS decided to maintain the consecutive numbering of the fitting experiments.

- 6) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in BBA 2.1 soil (study by [Hellpointner; 1999]):

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-96 and in numerical form in the table B.8.1.1.2.1.1_CA-193. Additionally the table B.8.1.1.2.1.1_CA-194 provides the kinetic endpoints obtained with each of the kinetic models tested.

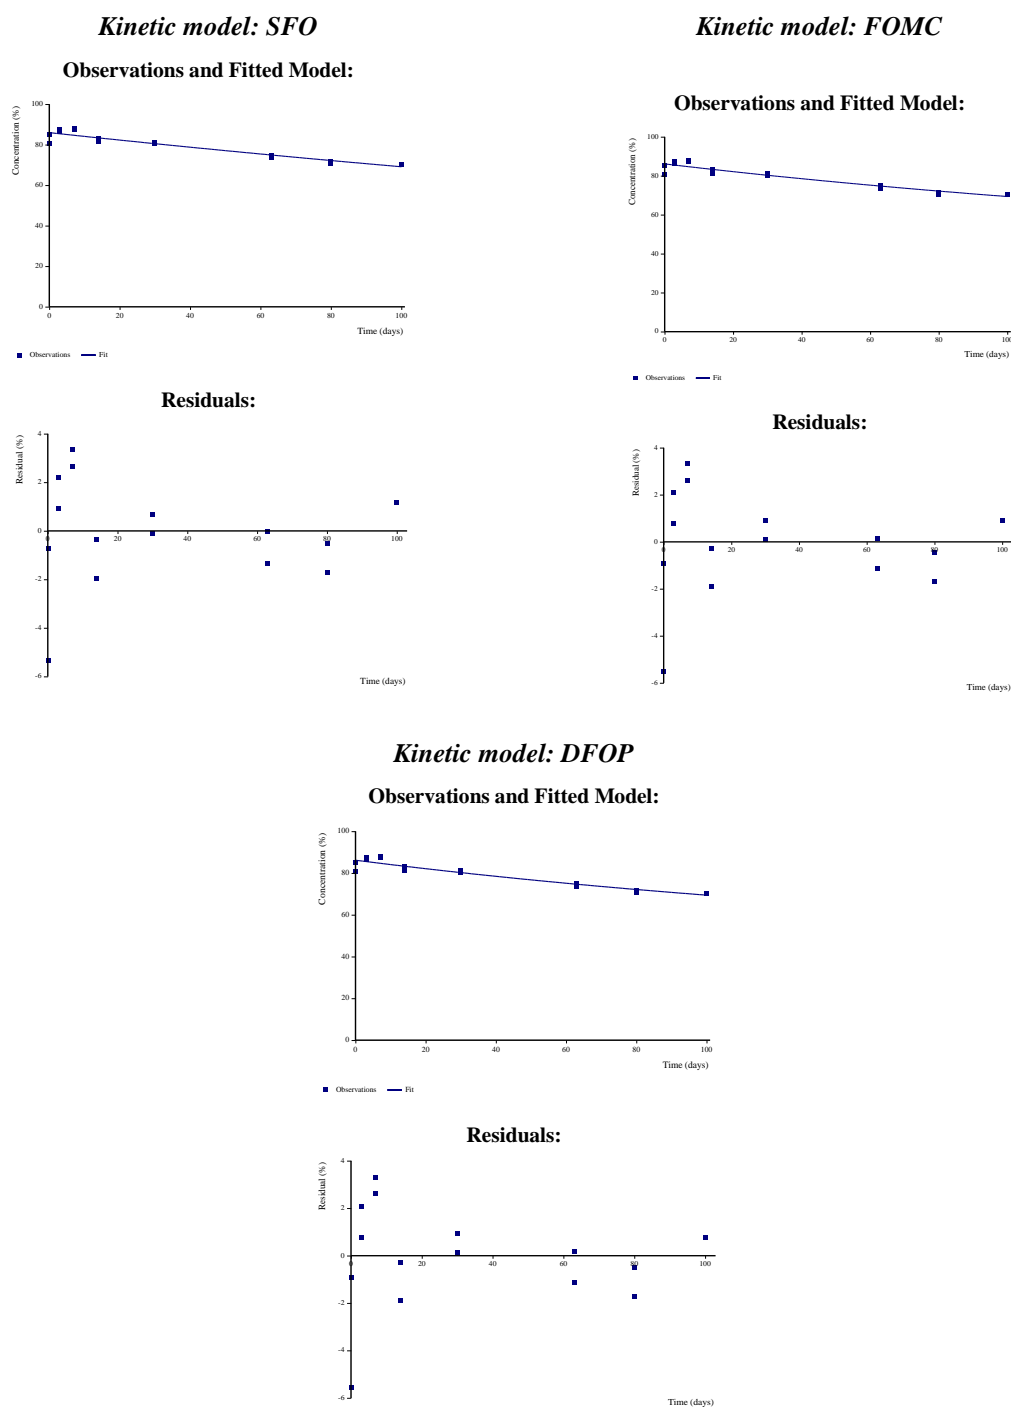

Figure B.8.1.1.2.1.1_CA-96: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-193: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	85.96	0.791	84.26	87.66	n. c. ¹⁾	1.78	0.902; Good fit
	k	2.179 E-3	1.97 E-4	1.757 E-3	0.003	1.32 E-8		
FOMC	M_0	86.12	1.019	83.92	88.32	n. c. ¹⁾	1.89	0.903; Good fit
	α	0.9652	3.484	-6.561	8.492	n. c. ¹⁾		
	β	398.2	1590	-3041	3840	n. c. ¹⁾		
DFOP	M_0	86.16	0.859	84.28	88.03	n. c. ¹⁾	2.03	0.903; Good fit

Footnotes to the table:

1) Value not calculated by the modelling tool;

2) Value not determined by the model because the covariance matrix could not be created;

Table B.8.1.1.2.1.1._CA-194: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	318	418	> 10000
	DT ₉₀ [days]	1060	3930	> 10000

Conclusion:

All three models returned visually and statistically good fits, with SFO being superior of the three. RMS noticed that the fits visually did not significantly differ, what may indicate that there were problems with the appropriate fitting of the bi-phasic models. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC both α and β were not reliable because CI passed through zero. In case of DFOP the model was able to provide statistical analysis only for the parameter k_1 , which therefore can be solely considered reliable. As a result DFOP fit should not be taken into account.

Therefore only the results obtained for SFO fit shall be considered fully reliable and providing persistence and modelling endpoints for FOE Sulfonic acid in BBA 2.1 soil.

RMS noticed also that the results of the fitting improved for SFO kinetic model when the DAT-0 time point was removed from the data set. Therefore, the problems with the fitting, observed in case of the kinetic analysis performed by the Applicant were most probably caused by the inclusion of the artificially set DAT-0 time point.

RMS proposes to include the results of the repeated kinetic analysis into the data set for FOE Sulfonic acid.

- 7) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in BBA 2.2 soil Study by [Hellpointner; 1999]:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-97 and in numerical form in the table B.8.1.1.2.1.1_CA-195. Additionally the table B.8.1.1.2.1.1_CA-196 provides the kinetic endpoints obtained with each of the kinetic models tested.

	g	0.0686	0.0264	0.0111	0.126	n. c. ¹⁾		

Footnotes to the table:

1) Value not calculated by the modelling tool;

Table B.8.1.1.2.1.1._CA-196: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	211	681	214
	DT ₉₀ [days]	701	> 10000	767

Conclusion:

All three models returned visually and statistically good fits, although it shall be stated that the fits returned by bi-phasic models were visually and statistically superior to SFO fit. In terms of χ^2 error the best fit was obtained using DFOP model, although it shall be pointed out that the value of that parameter was very close for all three models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated β was not reliable because CI passed through zero. In case of DFOP not fully reliable was k_1 — for that parameter the *prob. > t* was higher than 0.1. That may indicate that the fast degradation phase may not be relevant for overall degradation kinetics of FOE Sulfonic acid in BBA 2.2 soil.

Therefore the results obtained for SFO fit may be considered as well representing the kinetic behaviour of FOE Sulfonic acid in BBA 2.2 soil and appropriate to derive persistence and modelling endpoints.

RMS noticed also that the results of the fitting improved for SFO kinetic model when the DAT-0 time point was removed from the data set. Therefore, the problems with the fitting, observed in case of the kinetic analysis performed by the Applicant were most probably caused by the inclusion of the artificially set DAT-0 time point.

RMS proposes to include the results of the repeated kinetic analysis into the data set for FOE Sulfonic acid.

- 8) The results of the kinetic analysis of the data obtained for FOE Sulfonic acid in Laacherhof soil (study by [Hellpointner; 1999]):

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-98 and in numerical form in the table B.8.1.1.2.1.1_CA-197. Additionally the table B.8.1.1.2.1.1_CA-198 provides the kinetic endpoints obtained with each of the kinetic models tested.

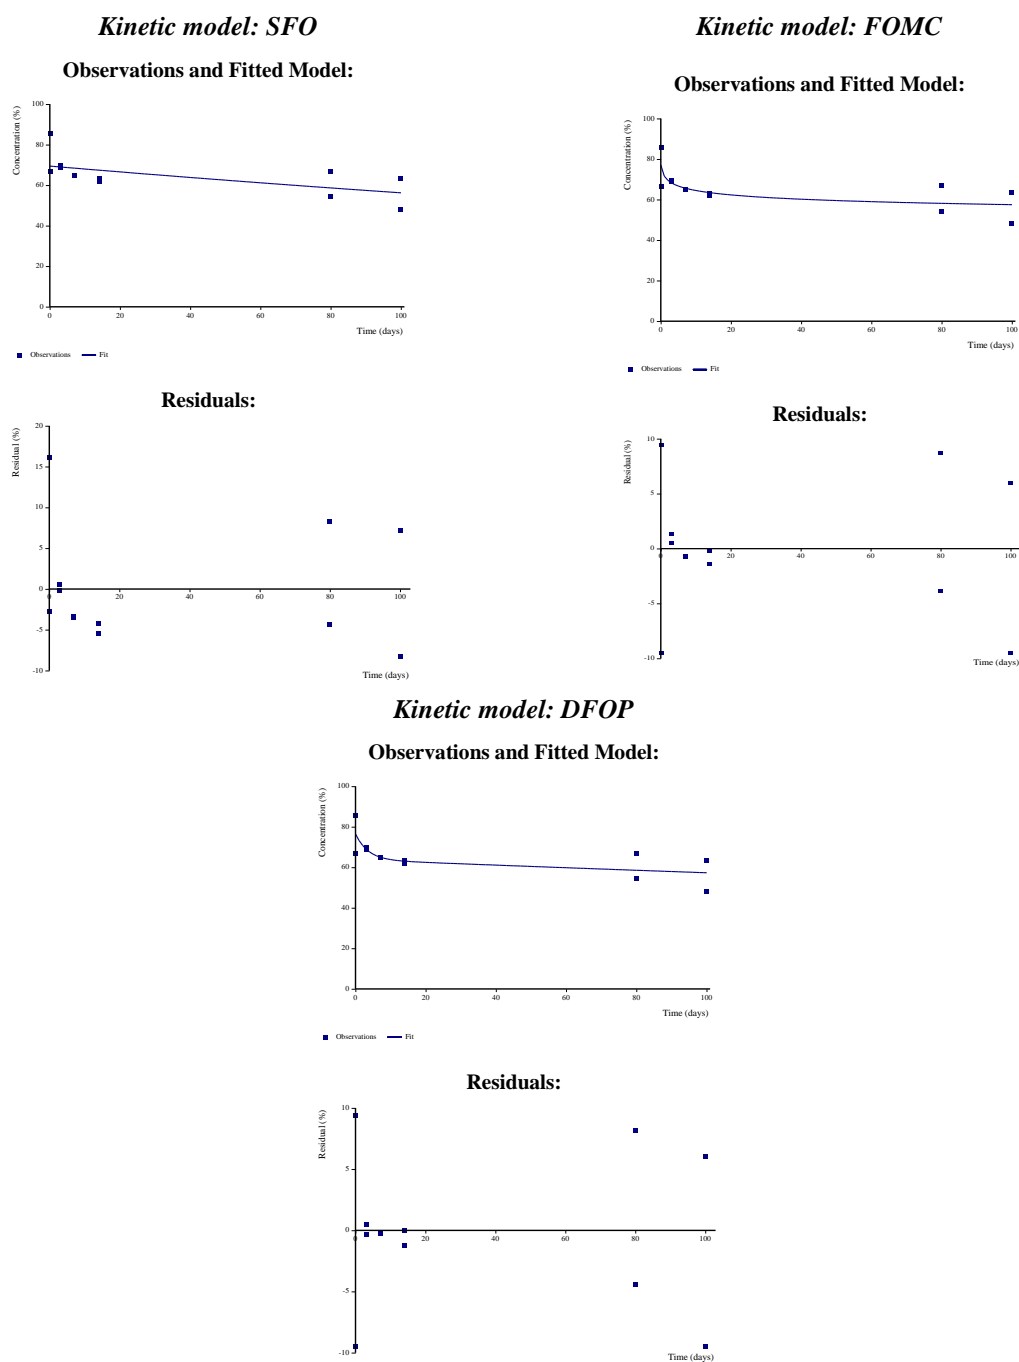

Figure B.8.1.1.2.1.1_CA-98: The graphical results of the kinetic analysis.

SFO	M_0	69.45	2.838	63.12	75.77	n. c. ¹⁾	4.6	0.380; Poor fit
	k	2.106 E-3	8.80 E-4	1.45 E-4	0.004	0.01888		
FOMC	M_0	77.12	6.571	62.26	91.99	n. c. ¹⁾	3.304	0.546; Acceptable fit
	α	0.05034	0.02882	-0.01486	0.116	n. c. ¹⁾		
	β	0.2956	1.048	-2.075	2.667	n. c. ¹⁾		
DFOP	M_0	76.49	5.114	64.74	88.29	n. c. ¹⁾	1.67	0.556; Acceptable fit
	k_1	0.2822	0.4032	-2.04 E-3	1.212	0.2519		
	k_2	1.062 E-3	1.345 E-3	-2.04 E-3	0.004	0.2263		
	g	0.1664	0.09631	-0.05565	0.389	n. c. ¹⁾		

Footnotes to the table:

1) Value not calculated by the modelling tool;

Table B.8.1.1.2.1.1_CA-198: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
FOE Sulfonic acid	DT ₅₀ [days]	329	> 10000	481
	DT ₉₀ [days]	1090	> 10000	2000

Conclusion:

The modification of the data set by removal of the alleged outlier did not significantly improve the results of the fitting. The fits, although statistically acceptable, were visually either poor – SFO fit, or only acceptable – FOMC and DFOP. Additionally, neither FOMC nor DFOP returned reliable kinetic parameters. It shall be noted that the concentrations at the end of experiment were well above 10% of the assumed initial concentration, therefore FOMC fit, even if reliable, should not be used to derive kinetic modelling endpoints.

As a result RMS is of the opinion that none of the obtained kinetic fits may be considered acceptable and the results for that soil should not be included into the data set for FOE Sulfonic acid.

As it was not possible to obtain the reliable kinetic fit for FOE Sulfonic acid in Laacherhof soil using the data set with replicates the RMS, having analysed the available data, decided to repeat the fitting for that soil using the average values for each time point. The analysis was performed for modified data-set, from which the DAT-30 and DAT-63 time points were removed as outliers. The resulting data set used in the fitting is presented below in the table B.8.1.1.2.1.1_CA-199.

Table B.8.1.1.2.1.1_CA-199: The data set used in the kinetic examination.

Time Point – DAT [days]	0.08	3	7	14	80	100
Average concentration [%] of FOE Sulfonic acid	76.2	69.2	64.9	62.6	60.6	55.7

The processed data were kinetically examined using CAKE ver. 3.1 modelling tool, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The settings of the optimiser were the defaults of the tool:

- maximum iterations: 100,
- maximum reweighing: 10,
- SANN maximum iterations: 10000,
- convergence tolerance: 1 E-5,
- error variance tolerance: 1 E-5,
- extra solver: yes, if required.

To reproduce as closely as possible the evaluation performed by the Applicant the RMS used all three kinetic models – SFO, FOMC and DFOP. The initial parameters were the same as presented in the study report.

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-99 and in numerical form in the table B.8.1.1.2.1.1_CA-200.

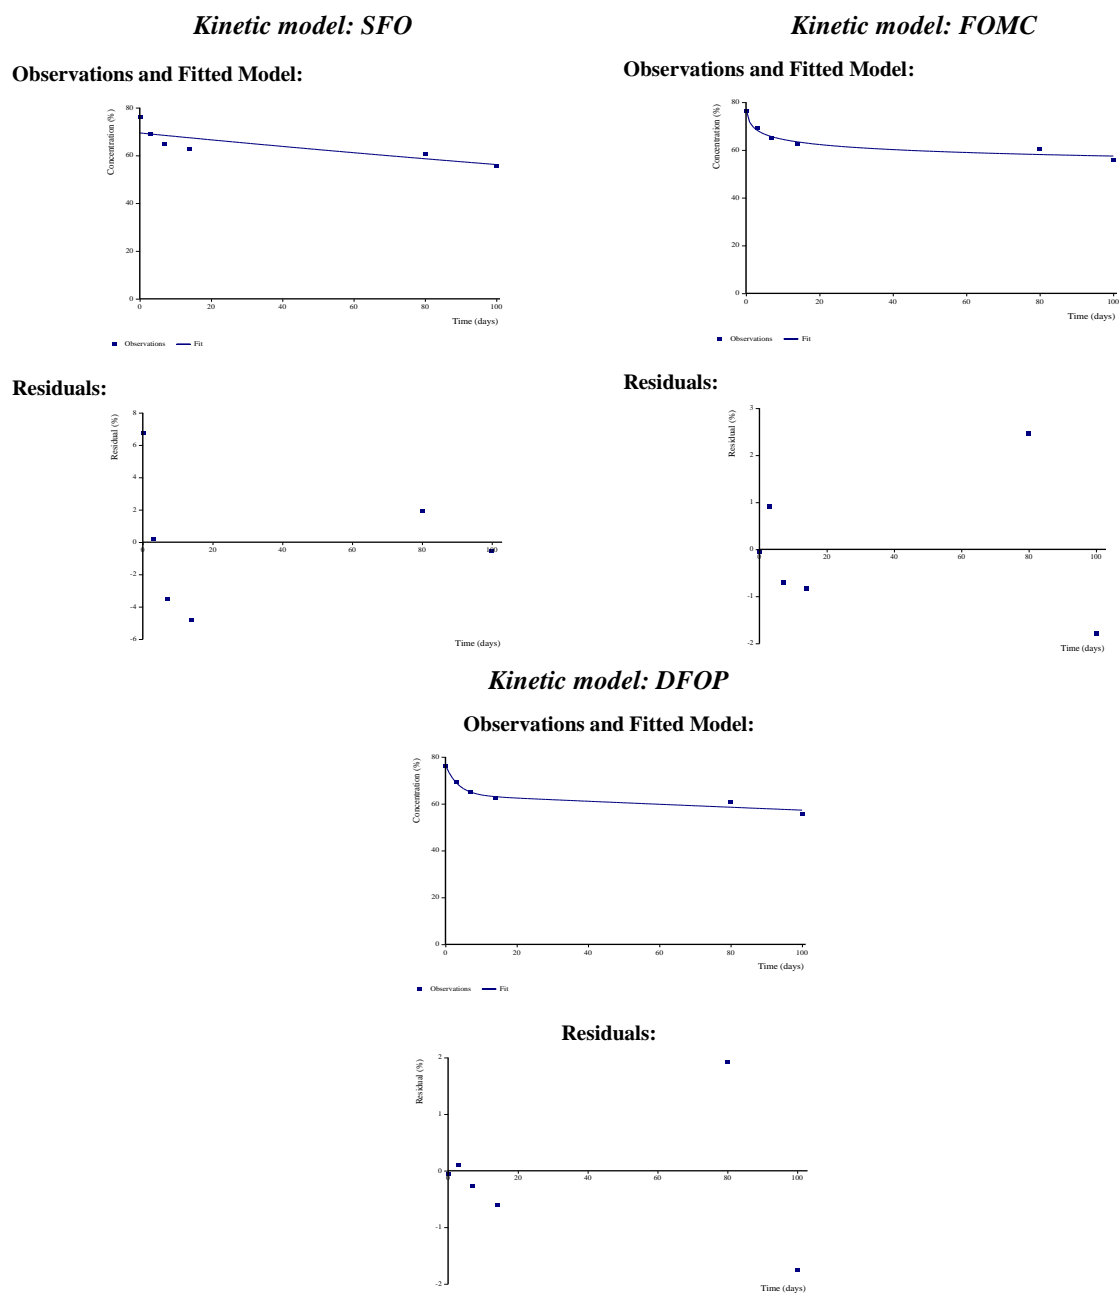

Figure B.8.1.1.2.1.1_CA-99: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-200: The numerical results of the kinetic analysis.

	k_1	0.2846	0.1531	-0.3741	0.943	0.102		
	k_2	1.068 E-3	5.08 E-4	-1.118 E-3	0.003	0.0852		
	g	0.1671	0.03636	0.0106	0.324	n. c. ¹⁾		

Footnotes to the table:

1) Value not calculated by the modelling tool;

Conclusion:

The use of the average concentrations instead of replicates for each time points resulted in improvement of all visual fits – SFO fit became acceptable, while both bi-phasic fits – FOMC and DFOP can be classified as good fits. All three fits are statistically reliable, with DFOP being superior of all three. However, none of bi-phasic fits may be considered acceptable due to the lack of reliability of the kinetic parameters. In case of DFOP fit not reliable was k_1 , for which $prob. > t$ was slightly above 0.1, while in case of FOMC in was β , for which CI passed through zero. Additionally it was noticed that FOMC could not be used because the concentration of the test compound at the end of the experiment – on DAT 100, was well above 10% of the initial (FOCUS Kinetics recommendation). As a result, the statement made previously by the RMS, none of the obtained kinetic fits may be considered acceptable and the results for Laacherhof soil from the study by [Hellpointner; 1999] should not be included into the data set for FOE Sulfonic acid.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-201. The results for Laacherhof were not presented as it was not possible to obtain fully reliable fit for FOE Sulfonic acid in that soil.

Table B.8.1.1.2.1.1._CA-201: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
Soil name	Soil type (USDA)	OC [%]	pH ¹⁾			χ^2 error	Visual fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]

2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

Study 14:

Report: Traub M., (2012): “FOE methylsulfone: Aerobic Degradation in Four European Soils.”; Eurofins Agrosience Services EcoChem GmbH, Eutinger Str. 24, 75223 Niefern-Öschelbronn, Germany, for Bayer Crop Science AG, 40789 Monheim, Germany; unpublished study No. S11-03808; 2012. 10.18; study reference number: M-443658-01-1;

Guidelines: The study was declared to be performed in line with the provisions of the OECD Guideline for the Testing of Chemicals No. 307 – Aerobic and Anaerobic Transformation in Soil. The Applicant stated that no deviations from that Guideline were found. Additionally, because the results of the study were kinetically evaluated and the results presented in the study report, it was declared that the following Guideline was used:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;

In this case also no deviations from the Guideline referred to were stated.

GLP: Yes;

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to determine the rate of degradation of FOE Methylsulfone in aerobic soil under laboratory conditions. The experiment was performed on four test soils taken from the agriculturally used areas, representing different geographical origin and different soil properties, in line with the requirement of the relevant Guideline. The characteristic of the test soils is provided below in the table B.8.1.1.2.1.1._CA-202.

Table B.8.1.2.1.1.CA-202: The characteristic of soils used in the study.

Parameter		Soil

Footnotes to the table:

- 1) Value calculated from experimentally determined OC content, using the following equation: OM = 1.724 OC;
- 2) Determined using the SIR method developed by Anderson & Domsch [1978];
- 3) Values recalculated by the RMS using the OC content reported in the table for each test soil;
- 4) Determined in samples not treated with blank application solution – 0.4 mL of 1:1 MeOH/H₂O;
- 5) Determined in samples treated with blank application solution – 0.4 mL of 1:1 CH₃OH/H₂O;

The test soils were sampled shortly before being used (20 days before the experiment began) with shovel from 0-20 cm layer of grassland plot. No Plant Protection Products were used on the sampling field for 5 years preceding sampling. The samples of the test soils were transported to the test facility in plastic bags. There they were stored at $T = 6^{\circ}\text{C}$ until being used. Prior to their use test soils were sieved through 2-mm sieve. The whole soil sampling-and-handling procedure was declared to be performed in accordance with ISO 10381-6.

The experiment was performed using 300-mL Erlenmeyer flasks for kinetic samples and concurrent recovery samples, and in 250-mL Erlenmeyer flasks for the determination of soil biomass. 100-g (d. w.) portions of sieved test soils were weighed into each flask. Next the soil moisture of each sample was adjusted to $55 \pm 5\%$ MWHC by addition of the appropriate amount of deionised water. So prepared incubation flask were stoppered with cotton-wool plugs to allow free exchange of air. The example incubation vessel is presented below on figure B.8.1.1.2.1.1._CA-100. In total 32 incubation vessels were prepared – 22 as kinetic samples and 10 for the determination of soil biomass. Additionally there were prepared 47 flasks containing Laacherhof AXXa soi, used as concurrent recovery samples.

After adjustment of the soil moisture the incubation vessels were pre-conditioned for 5 days in the dark, in a temperature-controlled walk-in climatic chamber at $T = 20 \pm 2^{\circ}\text{C}$, until being treated with the test compound. The number of incubation vessels prepared for each test soils was such to grant at least to have duplicate treated samples at each sampling point and those for the determination of soil biomass in soil samples not treated and treated with blank application solution.

The treated soils were incubated in 300 mL Erlenmeyer glass flasks. The untreated soil samples for the biomass determination were incubated in 250 mL glass flasks with a screw thread. Each flask was closed by cotton wool.

Figure B.8.1.1.2.1.1._CA-100: The example incubation vessel (copied from the study report).

The test compound was a non-radiolabelled FOE Methylsulfone, having the chemical purity of 97.2%. Its structural formula is shown below on figure B.8.1.1.2.1.1._CA-101.

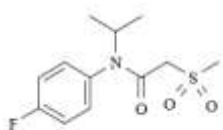

Figure B.8.1.1.2.1.1._CA-101: The structural formula of the test compound used in the experiment (copied from the study report).

It was delivered as a solid sample, in form of a light-yellow powder. That sample was used entirely to prepare firstly a **Stock solution** and then **Application solutions**.

The **Stock solution** was prepared by dissolving the whole delivered sample of FOE Methylsulfone in appropriate amount of $\text{CH}_3\text{OH}/\text{H}_2\text{O}$ (1:1 v/v), to obtain a solution having a nominal concentration 100 mg FOE Methylsulfone. From it, by dilution with the appropriate amounts of $\text{CH}_3\text{OH}/\text{H}_2\text{O}$ 1:1 (v/v), three following **Application solutions** were prepared:

- **Application solution S40**, having a concentration 40 mg FOE Methylsulfone/L, used to treat all kinetic samples and to prepare the **Application solution S2**, characterised below;
- **Application solution S44**, having a concentration 44 mg FOE Methylsulfone/L, used to treat the recovery samples at fortification level of 22 LOQ;

- Additionally, by diluting **Application solution S40**, was prepared the **Application solution S2**, having a concentration 2.0 mg FOE Methylsulfone/L and used to treat the concurrent recovery samples at LOQ level.

All application solutions were prepared in the same solvent as used for the **Stock solution** – CH₃OH/H₂O 1:1 (v/v).

The **Application solution S40** was used to treat degradation samples. To do that 0.198 mL of it was applied dropwise onto soil surface in each incubation vessel to obtain the application dose of 7.94 µg FOE Methylsulfone/100 g soil (d. w.). That application dose – equal to 0.0794 mg/kg soil, was determined using the following assumptions:

- field application rate of Flufenacet (parent compound, precursor of FOE Methylsulfone): 600 g/ha;
- maximum occurrence of FOE Methylsulfone in aerobic soil (determined in the laboratory studies): 6.6%;
- molar weight of Flufenacet $M = 363.3$ g/mol;
- molar weight of FOE Methylsulfone $M' = 273.3$ g/mol;
- soil bulk density: 1.5 g/cm³;
- thickness of the soil layer: 2.5 cm.

RMS analysing the calculations noticed that the assumed soil layer was ½ of that routinely used to calculate field application rate (in [g/ha]) Therefore the would-be application rate for Methylsulfone was recalculated using the standard assumptions:

- soil bulk density: 1.5 g/cm³;
- thickness of the soil layer: 5 cm.

The so calculated field application rate **A = 59.55 g FOE Methylsulfone/ha**.

Using the measured soil bulk density of each test soil used in the experiment that value would be:

- for Laacherhof AXXa soil: **A = 47.24 g/ha**;
- for Dollendorf II soil: **A = 40.89 g/ha**;
- for Höfchen am Hohenseh 4a soil: **A = 43.27 g/ha**;
- for Wurmwiese soil: **A = 46.45 g/ha**

The verification of application rate and homogeneity of application of kinetic samples was performed using **Application solution S40** (100% application level), in duplicate, at the beginning and at the end of application. That was done by transferring 0.198-mL portions of the application solution into volumetric flask The solution was brought to the volume with 4:1 (v/v) CH₃CN/H₂O and analysed using HPLC-MS/MS.

In the same manner, using the appropriate application solutions, was performed the verification of application rate and homogeneity of application of concurrent recovery samples, fortified at 110% application level and at LOQ level.

Immediately after treatment the incubation vessels designated as degradation samples were stoppered with cotton wool plugs, placed in the darkness in temperature-controlled walk-in climatic chamber and incubated for up to 120 days under aerobic conditions at $T = 20 \pm 2^\circ\text{C}$. Duplicate samples were removed from incubation chamber at following time-points (DAT stands for “Days After Treatment”):

- for Laacherhof AXXa soil: DAT 0, DAT 1, DAT 2, DAT 6, DAT 13, DAT 27, DAT 61, DAT 92 and DAT 120;
- for Dollendorf II soil: DAT 0, DAT 1, DAT 2, DAT 6, DAT 13, DAT 27, DAT 61, DAT 92 and DAT 120;
- for Höfchen am Hohenseh 4a soil: DAT 0, DAT 1, DAT 2, DAT 6, DAT 13, DAT 27, DAT 61, DAT 92 and DAT 120;
- for Wurmwiese soil: DAT 0, DAT 1, DAT 2, DAT 6, DAT 13, DAT 27, DAT 61, DAT 70, DAT 92 and DAT 120.

The soil moisture content in incubation vessels was controlled by weighing them twice a week during incubation and adjusting water content, if necessary, to the designated level by adding the appropriate amount of distilled water.

Samples removed from the incubation chamber were processed and analysed immediately after sampling. That was done for the entire portions of the test soil recovered at each sampling point, using the procedure presented below on figure B.8.1.1.2.1.1._CA-102. The same procedure was applied to Concurrent Recovery Samples.

Flow Chart of the Procedure for Sample Analysis

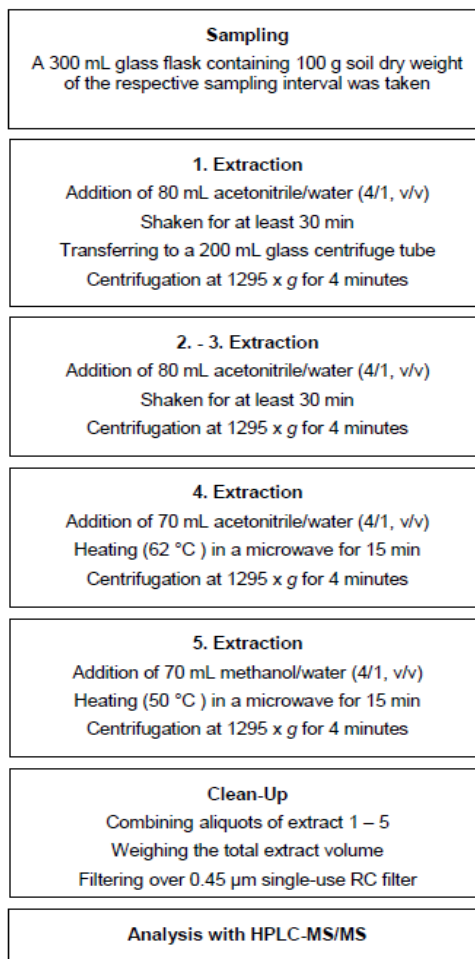

Figure B.8.1.1.2.1.1._CA-102: The sample-processing procedure used in the experiment (scheme copied from the study report).

The samples for the determination of soil biomass were set alongside the degradation samples. The soil biomass was determined in pre-conditioned test soil samples sampled on DAT 0 (beginning of the incubation period), DAT 58 (middle of the incubation period) and DAT 120 (end of incubation period). The experiment was performed in two variants:

- “BIO-” samples, not treated with blank application solution; these samples were taken for the analysis on DAT 0, DAT 58 and DAT 120;
- “BIO+” samples, treated with 0.198 mL of blank application solution (CH₃OH/H₂O 1:1 v/v); these samples were taken for the analysis on DAT 58 and DAT 120.

The quantitative and qualitative analysis of combined soil extracts and other liquid samples was performed by means of HPLC-MS/MS. The analysis was performed using Agilent LC-system equipped with autosampler and Sciex API5000 detector. The chromatographic separation was performed on Phenomenex Synergi Fusion-RP 80-A 50*2 mm chromatographic column, preceded by 4-mm guard column of the same type, working in a gradient mode. The column was maintained at constant temperature T = 20°C. The gradient elution programme is presented below in the table B.8.1.1.2.1.1._CA-203.

Table B.8.1.1.2.1.1._CA-203: The HPLC gradient modes used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% CH₃COOH</i>	<i>Solvent B – CH₃OH + + 0.1% CH₃COOH</i>
0.00	80	20
0.50	80	20
2.00	10	90
3.50	10	90
3.51	80	20
4.00	80	20

The elution lasted for 6 minutes and the flow rate of the mobile phase was 0.5 mL/min.

The identification of the test compound was performed by means of MS analysis. Its parameters were following:

- ionization mode: ESI;
- source polarity: positive;
- Ion spray voltage: 5500V;
- Temperature: 450⁰C;
- Collision gas: 5V;
- Entrance potential: 10V;
- Declustering potential: 116V.

The analysis was performed using the following fragment ions:

- m/z = 231.8 as quantifier;
- m/z = 111.9 as qualifier.

Additional identification parameter for FOE Methylsulfone was the retention time $R_t = 2.1$ min. (approx.).

The quantitative analysis was performed using the external 10-point calibration curve ranging from 0.2 ng/mL to 40 ng/mL. It was prepared from the stock solution of the test compound in CH₃OH/H₂O 1:1 (v/v). The concentration of the stock solution was 100 mg/L. The calibration curve was prepared for each test soil in blank soil matrix obtained by processing 100-g test soil samples in a manner identical to that presented on figure B.8.1.1.2.1.1._CA-102 for kinetic samples. The solutions used to construct the calibration curves had following nominal concentrations of FOE Methylsulfone: 0.2 ng/mL, 0.3 ng/mL, 0.5 ng/mL, 1.0 ng/mL, 5.0 ng/mL, 8.0 ng/mL, 10.0 ng/mL, 20.0 ng/mL, 30 ng/mL and 40 ng/mL.

The accuracy and repeatability was assessed for each test soil. That was done using recovery samples prepared at each sampling point and fortified with the test compound at LOQ- and 22-fold LOQ- levels.

The obtained results – concentrations of FOE Methylsulfone in each test soil at each time point, were subjected to the kinetic analysis in order to identify the best-fit kinetic model and determine persistence kinetic endpoints for FOE Methylsulfone in each test soil.

The kinetic analysis was performed in line with the recommendations of the FOCUS Kinetics Guidance Document [FOCUS; 2006], using KinGUI 2 modelling tool. It followed the procedure used in several already summarised studies, in particular **Study 4** and **Study 5** models. Three kinetic models were used in the assessment – SFO, FOMC and DFOP. The obtained fit were evaluated using the same principles as presented in the summaries of **Studies 2 – 8**.

The results of the study are presented below.

Results and their discussion:

The results of the determination of soil physicochemical properties and soil microbial activity in each test soil are presented in the table B.8.1.1.2.1.1._CA-202 at the beginning of this summary. On their basis it can be stated that the soils were appropriately selected, in line with the recommendations of OECD 307 Guideline, and were biologically viable throughout the experiment.

The results of the monitoring of the incubation temperature are presented below on figure B.8.1.1.2.1.1._CA-103. In the study report it was stated that the mean incubation temperature was 19.7⁰C and it ranged from 17.7⁰C to 22.3⁰C. It was indicated however, that that highest temperature was measured sporadically – on three occasions during incubation period, and it lasted for no longer than 1 hour, therefore it had no impact on the study results.

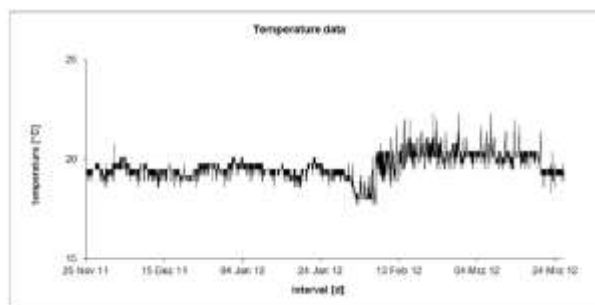

Figure B.8.1.1.2.1.1_CA-103: The temperature recorded during soil pre-conditioning and samples incubation period (copied from the study report).

The results of the monitoring of soil moisture during the experiment demonstrated that that parameter was maintained at the designated level of $55 \pm 5^{\circ}\text{C}$ throughout the study duration.

The results of the determination of application rate and the homogeneity of application are presented below, in the table B.8.1.1.2.1.1_CA-204. On their basis it was stated that the actual application rate was $8.17 \mu\text{g}$ FOE Methylsulfone/100 g soil (d.w.) – 0.0817 mg FOE Methylsulfone/kg soil (d. w.). That value was set as 100% applied – a reference value for expressing the concentration of FOE Methylsulfone as [% Applied].

Table B.8.1.1.2.1.1_CA-204: The results of the verification of application rate and homogeneity of application.

Sample	Replicate	Chromatographic peak area [counts]	Amount of FOE Methylsulfone [μg]	% of theoretically applied
100% before application	1	127895.4	8.81	107.8
	2	94395.4	7.79	95.4
100% after application	1	82948.8	7.34	89.8
	2	126418.8	8.75	107.1

The LOQ – limit of quantification, was defined as 1.0 ng/mL . The corresponding LOD was set to 0.2 ng/mL – 1% of applied.

The results of the determination of linearity of analytical method is presented below, in numerical and graphical form, individually for each calibration curve constructed using each test soil blank matrix.

The linearity of the calibration curve constructed using blank matrix of Laacherhof AXXa soil is presented below in table B.8.1.1.2.1.1_CA-205 and on figure B.8.1.1.2.1.1_CA-104.

Table B.8.1.1.2.1.1_CA-205: The numerical results of the determination of the linearity of the response of MS/MS detector for calibration curve constructed on soil blank matrix from Laacherhof AXXa soil.

Calibration sample No.	Nominal concentration [ng/mL]	Peak area [a.u.]			Accuracy [%]

10	0.2	17009	14633	15821	104.5

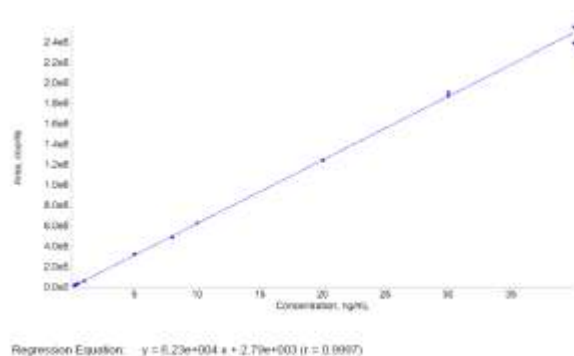

Table B.8.1.1.2.1.1._CA-107: The graphical results of the determination of the linearity of the response of MS/MS detector for calibration curve constructed on soil blank matrix from Wurmwiese soil (copied from the study report).

The results of the validation of the method on the basis of recovery, accuracy and precision, were following:

- for Laacherhof AXXa soil recovery at fortification level of 0.004 mg/kg (mean of five) was $91.1 \pm 2.0\%$, recovery at fortification level 0.101 mg/kg (mean of five) was $93.4 \pm 1.8\%$ and the overall mean recovery was $92.3 \pm 2.2\%$;
- for Dollendorf II soil recovery at fortification level of 0.004 mg/kg (mean of five) was $103.8 \pm 1.7\%$, recovery at fortification level 0.101 mg/kg (mean of five) was $90.7 \pm 2.0\%$ and the overall mean recovery was $97.2 \pm 7.3\%$;
- for Höfchen am Hohenseh 4a soil recovery at fortification level of 0.004 mg/kg (mean of five) was $96.5 \pm 2.8\%$, recovery at fortification level 0.101 mg/kg (mean of five) was $104.6 \pm 3.3\%$ and the overall mean recovery was $100.5 \pm 5.1\%$;
- for Wurmwiese soil recovery at fortification level of 0.004 mg/kg (mean of five) was $96.2 \pm 2.3\%$, recovery at fortification level 0.101 mg/kg (mean of five) was $100.3 \pm 2.9\%$ and the overall mean recovery was $98.3 \pm 3.3\%$.

On that basis it was stated that the accuracy and precision of analytical method was acceptable, with mean recoveries in range 70-110% and RSD < 20%.

The results of the concurrent recoveries, determined using Laacherhof AXXa soil, are presented below in the table B.8.1.1.2.1.1._CA-209. On their basis, as well as on the basis of the recoveries for each test soil, it was stated that the applied soil processing method was appropriate.

Table B.8.1.1.2.1.1._CA-209: The results of the determination of the recovery in concurrent recovery samples.

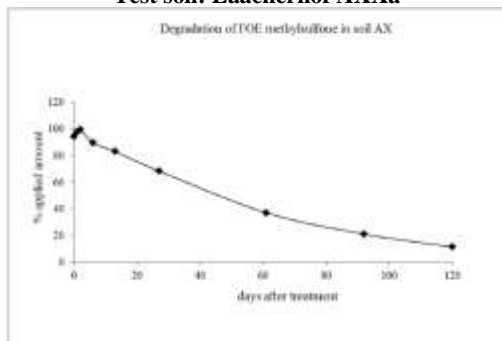

Time point – DAT [days]	Recovery in concurrent samples treated at LOQ level (0.004 mg/kg)				Recovery in concurrent samples treated at 22-fold LOQ level (0.0899 mg/kg)			
	Recovery [% applied]:			RSD [%]	Recovery [% applied]:			RSD [%]

The results of the experiment – concentrations of FOE Methylsulfone in soil in function of time, are presented below in the table B.8.1.1.2.1.1._CA-210. For each test soil the concentrations of the test compound are reported as % of applied amount – [% AA] and in [µg/kg soil]. The values expressed as [% AA] were calculated using the determined experimentally application rate – 0.0817 mg FOE Methylsulfone/kg soil, as 100% level. The graphic presentation of the results is given on figure B.8.1.1.2.1.1._CA-108.

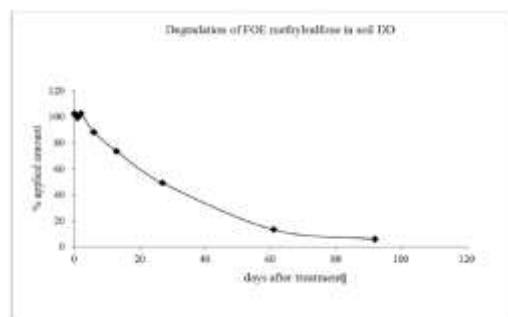

Table B.8.1.1.2.1.1._CA-210: Concentration of FOE Methylsulfone in test soils in function of time.

Test soil: Laacherhof AXXa

Test soil: Dollendorf II

Test soil: Höfchen am Hohenseh 4a

Test soil: Wurmwiese

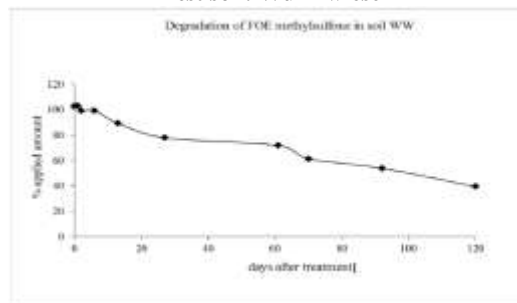

Figure B.8.1.1.2.1.1._CA-108: The graphic presentation of the results obtained in test soils (copied from the study report).

The data presented in the table B.8.1.1.2.1.1._CA-210 were subjected to the kinetic analysis aimed on the determination of the best kinetic fit and derivation of the kinetic endpoints representing persistence of the test compound. For that purpose the values obtained for replicates, expressed as [%AA], were used. The values were inserted to the model as they are presented in the table evoked above. RMS noticed that the same data set was analysed in a separate study, aimed on the identification of the appropriate fit and derivation of the kinetic endpoints representing persistence of FOE Methylsulfone in soil and suitable for modelling – study by [Reinken and Partsch; 2014] summarised below as **Study 15**. The methodology of the kinetic analysis and its results presented in both studies were compared by the RMS. It was stated that while the methodology was very similar, taking into account somewhat different goals of the kinetic analysis, the results obtained in both studies were generally the same. The differences resulted from the different aims of the kinetic analysis – in case of the currently summarised study it was to identify the best-fit kinetic model and determine the persistence endpoints for FOE Methylsulfone in the test soils. In case of the summarised below study by [Reinken and Partsch; 2014], the major goal was to kinetically examine the data set in order to derive kinetic endpoints suitable for modelling. It was stated that, due to the fact that the study was specifically aimed on the kinetic analysis of the data, the procedure of kinetic fitting was characterised in a more detailed way, e.g. the optimisation method was reported.

As a results, in order not to duplicate the identical results and by that overburden the Assessment Report, RMS decided not to present the results of the kinetic analysis provided in the currently summarised study by [Traub; 2012], focusing instead on the study by [Reinken and Partsch; 2014] summarised below as **Study 15**.

Study 15:

Report: Reinken G., Partsch S., (2014): “Kinetic Evaluation of the Degradation of Flufenacet Degradation Product FOE methylsulfone under Aerobic Soil conditions in Laboratory according to FOCUS Kinetics Using the KinGUI 2 Tool. FOE methylsulfone acid.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished Study Report No. EnSa-12-0578; 2014. 02. 17; study reference number: M-477839-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above. It was stated that the study generally complied with the two evoked Guidance Documents. The study was aimed on the derivation of the modelling kinetic endpoints for FOE Methylsulfone. It followed modelling approach outlined already in other studies summarised above – **Study 2**, **Study 7** and **Study 8**. The analysis was performed for the results of the summarised above study by [Traub; 2012] (**Study 14**). The study was found to be acceptable and is summarised below.

Summary:

The aim of the study was to kinetically examine the data for FOE Methylsulfone obtained in summarised above as **Study 14** the study by [Traub; 2012], in order to derive the kinetic endpoints suitable for use in modelling exposure assessment.

In the source study the the degradation of FOE Methylsulfone was examined in four soils. Their key properties are presented below in the table B.8.1.1.2.1.1._CA-211. The experimental conditions used in the study are summarised further down, in the table B.8.1.1.2.1.1._CA-212.

Table B.8.1.1.2.1.1._CA-211: The brief characteristic of the test soils.

Soil name	Soil type (USDA classification)	Soil properties			
		pH in CaCl ₂	OC [%]	Soil microbial biomass at the beginning of the study	
				mg microbial C/kg soil	% OC
Laacherhof AXXa	Loamy sand	6.2	1.7	2044	7.05
Dollendorf II	Loam	7.0	4.6	4474	9.73
Höfchen am Hohenseh 4a	Silt loam	6.1	2.0	2299	111.50
Wurmweise	Sandy loam	5.0	1.8	1963	10.91

Table B.8.1.1.2.1.1._CA-212: The experimental conditions used in each experiment.

Test soil		Experimental conditions			
Name	Type (USDA classification)	Incubation temperature T [°C]	Soil moisture		
			In experiment [% MWHC]	Reference value	
				MWHC [g/100g soil d. w.]	% MWHC at 1/3bar
Laacherhof AXXa	Loamy sand	20 ± 2	55 ± 5	48.5	10.8
Dollendorf II	Loam	20 ± 2	55 ± 5	79.1	35.1
Höfchen am Hohenseh 4a	Silt loam	20 ± 2	55 ± 5	54.8	20.9
Wurmweise	Sandy loam	20 ± 2	55 ± 5	56.3	15.6

The not-processed input data used in the kinetic analysis are presented below in the table B.8.1.1.2.1.1._CA-213.

Table B.8.1.1.2.1.1._CA-213: The non-processed data obtained in the test soils, used in kinetic analysis.

The data presented above were subjected to a multistep evaluation procedure, almost identical to that already presented above in the summary of the **Study 2**, for convenience repeated below. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool, in order to determine the appropriate kinetic model.
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The data-processing to obtain the input values for kinetic analysis (**Step 1**) was identical to the procedure described in the summary of the **Study 2**, on page 166. The processed data used as input in the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-214.

Table B.8.1.1.2.1.1._CA-214: The processed residue data used in the kinetic analysis.

									120	37.5	41.4

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighted Nonlinear Least Squares) algorithm. The fitting procedure consisted on the determination of the appropriate kinetic model for FOE Methylsulfone

The conceptual metabolic pathway built in the modelling tool was based on the transformation pathway which, in form of a simplified scheme, is presented below on figure B.8.1.1.2.1.1._CA-109.

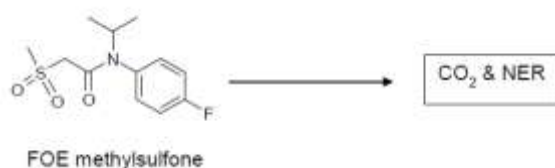

Figure B.8.1.1.2.1.1_CA-109: The simplified transformation pathway used to create conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of the evaluation procedure was presented in the summary of the **Study 2** on pages 170 – 171. RMS decided not to repeat it here in order to not overburden the Renewal Assessment Report.

On that basis the following multistep assessment procedure was followed:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in modelling, the SFO kinetic model was tested as first option and if passed the acceptance criteria (visually acceptable, χ^2 -error not exceeding or not significantly exceeding 15%, *prob. > t* value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the χ^2 -error was significantly greater than 15%, model parameters were fixed and fitting repeated using SFO model;
- **Step 3:** if the **Step-2** fitting failed the χ^2 -error test, bi-phasic models were included. These were FOMC, DFOP and, possibly HS. The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved fit, SFO model was selected if visually acceptable; that was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic analysis are presented below, individually for each test soil.

- 1) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in Laacherhof AXXa soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-110 and in numerical form in the table B.8.1.1.2.1.1._CA-215. Additionally the table B.8.1.1.2.1.1._CA-216 provides the kinetic endpoints obtained with each of the kinetic models tested.

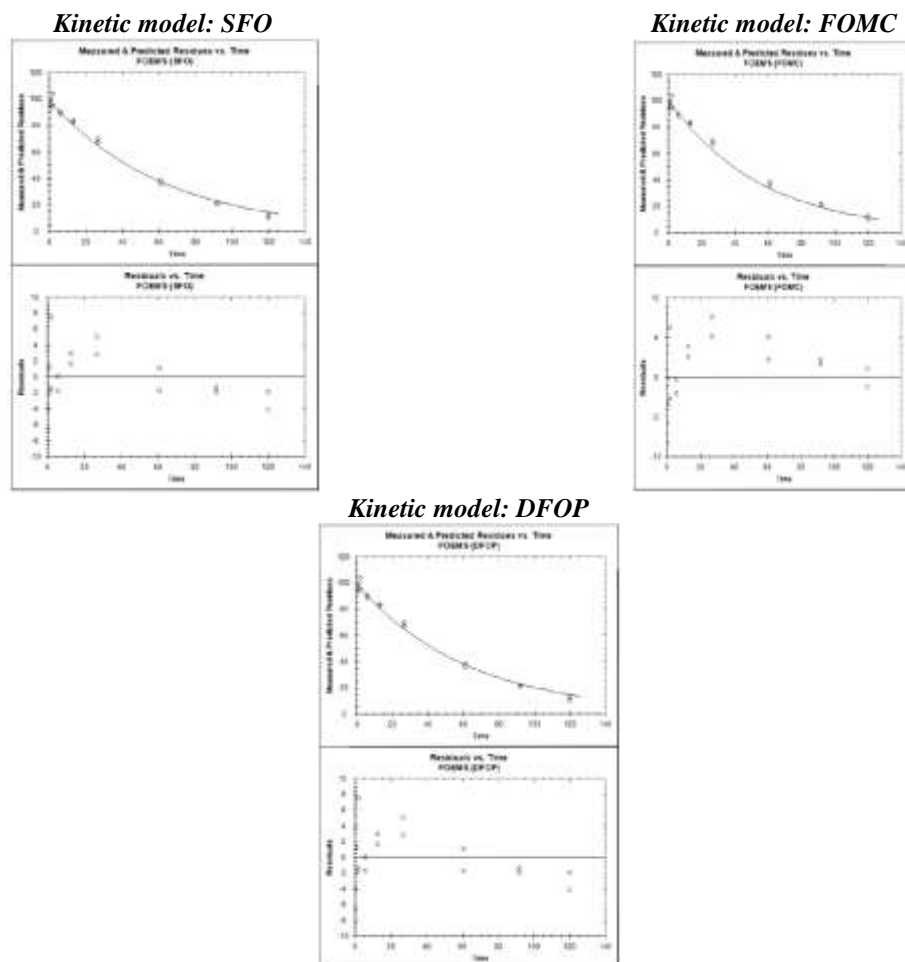

Figure B.8.1.1.2.1.1._CA-110: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-215: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	99.34	1.266	96.86	101.82	< 2 E-16	3.373	0.990; Good fit
	k	0.01607	6.741 E-4	0.01474	0.017	3.16 E-14		
FOMC	M_0	101.00	1.522	98.017	104.0	< 2 E-16	4.74	0.986; Good fit
	α	280.479	645.370	-984.423	1545.4	0.335		
	β	15418.321	35539.153	-54237.14	85073.8	0.335		
DFOP	M_0	99.338	1.334	96.724	101.951	< 2 E-16	3.802	0.990; Good fit
	k_1	0.01607	4.268 E-3	7.703 E-3	0.024	1.05 E-3		
	k_2	0.01606	2.243 E-3	0.01167	0.020	2.42 E-6		
	g	0.3365	0.6477	-0.9330	1.606	0.3057		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-216: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Methylsulfone</i>	DT ₅₀ [days]	43.14	38.15	43.14
	DT ₉₀ [days]	143.32	127.10	143.32

Conclusion:

All three models returned visually and statistically good fits. SFO was superior of the three fits with fully reliable kinetic parameters. Neither FOMC nor DFOP, despite being visually and statistically good fits, can be considered acceptable, because they returned not reliable kinetic parameters. In case of FOMC fit the problem concerned α and β , which were not reliable because CI for them passed through zero. The additional problem was that the concentration of the test compound at the end of the experiment was still, although slightly, above the level of 10%.

For DFOP not fully reliable was g , for which the $prob. > t$ was higher than 0.1. Additionally it was noticed that the model calculated the DT₅₀ and DT₉₀ values for DFOP fit exactly the same as for SFO. Also k_1 and k_2 values were practically identical, indicating that DFOP fit was artificial.

As a result, the Applicant stated that SFO model shall be considered as returning the appropriate fit for FOE Methylsulfone acid in Laacherhof AXXa soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. It shall be noted that also in the preceding study by [Traub; 2012] SFO was identified as returning the best fit with the same kinetic endpoints reported.

RMS accepted the Applicant's proposal.

- 2) The results of the kinetic analysis of the data obtained for FOE Methylsulfone acid in Dollendorf II soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-111 and in numerical form in the table B.8.1.1.2.1.1._CA-217. Additionally the table B.8.1.1.2.1.1._CA-218 provides the kinetic endpoints obtained with each of the kinetic models tested.

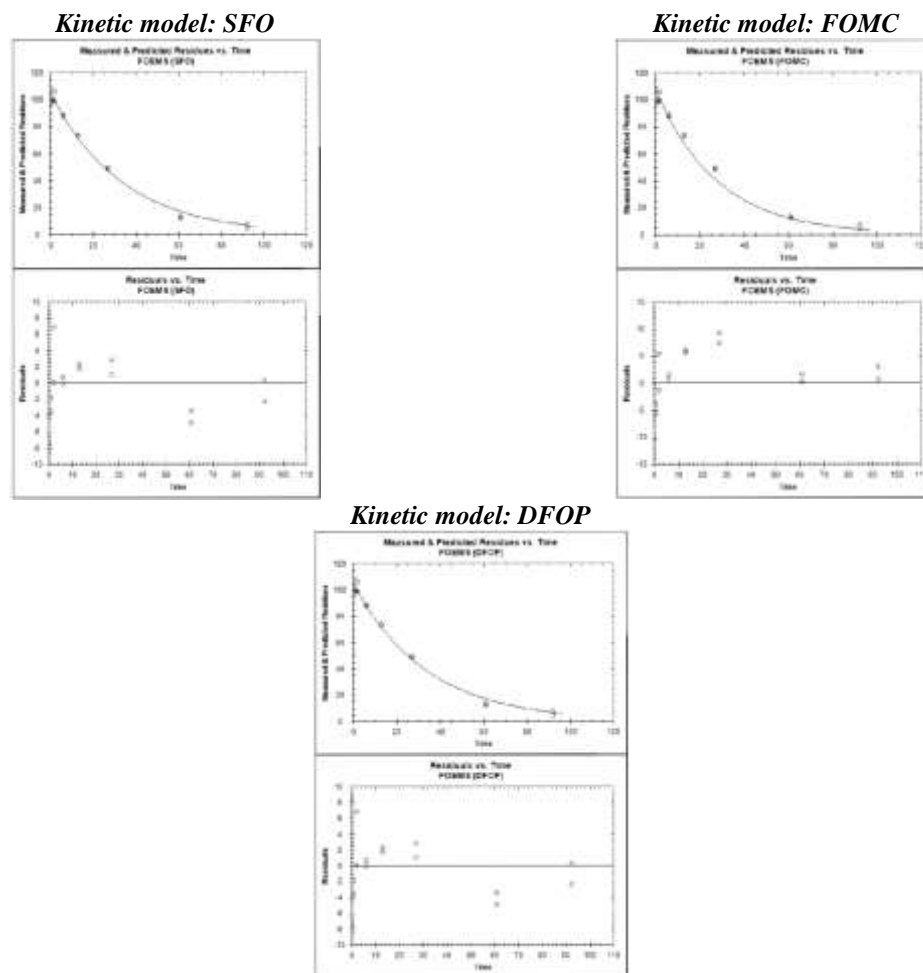

Figure B.8.1.1.2.1.1._CA-111: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-217: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	105.0	1.449	102.2	107.856	< 2 E-16	3.042	0.992; Good fit
	k	0.02975	1.399 E-3	0.0270	0.032	2.35 E-12		
FOMC	M_0	107.86	2.12	103.70	112.0	< 2 E-16	5.765	0.986; Acceptable fit
	α	372.39	794.69	-1185.18	1930.0	0.324		
	β	10322.53	22067.69	-32929.35	53574.0	0.324		
DFOP	M_0	105.015	1.568	101.942	108.089	< 2 E-16	3.505	0.992; Good fit
	k_1	0.02974	5.30 E-3	0.01936	0.040	5.96 E-5		
	k_2	0.02975	6.897 E-3	0.01623	0.043	5.04 E-4		
	g	0.5527	2.5975	-4.5382	5.644	0.4175		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1_CA-218: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Methylsulfone</i>	DT ₅₀ [days]	23.30	19.23	23.30
	DT ₉₀ [days]	77.41	64.03	77.41

Conclusion:

SFO and DFOP model returned fits that were classified by the Applicant as visually good. The fit returned by FOMC model was classified as acceptable, mainly because of the levels of residuals and their distribution. All three fits were statistically reliable – the χ^2 level for them was well below the threshold value of 15%.

The Applicant indicated the SFO model fit as returning the appropriate fit for determining the kinetic endpoints representing persistence and suitable for modelling. That model was fit was also identified as returning the best fit in the previously summarised study by [Traub; 2012].

RMS analysing the results stated that neither FOMC nor DFOP fits can be considered acceptable, because they returned not reliable kinetic parameters.

In case of FOMC fit the problem concerned α and β , which were not reliable because CI for them passed through zero.

For DFOP not fully reliable was g , for which the $prob. > t$ was higher than 0.1. Additionally it was noticed that the model calculated the DT₅₀ and DT₉₀ values for DFOP fit exactly the same as for SFO. Also k_1 and k_2 values were practically identical, indicating that DFOP fit was artificial.

The final conclusion drawn by the Applicant was that SFO model shall be considered as returning the appropriate fit for FOE Methylsulfone acid in Dollendorf II soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. It was in line with the conclusion drawn in the study by [Traub; 2012], with the identical set of kinetic endpoints determined.

RMS accepted the Applicant's proposal.

- 3) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in Höfchen am Hohenseh 4a soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-112 and in numerical form in the table B.8.1.1.2.1.1._CA-219. Additionally the table B.8.1.1.2.1.1._CA-220 provides the kinetic endpoints obtained with each of the kinetic models tested.

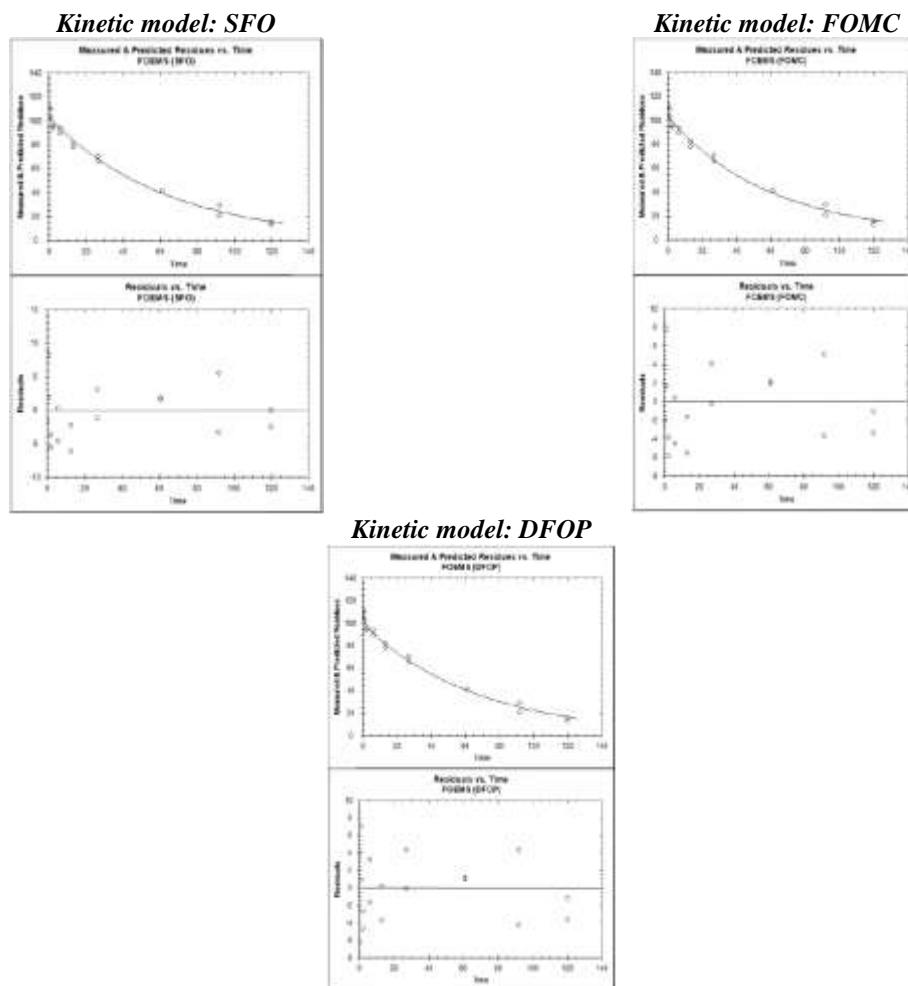

Figure B.8.1.1.2.1.1._CA-112: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-219: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	102.9	1.588	99.82	106.041	< 2 E-16	3.578	0.984; Good fit
	k	0.01581	8.267 E-4	0.01419	0.017	9.54 E-13		
FOMC	M_0	103.384	1.912	99.636	107.13	< 2 E-16	3.732	0.984; Acceptable fit
	α	9.996	22.411	-33.928	53.92	0.331		
	β	593.503	1415.817	-2181.448	3368.45	0.341		
DFOP	M_0	107.5	2.558	102.5	112.516	< 2 E-16	2.915	0.988; Acceptable fit
	k_1	0.5465	0.4315	-0.2992	1.392	0.1130		
	k_2	0.01487	8.423 E-4	0.01322	0.017	2.89 E-11		
	g	0.08144	0.03370	0.01539	0.147	0.0150		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1_ CA-220: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Methylsulfone</i>	DT ₅₀ [days]	43.84	42.62	40.90
	DT ₉₀ [days]	145.64	153.74	149.11

Conclusion:

All three models returned first that were statistically reliable – the χ^2 error for them was well below 15%, however the applicant classified only SFO fit as good in terms of visual assessment, while both FOMC and DFOP were classified as acceptable. As a result the Applicant proposed to consider SFO fit appropriate for deriving the persistence and kinetic endpoints.

That assessment differed from the presented in the study by [Traub; 2012] in the following points:

- in the study by [Traub; 2012] all three fits were considered good in terms of the visual assessment, and that classification in RMS's opinion better reflects the results;
- in the study by [Traub; 2012] DFOP was proposed as returning the best fit.

It shall be pointed out however that neither DFOP nor FOMC fits can be considered acceptable, as they returned not reliable kinetic endpoints. In case of FOMC fit the problem concerned α and β , which were not reliable because CI for them passed through zero. The additional problem was that the concentration of the test compound at the end of the experiment was still above the level of 10%.

For DFOP fit not fully reliable was k_1 , for which the *prob.* > *t* was higher than 0.1. Also the *g* value, although statistically reliable, made the fit problematic, being low – 0.081. That indicated that DFOP fit was probably artificial. Similar problems were identified in the kinetic analysis presented in the study by [Traub; 2012].

As a result it may be stated that the Applicant's proposal to consider SFO fit as appropriately representing persistence of FOE Methylsulfone in Höfchen am Hohenseh 4a soil and appropriate for deriving modelling endpoints is correct. As such it was found acceptable by the RMS.

- 4) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in Wurmwiese soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1_CA-113 and in numerical form in the table B.8.1.1.2.1.1_CA-221. Additionally the table B.8.1.1.2.1.1_CA-222 provides the kinetic endpoints obtained with each of the kinetic models tested.

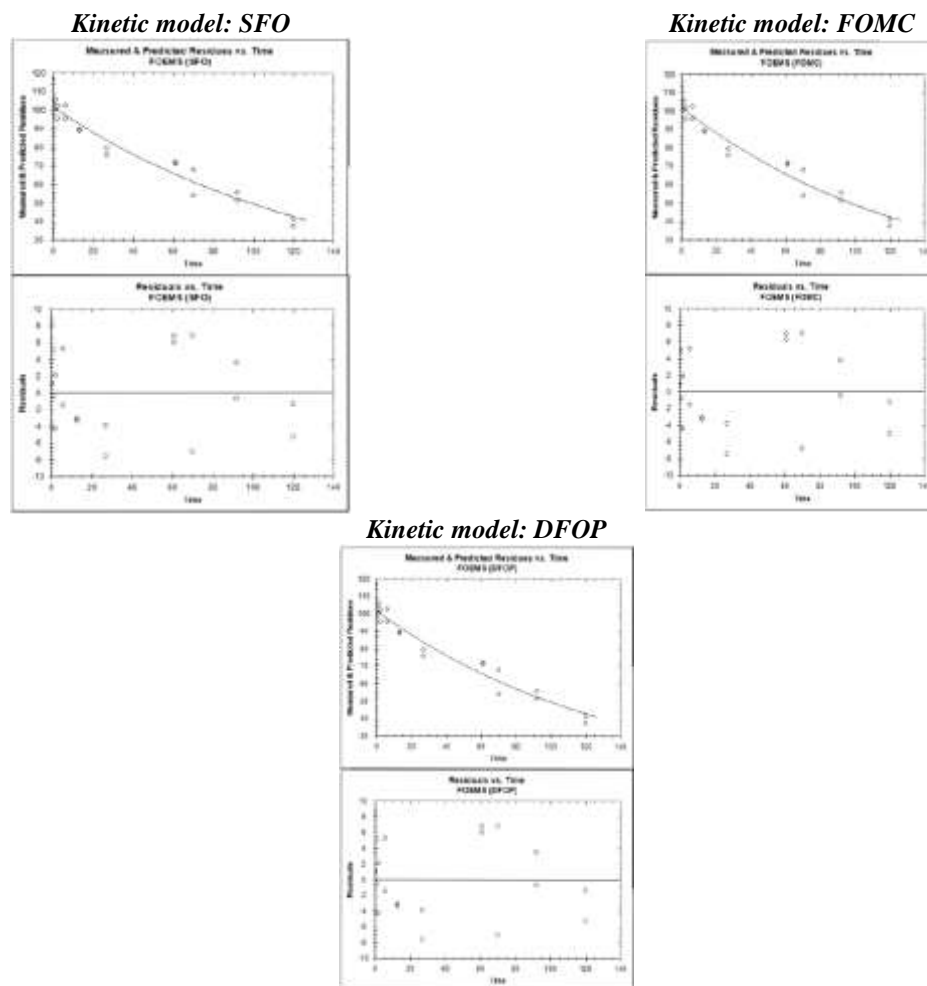

Figure B.8.1.1.2.1.1_CA-113: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1_CA-221: The numerical results of the kinetic analysis.

		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	101.6	1.551	98.53	104.612	< 2 E-16	3.317	0.958; Good fit
	k	7.211 E-3	4.179 E-4	6.392 E-3	0.008	6.05 E-13		
FOMC	M_0	101.71	1.42	98.93	104.5	< 2 E-16	3.488	0.958; Good fit
	α	89.45	111.88	-129.84	308.7	0.218		
	β	12253.25	15384.63	-17900.08	42406.6	0.218		
DFOP	M_0	101.565	39.740	23.676	179.45	0.0106	3.681	0.958; Good fit
	k_1	7.307 E-3	0.2615	-0.5053	0.52	0.4890		
	k_2	7.176 E-3	0.07785	-0.1454	0.16	0.4639		
	g	0.2495	8.0076	-15.4451	15.94	0.4878		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-222: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Methylsulfone</i>	DT ₅₀ [days]	96.13	95.32	96.16
	DT ₉₀ [days]	319.32	319.52	319.46

Conclusion:

All three models returned visually and statistically good fits. SFO was superior of the three fits with fully reliable kinetic parameters. Neither FOMC nor DFOP, despite being visually and statistically good fits, can be considered acceptable, because they returned not reliable kinetic parameters.

In case of FOMC fit the problem concerned α and β , which were not reliable because CI for them passed through zero. The additional problem was that the concentration of the test compound at the end of the experiment was still, although slightly, above the level of 10%.

For DFOP none of the three determined kinetic parameters – k_1 , k_2 or g , may be considered reliable, because for calculated for them $prob. > t$ was significantly higher than 0.1, being close to 0.5. Additionally it was noticed that the model calculated the DT₅₀ and DT₉₀ values for DFOP fit very similar to those determined for SFO kinetic fit. Finally, the k_1 and k_2 values were almost identical, what may indicate that DFOP fit was artificial.

As a result, the Applicant stated that SFO model shall be considered as returning the appropriate fit for FOE Methylsulfone acid in Wurmwiese soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. It shall be noted that also in the preceding study by [Traub; 2012] SFO was identified as returning the best fit with the same kinetic endpoints reported.

RMS accepted the Applicant's proposal.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-223.

Table B.8.1.1.2.1.1._CA-223: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
Soil name	Soil type (USDA)	OC [%]	pH ¹⁾			χ^2 error	Visual fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]
<i>Laacherhof AXXa</i>	Loamy sand	1.7	6.2	19.7°C/ 55% MWHC	SFO	3.373	G	k	1.607 E-2	43.14	143.3

Footnotes to the table:

1) Measured in 0.01M CaCl₂.

2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

Study 16: Ströch K., Junge T., (2013): „FOE methylsulfone: Degradation in Four Aerobic Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany; unpublished Study Report No. EnSa-13-0617; 2013. 10. 24; study reference number: M-467858-01-1;

Guidelines: The study was declared to be performed in line with the provisions of the OECD Guideline for the Testing of Chemicals No. 307 – Aerobic and Anaerobic Transformation in Soil. The Applicant declared that no deviations from that Guideline were found. Additionally, as the data obtained in the study were kinetically evaluated and the results presented in the study report, it was declared that the following Guideline was used:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;

In this case also no deviations from the Guideline referred to were stated.

GLP: Yes;

RMS comments: This is a new study submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. No deviations from the declared Guidelines were stated. The study is summarised below.

Summary:

The aim of the study was to determine the kinetic degradation rate of FOE Methylsulfone in aerobic soil under laboratory conditions. The experiment was performed on four test soils taken from the agriculturally used areas, representing different geographical origin and different soil properties, in line with the requirement of the relevant Guideline. The characteristic of the test soils is provided below in the table B.8.1.1.2.1.1_CA-224.

Table B.8.1.2.1.1.CA-224: The characteristic of soils used in the study.

Parameter		Soil			
		<i>Hanscheider Hof</i>	<i>Frankenforst</i>	<i>LUFA 2.3</i>	<i>LUFA 6S</i>
Soil origin		Burscheid/ North Rhine-Westphalia/ Germany	Vinxel/ North Rhine-Westphalia/ Germany	Offenbach/ Rheinland-Palatinate/ Germany	Siebelingen/ Rheinland-Palatinate/ Germany
Soil type (USDA)		Loam	Silt loam	Sandy loam	Clay

Footnotes to the table:

- 1) Value calculated from experimentally determined OC content, using the following equation: OM = 1.724 OC;
- 2) Determined using the SIR method developed by Anderson & Domsch [1978];
- 3) Values recalculated by the RMS using the OC content reported in the table for each test soil;
- 4) Determined in samples not treated with blank application solution – 0.4 mL of 1:1 CH₃OH/H₂O; instead 0.2 mL of distilled water was added;
- 5) Determined in samples treated with blank application solution – 0.4 mL of 1:1 CH₃OH/H₂O;
- 6) Due to deviation during measurement that sample was reanalysed on DAT 63.

The test soils were sampled shortly before being used (19 or 22 days before the experiment began) with shovel from 0-20 cm layer of grassland plot. No Plant Protection Products were used on the sampling field for 5 years preceding sampling. The samples of the test soils were transported to the test facility in plastic bags. There they were sieved through 2-mm sieve and stored in the darkness at either $T < 8^{\circ}\text{C}$ or $T = 20^{\circ}\text{C}$ until being used. The whole soil sampling-and-handling procedure was declared to be performed in accordance with ISO 10381-6.

The experiment was performed using 300-mL Erlenmeyer flasks into which 100-g (d. w.) portions of sieved test soils were weighed. Next, the soil moisture of each sample was adjusted to $55 \pm 5\%$ MWHC by addition of the appropriate amount of deionised water. So prepared incubation flask were then capped with PU plugs to allow free exchange of air. The example incubation vessel is presented below on figure B.8.1.1.2.1.1._CA-114. After adjustment of the soil moisture the incubation vessels were pre-conditioned for 3 days in the dark, in a temperature-controlled walk-in climatic chamber at $T = 20 \pm 2^{\circ}\text{C}$, until being treated with the test compound. The number of incubation vessels prepared for each test soils was such to grant at least to have duplicate treated samples at each sampling point and those for the determination of soil biomass in soil samples not treated and treated with blank application solution.

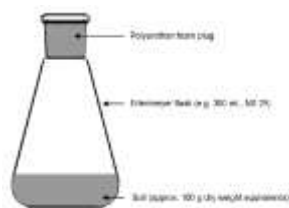

Figure B.8.1.1.2.1.1._CA-114: The example incubation vessel (copied from the study report).

The test compound was not radiolabelled FOE Methylsulfone, having the chemical purity of 97.2%. Its structural formula is shown below on figure B.8.1.1.2.1.1._CA-115.

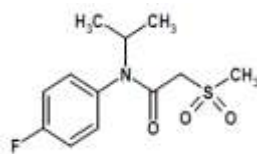

Figure B.8.1.1.2.1.1._CA-115: The structural formula of the test compound used in the experiment (copied from the study report).

It was delivered as a solid sample, in form of a light-yellow powder. The whole delivered amount of the test compound was used to prepare first a **Stock solution** and then **Application solutions**.

The **Stock solution** was prepared by dissolving the whole delivered sample of FOE Methylsulfone in 1.0 mL of CH_3CN , followed by 10-minutes lasting sonication, to obtain a solution having a nominal concentration 9.7 mg FOE Methylsulfone/mL. The so prepared **Stock solution**, labelled **TM108_SS**, was stored in the darkness at $T \leq -18^{\circ}\text{C}$ until being used.

The **Stock solution TM108_SS** was subsequently used to prepare the **Application solution of Test Item at Application Rate Level**, labelled **TM108_AS_AR**, further called **Application solution TM 108_AS_AR**. The **Application solution TM 108_AS_AR** was in turn used to prepare the **Application solution of Test Item at LOQ Level**, labelled **TM108_AS_LOQ**, further called **Application solution TM 108_AS_LOQ**.

The **Application solution TM 108_AS_AR** was used to treat degradation samples and method validation samples, and to create the calibration curve used in quantitative HPLC-MS/MS analysis. The **Application solution TM 108_AS_LOQ** was used for treatment of concurrent recovery samples at LOQ and for method validation.

The **Application solution TM 108_AS_AR** was prepared by transferring 0.205 mL of the **Stock solution TM108_SS** into 100-mL volumetric flask and evaporating it to dryness under the constant gentle stream of N_2 . The residue was redissolved in appropriate amount of $\text{CH}_3\text{OH}/\text{H}_2\text{O}$ 1:1 (v/v) solution and sonicated for 10 minutes. The obtained solution had a nominal concentration 19.9 $\mu\text{g}/\text{mL}$. The identity of the test compound in so prepared solution was conformed by HPLC-MS/MS. The **Application solution TM 108_AS_AR** was stored in the dark at $T \leq 8^{\circ}\text{C}$.

The **Application solution TM 108_AS_LOQ** was prepared from **Application solution TM 108_AS_AR** by diluting the latter. That was done in the following way: 2.5 mL of the **Application solution TM 108_AS_AR** was transferred to the 50-mL volumetric flask, brought to volume with the adequate amount of CH₃OH/H₂O 1:1 (v/v) solution and sonicated for 10 minutes. The obtained solution had a nominal concentration 1.0 µg/mL. That solution was also stored in the dark at $T \leq 8^{\circ}\text{C}$.

Additionally the stable-labelled test compound was used in the experiment. The labelling was performed in isopropyl group and consisted on replacing ¹H (*protium*) atoms with ²H (*deuterium*, marked with symbol D) atoms. Its structural formula is presented below on figure B.8.1.1.2.1.1._CA-116. The compound's chemical purity was > 98%. It was used as an internal standard in quantitative analysis of FOE Methylsulfone performed using HPLC-MS/MS method.

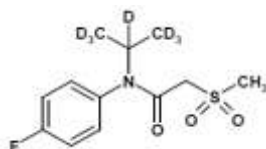

Figure B.8.1.1.2.1.1._CA-116: The structural formula of the deuterised test compound (internal standard) used in the experiment (copied from the study report).

It was delivered as a solid sample, in form of a light-yellow powder. The whole delivered amount of the test compound was used to prepare first a **Stock solution** and then a set of **Internal standard solutions**.

The **Stock solution** was prepared by dissolving the whole delivered sample of ²H-FOE Methylsulfone in 5.0 mL of CH₃CN and sonicating it for 10 minutes, to obtain a solution having a nominal concentration 0.980 mg ²H-FOE Methylsulfone/mL. The so prepared **Stock solution**, labelled **TM108IS_SS**, was stored in the dark at $T \leq -18^{\circ}\text{C}$ until being used.

The prepared from **TM108IS_SS** solution **Internal standard solutions** were following:

- **Internal standard solution TM108IS_AR**, prepared by transferring 0.406 mL of the **Stock solution TM108IS_SS** into 50-mL volumetric flask, bringing it to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicating it for 10 minutes; the nominal concentration of so prepared solution was 0.0079 mg/mL;
- **Internal standard solution TM108IS_D1**, prepared by transferring 0.041 mL of the **Stock solution TM108IS_SS** into 20-mL volumetric flask, bringing it to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicating it for 10 minutes; the nominal concentration of so prepared solution was 0.0020 mg/mL;
- **Internal standard solution TM108IS_D2**, prepared by transferring 5 mL of the **Internal standard solution TM108IS_D1** into 20-mL volumetric flask, bringing it to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicating it for 10 minutes; the nominal concentration of so prepared solution was 0.0005 mg/mL;

All listed above **Internal standard solutions** were stored in the darkness at $T \leq -18^{\circ}\text{C}$. **Internal standard solution TM108IS_AR** was added to soil extracts and was used in the verification of application rate and homogeneity of application. The **Internal standard solution TM108IS_D2** was added to the standard solutions used to construct the calibration curve.

The **Application solution TM 108_AS_AR** was used to treat degradation samples. To do that its 0.4-mL aliquots were applied dropwise onto soil surface in each incubation vessel to obtain the target application dose of 7.9 µg FOE Methylsulfone/100 g soil (d. w.). That application dose – equal to 0.079 mg/kg soil, was determined using the following assumptions:

- field application rate of Flufenacet (parent compound, precursor of FOE Methylsulfone): 600 g/ha;
- maximum occurrence of FOE Methylsulfone in aerobic soil (determined in the laboratory studies): 6.6%;
- molar weight of Flufenacet $M = 363.3 \text{ g/mol}$;
- molar weight of FOE Methylsulfone $M' = 273.3 \text{ g/mol}$;
- soil bulk density: 1.5 g/cm^3 ;
- thickness of the soil layer: 2.5 cm.

RMS analysing the calculations noticed that the assumed soil layer was $\frac{1}{2}$ of that routinely used to calculate field application rate (in [g/ha]) from that expressed in mg/kg soil. Therefore the RMS back calculated the would-be field application rate for FOE Methylsulfone using the standard assumptions:

- soil bulk density: 1.5 g/cm³;
- thickness of the soil layer: 5 cm.

The so calculated would-be field application rate **A = 59.55 g FOE Methylsulfone/ha**.

Using the measured soil bulk density of each test soil used in the experiment that value would be:

- for Hanscheider Hof soil: **A = 41.08 g/ha**;
- for Frankforst soil: **A = 45.43 g/ha**;
- for LUFA 2.3 soil: **A = 50.56 g/ha**;
- for LUFA 6S soil: **A = 48.19 g/ha**

The verification of application rate and homogeneity of application was performed using **Application solution TM 108_AS_AR**, at the beginning of application procedure and after treatment of each test soil. That was done by transferring of 0.4-mL portions of the application solution into 250-mL volumetric flasks, to which 0.1-mL portions of the **Internal standard solution TM108IS_AR** were added next. The solutions were then brought to volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and mixed thoroughly.

The same **Application solution** and the **Application solution TM 108_AS_LOQ** were used to treat the Concurrent Recovery Samples. The dosing of each **Application solution** was the same as for degradation samples – 0.4 mL/100 g soil. That resulted in fortification level of 0.079 mg/kg soil for samples treated with **Application solution TM 108_AS_AR** and 0.395 µg/100 g/soil (0.00395 mg/kg soil) – 5% of the nominal application rate for samples treated with **Application solution TM 109_AS_LOQ**. The samples were freshly prepared at each sampling point using LUFA 2.3 soil.

The verification of application rate and homogeneity of application was performed in the same manner as for degradation samples.

Immediately after treatment the incubation vessels designated as degradation samples were closed with PU plugs to grant free access of air, placed in the darkness in temperature-controlled walk-in climatic chamber and incubated for up to 120 days under aerobic conditions at $T = 20 \pm 2^{\circ}\text{C}$. Duplicate samples were removed from incubation chamber at following time-points (DAT stands for “Days After Treatment”): DAT 0, DAT 3, DAT 7, DAT 14, DAT 30, DAT 59, DAT 93 and DAT 120.

The soil moisture content in incubation vessels was controlled by weighing them at designated time points: DAT 0, DAT 3, DAT 7, DAT 9, DAT 14, DAT 22, DAT 30, DAT 37, DAT 44, DAT 59, DAT 71, DAT 93, DAT 99 and DAT 120. Soil moisture in the test vessels was adjusted to the designated level, by addition of appropriate amount of deionised water, at following time-points: DAT 3, DAT 9, DAT 22, DAT 37, DAT 44, DAT 59, DAT 71, DAT 93 and DAT 99.

The samples for the determination of soil biomass were set alongside the degradation samples. The soil biomass was determined in pre-conditioned test soil samples sampled on DAT 0 (beginning of the incubation period), DAT 59 (middle of the incubation period) and DAT 120 (end of incubation period). The experiment was performed in two variants:

- “BIO-” samples, not treated with blank application solution (instead 0.2 mL of distilled water was added to each test vessel) ; these samples were taken for the analysis on DAT 0, DAT 59 and DAT 120;
- “BIO+” samples, treated with 0.4 mL of blank application solution (CH₃OH/H₂O 1:1 v/v); these samples were taken for the analysis on DAT 59 and DAT 120.

Samples removed from the incubation chamber were processed and analysed immediately after sampling. That was done for the entire portions of the test soil recovered at each sampling point, using the procedure presented below on figure B.8.1.1.2.1.1._CA-117. The same procedure was applied to Concurrent Recovery Samples.

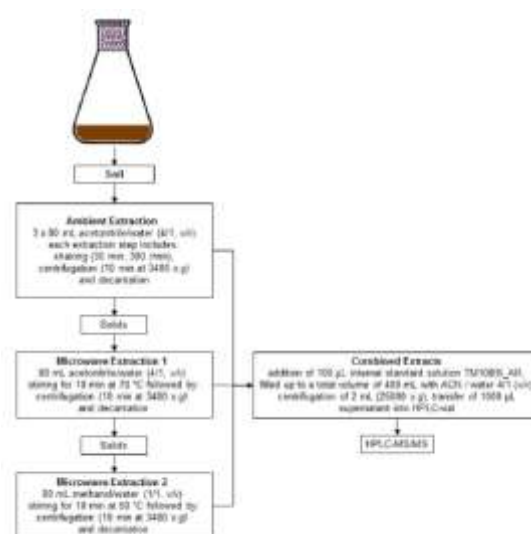

Figure B.8.1.1.2.1.1._CA-117: The sample-processing procedure used in the experiment (scheme copied from the study report).

The quantitative and qualitative analysis of combined soil extracts and other liquid samples was performed by means of HPLC-MS/MS. The analysis was performed using Agilent HP1200 chromatography workstation equipped with Finnigan TSQ Vantage (Thermo Electron Corporation, San Jose, CA, USA) MS detector. The chromatographic separation was done on Nucleodur Gravity C8 50*2 mm * 5 µm chromatographic column working in a gradient mode. The column was maintained at constant temperature $T = 40^{\circ}\text{C}$. The gradient elution programme is presented below in the table B.8.1.1.2.1.1._CA-225.

Table B.8.1.1.2.1.1._CA-225: The HPLC gradient modes used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% HCOOH</i>	<i>Solvent B – Acetonitrile + 0.1% HCOOH</i>
0	80	20
1	80	20
2	60	40
5	40	60
6	5	95

The elution lasted for 6 minutes and the flow rate of the mobile phase was 0.3 mL/min.

The identification of the test compound was performed by means of MS analysis using the following MS signals:

- for non-labelled test item: $m/z = 274.1$ as parent ion and $m/z = 232.1$ as product ion (quantifier);
- for ^2H -labelled internal standard: $m/z = 281.1$ as parent ion and $m/z = 233.1$ as product ion (quantifier).

Additional identification parameter for FOE Methylsulfone was the retention time $R_t = 3.5$ min. (approx.).

The quantitative analysis was performed using the external calibration curve constructed using the calibration solutions having concentration 1% SAR (0.198 µg FOE Methylsulfone/L), 5% SAR (0.988 µg FOE Methylsulfone/L), 10% SAR (1.975 µg FOE Methylsulfone/L), 50% SAR (9.875 µg FOE Methylsulfone/L), 100% SAR (19.750 µg FOE Methylsulfone/L) and 150% SAR (29.625 µg FOE Methylsulfone/L), where SAR stands for Standard Application Rate, defined as 7.9 µg test compound in 400 mL of extract. The calibration curve was constructed using $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 4:1 (v/v) as a solvent.

The procedure of the preparation of calibration curve is described below.

Firstly the **Standard solution TM108_SS_D1** was prepared by transferring 2 mL of the **Application solution TM 108_AS_AR** to 20-mL volumetric flask, filling it to the volume with the appropriate amount of $\text{CH}_3\text{CN}/\text{H}_2\text{O}$ 4:1 (v/v) and sonicating for 10 minutes. The nominal concentration of so obtained solution was 2.0 µg/mL. That solution was used to prepare next dilute – **Standard solution TM108_SS_D2**. That was done by

transferring 2 mL of the **Standard solution TM108_SS_D1** to 20-mL volumetric flask, filling it to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicating for 10 minutes. The nominal concentration of so obtained solution was 0.2 µg/mL. These two **Standard solutions** were stored in the dark at T ≤ -18°C until being used.

The solutions used to build calibration curve were freshly prepare on the day of measurements in the following way:

- 0.375 mL of the **Standard solution TM108_SS_D1** and 0.1 mL of the **Internal standard solution TM108IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicated for 10 minutes to obtain 150% SAR calibration solution,
- 0.25 mL of the **Standard solution TM108_SS_D1** and 0.1 mL of the **Internal standard solution TM108IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicated for 10 minutes to obtain 100% SAR calibration solution,
- 0.125 mL of the **Standard solution TM108_SS_D1** and 0.1 mL of the **Internal standard solution TM108IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicated for 10 minutes to obtain 50% SAR calibration solution,
- 0.25 mL of the **Standard solution TM108_SS_D2** and 0.1 mL of the **Internal standard solution TM108IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 4:1 (v/v) and sonicated for 10 minutes to obtain 10% SAR calibration solution
- 0.125 mL of the **Standard solution TM108_SS_D2** and 0.1 mL of the **Internal standard solution TM108IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 5% SAR calibration solution,
- 0.025 mL of the **Standard solution TM108_SS_D2** and 0.1 mL of the **Internal standard solution TM108IS_D2** were transferred into 25-mL volumetric flask, the resulting solution was brought up to the volume with the appropriate amount of CH₃CN/H₂O 1:1 (v/v) and sonicated for 10 minutes to obtain 1% SAR calibration solution.

The obtained results – concentrations of FOE Methylsulfone in each test soil at each time point, were subjected to the kinetic analysis in order to identify the best-fit kinetic model and determine persistence and modelling kinetic endpoints for FOE Methylsulfone in each test soil.

The kinetic analysis was performed in line with the recommendations of the FOCUS Kinetics Guidance Document [FOCUS; 2006], using KinGUI 2 modelling tool. It followed the procedure used in several already summarised studies, in particular **Study 4** and **Study 5**. Two kinetic models were used in the assessment – SFO and FOMC. The obtained fits were evaluated using the same principles as presented in the summaries of **Studies 2 – 8**.

The results of the study are presented below.

Results and their discussion:

The results of the determination of soil physicochemical properties and soil microbial activity in each test soil are presented in the table B.8.1.1.2.1.1._CA-224 at the beginning of this summary. On their basis it can be stated that the soils were appropriately selected, in line with the recommendations of OECD 307 Guideline, and were biologically viable throughout the experiment.

The results of the monitoring of the incubation temperature are presented below on figure B.8.1.1.2.1.1._CA-118. In the study report it was stated that the main incubation temperature was 19.9°C and it ranged from 19.4°C to 20.7°C.

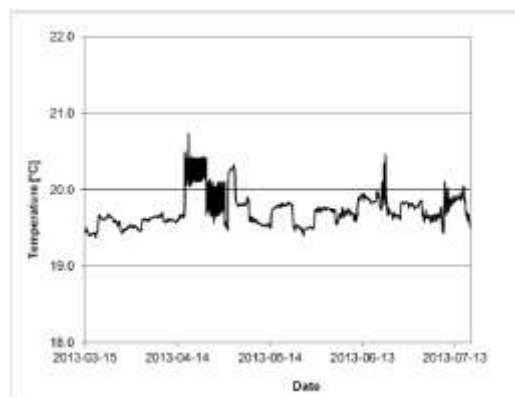

Figure B.8.1.2.1.1_CA-118: The temperature recorded during soil pre-conditioning and samples incubation period (copied from the study report).

The results of the monitoring of soil moisture during the experiment are presented below, in the table B.8.1.2.1.1_CA-226. On their basis it may be stated that this parameter was maintained on the assumed level during the whole experiment.

Table B.8.1.2.1.1_CA-226: The results of the determination of soil moisture content.

Test soil	Soil moisture content [g H ₂ O/100 g soil]			Soil moisture during incubation [% MWHC]		
	MWHC	55% MWHC	Actual – in sieved soil	mean	min.	max.
Hanscheider Hof	64.4	35.4	27.6	55.1	52.4	58.0
Frankenforst	56.7	31.2	17.1	54.7	51.4	58.1
LUFA 2.3	39.3	21.6	8.0	53.6	50.2	58.2
LUFA 6S	48.3	26.6	8.5	54.0	50.2	58.1

The results of the determination of application rate and the homogeneity of application for DAT 0 – DAT 120 samples were following:

- the application rate at the beginning of the process was determined to be 78.1 µg/kg;
- the application rate at the end of the 1st series was determined to be 80.7 µg/kg;
- the application rate at the end of the 2nd series was determined to be 77.2 µg/kg;
- the application rate at the end of the 3rd series was determined to be 78.3 µg/kg;
- the application rate at the end of the 4th series was determined to be 78.8 µg/kg;
- the mean application rate was determined to be 78.6 µg/kg with RSD = 1.5%.

On that basis it was stated that the application was homogenous and in good agreement with assumed theoretical application rate.

The LOQ – limit of quantification, was defined as 5% of nominal study application rate – 4.0 µg/kg soil. The corresponding LOD was set to $\frac{1}{5}$ LOQ – 1% of the nominal study application rate, and was equal to 0.8 µg/kg soil. The values were determined experimentally by examining the linearity of the response of MS/MS detector to the calibration curve. The numerical results of this examination presented below in the table B.8.1.2.1.1_CA-227 and in the graphical form on figure B.8.1.2.1.1_CA-119. They conform the good linearity of the detector's response and hence the correctness of the determined LOQ and LOD values.

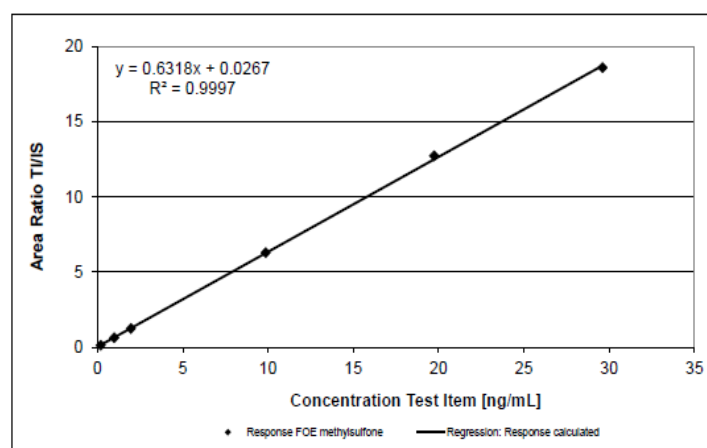

Table B.8.1.1.2.1.1._CA-227: The numerical results of the determination of the linearity of the response of MS/MS detector.

Calibration sample No.	Nominal concentration		Peak area ratio TI ¹⁾ /IS ²⁾				RSD [%]
	[% AA]	[ng/mL]	Replicate 1	Replicate 2	Replicate 3	Mean	
1	1	0.198	0.1193	0.1123	0.1262	0.1193	4.8
2	5	0.988	0.6147	0.6338	0.6223	0.6236	1.3
3	10	1.975	1.2156	1.3208	1.1915	1.2426	4.5
4	50	9.875	6.1497	6.5333	6.1817	6.2882	2.8
5	100	19.750	12.5513	12.7374	12.8824	12.7237	1.1
6	150	29.625	18.0628	19.3203	18.3995	18.5942	2.9

Footnotes to the table:

1) TI – Test Item;

2) IS – Internal standard; its amount is always 10% of the nominal study's application rate.

**Table B.8.1.1.2.1.1._CA-119:** The graphical results of the determination of the linearity of the response of MS/MS detector – calibration curve (copied from the study report).

The determination of the accuracy and precision of the method, assessed on the basis of the recovery rates at LOQ level (5% SAR) and application level (100% SAR), looked as follows:

- for Hanscheider Hof soil mean recovery at LOQ and application levels was 98.8% (91.4 – 103.5%) with RSD = 3.5%;
- for Frankenforst soil mean recovery at LOQ and application levels was 97.3% (93.0 – 100.8%) with RSD = 2.1%;
- for LUFA 2.3 soil mean recovery at LOQ and application levels was 102.3% (96.9 – 106.8%) with RSD = 2.7%;
- for LUFA 6S soil mean recovery at LOQ and application levels was 101.2% (95.7 – 107.0%) with RSD = 3.6%;
- the mean recovery at LOQ and application levels was 99.9% (91.4 – 107.0%) with RSD = 3.5%.

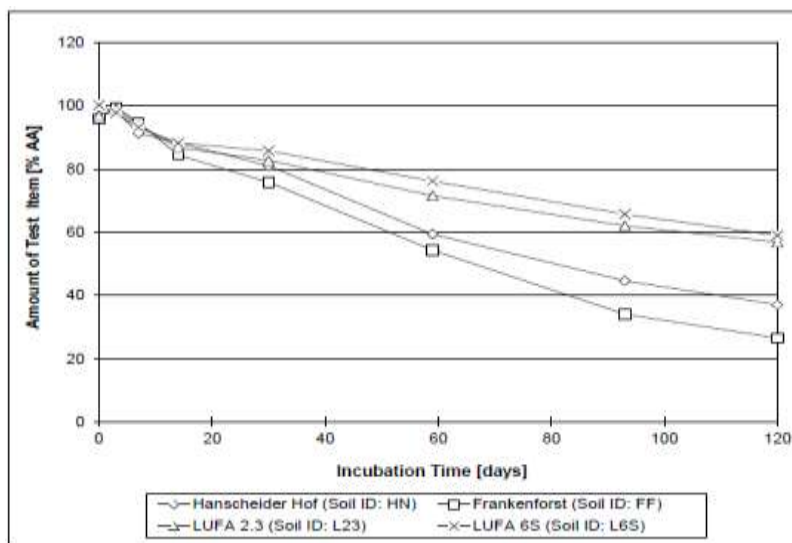

The results of the experiment – concentrations of FOE Methylsulfone in soil in function of time, are presented below in the table B.8.1.1.2.1.1._CA-228. For each test soil the concentrations of the test compound are reported as % of applied amount – [% AA] and in [µg/kg soil]. The values expressed as [%AA] were calculated using the following assumptions:

- for all samples the application rate was determined to be 7.9 µg/ test system, corresponding to 79 µg/kg soil, and that value was set to 100% AA (Applied Amount);

The graphic presentation of the results is given on figure B.8.1.1.2.1.1._CA-120.

Table B.8.1.1.2.1.1._CA-228: Concentration of FOE Sulfonic acid in tets soils in function of time.

**Figure B.8.1.1.2.1.1._CA-120:** The graphic presentation of the obtained results (copied from the study report).

The data presented in the table B.8.1.1.2.1.1._CA-228 were subjected to the kinetic analysis aimed on the determination of the best kinetic fit and derivation of the kinetic endpoints representing persistence of the test compound and suitable for modelling. For that purpose the values obtained for replicates, expressed as [%AA], were used. The values were inserted to the model as they are presented in the table above. The results of the kinetic analysis are presented below, separately for each test soil. The results are provided only for two kinetic models – SFO and FOMC. That was due to the fact that the kinetic evaluation using FOMC model was demonstrated to be statistically not reliable. Additionally the χ^2 error was demonstrated to be not significantly different between SFO and FOMC, therefore it was decided not to test DFOP model.

- 1) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in Hanscheider Hof soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-121 and in numerical form in the table B.8.1.1.2.1.1._CA-229. Additionally the table B.8.1.1.2.1.1._CA-230 provides the kinetic endpoints obtained with each of the kinetic models tested.

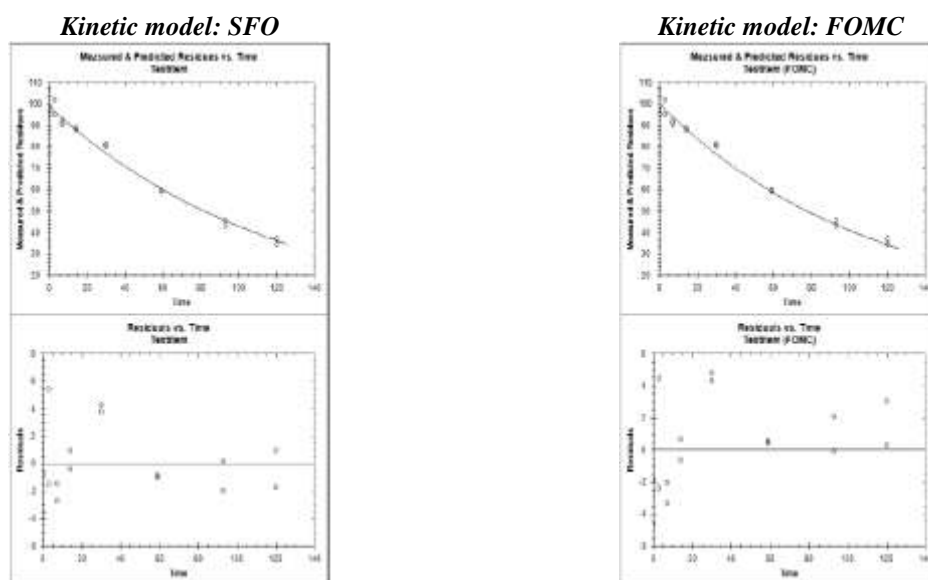

Figure B.8.1.1.2.1.1._CA-121: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-229: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	98.97	1.013	96.98	100.956	< 2 E-16	2.106	Good fit
	k	8.399 E-3	2.989 E-4	7.813 E-3	0.009	5.15 E-14		
FOMC	M ₀	100.053	1.135	97.830	102.3	< 2 E-16	2.666	Good fit
	α	293.917	271.037	-237.306	825.1	0.149		
	β	32692.219	30199.389	-26497.495	91881.9	0.149		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-230: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Methylsulfone	DT ₅₀ [days]	82.53	77.19
	DT ₉₀ [days]	274.14	257.12

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was very similar for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Methylsulfone in Hanscheider Hof soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 2) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in Frankenforst soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-122 and in numerical form in the table B.8.1.1.2.1.1._CA-231. Additionally the table B.8.1.1.2.1.1._CA-232 provides the kinetic endpoints obtained with each of the kinetic models tested.

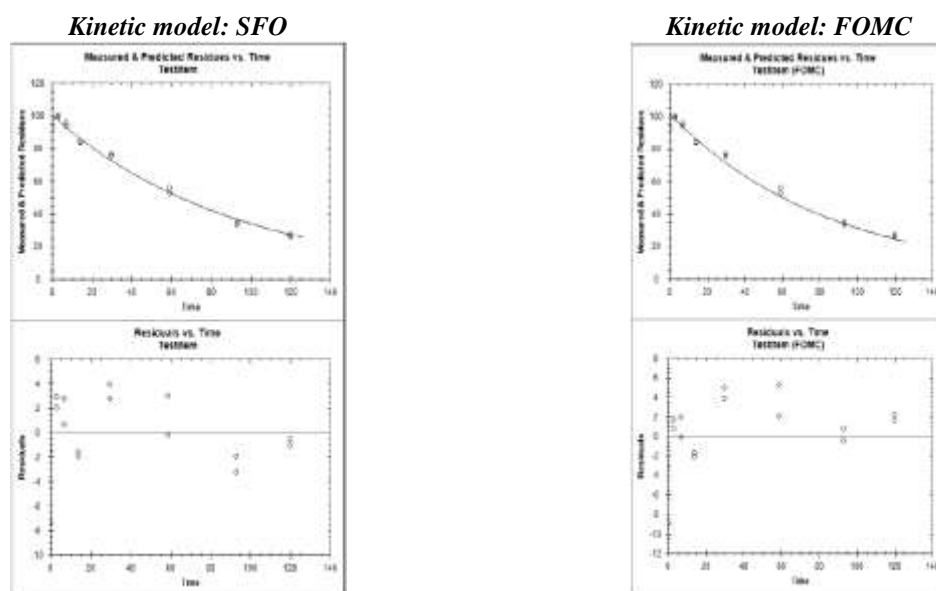

Figure B.8.1.1.2.1.1._CA-122: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-231: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	100.3	1.207	97.92	102.651	< 2 E-16	2.878	Good fit
	k	0.01083	4.096 E-4	0.01003	0.012	1.18 E-13		
FOMC	M ₀	101.821	1.353	99.170	104.5	<2 E-16	3.772	Good fit
	α	493.459	794.8135	-1064.345	2051.3	0.273		
	β	41635.283	67127.354	-89931.913	173202.5	0.273		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-232: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Methylsulfone	DT ₅₀ [days]	63.98	58.53
	DT ₉₀ [days]	212.53	194.73

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using SFO model, although it shall be pointed out that the value of that parameter was similar for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Methylsulfone in Frankenforst soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 3) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in LUFA 2.3 soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-123 and in numerical form in the table B.8.1.1.2.1.1._CA-233. Additionally the table B.8.1.1.2.1.1._CA-234 provides the kinetic endpoints obtained with each of the kinetic models tested.

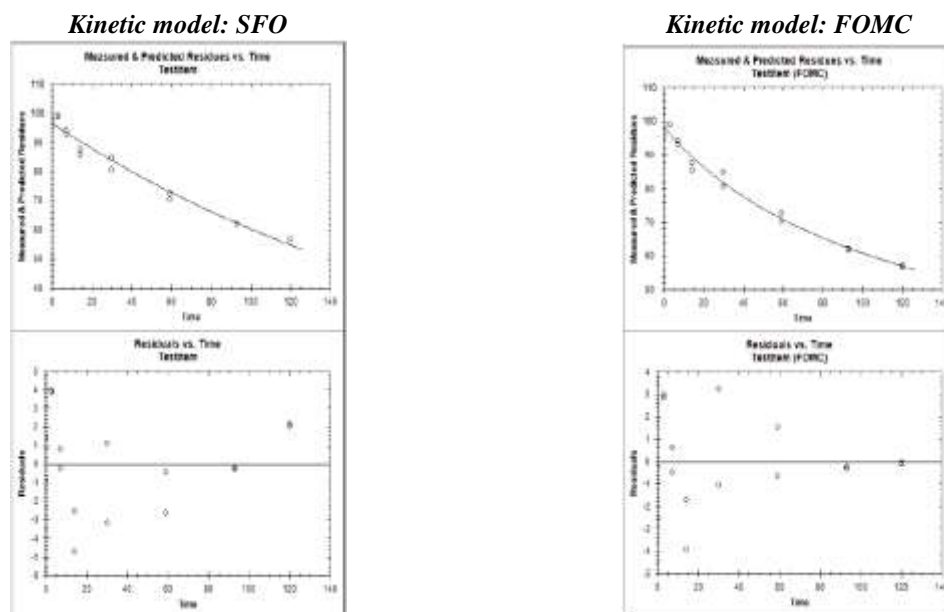

Figure B.8.1.1.2.1.1._CA-123: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-233: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M ₀	96.50	0.939	94.66	98.337	< 2 E-16	2.095	Good fit
	k	4.722 E-3	2.241 E-4	4.238 E-3	0.005	2.65 E-12		
FOMC	M ₀	98.154	1.048	96.100	100.208	<2 E-16	1.65	Good fit
	α	0.6659	0.2507	0.1645	1.147	0.0107		
	β	92.6605	49.9191	-5.1792	190.500	0.0431		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-234: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Methylsulfone	DT ₅₀ [days]	146.78	173.92
	DT ₉₀ [days]	487.60	3008.1

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using FOMC model, although it shall be pointed out that the value of that parameter was very close for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated β was not reliable because CI for it passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Methylsulfone in in LUFA 2.3 soil, hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

- 4) The results of the kinetic analysis of the data obtained for FOE Methylsulfone in LUFA 6S soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-124 and in numerical form in the table B.8.1.1.2.1.1._CA-235. Additionally the table B.8.1.1.2.1.1._CA-236 provides the kinetic endpoints obtained with each of the kinetic models tested.

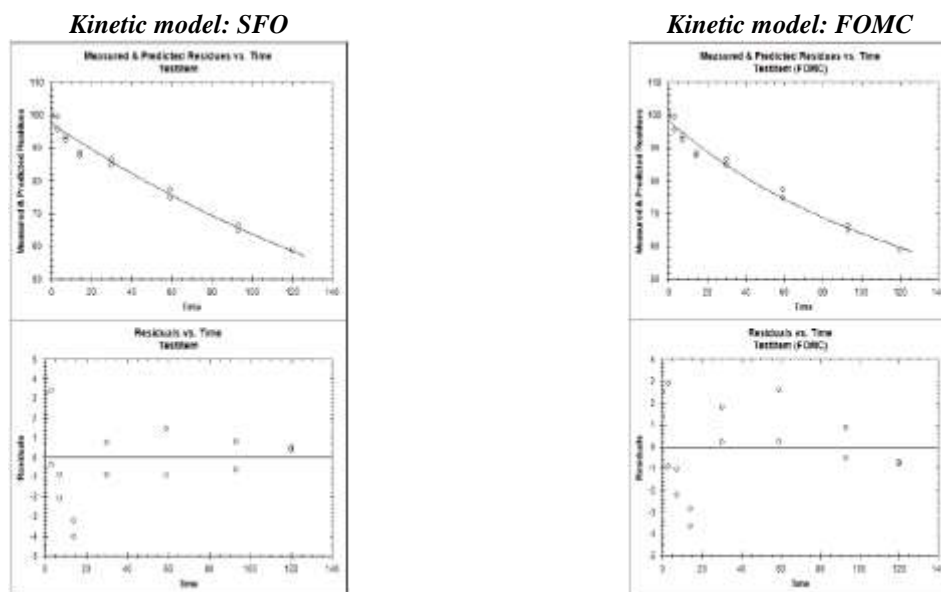

Figure B.8.1.1.2.1.1._CA-124: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-235: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	97.41	0.7858	95.872	98.949	< 2 E-16	1.697	Good fit
	k	4.251 E-3	1.796 E-4	3.899 E-3	0.005	5.42 E-13		
FOMC	M_0	98.228	1.099	96.075	100.382	< 2 E-16	1.668	Good fit
	α	1.0587	0.8623	-0.6314	2.749	0.121		
	β	199.5828	199.4171	-191.2675	590.433	0.168		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-236: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested	
		SFO	FOMC
FOE Methylsulfone	DT ₅₀ [days]	163.06	184.54
	DT ₉₀ [days]	541.68	1557.1

Conclusion:

Both models returned visually and statistically good fits. In terms of χ^2 error better fit was obtained using FOMC model, although it shall be pointed out that the value of that parameter was very close for both models tested. At the same time only SFO model returned fully reliable kinetic parameters. In case of FOMC the calculated α and β were not reliable because CI for them passed through zero. Therefore the Applicant stated that SFO model shall be considered as returning the best fit for FOE Methylsulfone in LUFA 6S soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-237.

Table B.8.1.1.2.1.1._CA-237: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
Soil name	Soil type (USDA)	OC [%]	pH ¹⁾			χ^2 error	Visual fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]
<i>Hanscheider Hof</i>	Loam	2.8	5.6	19.9°C/ 55% MWHC	SFO	2.106	G	<i>k</i>	8.40 E-3	82.53	274.14
<i>Frankenforst</i>	Silt loam	1.8	6.8	19.9°C/ 55% MWHC	SFO	2.878	G	<i>k</i>	0.01083	63.98	212.53
<i>LUFA 2.3</i>	Sandy loam	1.1	6.8	19.9°C/ 55% MWHC	SFO	2.095	G	<i>k</i>	4.72 E-3	146.78	487.60
<i>LUFA 6S</i>	Clay	1.9	7.0	19.9°C/ 55% MWHC	SFO	1.697	G	<i>k</i>	4.25 E-3	163.06	541.68

Footnotes to the table:

2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

Study 17:

Report: Lentz N. R., Bloomberg A. M., (1999): “Rate of Aerobic Soil Degradation for Thiadone (A Metabolite of FOE 5043).”; Ricerca LLC, Department of Environmental and Metabolic Fate, 7528 Auburn Road, Painesville, Ohio 44077, USA (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, MO 64120, USA; Ricerca document No. 7410-0055-EF-001, study No. F3082103 (Bayer); Bayer Report No. 108722; 16 February 1999, amended on 24 March 1999; study reference number: M-009828-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. Environmental Protection Agency Assessment Guidelines, Subdivision N Chemistry: Environmental Fate, Section 162-1

No deviations from the Guidelines were stated.

Several deviations were stated from the study protocol, however none of them indicated as adversely affecting the results or conclusions of the study. The stated protocol deviations were:

- 1) Additional soil samples were analysed for Iowa test soil on DAT 0.25 (6 hours) and on DAT 2 for Indiana and Nebraska test soils;
- 2) Additional analysis of 1N NaOH traps for volatile compounds was performed on DAT 0.25 and DAT 4 for Iowa test soil, on DAT 0.25, DAT 2 and DAT 4 for Indiana test soil, and on DAT 2 and DAT 4 for Nebraska test soil;
- 3) Additional analysis of the carbotraps for VOC was performed on DAT 4 for Iowa and Indiana test soils, and on DAT 3, DAT 7 and DAT 10 for Nebraska test soil;
- 4) Temperature in the incubation chamber was for a short time 22.1⁰C (short period during the morning of one of incubation days).

GLP: Yes;

RMS comments: This is a newly submitted study, the aim of which was to further examine the rate of degradation of FOE Thiadone in aerobic soil. It was evaluated for its compliance with the following guidelines:

- OECD Guideline 307 – Aerobic and Anaerobic transformation in Soil;
- US EPA Guidelines for Pesticide Registration, Subdivision N, Section 162-1 - Aerobic Soil Metabolism (indicated as reference Guideline in the study report).

RMS stated that the study was compliant with the provisions of the Guidelines listed above, therefore it was found acceptable and is summarised below.

Summary:

The aim of the study was to examine the rate of degradation of FOE Thiadone – the major soil metabolite of Flufenacet, in aerobic soils and to identify major degradation products of that process. The experiment was performed on three soils, obtained from maize growing areas in the USA – Janesville in Iowa, Howe in Indiana and Minden in Nebraska. Justifying the selection of the test soils the authors stated that Iowa and Nebraska soils originated from the sites where GW monitoring studies for Flufenacet were carried out, while Indiana soil was used in other experiments examining fate and behaviour of Flufenacet in soil. Their characteristic is provided below in the table B.8.1.1.2.1.1._CA-238. Iowa and Nebraska soils were declared to come from the field not being treated with any pesticide during the period 1995 – 1998. No such information was provided for Indiana soil, but the cross-examination of other experiments with that soil conformed that it originated from the field not being treated with any pesticide during the period 1995 – 1998. After being shipped to the test laboratory, the test soils were air-dried and sieved through 2-m sieve to remove all skeletal elements.

Table B.8.1.1.2.1.1._CA-238: The characteristic of soils used in the study.

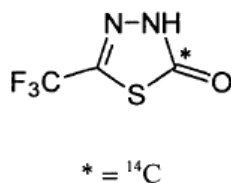

Parameter		Soil		
		<i>Iowa Loamy sand</i>	<i>Indiana sandy loam</i>	<i>Nebraska silt loam</i>
Soil origin		Janesville, Iowa, USA	Howe, Indiana, USA	Minden, Nebraska, USA
Soil type (USDA)		Loamy sand	Sandy loam	Silt loam
Particle size distribution	Sand (50 µm – 2 mm) [%]	79.2	63.6	25.6
	Silt (2 – 50 µm) [%]	12.0	25.6	55.6
	Clay (< 2 µm) [%]	8.8	10.8	18.8
pH value (medium not specified)		7.2	6.5	7.7
Organic carbon content (OC) [%] ¹⁾		1.11	0.74	0.96
Organic matter content (OM) [%] ²⁾		1.91	1.28	1.66
Cation Exchange Capacity – CEC [mEq/100g]		5.64	15.12	6.44
Water holding capacity	at 15 bar [% MWHC]	4.06	3.87	9.16
	at ½ bar [% MWHC]	9.92	13.27	24.19
Bulk density [g/cm ³]		1.34	1.62	1.37
Soil microbial activity expressed as [CFU/g soil] ³⁾ determined on	23/30 march 1998 (beginning of the study)	3.8 E4 – fungi 1.2 E7 – bacteria	4.8 E4 – fungi 9.1 E6 – bacteria	1.0 E5 – fungi 1.0 E7 – bacteria
	2/13 april 1998 (end of the study)	6.0 E4 – fungi 1.1 E7 – bacteria	2.8 E4 – fungi 1.2 E7 – bacteria	1.1 E5 – fungi 6.0 E7 – bacteria

Footnotes to the table:

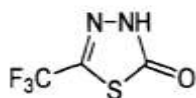

- 1) Value recalculated by the RMS from the OM content given in the study report, using the following equation: OM = 1.724 * OC;
- 2) Value provided in the study report;
- 3) CFU/ g soil = Colony Forming Units/gram of test soil (determined using *plate count agar* method).

50-g portions of test soils, 20 for each test soil, were weighed into 250-mL Nalgene PPCO centrifuge bottles (further called soil sample containers) and adjusted to the target moisture content – 75% of ½ bar, with appropriate amount of distilled water. So prepared individual kinetic samples, samples for the determination of soil microbial activity and spare samples, were randomized and placed in incubation vessels – transparent Nalgene™ dessicators equipped with inlet and outlet tubes. Then they were preincubated for 1 week in the darkness at constant temperature $T = 20 \pm 1^\circ\text{C}$, before being treated with the test compound. The incubation system used in the experiment for both pre-incubation phase and main experiment is presented further down this summary.

The test compound was [2-¹⁴C]-Thiadone, having a specific activity of 50 mCi/mmol, corresponding to 652680 dpm/µg, and radiochemical purity of 97.7%. The structural formula of the test compound, with radiolabelling position indicated by an asterisk, is presented below on figure B.8.1.1.2.1.1._CA-125. The compound was delivered in form of the **Stock solution** in acetone, having a concentration 2.54 µg/mL.

**Figure B.8.1.1.2.1.1._CA-125:** The structural formula of [2-¹⁴C]-FOE Thiadone used in the experiment (copied from the study report).

Additionally the non-radiolabelled FOE Thiadone, having a chemical purity of 99.3% was used as a reference substance. Its structural formula is presented below on figure B.8.1.1.2.1.1._CA-126.

**Figure B.8.1.1.2.1.1._CA-126:** The structural formula of non-radiolabelled FOE Thiadone used in the experiment (copied from the study report).

The reference substance was used in the experiment in form of the **Stock solution**, prepared by dissolving 10.0 mg of it in 10 mL of CH₃CN. The concentration of the so prepared solution, further called **Stock solution 1**, was 1 µg/mL.

Next the **Fortification solution** was prepared by mixing 0.520 mL of the **Stock solution** (containing radiolabelled test substance) with 1.250 mL of the **Stock solution 1** (containing the non-radiolabelled reference substance) and diluting the obtained solution with acetone to the final volume of 10 mL. The so prepared solution had a concentration 0.2571 µg FOE Thiadone/mL and specific activity of 335433 dpm/µg. It was verified for concentration of radiolabelled compound and radiochemical purity by LSC and HPLC-LSC. The prepared **Fortification solution** was stored at T < -5°C until being used.

The kinetic samples were treated with the test compound by applying 0.1 mL of **Fortification solution** onto the soil surface in each sample container. The amount of the **Fortification solution** applied was such to give the nominal fortification level of 0.5 ppm (0.5 mg/kg soil). That level was calculated using the following assumptions:

- the target concentration of Flufenacet in soil (used in the study by [Pangilinan and Smith; 1994], summarised under the point B.8.1.1.1.1. of this Assessment Report as **Study 2**): **1.101 mg/kg**, corresponding to application rate of 0.8 lb a.i./ha (according to RMS that resulted in field application rate 825.75 mg Flufenacet/ha);
- conversion of Flufenacet into FOE Thiadone: **100%**;
- molar weight of Flufenacet: **M = 363 g/mol**;
- molar weight of FOE Thiadone: **M' = 170 g/mol**;

RMS checked the calculations and found them correct.

The samples containing Iowa and Indiana test soils were treated on the same day and those containing Nebraska test soil a week later. After treatment all samples, except DAT-0 samples processed immediately after treatment, were placed in incubation vessel – transparent Nalgene™ dessicators connected to air-supply system (inlet) and the volatile traps-system (outlet), and incubated for up to 14 days in the darkness at T = 20 ± 1°C. The incubation system used in the experiment is presented below on figure B.8.1.1.2.1.1._CA-127.

The sampling regime, set individually for each test soil, looked as follows:

- for Iowa loamy sand soil:
 - soil samples were taken for the analysis on DAT 0, DAT 0.25, DAT 1, DAT 2, DAT 3, DAT 5, DAT 7 and DAT 10; DAT-0, DAT-1, DAT-2, DAT-3 and DAT-5 samples were taken in duplicate;
 - the ¹⁴CO₂ traps were changed and analysed on DAT 0.25, DAT 1, DAT 2, DAT 3, DAT 4, DAT 5, DAT 7 and DAT 10;
 - the VOC traps were changed and analysed on DAT 3, DAT 4 and DAT 10.
- for Indiana sandy loam soil:
 - soil samples were taken for the analysis on DAT 0, DAT 0.5, DAT 1, DAT 2, DAT 3, DAT 5, DAT 7 and DAT 10; DAT-0, DAT-0.5, DAT-1, DAT-3 and DAT-5 samples were taken in duplicate;
 - the ¹⁴CO₂ traps were changed and analysed on DAT 0.25, DAT 0.5, DAT 1, DAT 2, DAT 3, DAT 4, DAT 5, DAT 7 and DAT 10;
 - the VOC traps were changed and analysed on DAT 3, DAT 4 and DAT 10.
- for Nebraska silt loam soil:
 - soil samples were taken for the analysis on DAT 0, DAT 1, DAT 2, DAT 3, DAT 5, DAT 7, DAT 10 and DAT 14; DAT-0, DAT-3, DAT-5 and DAT-7 samples were taken in duplicate;
 - the ¹⁴CO₂ traps were changed and analysed on DAT 1, DAT 2, DAT 3, DAT 4, DAT 5, DAT 7, DAT 10 and DAT 14;
 - the VOC traps were changed and analysed on DAT 3, DAT 5, DAT 7, DAT 10 and DAT 14.

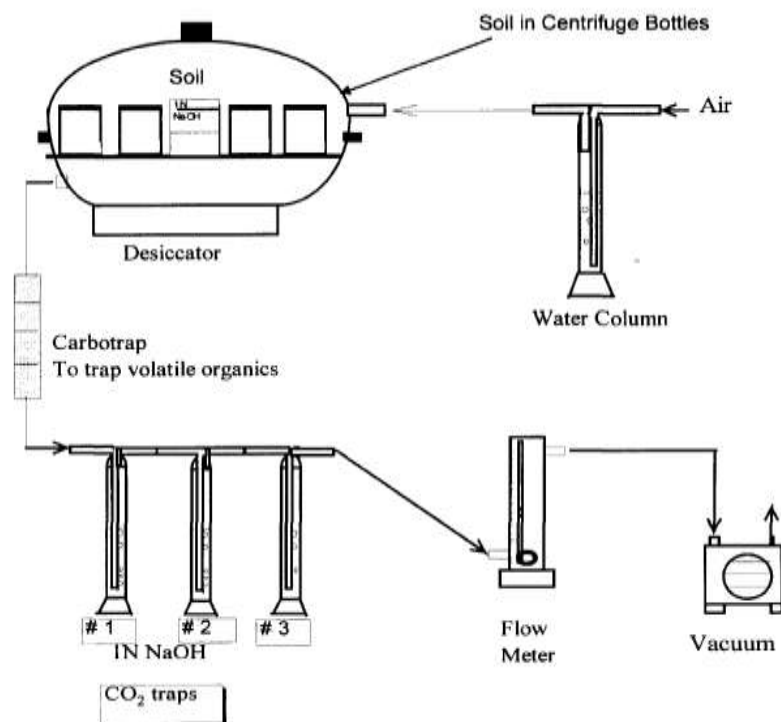

Figure B.8.1.1.2.1.1_CA-127: The schematic presentation of the incubation system used in the experiment (copied from the study report).

Soil from each sample collected at the designated time-points listed above was processed and analysed quantitatively and qualitatively for residues of [¹⁴C]Thiadone using the analytical procedure presented below on figure B.8.1.1.2.1.1_CA-128. Whole samples were used in the analysis which occurred within 24 hours after sampling.

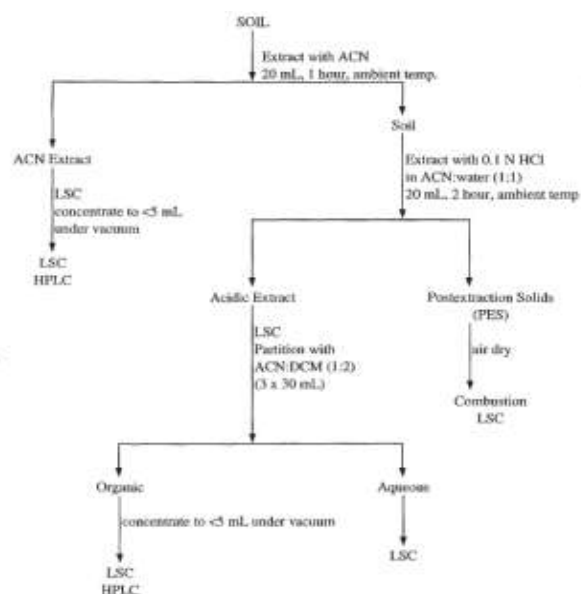

Figure B.8.1.1.2.1.1_CA-128: The sample-processing procedure used in the experiment (copied from the study report).

The extracted soil pellets were air-dried at ambient temperature, ground and their three 500-mg aliquots analysed after combustion for radioactivity content.

The collected VOC-traps (Carbotrap™ 400 tubes) were combusted and the evolved $^{14}\text{CO}_2$ quantified by LSC.

The radioactivity trapped in each alkaline trap for $^{14}\text{CO}_2$ was determined by LSC. That was done in 2-mL aliquots to which 10 mL of liquid scintillation cocktail was added. The conformation of that the trapped radioactivity was $^{14}\text{CO}_2$, was done in a following way:

- the content of alkaline traps for $^{14}\text{CO}_2$ collected at each sampling point was pooled;
- next, to its 2-mL aliquots was added 5 mL of aqueous 5% BaCl_2 /5% NH_4Cl solution;
- sample was then thoroughly mixed and formed solid precipitated by centrifugation;
- finally supernatants were analysed by LSC.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using either Tractor Mark V Model 5303 LS counter or Beckman LS 6500 counter.

Liquid samples were analysed in duplicate with 5 mL or 10 mL of Ultima Gold liquid scintillation cocktail. The counting of each analysed sample lasted for 2 minutes.

Solid samples (500-mg aliquots) were analysed in triplicate by their combustion in biological oxidiser. The evolved $^{14}\text{CO}_2$ was trapped in 20 mL of Carbon 14 Cocktail and counted by LSC. The results were corrected for oxidiser efficiency.

Sample extracts were analysed using the following techniques:

- HPLC – major identification and quantitation method for parent compound and its degradation products;
- HPLC-MS – conformatory identification method for parent compound and its degradation products;
- GC-MS – conformatory identification method for parent compound and its degradation products.

The HPLC analysis was performed using a Waters™ HPLC system equipped with autosampler, Tunable Absorbance Detector and fraction collector, coupled to one of the following LSC detectors:

- Radiomatic A-500 Radio-chromatography Detector;
- β Radio-Chromatography Detector.

The system was equipped with Phenomenex Luna™, 5 μm C18, 150 x 4.6 mm chromatographic column and Zorbax® RX-C18 10 x 4.6 mm guard column. The chromatographic separation was performed in a gradient mode, using the mobile phase consisting of:

- water + 0.5% CH_3COOH as **Solvent A**, and
- CH_3OH as **Solvent B**.

Gradient elution lasted 70 minutes. Its parameters are shown below in the table B.8.1.1.2.1.1._CA-239. The flow rate was set to 1.5 mL/min. UV detection was performed at $\lambda = 254$ nm.

Table B.8.1.1.2.1.1._CA-239: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.4% CH_3COOH</i>	<i>Solvent B – Methanol</i>
0	100	0
40	30	70
60	30	70
61	100	0
70	100	0

The changes in the gradient of mobile phase were linear.

The minimum detection limit for HPLC method was 300 dpm and its response was demonstrated to be linear within the range 300 – 200000 dpm.

Sample volume injected onto the column was sufficient to detect residues at the level of 1.5% of injected radioactivity for CH_3CN extracts and 8.5% of injected radioactivity for CH_3CN ;0.1N HCl extracts.

The identification of the chromatographic peaks was performed by means of the comparison of their retention times R_t with those of the standards.

The HPLC-MS analysis was performed using Finnigan SSQ710 LC/MS device equipped with Phenomenex Luna 5 μm C8 150 x 2 mm LC column. The chromatographic analysis was carried out in a gradient mode. Its parameters were following:

- **Mobile phase A:** 0.05% HCOOH in Water,
- **Mobile phase B:** CH_3OH ,

- **Gradient mode:** A/B1:1 hold 2 min to A/B 3:7 at 8 min.

The flow rate was set to 0.2 mL/min.

The reported parameters of MS detector were following:

- Ionization mode: (-)ESI;
- Mass range: 115 – 300 amu;
- Scan rate: 1.5 sec/scan;
- Source temperature: 220°C;
- ESI spray voltage: 4.0 kV.

That method was used to direct identification of the test compound – FOE Thiadone, and its degradation product – propionic acid conjugate of FOE Thiadone, in selected extracts. The extracts selected for that analysis were organic partition concentrates of the acid extract obtained from both replicates of DAT-1 Iowa loamy sand sample.

The propionic acid conjugate of FOE Thiadone was further characterised, after hydrolysis or methylation, in selected acid extracts by GC-MS.

Results and their discussion:

The examination of the microbial viability of the test soils showed that they were viable throughout the whole experiment. The detailed results are shown in the table B.8.1.1.2.1.1._CA-238.

The monitoring of incubation temperature showed that the samples were kept in the constant temperature $T = 20 \pm 1^\circ\text{C}$.

The determination of the soil moisture content of air-dried soils showed that that parameter was on the following level:

- in Iowa soil: 1.75%;
- in Indiana soil: 1.98%
- in Nebraska soil: 5.98%.

When adjusted to the designated level – 75% of $\frac{1}{3}$ bar, it became:

- in Iowa soil: 7.44%;
- in Indiana soil: 9.95%
- in Nebraska soil: 18.14%.

The radiochemical purity of the test substance in **Fortification solutions** prepared to treat each test soil, expressed as % [^{14}C]-FOE Thiadone, was following:

- for Iowa soil: 95.4%;
- for Indiana soil: 95.4%
- for Nebraska soil: 95.0%;

The verification of the application rate in each test soil showed that it was in line with the value of nominal application – 0.5 mg/kg. It was performed assuming that the specific activity of the test compound was 335433 dpm/ μg and the amount of the treated soil 50 g (d.w.). The detailed results of that verification are presented below in the table B.8.1.1.2.1.1._CA-240.

Table B.8.1.1.2.1.1._CA-240: The results of the verification of application rate.

Test soil	Applicaton rate of [^{14}C]-FOE Thiadone	
	dpm	ppm
<i>Iowa loamy sand</i>	8654025	0.52
<i>Indiana sandy loam</i>	8654025	0.52
<i>Nebraska silt loam</i>	8535625	0.51

The quantitative analysis of extracts, extracted soil pellets and traps for volatile compounds showed that the recovery of applied radioactivity throughout the study was within the recommended range:

- in Iowa soil: 92.5 – 103.7% AR, mean recovery – 95.75 AR;
- in Indiana soil: 90.7 – 99.9% AR, mean recovery – 96.4% AR ;
- in Nebraska soil: 91.6 – 98.6% AR, mean recovery – 94.9% AR.

The level of radioactivity extracted from soil decreased with time:

- in Iowa soil: from 102.6% AR on Day 0 to 9.6% AR on DAT 10;
- in Indiana soil: from 99.0% AR on Day 0 to 6.2% AR on DAT 10;
- in Nebraska soil: from 97.0% AR on Day 0 to 5.5% AR on DAT 14.

The level of volatile compounds detected at the end of experiment was following:

- in Iowa soil: 63.2% AR as CO₂ and 2.3% AR as VOC (DAT 10);
- in Indiana soil: 82.1% AR as CO₂ and 4.0% AR as VOC (DAT 10);
- in Nebraska soil: 71.8% AR as CO₂ and 3.3% AR as VOC (DAT 14).

The level of NER fraction at the end of incubation period was following:

- in Iowa soil: 19.5% AR (DAT 10);
- in Indiana soil: 7.6% AR (DAT 10);
- in Nebraska soil: 14.7% AR (DAT 14).

Finally, the decrease of the test compound – FOE Thiadone in each test soil looked as follows:

- in Iowa soil: from 98.3% AR on Day 0 to 6.6% AR on DAT 10;
- in Indiana soil: from 94.8% AR on Day 0 to 3.0% AR on DAT 10;
- in Nebraska soil: from 93.5% AR on Day 0 to 3.3% AR on DAT 14.

Apart from FOE Thiadone following compounds were identified in samples:

- propionic acid conjugate of FOE Thiadone,
- Other fraction,
- fortification impurity (1),
- fortification impurity (2),

The structural formula of propionic acid conjugate of FOE Thiadone is presented below on figure B.8.1.1.2.1.1._CA-129.

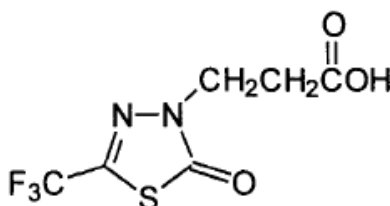

Figure B.8.1.1.2.1.1._CA-129: The postulated structural formula of the propionic acid conjugate of FOE Thiadone (copied from the study report).

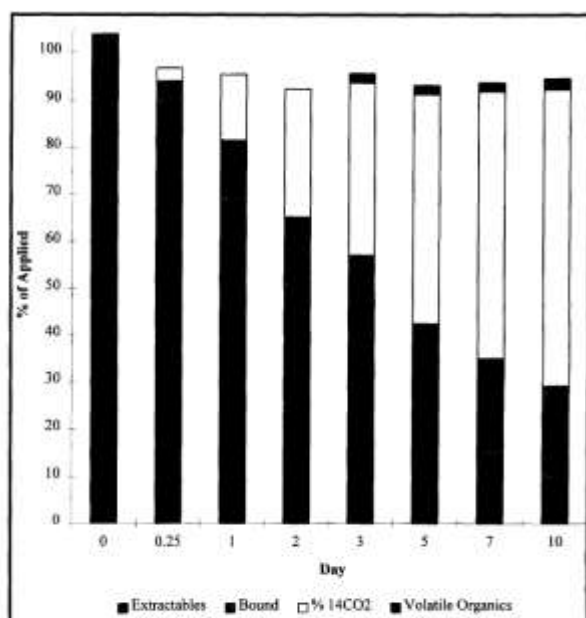

The detailed results of the experiment are presented below, separately for each test soil, in tables B.8.1.1.2.1.1._CA-241 – B.8.1.1.2.1.1._CA-243. Additionally they are presented in graphical form on figures B.8.1.1.2.1.1._CA-130 – B.8.1.1.2.1.1._CA-132 in form of two parallel graphs showing the distribution of radioactivity in the test systems and concentrations of FOE Thiadone and its degradation product – propionic acid conjugate, in function of time.

Table B.8.1.1.2.1.1_CA-241: The detailed results of the experiment obtained in Iowa loamy sand soil.

Concentrations of FOE Thiadone and propionic acid conjugate of FOE Thiadone

Figure B.8.1.2.1.1._CA-132: The graphical results of the experiment obtained in Nebraska silt loam soil (copied from the study report).

On the basis of the obtained results the transformation pathway of FOE Thiadone radiolabelled in C2 position was proposed in the study report. It is presented below on figure B.8.1.1.2.1.1_CA-133. RMS noted that it is the same as the transformation pathway resulting from the examination of photodegradation of FOE Thiadone in soil (please refer to the summary of the **Study 2** presented under the point B.8.1.1.1.3. of this Assessment Report).

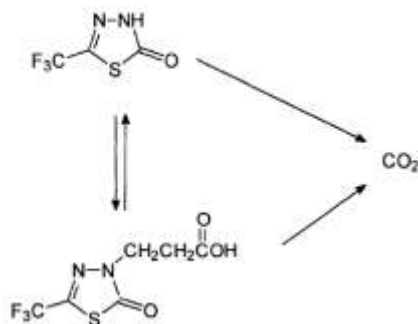

Figure B.8.1.1.2.1.1_CA-133: The transformation pathway of [¹⁴C]-2-FOE Thiadone in soil (copied from the study report).

The data obtained for FOE Thiadone, presented in tables B.8.1.1.2.1.1_CA-241 – B.8.1.1.2.1.1_CA-243, were further kinetically examined. The analysis was performed using first order kinetics and linear-regression model. As it does not comply with the current standards, set by FOCUS Kinetics Guidance (FOCUS, 2006) it is not presented here. The same data set was kinetically examined in a separate study, summarised below as **Study 18**.

Study 18:

Report: Reinken G., Partsch S., (2014): “Kinetic Evaluation of the Degradation of Flufenacet Degradation Product FOE-thiadone under Aerobic Soil conditions in Laboratory according to FOCUS Kinetics Using the KinGUI 2 Tool. FOE-thiadone.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished Study Report No. EnSa-12-0579; 2014. 02. 17; study reference number: M-447840-01-1;

Guidelines: The study was declared to be performed to comply with the following guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

GLP: No, not applicable – this is a modelling study;

RMS comments: RMS verified the study for its compliance with the provisions of the Guidelines listed above. It was stated that the study generally complied with the two evoked Guidance Documents. The study was aimed on the derivation of the modelling kinetic endpoints for FOE Thiadone. It followed modelling approach outlined already in other studies summarised above – **Study 2, Study 7 and Study 8**. The analysis was performed for the results of the summarised above study by [Lentz and Bloomberg; 1999] (**Study 17**). The study was found to be acceptable and is summarised below.

Summary:

The aim of the study was to kinetically examine the data for FOE Thiadone obtained in summarised above as **Study 17** the study by [Lentz and Bloomberg; 1999], in order to derive the kinetic endpoints suitable for use in modelling exposure assessment.

In the source study the the degradation of FOE Thiadone was examined in three soils. Their key properties are presented below in the table B.8.1.1.2.1.1._CA-244. The experimental conditions used in the study are summarised further down, in the table B.8.1.1.2.1.1._CA-245.

Table B.8.1.1.2.1.1._CA-244: The brief characteristic of the test soils.

Soil name	Soil type (USDA classification)	Soil properties			
		pH	OC [%]	Soil microbial biomass at the beginning of the study – [CFU/g soil]	
				bacteria	fungi
Iowa	Loamy sand	7.2	1.11	1.2 E7	3.8 E4
Indiana	Sandy loam	6.5	0.74	9.1 E6	4.8 E4
Nebraska	Silt loam	7.7	0.96	1.0 E7	1.0 E5

Table B.8.1.1.2.1.1._CA-245: The experimental conditions used in each experiment.

Test soil		Experimental conditions			
Name	Type (USDA classification)	Incubation temperature T [°C]	Reference value - % MWHC at ½ bar	Soil moisture	
				In experiment	
				declared	determined
Iowa	Loamy sand	20 ± 1	9.92%	75% of ½ bar	7.44%
Indiana	Sandy loam	20 ± 1	13.27%	75% of ½ bar	9.95%
Nebraska	Silt loam	20 ± 1	24.19%	75% of ½ bar	18.14%

The not-processed input data used in the kinetic analysis are presented below in the table B.8.1.1.2.1.1._CA-246.

Table B.8.1.1.2.1.1._CA-246: The non-processed data obtained in the test soils used as input in kinetic analysis.

2	62.7	1.1	63.8	
3	52.2	1.0	53.2	
5	28.9	0.7	29.6	
7	16.2	0.2	16.4	
10	7.7	not determined	7.7	
14	3.3	not determined	3.3	

The values presented above as “sum” were subjected to a multistep evaluation procedure almost identical to that already presented above in the summary of the **Study 2**, for convenience repeated below. It consisted of the following steps:

- **Step 1:** Processing of the raw input data;
- **Step 2:** Kinetic evaluation of the processed data using the following 1st – order kinetic models: SFO, FOMC and DFOP, and KinGUI 2 as a modelling tool, in order to determine the appropriate kinetic model.
- **Step 3:** Evaluation of the results of kinetic examination of the data;
- **Step 4:** Reporting of the obtained results, in particular kinetic parameters recommended for modelling.

The data-processing to obtain the input values for kinetic analysis (**Step 1**) was identical to the procedure described in the summary of the **Study 2**, on page 168. The processed data used as input in the kinetic examination are presented below in the table B.8.1.1.2.1.1._CA-247. The Applicant indicated that DAT-0 values were set to total recovery level recorded on that time point.

Table B.8.1.1.2.1.1._CA-247: The processed residue data used in the kinetic analysis.

Results obtained in Iowa Loamy sand soil		Results obtained in Indiana Sandy loam soil		Results obtained in Nebraska Silt loam soil	
DAT	Concentration [%] of FOE Thiadone	DAT	Concentration [%] of FOE Thiadone	DAT	Concentration [%] of FOE Thiadone
0	103.7	0	99.6	0	98.4
0.25	82.5	0.5	69.9	1	80.5
1	65.0	1	58.4	2	63.8
2	46.8	2	36.0	3	53.2
3	34.1	3	21.6	5	29.6
5	19.2	5	11.5	7	16.4
7	10.1	7	4.6	10	7.7
10	6.7	10	3.1	14	3.3

The processed data were kinetically examined using KinGUI ver. 2 modelling tool, developed by Bayer. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The fitting procedure consisted on the determination of the appropriate kinetic model for FOE Thiadone.

The conceptual metabolic pathway built in the modelling tool was based on the transformation pathway which, in form of a simplified scheme, is presented below on figure B.8.1.1.2.1.1._CA-134.

Figure B.8.1.1.2.1.1._CA-134: The simplified transformation pathway used to create conceptual transformation scheme assumed in the modelling tool (copied from the study report).

The obtained results of the kinetic analysis of the data were evaluated by the Applicant. That was done by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

The detailed characteristic of the evaluation procedure was presented in the summary of the **Study 2** on pages 170 – 171. RMS decided not to repeat it here in order to not overburden the Renewal Assessment Report.

On that basis the following multistep assessment procedure was followed:

- **Step 1:** bearing in mind the aim of the kinetic evaluation of the data – determination of the kinetic parameters used in modelling, the SFO kinetic model was tested as first option and if passed the acceptance criteria (visually acceptable, χ^2 -error not exceeding or not significantly exceeding 15%, *prob. > t* value in t-test less than 0.05 for parent and 0.10 for the degradation products), it was considered acceptable;
- **Step 2:** in case the χ^2 -error was significantly greater than 15%, model parameters were fixed and fitting repeated using SFO model;
- **Step 3:** if the **Step-2** fitting failed the χ^2 -error test, bi-phasic models were included. These were FOMC, DFOP and, possibly, HS. The model with smaller error was indicated as the most appropriate;
- **Step 4:** if none of the bi-phasic model returned significantly improved fit, SFO model was selected if visually acceptable; that was done in order to avoid of an over-parameterised model based on a marginally better fit.

Analysing the proposed assessment procedure RMS stated that it complied with the procedure for determination of the kinetic endpoints for modelling, presented in FOCUS Kinetics Guidance Document [FOCUS; 2006].

The results of the kinetic analysis are presented below, individually for each test soil.

- 1) The results of the kinetic analysis of the data obtained for FOE Thiadone in Iowa Loamy sand soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-135 and in numerical form in the table B.8.1.1.2.1.1._CA-248. Additionally the table B.8.1.1.2.1.1._CA-249 provides the kinetic endpoints obtained with each of the kinetic models tested.

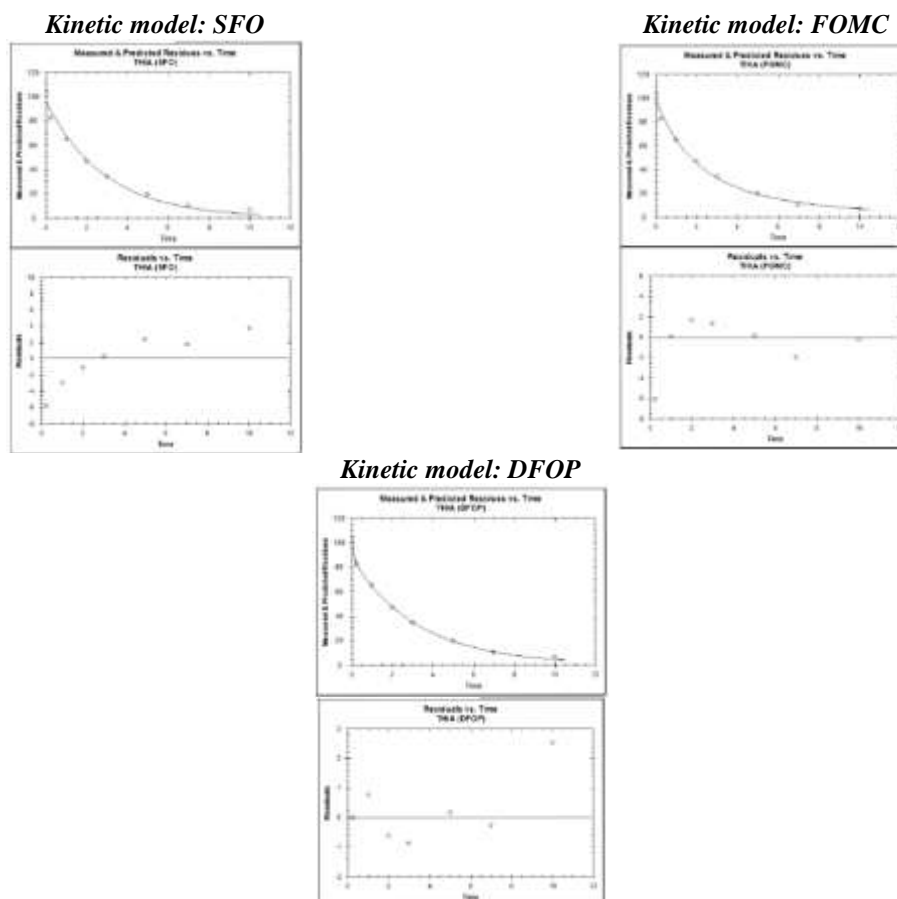

Figure B.8.1.1.2.1.1._CA-135: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-248: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	96.430	3.270	90.020	102.839	5.04 E-8	6.725	0.987; Acceptable fit
	k	0.3494	0.02951	0.2915	0.407	1.10 E-5		
FOMC	M_0	99.220	2.997	93.346	105.094	2.36 E-7	5.348	0.992; Good fit
	α	2.6336	1.2352	0.2126	5.055	0.0431		
	β	5.7293	3.4314	-0.9962	12.455	0.0779

	k_1	8.8492	5.2636	-1.4674	19.166	0.0840		
	k_2	0.3039	0.01355	0.2774	0.330	1.17 E-5		
	g	0.1606	0.02764	0.1064	0.215	0.00218		

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-249: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Thiadone</i>	DT ₅₀ [days]	1.98	1.72	1.70
	DT ₉₀ [days]	6.59	8.00	7.00

Conclusion:

All three models returned visually and statistically good fits, although Applicant classified SFO fit as only acceptable, most probably due to the distribution of residuals, which is not random. Both FOMC and DFOP returned visually and statistically better fits, DFOP being superior of the three. However, neither FOMC nor DFOP, despite being visually and statistically good fits, can be considered acceptable, because they returned not reliable kinetic parameters. In case of FOMC fit the problem concerned β , not reliable because its CI passed through zero. For DFOP not fully reliable was k_1 , for which the *prob. > t* was higher than 0.05.

Analysing the fits RMS stated that the better fitting results for both bi-phasic models was most probably caused by the fact, that the DAT-0 concentration was adjusted to the procedural recovery, significantly higher than the concentration measured at the next time point – DAT 0.25

As a result, the Applicant stated that SFO model shall be considered as returning the appropriate fit for FOE Thiadone in Iowa Loamy sand soil and hence appropriate to derive persistence and modelling endpoints for that compound in that test soil. RMS accepted that proposal noticing that the compound was very short-living in soil, therefore bi-phasic kinetic behaviour would be hardly explicable in this case.

2) The results of the kinetic analysis of the data obtained for FOE Thiadone in Indiana sandy loam soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-136 and in numerical form in the table B.8.1.1.2.1.1._CA-250. Additionally the table B.8.1.1.2.1.1._CA-251 provides the kinetic endpoints obtained with each of the kinetic models tested.

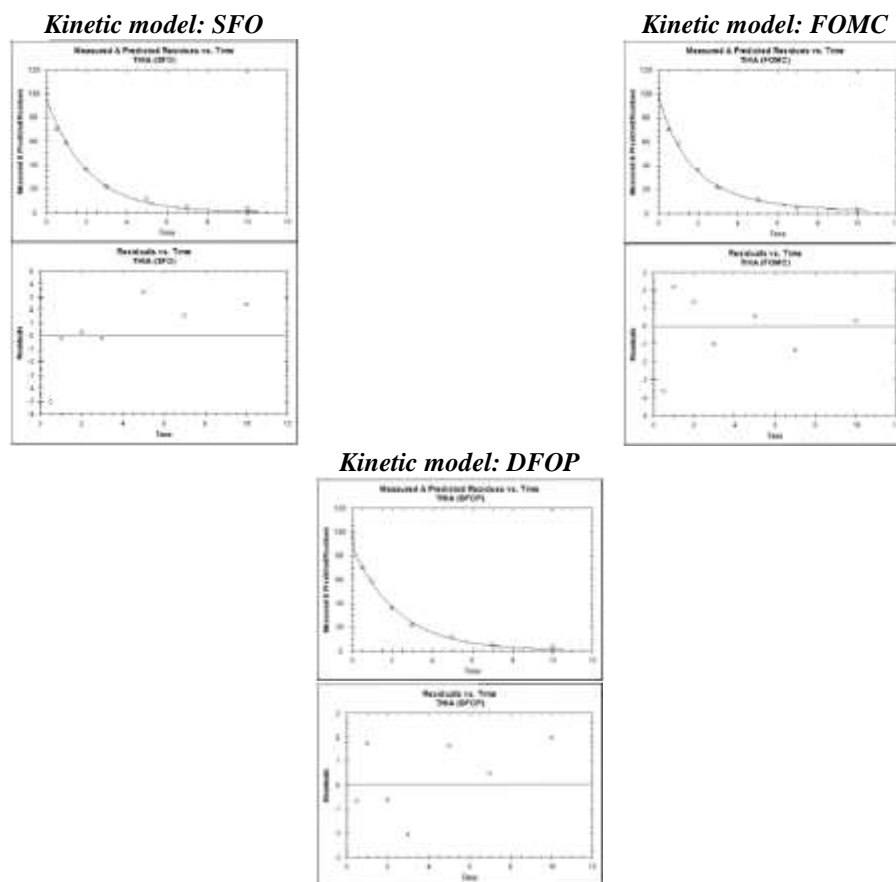

Figure B.8.1.1.2.1.1._CA-136: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-250: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	95.989	2.660	90.775	101.203	1.51 E-8	5.67	0.994; Acceptable fit
	k	0.4945	0.03176	0.4323	0.557	2.22 E-6		
FOMC	M_0	98.351	2.113	94.210	102.493	4.32 E-8	3.933	0.997; Good fit
	α	3.6089	1.3854	0.8935	6.324	0.0240		
	β	5.9648	2.7677	0.5401	11.389	0.0419		
DFOP	M_0	99.60	1.548	96.57	102.634	1.75 E-7	3.277	0.999; Good fit
	k_1	28.85	931.1	-1796	1853.682	0.4884		
	k_2	0.4372	0.02621	0.3859	0.489	3.79 E-5		
	g	0.1186	0.0342	0.05153	0.186	0.0128		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-251: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Thiadone</i>	DT ₅₀ [days]	1.40	2.93	1.30
	DT ₉₀ [days]	4.66	9.76	4.98

Conclusion:

FOMC and DFOP models returned fits that were classified by the Applicant as visually good. The fit returned by SFO model was classified as acceptable, mainly because of the levels of residuals and their distribution. All three fits were statistically reliable – the χ^2 level for them was well below the threshold value of 15%.

The Applicant indicated the SFO model fit as returning the appropriate fit for determining the kinetic endpoints representing persistence and suitable for modelling.

RMS analysing the results stated that DFOP fit cannot be considered acceptable, because it returned not reliable kinetic parameters. The problem concerned the rate constant k_1 , for which the *prob.* > *t* was very close to 0.5.

FOMC fit was fully reliable.

It shall be pointed out that the inspection of the visual fit performed by the RMS led to the conclusion that also SFO fit should be classified as good.

The better representation of the kinetic behaviour of FOE Thiadone in the test soil by the bi-phasic models may be caused by the fact that the DAT-0 concentration was adjusted to the procedural recovery. Also it shall be noted that for so short-living compound bi-phasic kinetic behaviour is not fully understandable.

The Applicant, indicating that SFO fit was reliable, proposed to consider it as appropriate for deriving persistence and modelling endpoints for FOE Thiadone in Indiana Sandy loam soil. RMS accepted that proposal.

3) The results of the kinetic analysis of the data obtained for FOE Thiadone in Nebraska silt loam soil.

The results of the kinetic analysis performed by the Applicant are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-137 and in numerical form in the table B.8.1.1.2.1.1._CA-252. Additionally the table B.8.1.1.2.1.1._CA-253 provides the kinetic endpoints obtained with each of the kinetic models tested.

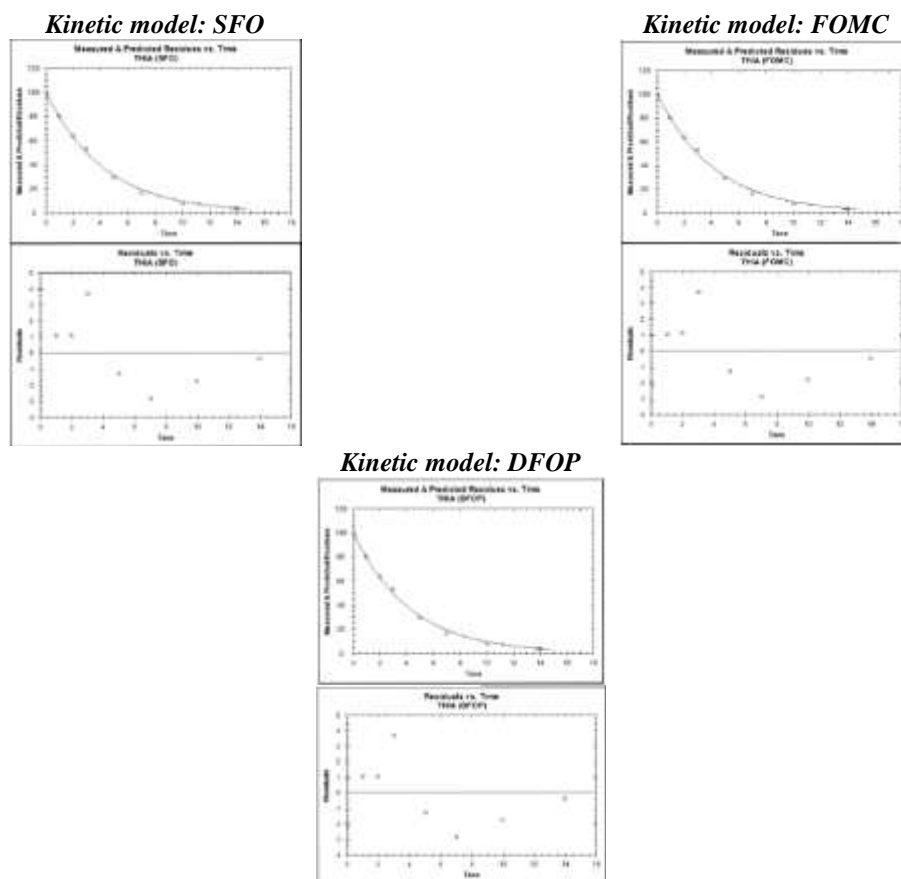

Figure B.8.1.1.2.1.1._CA-137: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.1._CA-252: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper			
SFO	M_0	100.6	1.922	96.84	104.377	1.63 E-9	3.709	0.996; Acceptable fit
	k	0.2363	8.967 E-3	0.2187	0.254	9.85 E-8		
FOMC	M_0	100.646	2.089	96.552	104.7	3.64 E-8	4.006	0.996; Acceptable fit
	α	237.143	9.774	217.985	256.3	1.11 E-6		
	β	1000.695	4.228	992.409	1009.0	1.28 E-11		
DFOP	M_0	100.610	8.183	84.571	116.648	1.26 E-3	4.273	0.996; Acceptable fit
	k_1	0.2363	0.01784	0.2013	0.271	9.39 E-5		
	k_2	0.2363	0.3316	-0.4135	0.886	0.2577		
	g	0.9520	2.5414	-4.0291	5.933	0.3635		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Table B.8.1.1.2.1.1._CA-253: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>
<i>FOE Thiadone</i>	DT ₅₀ [days]	2.93	2.93	2.93
	DT ₉₀ [days]	9.74	9.76	9.74

Conclusion:

All three models returned first that were statistically reliable – the χ^2 error for them was well below 15%, but the Applicant classified them as only acceptable in terms of visual assessment. RMS however is of the opinion that all three may be classified as visually good fits.

Of the three SFO was superior, displaying the lowest level of χ^2 error.

RMS also noticed that DFOP fit cannot be classified as acceptable because of the lack of reliability of its two kinetic parameters – k_2 and g , for which the *prob. > t* was higher than 0.1.

As a result it may be stated that the Applicant's proposal to consider SFO fit as appropriately representing persistence of FOE Thiadone in Nebraska Silt loam soil and appropriate for deriving modelling endpoints is acceptable.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-254.

Table B.8.1.1.2.1.1._CA-254: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
<i>Soil name</i>	<i>Soil type (USDA)</i>	<i>OC [%]</i>	<i>pH¹⁾</i>			χ^2 error	<i>Visual fit²⁾</i>	<i>Par.</i>	<i>Value</i>	<i>DT₅₀ [days]</i>	<i>DT₉₀ [days]</i>
<i>Iowa</i>	Loamy sand	1.11	7.2	20.1 ± 1°C; 75% of ½ bar	SFO	6.72	A	<i>k</i>	0.3494	1.98	6.59
<i>Indiana</i>	Sandy loam	0.74	6.5	20.1 ± 1°C; 75% of ½ bar	SFO	5.67	A	<i>k</i>	0.4945	1.40	4.66
<i>Nebraska</i>	Silt loam	0.96	7.7	20.1 ± 1°C; 75% of ½ bar	SFO	3.71	A	<i>k</i>	0.2363	2.93	9.74

Footnotes to the table:

- 1) Measuring medium not given;

Study 19:

Report: Eckermann N., (2012): “[1-¹⁴C]Trifluoroacetate: Aerobic Degradation in Four European Soils.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany; unpublished Study Report No. EnSa-12-0393; 2012. 09. 26; study reference number: M-439283-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

Additionally, as the data obtained in the study were kinetically evaluated and the results presented in the study report, it was declared that the following Guideline was used:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;

GLP: Yes

RMS comments: This is a new study, submitted specifically for purpose of this assessment. It was verified by the RMS and found acceptable. However, as the full results of the kinetic analysis were presented for only one test soils, considered to be a representative example, RMS had to repeat the kinetic assessment, because it was not possible to fully verify that performed by the Applicant. As a result, RMS decided not to take into account and present in the summary the Applicant’s results, replacing them with those obtained during repeated assessment. The study is summarised below.

Summary:

The aim of the study was to examine the degradation TFA (Trifluoroacetic acid) – a major soil degradation product of Flufenacet, in aerobic soil. The experiment was performed on four EU-soils, used in other studies examining the degradation of Flufenacet and its degradation products in soil. The test soils were taken from the agriculturally used areas, representing different geographical origin and different soil properties, in line with the requirement of the relevant Guideline. The characteristic of the test soils is provided below in the table B.8.1.1.2.1.1._CA-255.

Table B.8.1.2.1.1.CA-255: The characteristic of soils used in the study.

Parameter		Soil			
		<i>Laacher Hof AXxa</i>	<i>Dollendorf II</i>	<i>Hoefchen Am Hohenseh 4a</i>	<i>Laacher Hof Wurmweise</i>

	DAT-120	1.55	2.57	1.61	2.23

Footnotes to the table:

- 1) Determined using the SIR method developed by Anderson & Domsch [1978];
- 2) Values recalculated by the RMS using the OC content reported in the table for each test soil.

The test soils were sampled shortly before being used (14 days before the experiment began) with shovel from 0-20 cm layer of grassland plot. No Plant Protection Products were used on the sampling field for 5 years preceding sampling. The samples of the test soils were transported to the test facility in plastic bags. There they were sieved through 2-mm sieve and stored in the darkness at either $T < 8^{\circ}\text{C}$ or $T = 20^{\circ}\text{C}$ until being used.

The experiment was performed using biometer flasks, presented below on figure B.8.1.1.2.1.1_CA-138, containing 100-g portions of the test soils.

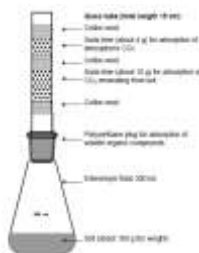

Figure B.8.1.1.2.1.1_CA-138: The biometer flask used in the experiment (copied from the study report).

The experiment started with weighing 100-g (d. w.) portions of the test soil into 300-mL Erlenmeyer test flasks. Next soil in each flask was brought to the designated level of moisture content – 55% MWHC, by addition of the appropriate amount of distilled water. Then the flasks were weighed and pre-incubated in incubation chamber, in the dark at constant temperature $T = 20.0 \pm 0.1^{\circ}\text{C}$, over weekend.

After that period soil in each biometer flask was treated with the test compound.

The test compound used in the experiment was the radiolabelled trifluoroacetic acid in form of its sodium salt. The reason for that was the fact that Trifluoroacetic acid has $pK_a = 1.3$, therefore under environmental conditions it occurs in deprotonated form – as trifluoroacetate (CF_3COO^-). For that reason sodium salt was selected as the relevant deprotonated species. The structural formula of the test compound is presented below on figure B.8.1.1.2.1.1. CA-139. The radiolabelling position is marked with asterisk (*). The test compound had specific activity of 3.48 MBq/mg (94.04 $\mu Ci/mg$) and radiochemical purity, determined by radio-HPLC, of > 98 - 99%. It was delivered to the test facility as a solid sample.

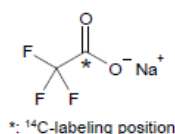

Figure B.8.1.1.2.1.1_CA-139: The structural formula of the test compound used in the experiment (copied from the study report).

The whole delivered sample of the test compound was used to make the **Stock solution**, from which the **Application solution** was prepared. The **Stock solution** was prepared by dissolving the test compound in 11.7 mL of ultrapure water. The so prepared solution had a concentration, expressed in radioactivity units, of 74.1 kBq/mL and radiochemical purity (determined by HPLC) > 99%. The **Stock solution** was stored in the dark, in a freezer until being used.

The **Application solution** was prepared by diluting 2.4 mL of the **Stock solution** with 117.6 mL of ultrapure water to obtain a solution having a concentration 20 µg/mL. That solution was used to treat test soils in biometer flasks. The amount of the **Application solution**, applied in small droplets to the soil surface using 1000-µL

pipette, was 1 mL. That amount resulted in the soil concentration of the test compound 0.2 mg/kg (0.02 mg/100 g soil d.w.). It was determined using the following assumptions:

- field application rate of Flufenacet: 250 g/ha;
- maximum formation level of TFA: 25%;
- molar mass ratio TFA/Flufenacet: 0.3;
- soil bulk density: 1.5 g/cm³;
- depth of the soil layer: 2.5 cm
- factor for increase of application rate: 4.

That factor was declared to be introduced to compensate the analytical limitations. It shall be noted however that the actual formation level of TFA is significantly higher than the proposed 25% and, on the basis of the results of the studies examining the route of degradation of Flufenacet in soil, is expected to reach the level of 75-100% of the applied parent compound, therefore the introduced factor corrected the inaccurate assumption concerning the level of formation of TFA from Flufenacet.

RMS analysing the calculations noticed that the assumed soil layer was ½ of that routinely used to calculate field application rate (in [g/ha]). Therefore the would-be application rate for TFA-Na was recalculated using the standard assumptions:

- soil bulk density: 1.5 g/cm³;
- thickness of the soil layer: 5 cm.

The so calculated theoretical field application rate **A = 150 g TFA-Na/ha**.

Using the measured soil bulk density of each test soil used in the experiment that value would be:

- for Laacherhof AXXa soil: **A = 126 g/ha**;
- for Dollendorf II soil: **A = 97 g/ha**;
- for Höfchen am Hohenseh 4a soil: **A = 108 g/ha**;
- for Wurmweise soil: **A = 113 g/ha**

The level of application and its homogeneity was verified at the beginning, in the middle and at the end of the application procedure, by verification of the concentration of the **Application solution**. For that purpose its 1-mL samples were diluted with ultrapure water to 25- mL and analysed by LSC.

For treatment the pre-incubated biometric flasks were removed from the incubation chamber. After application of the test compound the vessels, except those designated as DAT-0 samples, were fitted with the traps for volatile compounds and returned to incubation chamber to be incubated at constant temperature $T = 20.0 \pm 0.1^{\circ}\text{C}$ and soil moisture level $55 \pm 5\%$ MWHC for up to 120 days. At the designated time points – DAT 3, DAT 7, DAT 14, DAT 28, DAT 34, DAT 59, DAT 92 and DAT 120, duplicate samples of each test soil were removed from the incubation chamber and further processed. At the same time points the soil moisture content was checked and corrected if necessary. That was done by weighing the test vessels without the traps for volatile compounds, calculating the loss of water and, when necessary, readjusting the water content to the designated level by adding the appropriate amount of water.

The samples collected at each sampling point were processed and analysed entirely. The processing of the collected samples followed the procedure presented below on figure B.8.1.1.2.1.1_CA-140. Firstly the biometer flask were placed in a dessicator and the volatile compounds possibly present in the headspace above soil surface were transferred to the trap by evaporating the entire system. Then the flasks were dissected, traps stored for further analysis and soil samples extracted entirely. The extracted soil pellets were freeze-dried, homogenised and analysed for the content of NER fraction.

The recovered traps for volatile compounds were dissected into the PU (Polyurethane Foam) plugs and soda lime traps.

The VOCs possibly retained in PU plugs were extracted by shaking plugs with 50 mL of $\text{CH}_3\text{COC}_2\text{H}_5$. 5-mL aliquots of the obtained extracts were analysed firstly by LSC and then, if necessary, chromatographically.

The soda-lime traps for $^{14}\text{CO}_2$ formed in the experiment were processed in a way identical to that described in details in the summaries of the route-of-degradation studies by [Pangilinan and Smith; 1994a] (aerobic soil route-of-degradation **Study 4**) and by [Kasper and Shadrick; 1995] (soil photolysis **Study 1**), but used also in other studies examining the degradation of Flufenacet in soil under aerobic conditions – e.g. studies [Hein; 2012] (aerobic soil route-of-degradation **Study 5**) and [Hein; 2012 a] (aerobic soil route-of-degradation **Study 6**). The released $^{14}\text{CO}_2$ was absorbed in a scintillation cocktail and analysed by LSC.

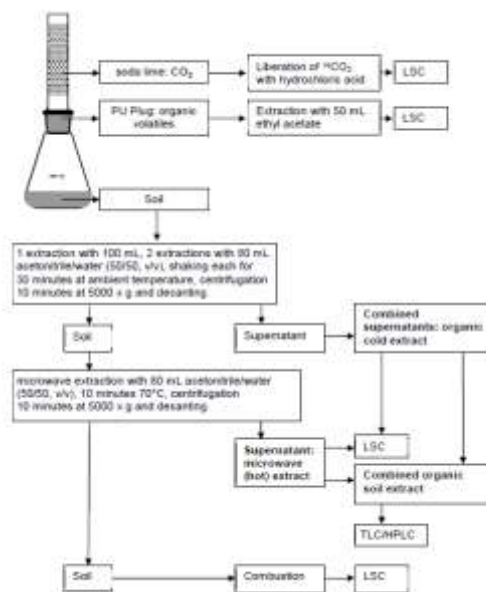

Figure B.8.1.1.2.1.1._CA-140: The sample-processing procedure used in the experiment (copied from the study report).

The extracted soil pellets were analysed for the content of NER fraction. To do that each soil sample was allowed to air-dry overnight, after what its triplicate aliquots (50 – 100 mg) were oxidized by combustion. The formed $^{14}\text{CO}_2$ was trapped in alkaline solution which, after mixing with scintillation cocktail, was analysed by LSC. The further characterisation of NER fraction was not performed, because of its low content – max. 13.5% AR.

All samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using LS 6500 (Beckmann) or LKB-Wallac 1219 Spectral (Perkin Elmer Life Science) counters.

The radioactivity in solutions was determined in either:

- mini-vials, using the sample aliquots of up to 0.5 mL and 2 mL of Quicksafe® A solution containing 5% of water; the counting was performed using LS 6500 counter, the counting efficiency was 83.07 – 91.01% and the background 13 – 16 cpm;
- maxi-vials, using the sample aliquots of up to 7 mL and 7 mL of Quicksafe® A solution containing 5% of water; the counting was performed using LKB-Wallac 1219 Spectral counter, the counting efficiency was 70.4 – 88.5% and the background 22 – 23 cpm.

The $^{14}\text{CO}_2$ recovered from soda lime was absorbed in 15 mL of Oxysolve C400 and analysed quantitatively using LKB-Wallac 1219 Spectral counter. The counting efficiency was 70.4 – 88.5% and the background 17 – 20 cpm.

The radioactivity in extracts from PU plugs was determined in the same way as in other liquid samples (see above).

The radioactivity in solid samples – extracted soil pellets, was determined after combustion of three 1-g aliquots of dried and homogenised material. The resulting $^{14}\text{CO}_2$ was absorbed in 15 mL of Oxysolve C400 scintillation cocktail and analysed quantitatively using LKB-Wallac 1219 Spectral counter. The counting efficiency was 70.4 – 88.5% and the background 17 – 20 cpm.

The combined organic soil extracts were subjected to chromatographic analysis performed as either:

- radio-TLC analysis – the primary identification and quantitation method used in the study;
- HPLC analysis with radio- and MS detection – conformatory method for TLC analysis.

The TLC analysis was performed on silica gel plates – Si60, F_{254} , 20 cm x 20cm, developed in a chromatographic chamber without solvent saturation, using the following mobile phase:

ethyl acetate/2-propanol/ultrapure water/glacial acetic acid 65:24:11:1 (v/v/v/v). The volume of the analysed sample injected onto the plate was 20 µL. The distribution and quantitation of the radioactivity zones was determined using Bio-Imaging Analyzer BAS 2000, Fuji, Co.

The identification was performed using LC-MS or LC-MS/MS methods characterised below, but the additional identification method was the comparison of the R_f values of the radioactivity zones with those of the known standards, chromatographed in parallel.

The LC/MS analysis was performed using Agilent HP 1100 instrument equipped with Nucleodur C18 Gravity 250 x 2 mm, 3 µm, chromatographic column and UV detector, coupled to Ramona Star radioactivity detector and LTQ Orbitrap XL MS detector. The chromatographic analysis was performed in a gradient mode using a gradient programme presented below in the table B.8.1.1.2.1.1._CA-256. The flow rate was 0.2 mL/min and elution lasted for 35 minutes. The changes in the gradient of mobile phase were linear.

Table B.8.1.1.2.1.1._CA-256: The gradient mode used in the LC-MS analysis.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% HCOOH</i>	<i>Solvent B – CH₃CN + 0.1% HCOOH</i>
0	95	5
1	95	5
25	5	95
35	5	95

The method was used to conform the identity of the test compound in application solution and in selected organic extracts.

The radio-RP-HPLC method was used to check the purity of the **Stock solution** and to conform the results of the TLC analysis in selected extracts – the DAT-120 combined organic extracts.

The analysis was performed using Agilent 1100/1200 HPLC instrument equipped with Purospher Star RP18-e 250 x 4.6 mm, 5 µm, chromatographic column preceded by Purospher Star RP18-e 4 x 4 mm, 5 µm guard column, a column oven set to T = 40°C and Agilent VW detector set at $\lambda = 254$ nm. The chromatographic station was coupled with Ramona Star, Raytest, flow-through LS detector.

The elution was performed in a gradient mode, using one of the following two methods:

- Flurtaboden, used to check purity of the **Stock solution**;
 - “KOE78_TFA, used to conform the results of the TLC analysis of DAT-120 combined organic extracts.
- Both methods are characterised below, in the table B.8.1.1.2.1.1._CA-257.

Table B.8.1.1.2.1.1._CA-257: The gradient modes used in the radio-RP-HPLC analysis.

Method 1: “Flurtaboden”		
Time [min]	Solvent ratio

60	100	0

The obtained results are presented below. The determined concentrations of TFA in soil were subjected to the kinetic analysis performed in line with the recommendations given by FOCUS [2006].

Results and their discussion:

The examination of the microbial viability of the test soils showed that they were viable throughout the whole experiment. The detailed results are shown in the table B.8.1.1.2.1.1._CA-255.

The monitoring of incubation temperature showed that the samples were kept in the constant temperature $T = 20 \pm 1^{\circ}\text{C}$. The mean incubation temperature was $T = 20.0^{\circ}\text{C}$ and it ranged from $T = 19.8^{\circ}\text{C}$ to $T = 20.4^{\circ}\text{C}$. The results of the monitoring of the temperature in the incubation chamber are shown below, in the graphical form, on figure B.8.1.1.2.1.1._CA-141.

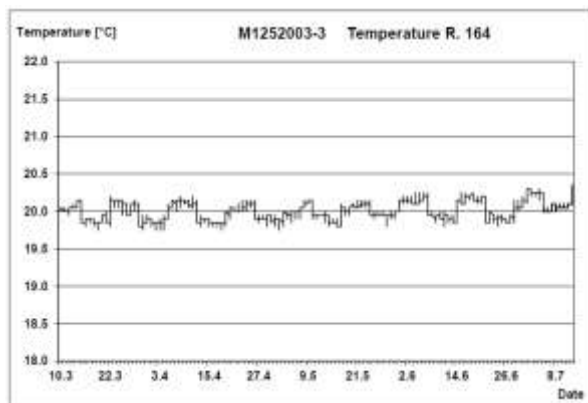

Figure B.8.1.1.2.1.1._CA-141: The temperature recorded in incubation chamber during the experiment (copied from the study report).

The results of the determination of the soil moisture are presented below in the table B.8.1.1.2.1.1._CA-258. These values were subsequently used in normalisation procedure.

Table B.8.1.1.2.1.1._CA-258: The results of the determination of soil moisture content.

Test soil		Soil moisture [g H ₂ O/100 g soil d. w.]			Water addition [ml H ₂ O/100 g soil d. w.]
Soil name	Soil type (USDA)	Actual (air-dried, sieved through 2-mm sieve)	at MWHC	at 55% MWHC	
<i>Laacher Hof AXXa</i>	Sandy loam	16.1	46.9	25.8	10
<i>Dololendorf II</i>	Clay loam	37.5	84.9	46.7	9
<i>Laacher Hof Wurmweise</i>	Silt loam	19.9	57.6	31.7	12
<i>Hoefchen Am Hohenseh 4a</i>	Sandy loam	24.7	62.0	34.1	9

The results of the verification of the application rate and homogeneity of application are presented below in the table B.8.1.1.2.1.1._CA-259. On the basis of the obtained results the value of 72697 Bq, corresponding to 20.89 µg of ¹⁴C equivalents, was regarded as 100% AR for all calculations.

Table B.8.1.1.2.1.1._CA-259: The results of verification of application rate and homogeneity of application.

Sample No.	Sample volume [mL]		Radioactivity [Bq]		¹⁴ C equivalents [µg]
	Total sample volume	Volume of LSC aliquot	Measured in LSC-aliquot	Total in sample	
1	25	0.5	1449.33	72467	20.82
2	25	0.5	1451.01	72551	290.85
3	25	0.5	1451.65	72233	20.76
4	25	0.5	1451.67	72548	20.86
5	25	0.5	1458.26	72913	20.95
6	25	0.5	1446.78	72339	20.79
7	25	0.5	1459.32	72966	20.97
8	25	0.5	1462.91	73146	21.02
9	25	0.5	1461.47	73074	21.00
Mean value				72697	20.89
SD				334	0.10
RSD [%]				----	0.46

The determination of the LOD and LOQ values for LSC and chromatographic analyses resulted in following values:

- the instrumental LOD and LOQ values for LSC analysis were: LOD = 2 times maximum instrument background count rate (0.25 Bq) and LOQ = three times maximum instrument background count rate (0.4 Bq);
- for liquid samples in 2 mL of Quicksafe A scintillation cocktail (mini-vials) LOD = 0.5 Bq and LOQ = 0.8 Bq;
- for liquid samples in 7 mL of Quicksafe A scintillation cocktail (maxi-vials) LOD = 0.8 Bq and LOQ = 1.2 Bq;
- for combustion samples LOD = 0.7 Bq and LOQ = 1.0 Bq;

As a result the corresponding values for entire extracts (worst case) were:

- for organic cold extracts, having volume of 256 mL, LOD = 256 Bq and LOQ = 384 Bq;
- for organic microwave extracts, having volume of 80 mL, LOD = 90 Bq and LOQ = 135 Bq;
- for combustion samples LOD = 80 Bq and LOQ = 121 Bq.

When expressed as % AR that corresponded to LOD < 0.4% AR and LOQ < 0.5% AR for all types of samples.

In case of TLC analysis the determined for combined organic extracts LOD = 0.7% AR and LOQ = 2.1 % AR (3*LOD).

The overview of the key results obtained in the experiment is presented below in the table B.8.1.1.2.1.1._CA-260. The detailed results of the experiment are presented further down the report.

Table B.8.1.1.2.1.1._CA-260: The key results obtained in the study.

Test soil		Determined parameter:				
Soil name	Soil type (USDA)	Total recovery (range) [% AR]	Radioactivity extracted (range) [% AR]	Maximum level of volatiles formed [% AR]	NER level (range) [% AR]	Extraction efficiency on DAT 0 [%]
Laacher Hof AXXa	Sandy loam	98.2 – 102.1	97.5 – 101.4	0.1	0.6 – 0.9	97.7
Dollendorf II	Clay loam	97.8 – 101.9	96.4 – 100.2	0.1	1.2 – 2.0	98.4
Laacher Hof Wurmweise	Silt loam	97.0 – 100.9	95.9 – 99.7	0.1	1.0 – 1.3	98.7
Hoefchen Am Hohenseh 4a	Sandy loam	98.2 – 103.4	97.0 – 102.1	0.1	0.9 – 1.3	99.2

The detailed numerical results of the experiment are presented below, individually for each test soil, in tables B.8.1.1.2.1.1._CA-261 – B.8.1.1.2.1.1._CA-264.

Table B.8.1.1.2.1.1._CA-261: The numerical results of the experiment performed on Laacher Hof AXXa Sandy loam soil.

The graphical results of the study – the distribution of radioactivity between fractions, is presented below on figure B.8.1.1.2.1.1_CA-142.

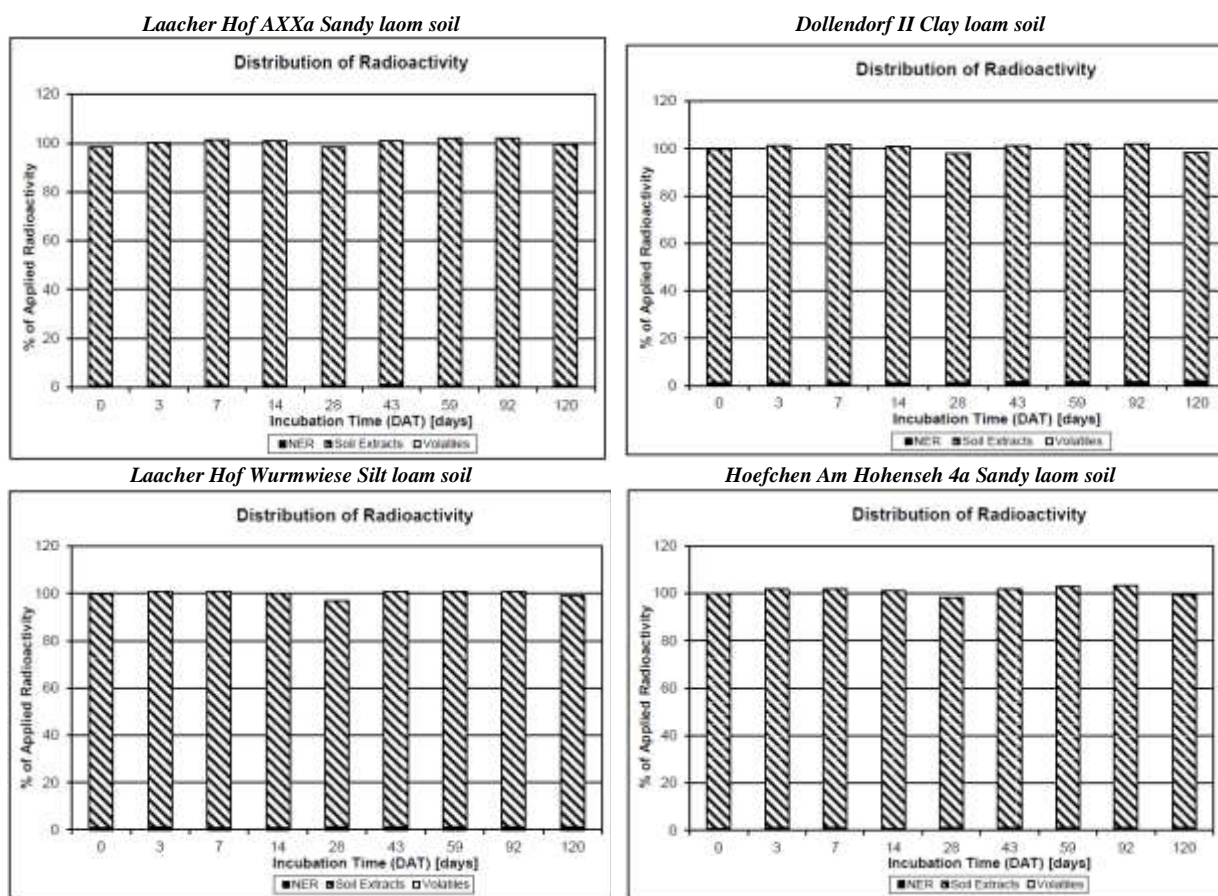

Figure B.8.1.1.2.1.1_CA-142: The distribution of radioactivity between fractions in each test soil (copied from the study report).

The Applicant performed the kinetic analysis of the data obtained for $[1-^{14}\text{C}]$ trifluoroacetate in each test soil, presented in tables B.8.1.1.2.1.1_CA-261 – B.8.1.1.2.1.1_CA-264 above. However, full set of the results, including visual fits, was given only for one soil – Laacher Hof AXXa soil. As a result, the verification of the correctness of the performed kinetic analysis was not possible. Therefore RMS decided not to present the results of the Applicant's kinetic analysis of the data, replacing it with own assessment.

The kinetic analysis was carried out in line with the recommendations given by FOCUS for the determination of the kinetic endpoints suitable for modeling. It followed the approach used by the Applicant and presented in several studies previously summarised in this section (e. g. **Studies 2 – 8**). The data used in the kinetic analysis were the same as presented above in the tables B.8.1.1.2.1.1_CA-261 – B.8.1.1.2.1.1_CA-264. For completeness they are presented below in the table B.8.1.1.2.1.1_CA-265.

Table B.8.1.1.2.1.1_CA-265: The concentrations of TFA in each test soil used in the kinetic analysis performed by the RMS.

Results obtained in <i>Laacher Hof AXXa</i> soil			Results obtained in <i>Dollendorf II</i> soil			Results obtained in <i>Laacher Hof Wurmweise</i> soil			Results obtained in <i>Hoefchen Am Hohenseh 4a</i> soil		
DAT	Concentration of TFA [% AR]		DAT	Concentration of TFA [% AR]		DAT	Concentration of TFA [% AR]		DAT	Concentration of TFA [% AR]	
	Rep. 1	Rep 2.		Rep. 1	Rep 2.		Rep. 1	Rep 2.		Rep. 1	Rep 2.
0	97.8	97.5	0	98.5	98.3	0	98.4	98.9	0	99.1	99.3

59	101.3	101.3	59	100.5	99.5	59	100.6	98.9	59	102.5	101.0
92	101.7	101.0	92	100.3	100.2	92	100.0	99.3	92	102.5	101.7
120	98.0	99.2	120	96.1	96.8	120	97.0	98.2	120	97.9	98.7

The presented above data were kinetically examined using CAKE ver. 3.1 modelling tool, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The settings of the optimiser were the defaults of the tool:

- maximum iterations: 100,
- maximum reweighing: 10,
- SANN maximum iterations: 10000,
- convergence tolerance: 1 E-5,
- error variance tolerance: 1 E-5,
- extra solver: yes, if required.

The kinetic analysis was performed using three kinetic models, also used by the Applicant in his analysis – SFO, FOMC and DFOP. RMS however noticed that, because of virtually no degradation of the test compound in all four test soils, only the results obtained with SFO kinetic model will be of any relevance. Never the less, the results of the fitting with FOMC and DFOP models were presented for completeness.

All results of the kinetic analysis of the data are presented below, separately for each test soil.

- 1) The results of the kinetic analysis of the data obtained for Trifluoroacetate in Laacher Hof AXXa soil.

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-143 and in numerical form in the table B.8.1.1.2.1.1._CA-266. Additionally the table B.8.1.1.2.1.1._CA-267 provides the kinetic endpoints obtained with each of the kinetic models tested.

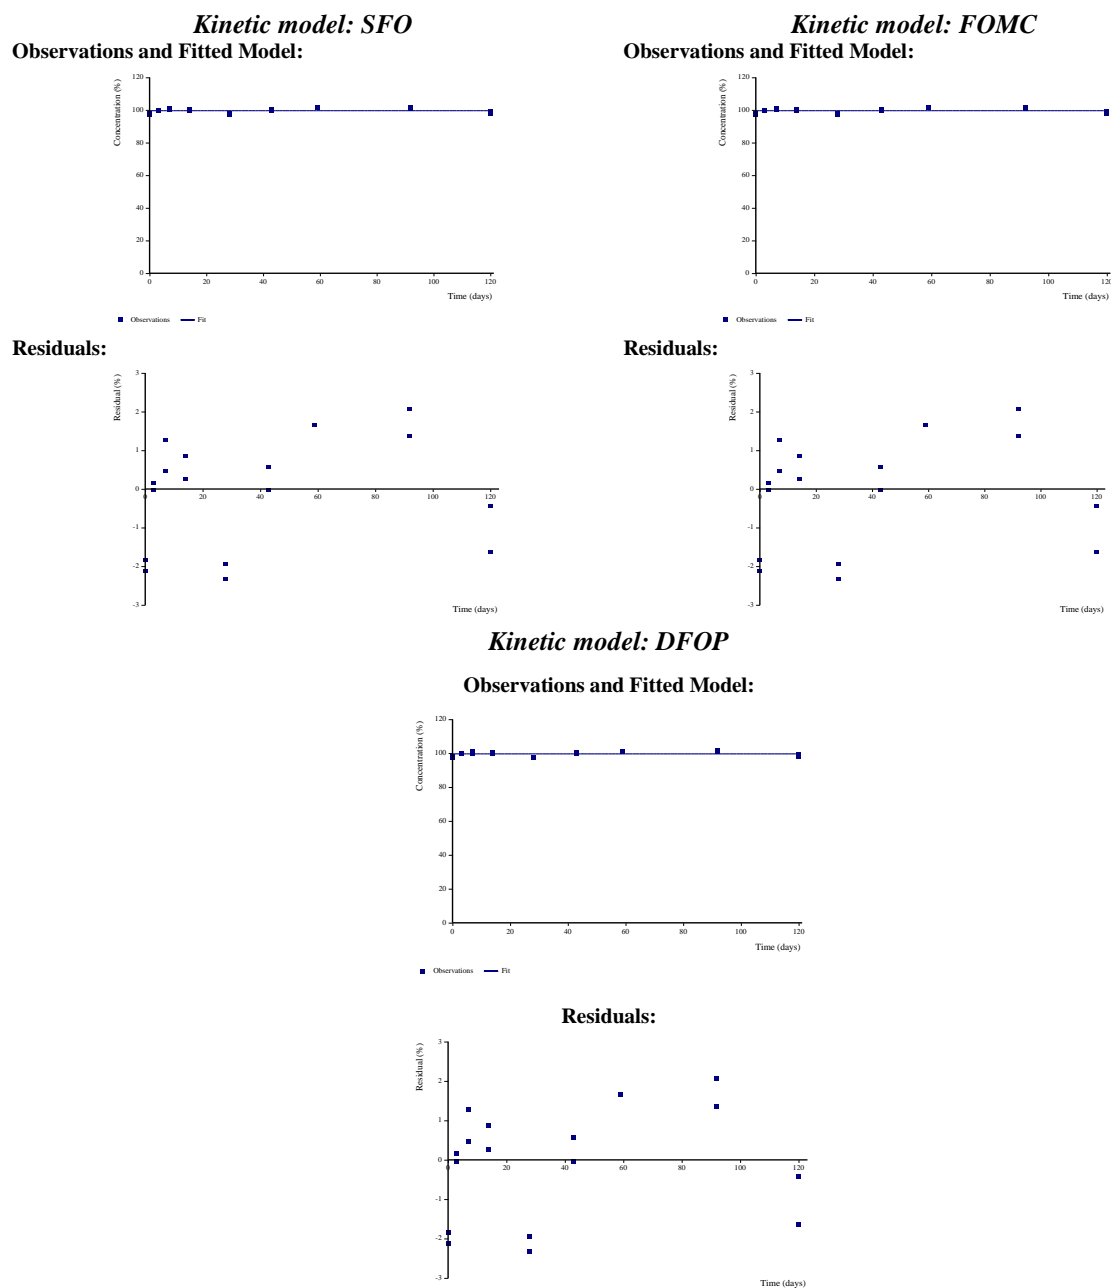

Figure B.8.1.1.2.1.1._CA-143: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-266: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	99.63	0.495	98.58	100.7	n. c. ¹⁾	1.09	0.0388; Acceptable fit
	k	2.24 E-14	8.72 E-5	-1.848 E-4	0.000	0.5		
FOMC	M_0	99.63	0.358	98.87	100.4	n. c. ¹⁾	1.15	R^2 not determined; Acceptable fit
	α	4.89 E-11	4.72 E-11	-5.16 E-11	0.00	n. d. ²⁾		
	β	9.041	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾		
DFOP	M_0	99.63	0.527	98.5	100.8	n. c. ¹⁾	1.22	R^2 not determined; Acceptable fit
	k_1	0.00163	1.71 E-4	0.00126	0.002	8.58 E-8		
	k_2	1.45 E-14	9.17 E-5	-1.968 E-4	0.00	0.5		
	g	7.91 E-6	0.00	7.91 E-6	0.00	n. c. ¹⁾		

Footnotes to the table:

1) n. c. = not calculated by the tool;

2) Values were not determined by the model because the covariance matrix could not be created.

Table B.8.1.1.2.1.1._CA-267: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Trifluoroacetate	DT ₅₀ [days]	> 10000	> 10000	> 10000
	DT ₉₀ [days]	> 10000	> 10000	> 10000

Conclusion:

All three models returned fits that were visually acceptable and statistically good. However for none of them the calculated kinetic endpoints may be considered reliable. That was due to the fact that practically no degradation was observed in the experiment. That outcome is in line with available literature data for TFA, stating that the compound is persistent in soil and the sole possible routes of dissipation from that environmental compartment are via volatilisation to air, possible however for the non-dissociated acid, and incorporation to soil matrix.

Therefore RMS proposes to consider SFO as a model giving the acceptable approximate of the kinetic behaviour of TFA in soil. Also for that compound RMS proposes to consider DT₅₀ = 10000 days (~27.4 years) as a kinetic endpoint appropriate to be used as persistence endpoint.

- 2) The results of the kinetic analysis of the data obtained for Trifluoroacetate in Dollendorf II soil.

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-144 and in numerical form in the table B.8.1.1.2.1.1._CA-268. Additionally the table B.8.1.1.2.1.1._CA-269 provides the kinetic endpoints obtained with each of the kinetic models tested.

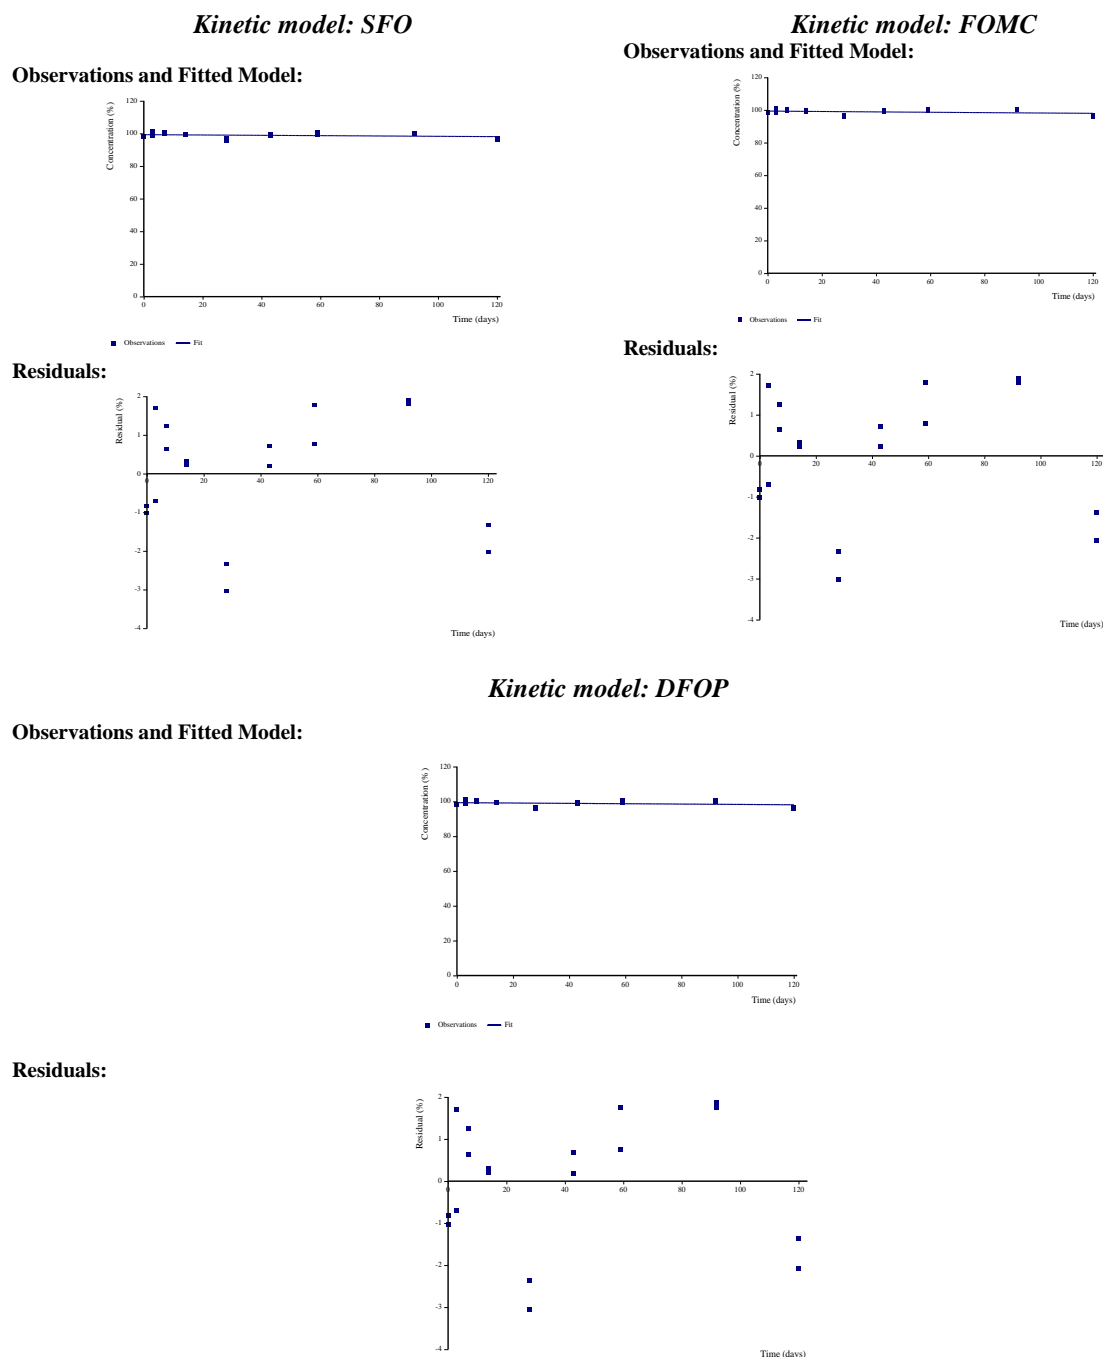

Figure B.8.1.1.2.1.1._CA-144: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-268: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	99.32	0.526	98.21	100.4	n. c. ¹⁾	1.12	0.0685; Acceptable fit

Footnotes to the table:

1) n. c. = not calculated by the tool;

2) Values were not determined by the model because the covariance matrix could not be created.

Table B.8.1.1.2.1.1._CA-269: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Trifluoroacetate	DT ₅₀ [days]	6870	> 10000	6870
	DT ₉₀ [days]	> 10000	> 10000	> 10000

Conclusion:

All three models returned fits that were visually acceptable and statistically good. However for none of them the calculated kinetic endpoints may be considered reliable. That was due to the fact that practically no degradation was observed in the experiment. That outcome is in line with available literature data for TFA stating that the compound is persistent in soil and the sole possible routes of dissipation from that environmental compartment are via volatilisation to air, possible however for the non-dissociated acid, and incorporation to soil matrix.

It shall be noted that for SFO and DFOP kinetic models the modelling tool calculated the DT₅₀ = 6870 days. That value however shall be considered with extreme care as the rate constants used to determine it were of very limited reliability. Therefore more appropriate, in RMS's opinion, would be the default maximum value returned by the model for the remaining soils – DT₅₀ > 10000 days.

Therefore RMS proposes to consider SFO as a model giving the acceptable approximate of the kinetic behaviour of TFA in soil. Also for that compound RMS proposes to consider DT₅₀ = 10000 days (~27.4 years) as a kinetic endpoint appropriate to be used as persistence endpoint.

- 3) The results of the kinetic analysis of the data obtained for Trifluoroacetate in Laacher Hof Wurmwielse soil.

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-145 and in numerical form in the table B.8.1.1.2.1.1._CA-270. Additionally the table B.8.1.1.2.1.1._CA-271 provides the kinetic endpoints obtained with each of the kinetic models tested.

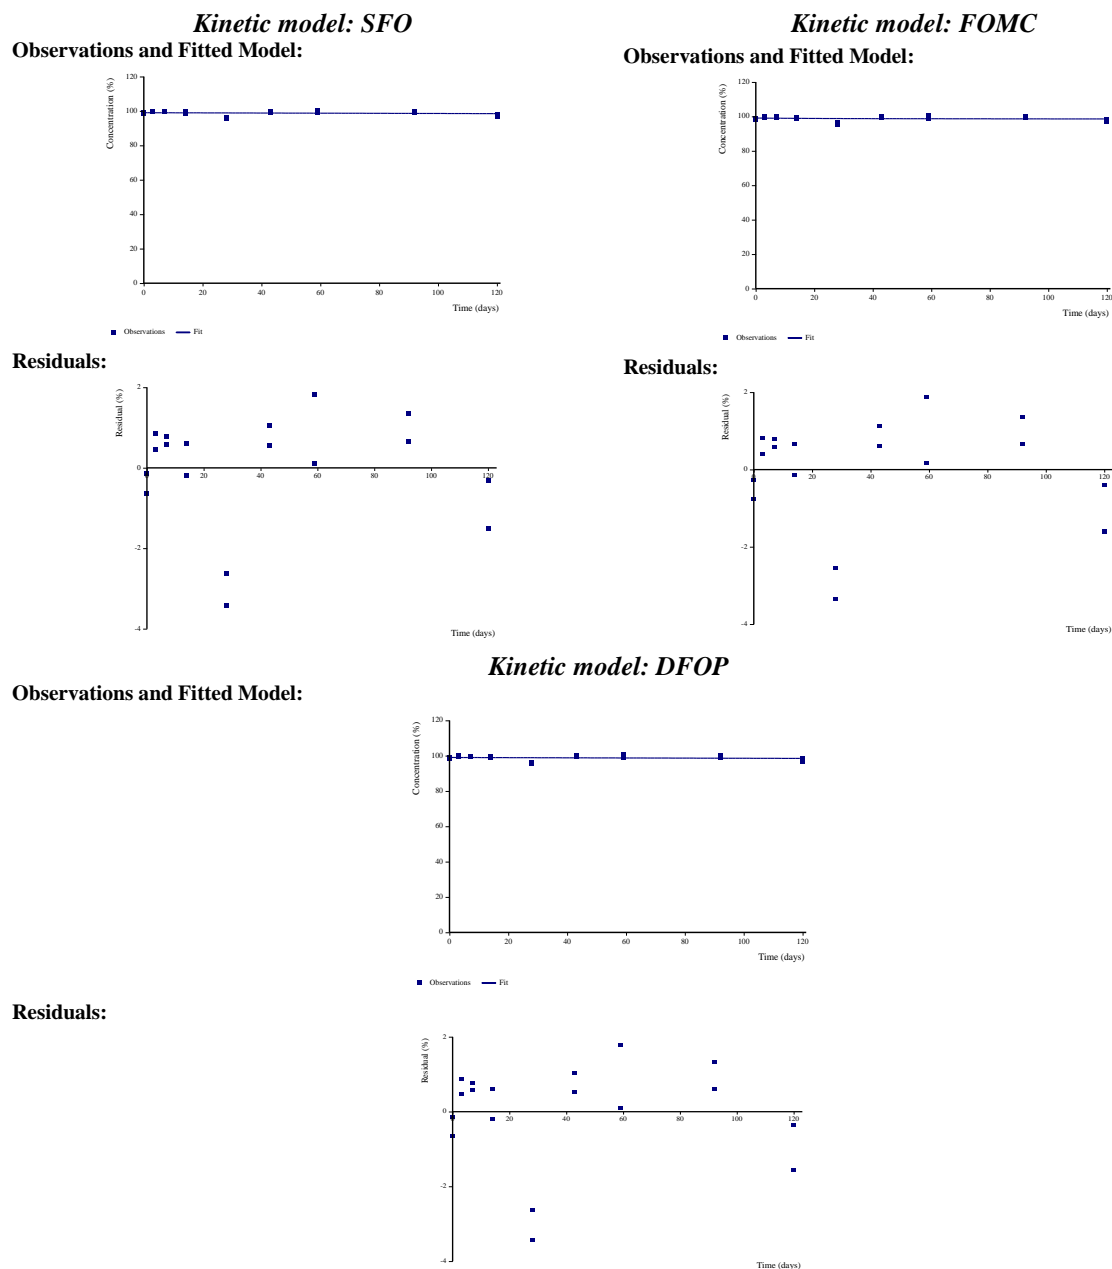

Figure B.8.1.1.2.1.1._CA-145: The graphical results of the kinetic analysis.

That outcome is in line with available literature data for TFA, stating that the compound is persistent in soil and the sole possible routes of dissipation from that environmental compartment are via volatilisation to air, possible however for the non-dissociated acid, and incorporation to soil matrix.

Therefore RMS proposes to consider SFO as a model giving the acceptable approximate of the kinetic behaviour of TFA in soil. Also for that compound RMS proposes to consider DT₅₀ = 10000 days (~27.4 years) as a kinetic endpoint appropriate to be used as persistence endpoint.

- 4) The results of the kinetic analysis of the data obtained for Trifluoroacetate in Hoefchen am Hohenseh 4a soil.

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.1.1._CA-146 and in numerical form in the table B.8.1.1.2.1.1._CA-272. Additionally the table B.8.1.1.2.1.1._CA-273 provides the kinetic endpoints obtained with each of the kinetic models tested.

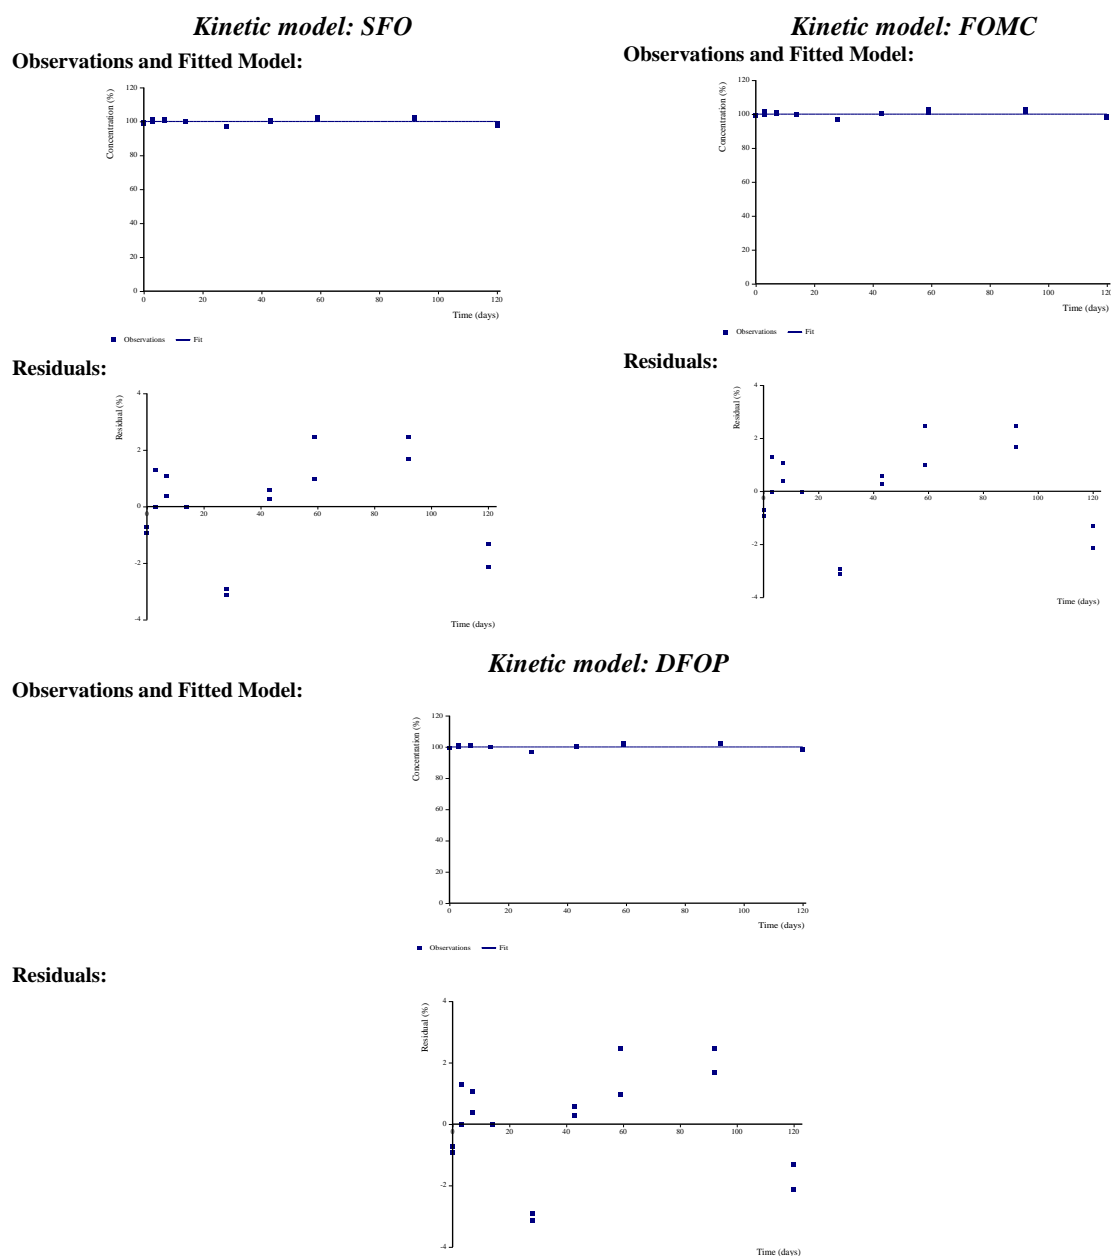

Figure B.8.1.1.2.1.1._CA-146: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.1._CA-272: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	100.0	0.566	98.828	101.2	n. c. ¹⁾	1.23	0.0022; Acceptable fit
	k	1.90 E-14	9.93 E-5	-2.105 E-4	0.00	0.5		
FOMC	M_0	100.0	0.410	99.15	100.9	n. c. ¹⁾	1.30	R^2 not determined; Acceptable fit
	α	1.35 E-10	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾		
	β	9.372	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾	n. d. ²⁾		
DFOP	M_0	100.0	0.603	98.73	101.3	n. c. ¹⁾	1.38	R^2 not determined; Acceptable fit
	k_1	1.929 E-3	1.002 E-3	-2.199 E-4	0.004	3.74 E-2		
	k_2	5.47 E-13	1.05 E-4	-2.241 E-4	0.00	0.5		
	g	7.11 E-6	0.00	7.11 E-6	0.00	n. c. ¹⁾		

Footnotes to the table:

1) n. c. = not calculated by the tool;

2) Values were not determined by the model because the covariance matrix could not be created.

Table B.8.1.1.2.1.1._CA-273: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Trifluoroacetate	DT ₅₀ [days]	> 10000	> 10000	> 10000
	DT ₉₀ [days]	> 10000	> 10000	> 10000

Conclusion:

All three models returned fits that were visually acceptable and statistically good. However for none of them the calculated kinetic endpoints may be considered reliable. That was due to the fact that practically no degradation was observed in the experiment. That outcome is in line with available literature data for TFA, stating that the compound is persistent in soil and the sole possible routes of dissipation from that environmental compartment are via volatilisation to air, possible however for the non-dissociated acid, and incorporation to soil matrix.

Therefore RMS proposes to consider SFO as a model giving the acceptable approximate of the kinetic behaviour of TFA in soil. Also for that compound RMS proposes to consider DT₅₀ = 10000 days (~27.4 years) as a kinetic endpoint appropriate to be used as persistence endpoint.

Final conclusion of the study:

On the basis of the results of the kinetic analysis presented above was determined the definitive set of the reliable kinetic parameters, presented below in the table B.8.1.1.2.1.1._CA-260.

Table B.8.1.1.2.1.1._CA-260: The definitive set of the kinetic endpoints determined in the study.

Soil		Soil properties		Incubation conditions	Selected best-fit model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints ⁴⁾	
Soil name	Soil type (USDA)	OC [%]	pH ¹⁾			χ^2 error	Visual fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]
<i>Laacher Hof AXXa</i>	Sandy loam	1.6	6.2	20.0°C/ 55% MWHC	SFO	1.09	A	<i>k</i>	n. d. ³⁾	10000	>10000
<i>Dollendorf II</i>	Clay loam	5.5	7.3	20.0°C/ 55% MWHC	SFO	1.12	A	<i>k</i>	n. d. ³⁾	10000	>10000
<i>Hoefchen Am Hohenseh 4a;</i>	Silt loam	2.4	6.4	20.0°C/ 55% MWHC	SFO	1.23	A	<i>k</i>	n. d. ³⁾	10000	>10000
<i>Laacher Hof Wurmweise</i>	Sandy loam	1.9	5.1	20.0°C/ 55% MWHC	SFO	0.997	A	<i>k</i>	n. d. ³⁾	10000	>10000

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂.
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) The reliable value could not be determined due to the fact that the decline of the test compound was not observed; as a result the corresponding DT₅₀ and DT₉₀ values are the defaults in range with the respective values proposed by the modelling tool;
- 4) For that soil, although the model calculated lower DT₅₀ value, the corresponding rate constant *k* lacked reliability and for that reason the RMS decided to use the default value instead (for justification please refer to the conclusions on the kinetic assessment for that test soil on p. 427).

Study 20:

Report: Eckermann N., (2012): “[1-¹⁴C]Trifluoroacetate: Concentration dependent Mineralization under Aerobic Conditions.”; Bayer CropScience AG, BCS-D-EnSa-Testing, 40789 Monheim, Germany; unpublished Study Report No. EnSa-12-0445; 2012. 10. 11; study reference number: M-441101-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- OECD Guideline for the Testing of Chemicals, No. 307, Aerobic and Anaerobic Transformation in Soil, 2002;
- US. EPA OCSPP Fate, Transport and Transformation Test Guidelines, OPPTS 835.4100 and OPPTS 835.4200, Aerobic and Anaerobic Soil Metabolism, 2008.

GLP: Yes

RMS comments: This is a new study, submitted specifically for purpose of this assessment. It was indicated by the Applicant to be supplementary to the summarised above study examining the degradation of TFA in soil, with specific aim to examine the possible influence of concentration of the test compound on its rate of degradation in soil. It was verified by the RMS and found acceptable. The study is summarised below.

Summary:

The study is a supplementary to the summarised above **Study 19** ([Eckermann; 2012]) examining rate of degradation of Trifluoroacetate (dissociated form of TFA) in soil. The aim of the present study was to further investigate the rate of degradation of TFA in soil, by verifying whether the process was not concentration-dependent. That was done by examining the mineralisation level of TFA in function of concentration and time.

The experiment was performed on four EU-soils, used in other studies examining the degradation of Flufenacet and its degradation products in soil. The test soils were taken from the agriculturally used areas, representing different geographical origin and different soil properties, in line with the requirement of the relevant Guideline. The characteristic of the test soils is provided below in the table B.8.1.1.2.1.1_CA-274.

Table B.8.1.2.1.1_CA-274: The characteristic of soils used in the study.

Parameter		Soil			
		<i>Laacher Hof AXXa</i>	<i>Dollendorf II</i>	<i>Hoefchen Am Hohenseh 4a</i>	<i>Laacher Hof Wurmwiess</i>

	DAT-59	3.68	6.08	3.52	2.42
	DAT-120	1.55	2.57	1.61	2.23

Footnotes to the table:

- 1) Determined using the SIR method developed by Anderson & Domsch [1978];
- 2) Values recalculated by the RMS using the OC content reported in the table for each test soil;

The test soils were sampled shortly before being used (7 days before the experiment began) with shovel from 0-20 cm layer of grassland plot. No Plant Protection Products were used on the sampling field for 5 years preceding sampling. The samples of the test soils were transported to the test facility in plastic bags. There they were sieved through 2-mm sieve and stored in the darkness at either $T < 8^{\circ}\text{C}$ or $T = 20^{\circ}\text{C}$ until being used.

The experiment was performed using biometer flasks containing 100-g portions of the test soils, the example of which is presented below on figure B.8.1.1.2.1.1._CA-147.

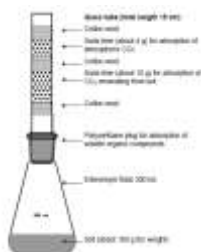

Figure B.8.1.1.2.1.1._CA-147: The biometer flask used in the experiment (copied from the study report).

The experiment started with weighing 100-g (d. w.) aliquots of each test soil into 300-mL Erlenmeyer test flask. Next the test soils in each flask were brought to the designated level of moisture content – 55% MWHC, by addition of the appropriate amount of distilled water. Then the flasks were weighed and pre-incubated in incubation chamber, in the dark at constant temperature $T = 20.0 \pm 0.1^{\circ}\text{C}$, over weekend. After that period soil in each biometer flask was treated with the test compound.

The test compound used in the experiment was the radiolabelled trifluoroacetic acid in form of its sodium salt. The reason for that was the fact that Trifluoroacetic acid has $\text{pK}_{\text{a}} = 1.3$, therefore under environmental conditions it is present in deprotonated form – as trifluoroacetate (CF_3COO^-). For that reason sodium salt was selected as the relevant deprotonated species. The structural formula of the test compound is presented below on figure B.8.1.1.2.1.1._CA-148. The radiolabelling position is marked with asterisk (*). The test compound had specific activity of 3.48 MBq/mg (94.04 $\mu\text{Ci/mg}$) and radiochemical purity, determined by radio-HPLC, $> 98 - 99\%$. It was delivered to the test facility as a solid sample.

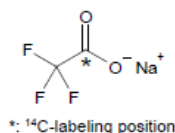

Figure B.8.1.1.2.1.1._CA-148: The structural formula of the test compound used in the experiment (copied from the study report).

The whole delivered sample of the test compound was used to prepare the **Stock solution**, from which three **Application solutions** were prepared. The **Stock solution** was prepared by dissolving the test compound in 11.7 mL of ultrapure water. The so prepared solution had a concentration, expressed in radioactivity units, 74.1 kBq/mL and radiochemical purity (determined by HPLC) $> 99\%$. The **Stock solution** was stored in the dark, in a freezer until being used.

The characterised above **Stock solution** was used to prepare three following **Application solutions**:

- **Application solution KOE7903A**, having a nominal concentration 20 μg test compound/mL;
- **Application solution KOE7903B**, having a nominal concentration 1 μg test compound/mL;
- **Application solution KOE7903C**, having a nominal concentration 0.1 μg test compound/mL.

Application solution KOE7903A, was prepared by diluting 1.4 mL of the **Stock solution** with 68.6 mL of ultrapure water (the dilution ratio was 1:50). The exact concentration, expressed in radioactivity units, was determined using LSC, while the identity of the test item in the solution by HPLC-MS and HPLC-MS/MS. The purity of the solution, determined using HPLC, was $\geq 99.7\%$ and when determined using TLC it was 100%.

Application solution KOE7903B, was prepared by diluting 3.5 mL of the **Application solution KOE7903A** with 66.5 mL of ultrapure water (the dilution ratio was 1:20). The exact concentration, expressed in radioactivity units, was determined using LSC.

Application solution KOE7903C, was prepared by diluting 6.0 mL of the **Application solution KOE7903B** with 54.0 mL of ultrapure water (the dilution ratio was 1:10). The exact concentration, expressed in radioactivity units, was determined using LSC.

The **Application solutions** characterised above were used to treat the test soils in each pre-equilibrated incubation vessels. That was done by applying 1 mL of the given **Application solution** to the soil surface in small droplets using the 1000- μ L Eppendorf pipette. The experimentally determined levels of fortification were following:

- for samples treated with **Application solution KOE7903A** – 20.9 μ g/vessel, which was the equivalent to 72591 Bq;
- for samples treated with **Application solution KOE7903B** – 1.05 μ g/vessel, which was the equivalent to 3668 Bq;
- for samples treated with **Application solution KOE7903C** – 0.10 μ g/vessel, which was the equivalent to 356.8 Bq;

The amount of radioactivity determined as application dose for each concentration variant and presented above was regarded as 100% AR for calculations.

The level of application and its homogeneity was verified at the beginning, in the middle and at the end of the application procedure by verification of the concentration of each of **Application solutions**. For that purpose its 1-mL samples were diluted with ultrapure water to 25 mL with CH₃CN/ultrapure water (1:1) and analysed by LSC.

For treatment the pre-incubated biometric flasks were removed from the incubation chamber. After application of the test compound the vessels, except those designated as DAT-0 samples, were fitted with the traps for volatile compounds and returned to the incubation chamber, to be incubated at constant temperature $T = 20.0 \pm 0.1^\circ\text{C}$ and soil moisture level $55 \pm 5\%$ MWHC, for up to 120 days. At the designated time points – DAT 30, DAT 59 and DAT 120, duplicate samples of each test soil were removed from the incubation chamber and further processed. At the same time points the soil moisture content was checked and corrected if necessary. That was done by weighing the test vessels without the traps for volatile compounds, determining the loss of water and, when necessary readjusting the water content to the designated level by adding the appropriate amount of water. The samples for the determination of biomass content were set alongside the treated samples. These were prepared in duplicate for each test soil and taken for analysis on DAT 0, DAT 59 and DAT 120.

Additionally for each test soil spare samples, incubated for up to 120 days were set.

The samples collected at each sampling point were processed and analysed following the procedure presented below on figure B.8.1.1.2.1.1._CA-149.

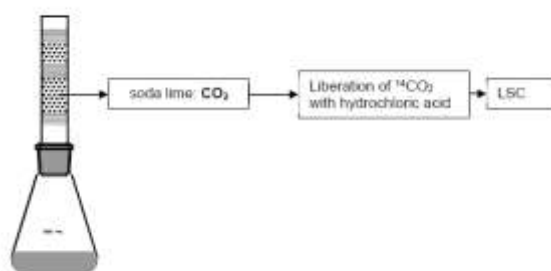

Figure B.8.1.1.2.1.1._CA-149: The sample-processing procedure used in the experiment (copied from the study report).

It shall be noted that, due to the aim of the study, only the volatile traps were analysed, while the soil in Erlenmeyer flasks was not further processed. Firstly the biometer flask were placed in a dessicator and the volatile compounds possibly present in the headspace above soil surface were transferred to the trap by evaporating the entire system. Then the flask were dissected and traps stored for further analysis, which occurred within 1 to 8 days after sampling.

The recovered traps for volatile compounds were dissected into the PU (Polyurethane Foam) plugs and soda lime traps.

The soda-lime traps for $^{14}\text{CO}_2$ formed in the experiment were processed in a way identical to that described in detail in the summaries of route-of-degradation studies by [Pangilinan and Smith; 1994a] (aerobic soil route-of-degradation **Study 4**) and by [Kasper and Shadrack; 1995] (soil photolysis **Study 1**), but used also in other studies examining the degradation of Flufenacet in soil under aerobic conditions – e.g. studies [Hein; 2012] (aerobic soil route-of-degradation **Study 5**) and [Hein; 2012 a] (aerobic soil route-of-degradation **Study 6**). The released $^{14}\text{CO}_2$ was absorbed in a scintillation cocktail and analysed by LSC.

All liquid samples were analysed for the content of radioactivity using LSC method. The LSC (Liquid Scintillation Counting) analysis was performed using LS 6500 (Beckmann) or LKB-Wallac 1219 Spectral (Perkin Elmer Life Science) counters.

The radioactivity in solutions was determined in either:

- a) mini-vials, using the sample aliquots of up to 0.5 mL and 2 mL of Quicksafe® A solution containing 5% of water; the counting was performed using LS 6500 counter, the counting efficiency was 87.9 – 88.0% and the background 15 cpm;
- b) maxi-vials, using the sample aliquots of up to 7 mL and 7 mL of Quicksafe® A solution containing 5% of water; the counting was performed using LKB-Wallac 1219 Spectral counter, the counting efficiency was 73.8 – 88.4% and the background 22 – 23 cpm.

The $^{14}\text{CO}_2$ recovered from soda lime was absorbed in 15 mL of Oxysolve C400 and analysed quantitatively using LKB-Wallac 1219 Spectral counter. The counting efficiency was 73.8 – 88.4% and the background 17 – 18 cpm.

The purity of the **Stock solution** and **Application solution KOE7903A** was verified chromatographically using the following techniques:

- radio-TLC analysis – method used to determine the purity of the **Application solution KOE7903A**;
- HPLC analysis with radio- and MS detection – method used to determine the purity of the **Stock solution** and **Application solution KOE7903A**, and to conform the identity of the test item – trifluoroacetate, in Application solution.

The TLC analysis was performed on silica gel plates – Si60, F₂₅₄, 20 cm x 20cm, developed in a chromatographic chamber without solvent saturation, using the following mobile phase: ethyl acetate/2-propanol/ultrapure water/glacial acetic acid 65:24:11:1 (v/v/v/v). For the purpose of the analysis the solution was diluted two times in parallel in a ratio 1:10 (v/v). The volume of each analysed dilution injected onto the plate was 20 µL. The distribution and quantitation of the radioactivity zones was determined using Bio-Imaging Analyzer BAS 2000, Fuji, Co.

The HPLC analysis was performed using Agilent HP 1100/1200 instrument equipped with chromatographic column oven, UV detector – Agilent VWD working at $\lambda = 254$, Ramona Star radioactivity detector and LTQ Orbitrap XL MS detector. The chromatographic analysis was performed as RP-chromatography and in a gradient mode using one of the following two methods:

- method “**Flurtaboden**” used to check the purity of the **Stock solution**;
- method “**Flurtaboden2**” used to check the purity of the **Application solution KOE7903A**.

In the method “**Flurtaboden**” chromatographic separation was performed on Purospher Star RP18-e 250 x 4.6 mm, 5 µm, chromatographic column preceded by Purospher Star RP18-e 4 x 4 mm, 5 µm guard column, placed in a chromatographic column oven set to $T = 40^\circ\text{C}$. The elution was performed in a gradient mode and lasted for 55 minutes. The flow rate was set to 1 mL/min. The characteristic of the gradient mode is presented below in the table B.8.1.1.2.1.1._CA-275.

Table B.8.1.1.2.1.1._CA-275: The gradient mode used in the chromatographic method “Flurtaboden”.

Time [min]	Solvent ratio

The obtained results are presented below. Kinetic analysis of the obtained results was not performed.

Results and their discussion:

The examination of the microbial viability of the test soils showed that they were viable throughout the whole experiment. The detailed results are shown in the table B.8.1.1.2.1.1._CA-274.

The monitoring of incubation temperature showed that the samples were kept in the constant temperature T = 20 ± 1°C. The mean incubation temperature was T = 20.0°C and it ranged from T = 19.8°C to T = 20.3°C. The results of the monitoring of the temperature in the incubation chamber are shown below, it the graphical form on figure B.8.1.1.2.1.1._CA-150.

**Figure B.8.1.1.2.1.1._CA-150:** The temperature recorded in incubation chamber during the experiment (copied from the study report).

The results of the determination of the soil moisture were identical to those obtained in the previously summarised **Study 19** and presented in the table B.8.1.1.2.1.1._CA-258. RMS decided to not reproduce them in order to not overburden the Assessment Report.

The results of the verification of the application rate and homogeneity of application are presented below, individually for each **Application solution** used in the experiment.

The results obtained for **Application solution KOE7903A** are given below in the table B.8.1.1.2.1.1._CA-277. On the basis of the obtained results the value of 72591 Bq, corresponding to 20.86 µg of ¹⁴C equivalents, was regarded as 100% AR for all calculations.

Table B.8.1.1.2.1.1._CA-277: The results of verification of application rate and homogeneity of application for **Application solution KOE7903A**.

The determination of the LOD and LOQ values for LSC and chromatographic analyses resulted in following values:

- the instrumental LOD and LOQ values for LSC analysis were: LOD = 2 times maximum instrument background count rate (0.25 Bq) and LOQ = three times maximum instrument background count rate (0.4 Bq);
- for liquid samples in 2 mL of Quicksafe A scintillation cocktail (mini-vials) LOD = 0.5 Bq and LOQ = 0.8 Bq;
- for liquid samples in 7 mL of Quicksafe A scintillation cocktail (maxi-vials) LOD = 0.8 Bq and LOQ = 1.2 Bq;
- for ¹⁴CO₂ samples in 15 mL Oxysolve C400 scintillation cocktail LOD = 0.6 Bq and LOQ = 0.9 Bq;

The detailed results of the study – the level of mineralisation in each test soil in function of time and different initial concentration of the test item, are provided below, individually for each test soil, in tables B.8.1.1.2.1.1_CA-280 – B.8.1.1.2.1.1_CA-283.

Table B.8.1.1.2.1.1_CA-280: The level of mineralisation of [1-¹⁴C] Trifluoroacetate determined in Laacher Hof AXXa Sandy loam test soil.

Time point - DAT	Level of mineralisation – ¹⁴ CO ₂ in soda traps, determined for the treatment level:

120	5.06	5.24	0.0070	0.0072	0.74	0.86	0.0202	0.0234	0.55	0.39	0.154	0.109

The results clearly indicate that the level of mineralisation was generally very low, not surpassing 0.3% AR. The Applicant in conclusion to the study stated that “No significant mineralization ($\geq 1\%$ AR) could be detected”. The conclusion related to it stated that:

“No significant amounts of CO_2 could be measured. Therefore, a kinetic evaluation was not performed.”

RMS analysing the results presented in the tables above stated that several values expressed in radioactivity units – Bq, were below the declared LOD level – 0.6 Bq. There were several other values that were above that level, but below the declared LOQ = 0.9 Bq. Such values should not be reported as the level of uncertainty associated to them is very high. Nowhere in the study report the Applicant provided the clarification concerning the way of derivation of the values either < LOD or < LOQ. RMS decided to keep those results, but marked those < LOD by giving them in italics.

It shall be noted however that this, being a clear deficiency of the study, does not change the final conclusion drawn from it.

Conclusion (RMS):

On the basis of the results presented above it can be stated that the test compound – Trifluoroacetate (a dissociated form of TFA) will not undergo significant mineralisation in soil over conceivable period of time, therefore it shall be considered persistent in that environmental compartment. It may be also stated that the concentration would have negligible influence on the level of the would-be mineralisation.

The results of the study, although indirectly, conform the appropriateness of the kinetic endpoints proposed by the RMS as the outcome of the previously summarised **Study 19**.

Study 21:

Report: Schäfer H. (1995): “Calculation of DT-50 values of two metabolites of FOE 5043 in soil under aerobic conditions.”; Bayer AG; unpublished Report No. MR-1085/95; 11. 10. 1995; study reference number: M-004479-02-1;

Guidelines: None declared.

GLP: No, not applicable – this is a modelling study;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its brief summaries can be found under the point B.7.1.2.1.1.2.2., in section B.7 of the Annex B to the Monograph and under the point B.7.1.2.1.1.2. of the Addendum to the DAR for Flufenacet issued in January 2003, both prepared by the then-RMS – France. For the purpose of the current assessment the study was evaluated for its compliance with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

RMS stated that the study did not comply with the Guidelines listed above. For that reason it was decided not to provide its extensive summary. Instead below was given the summary that was placed in the Addendum to the DAR for Flufenacet prepared by the then-RMS – France. For clarity RMS – Poland, decided also to present the methodology used in the assessment. The summary is presented for informative purposes and its results will not be used in the further assessment.

Summary:

Below is presented the summary of the study written by the then-RMS – France for the purpose of the first authorisation of that compound in the EU, presented in the Addendum to the DAR for Flufenacet issued in January 2003 under the point B.7.1.2.1.1.2. N.b. RMS noted that this summary provides more detailed information than the summary of the same study available in the Draft Assessment Report for Flufenacet, under the point B.7.1.2.1.1.2.2., in section B.7 of the Annex B to the Monograph.

Schafer H. (1995), report MR-1085/95

This study was included in the monograph but it was briefly presented. Therefore more details are given below. DT50 for the major metabolites FOE sulfonic acid and FOE oxalate were calculated using data from the Kelly et al. (1995a) parent study reported in the monograph (report MR 106664). Four routes of degradation were assumed leading to sulfonic acid, oxalate, thioglycolate sulfoxide and methylsulfone, respectively. These metabolites were assumed to be further degraded to CO₂ and bound residues. Assuming first order kinetics, a set of differential equations was written according to the proposed degradation pathway. This equation system was numerically solved to fit the experimental data (SIMUSOLV program package). DT50 values were derived from the estimated rate constants. For FOE oxalate DT50 was calculated to be 7 d in the Hofchen soil, 4 d in the BBA 2.2 soil and 18 d in the the Laacherhof soil (acceptable visual fit). For FOE sulfonic acid, no reliable DT50 values could be obtained (no decline).

The methodology used in the kinetic assessment is given below, as it was presented in the source study report.

1. Method

For the calculation of kinetic data of metabolites by using metabolism studies the knowledge of the degradation pathways is necessary. Based on a metabolism studies conducted by Panglilan et al. /3/ and Kelley et al. /1/ the degradation pathways can be described as depicted in figure 1:

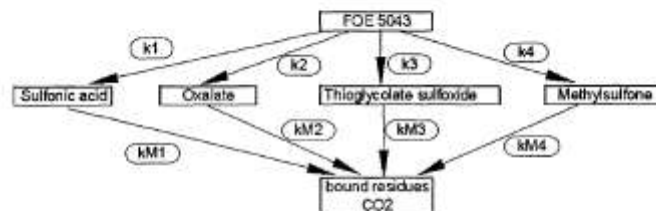

Figure 1: degradation pathways of FOE 5043 (chemical formulas see chapter abbreviations)

Assuming first order kinetics for the all reaction steps the following rate equations can be deduced:

$$r_1 = k_1 \cdot c_{FOE} \quad (1)$$

$$r_2 = k_2 \cdot c_{FOE} \quad (2)$$

$$r_3 = k_3 \cdot c_{FOE} \quad (3)$$

$$r_4 = k_4 \cdot c_{FOE} \quad (4)$$

$$r_{M1} = k_{M1} \cdot c_{SA} \quad (5)$$

$$r_{M2} = k_{M2} \cdot c_{OX} \quad (6)$$

$$r_{M3} = k_{M3} \cdot c_{TGS} \quad (7)$$

$$r_{M4} = k_{M4} \cdot c_{MS} \quad (8)$$

This leads to mass balance equations for each species. The concentrations are expressed in percent of applied radioactivity. Since the reaction of one radio labeled molecule leads again to only one radio labeled molecule, no stoichiometric coefficients have to be considered in the mass balance equations.

$$R_{FOE} = \frac{dc_{FOE}}{dt} = -(k_1 + k_2 + k_3 + k_4) \cdot c_{FOE} \quad (9)$$

$$R_{SA} = \frac{dc_{SA}}{dt} = k_1 \cdot c_{FOE} - k_{M1} \cdot c_{SA} \quad (10)$$

$$R_{OX} = \frac{dc_{OX}}{dt} = k_2 \cdot c_{FOE} - k_{M2} \cdot c_{OX} \quad (11)$$

$$R_{TGS} = \frac{dc_{TGS}}{dt} = k_3 \cdot c_{FOE} - k_{M3} \cdot c_{TGS} \quad (12)$$

$$R_{MS} = \frac{dc_{MS}}{dt} = k_4 \cdot c_{FOE} - k_{M4} \cdot c_{MS} \quad (13)$$

$$R_{REST} = \frac{dc_{REST}}{dt} = k_{M1} \cdot c_{SA} + k_{M2} \cdot c_{OX} + k_{M3} \cdot c_{TGS} + k_{M4} \cdot c_{MS} \quad (14)$$

$REST = CO_2 + \text{Bound residues}$

The coupled differential equation system is solved numerically. The calculated concentrations are fitted to experimental data by adjusting the parameters k_1 to k_4 and k_{M1} to k_{M4} . The fitting algorithm and the numerical solution of the differential equation is computed by using the "SIMUSOLV" program package /2/. For the problem definition within SIMUSOLV a FORTRAN-like language is used (see appendix 1).

The results of the parameter fitting are summarized in a report. The report consists of information on the parameter estimation, a comparison of observed and predicted data, a statistical summary, the correlation matrix, and the variance-covariance matrix (see appendices 2, 3, and 4).

The DT-50 values for sulfonic acid can then be obtained by:

$$DT50_{SA} = \frac{\ln 2}{k_{M1}} \quad (15)$$

and for oxalate by:

$$DT50_{OX} = \frac{\ln 2}{k_{M2}} \quad (16)$$

Study 22:

Report: Schäfer H. (1998): “Amendment to Report MR-1085/95.”; Bayer AG; unpublished Report No. MR-037/98; 15. 01. 1998; study reference number: M-004479-02-1;

Guidelines: None declared.

GLP: No, not applicable – this is a modelling study;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU. Its brief summary can be found under the point B.7.1.2.1.1.2. of the Addendum to the DAR for Flufenacet issued in January 2003, prepared by the then-RMS – France. For the purpose of the current assessment the study was evaluated for its compliance with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS (2011): “Generic guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration”, version 1.0 (issued on 23 November 2011).

RMS stated that the study did not comply with the Guidelines listed above. For that reason it was decided not to provide its extensive summary. Instead below was given the summary that was placed in the Addendum to the DAR for Flufenacet prepared by the then-RMS – France. For clarity RMS – Poland, decided also to present the methodology used in the assessment. The summary is presented for informative purposes and its results will not be used in the further assessment.

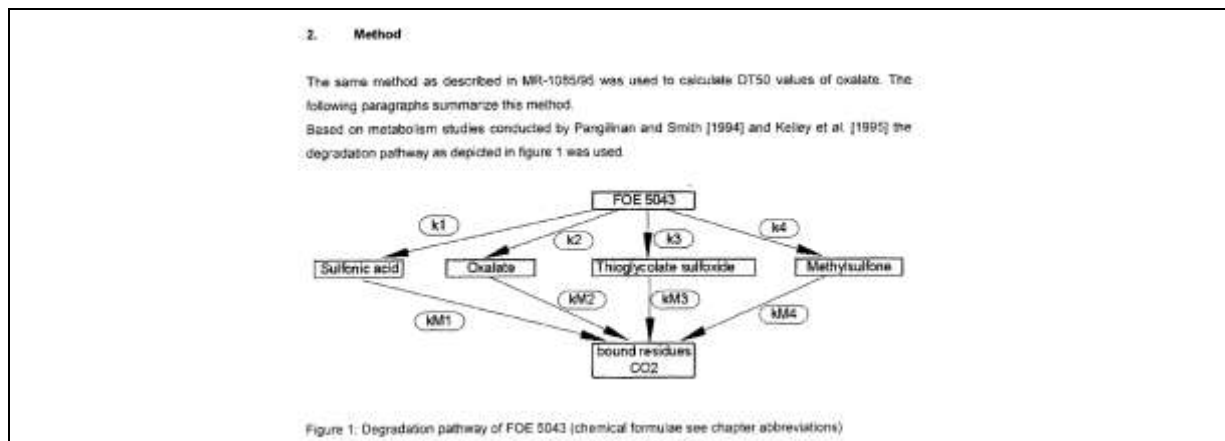

Summary:

Below is presented the summary of the study written by the then-RMS – France for the purpose of the first authorisation of that compound in the EU, presented in the Addendum to the DAR for Flufenacet issued in January 2003 under the point B.7.1.2.1.1.2.

Schafer H. (1998), report MR-037/98 (amendment to Report MR-1085/95)

The rate of degradation of the metabolite FOE oxalate was estimated as described above but the measured rate constants for FOE sulfonic acid (Hellpointner, 1996a, report PF 4110) were used. Under these conditions, DT50 values were estimated to be 5 d in the BBA 2.2 soil (measured DT50 189 d for sulfonic acid), 17 d in the Laacherhof soil (measured DT50 247 d for sulfonic acid) and 12 d in the Hoefchen soil (DT50 for sulfonic acid not measured in this soil, the mean value of 235 d for 3 studied soils was used). These values are deemed to be the most reliable.

The methodology used in the kinetic assessment is given below, as it was presented in the source study report.

Assuming first order kinetics for the all reaction steps the following rate equations and the following mass balances were derived:

Rate equations:

$$r_1 = k_1 \cdot c_{FOE} \quad (1)$$

$$r_2 = k_2 \cdot c_{FOE} \quad (2)$$

$$r_3 = k_3 \cdot c_{FOE} \quad (3)$$

$$r_4 = k_4 \cdot c_{FOE} \quad (4)$$

$$r_{MI} = k_{M1} \cdot c_{SA} \quad (5)$$

$$r_{MO} = k_{M2} \cdot c_{OX} \quad (6)$$

$$r_{MI} = k_{M3} \cdot c_{TOS} \quad (7)$$

$$r_{MI} = k_{M4} \cdot c_{MS} \quad (8)$$

Mass balances:

$$\frac{dc_{FOE}}{dt} = -(k_1 + k_2 + k_3 + k_4) \cdot c_{FOE} \quad (9)$$

$$\frac{dc_{SA}}{dt} = k_1 \cdot c_{FOE} - k_{M1} \cdot c_{SA} \quad (10)$$

$$\frac{dc_{OX}}{dt} = k_2 \cdot c_{FOE} - k_{M2} \cdot c_{OX} \quad (11)$$

$$\frac{dc_{TOS}}{dt} = k_3 \cdot c_{FOE} - k_{M3} \cdot c_{TOS} \quad (12)$$

$$\frac{dc_{MS}}{dt} = k_4 \cdot c_{FOE} - k_{M4} \cdot c_{MS} \quad (13)$$

$$\frac{dc_{MI}}{dt} = k_{M1} \cdot c_{SA} + k_{M2} \cdot c_{OX} + k_{M3} \cdot c_{TOS} + k_{M4} \cdot c_{MS} \quad (14)$$

$$\frac{dc_{MI}}{dt} = k_{M1} \cdot c_{SA} + k_{M2} \cdot c_{OX} + k_{M3} \cdot c_{TOS} + k_{M4} \cdot c_{MS} \quad (15)$$

$$\frac{dc_{MI}}{dt} = k_{M1} \cdot c_{SA} + k_{M2} \cdot c_{OX} + k_{M3} \cdot c_{TOS} + k_{M4} \cdot c_{MS} \quad (16)$$

$$\frac{dc_{MI}}{dt} = k_{M1} \cdot c_{SA} + k_{M2} \cdot c_{OX} + k_{M3} \cdot c_{TOS} + k_{M4} \cdot c_{MS} \quad (17)$$

REST=CO₂ + Bound residues

The coupled differential equation system is solved numerically. The calculated concentrations are fitted to experimental data by adjusting the parameters k_1 to k_4 and k_{M2} to k_{M4} . The fitting algorithm and the numerical solution of the differential equation is computed by using ACSL Optimize [1998].

Appendix 1 shows the program code used.

The DT50 values for oxalate can then be obtained by:

$$DT50_{OX} = \frac{\ln 2}{k_{M2}} \quad (15)$$

As mentioned before the method used now is identical to method reported in MR-1085/96. The only difference is that now the rate constant k_{M1} which describes the degradation of sulfonic acid is not fitted to experimental data but fixed to values observed by Hellpointner [1998].

Study 23:

Report: Reinken G. Porschewski R., (2014): “Flufenacet Core PECsoil and Accumulation: Modelling Core Info Document for Soil Exposure Assessment in Europe.”; Bayer CropScienceAG, Environmental Safety, Alfred-Nobel-Straße 50, 40789 Monheim, Germany; unpublished Report No. EnSa-13-1007; 2014. 02. 25; study reference number: M-478418-01-1;

Guidelines: Not specified, it was stated however that the assessment of the kinetic endpoints for Flufenacet and its major soil degradation products to select those suitable for calculating PEC_{SOIL} was performed to comply with the recommendations for modelling input selection given by the EU Commission, FOCUS and EFSA.

GLP: No, not applicable, modelling study

RMS comments: The study was performed as a supportive study to the main study presenting the results of the model exposure assessment for the soil compartment performed by the Applicant for Flufenacet and its major soil degradation products. It provides, for each compound of interest, the list of determined reliable DT_{50} values, the analysis of the data set aimed on the identification of potential outliers and identification, with justification, of the value considered suitable in calculation of PEC_{SOIL} values.

RMS evaluated the study and found it acceptable, although some of the conclusions drawn by the Applicant had to be modified as a result of the repeated kinetic analysis performed by the RMS. The study, although intended by the Applicant to be supportive for model exposure assessment for the soil compartment, is summarised here, as in RMS’s opinion it is closely related to the issues presented in this section, summarising the results of all studies presented under the point B.8.1.1.2.1.1.

Summary:

The aim of the study was to summarise the substance data used for the purpose of soil exposure and soil accumulation calculations, selected in line with the recommendations given by EU Commission, FOCUS and EFSA. It provided lists of the kinetic endpoints – DT_{50} values, together with the corresponding kinetic model, considered as appropriately representing persistence of Flufenacet and its major soil degradation products – FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfone, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid (TFESA) and Trifluoroacetic acid (TFA), in aerobic soil.

The conceptual compartmental scheme of transformation of Flufenacet in aerobic soil is presented below on figure B.8.1.1.2.1.1._CA-151.

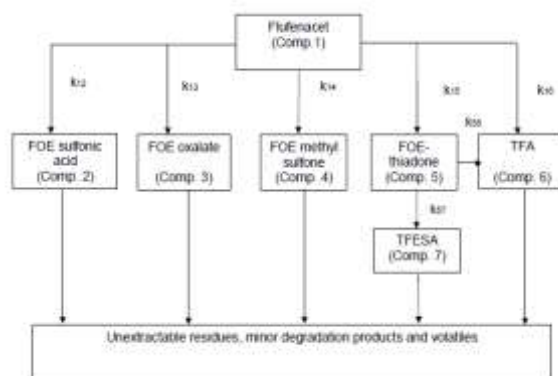

Figure B.8.1.1.2.1.1._CA-151: The conceptual compartmental scheme of transformation of Flufenacet in aerobic soil (copied from the study report).

The results of the kinetic analysis – the kinetic endpoints obtained for each of the compounds presented on the above scheme, were given in tables. They are presented below, individually for each of the compounds, also in tabularised form. Due to the fact, that in some cases RMS repeated the kinetic analysis, which resulted in different kinetic endpoints, the tables will contain additional column presenting the values found acceptable by

the RMS. In case the values proposed by the Applicant were changed by the RMS, the appropriate justification will be given under the table. Additionally, the Applicant's values not accepted by the RMS were marked italics.

a) The persistence kinetic endpoints obtained for Flufenacet:

In the study report the Applicant stated that the degradation of Flufenacet in aerobic soil was examined in six studies: [Kelley et al.; 1995], [Pangilinan and Smith; 1994], [Pangilinan and Smith; 1994a], [Hellpointner; 1999], [Hein; 2012] and [Hein; 2012a]. The kinetic analysis of the results obtained in these studies was performed and its results presented by Reinken and Partsch in five study reports. The Applicant decided to present the results obtained in three of them – [Reinken and Partsch; 2014], [Reinken and Partsch; 2014c] and [Reinken and Partsch; 2014d], in this report. That analysis resulted in the set of ten persistence kinetic endpoint determined in nine test soils. They are given below in the table B.8.1.1.2.1.1._CA-284. It shall be noted that while in case of Howe Indiana soil two DT₅₀ values are available for the same soil incubated under the same conditions, these values cannot be averaged, because they were determined in two separate studies, differing substantially in analytical protocol (soil processing and extracts quantitative analysis). As a result, the values cannot be regarded as replicates for the same soil but rather as separate values.

Table B.8.1.1.2.1.1._CA-284: The persistence kinetic endpoints – DT₅₀ values, determined for Flufenacet.

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT ₅₀ [days]	Kinetic model	DT ₅₀ [days]
			pH	OC [%]				
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	SFO	31.9	SFO	31.9
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	<i>15.2</i>	SFO	16.9
	Hoefchen im Tal	Silt loam	5.8	2.4	SFO	20.4	SFO	20.44
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	32.2	SFO	32.21
<i>Pangilinan and Smith; 1994a</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	55.0	SFO	57.63
<i>Hellpointner; 1999</i>	Laacherhof AXXa	Sandy loam	6.1	1.41	SFO	7.3	SFO	7.35
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	15.9	SFO	15.84
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	19.9	SFO	19.85
	Dollendorf II	Clay loam	7.2	5.3	SFO	16.3	SFO	16.30
	Laacherhof Wurmweise	Loam	5.4	2.2	SFO	14.9	SFO	14.91

The Applicant performing the further statistical analysis of the data set stated that the DT₅₀ value obtained in Howe, Indiana Sandy loam soil in the study by [Pangilinan and Smith; 1994a] should be considered as an outlier and as a result not taken into account in determining the DT₅₀ value suitable for the soil exposure assessment. The justification for that were the results of the statistical analysis presented below on the figure B.8.1.1.2.1.1._CA-152. However, RMS, having analysed the justification, did not agree on the rejection of the challenged value solely on the basis of the statistical assessment, moreover because another value, second highest one, determined for the same soil and the same experimental conditions, was maintained in the data base in spite of some substantial deficiencies of both studies.

Additionally, at the last stage of assessment of the data set, the Applicant averaged two DT₅₀ values obtained in Laacherhof AXXa soil. It shall be noted however that the values were determined in two soils having a common name, but being different in many other aspects – one Laacherhof AXXa soil is a Sandy loam, having pH = 6.1 and OC = 1.41, while the other is a Loamy sand, although having the same pH = 6.1, but different OC = 2.4. Additionally, the values were derived using the data coming from two separate studies, having different analytical protocol with regard to sample processing and analysing.

As a result, the values cannot be considered replicates for the same soil, but used as individual values in calculating the averaged kinetic endpoint.

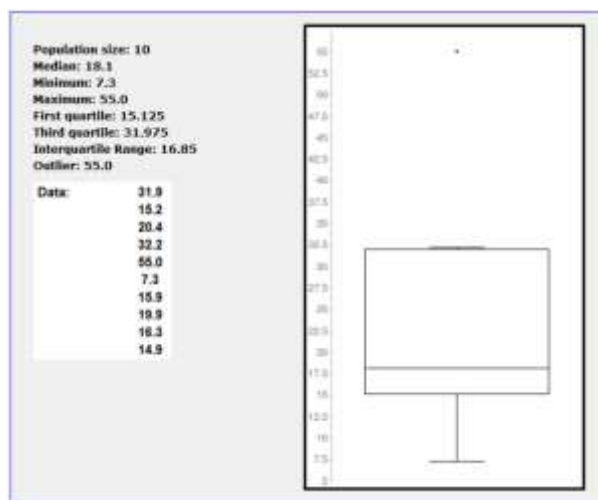

Figure B.8.1.1.2.1.1_CA-152: The results of the statistical analysis of the data set aimed on the identification of the outliers (copied from the study report).

Conclusion:

As a result of the evaluation presented above RMS identified the $DT_{50} = 57.63$ days, determined in Howe, Indiana, Sandy loam soil (study by [Pangilinan and Smith; 1994]) as appropriate value to be used in the exposure assessment for soil compartment performed for Flufenacet.

b) The persistence kinetic endpoints obtained for FOE Sulfonic acid:

The data on the persistence of FOE Sulfonic acid in soil were obtained in two studies with Flufenacet applied as parent compound and FOE Sulfonic acid forming as one of the primary major degradation products – [Kelley et al.; 1995] and [Pangilinan and Smith; 1994], and in four additional studies in which FOE Sulfonic acid was applied to soil as a parent compound – [Hellpointner; 1996], [Hellpointner; 2003], [Hein; 2013] and [Ströch and Junge; 2013]. The results of the studies by [Kelley et al.; 1995] and by [Pangilinan and Smith; 1994] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014]. The results obtained in the studies by [Hellpointner; 1996] and [Hellpointner; 2003] were subjected to subsequent kinetic analysis, the results of which were presented in another study report by Reinken and Partsch – [Reinken and Partsch; 2014e]. The two remaining studies – [Hein; 2013] and [Ströch and Junge; 2013], contain the appropriate kinetic analysis of the data.

That analysis resulted in the set of seventeen persistence kinetic endpoints, determined in seventeen test soils. The Applicant presenting the data set, initially divided it into two parts, presented separately in two tables. In one table were given the results obtained in the trials with Flufenacet applied as a parent compound – studies by [Kelley et al.; 1995] and [Pangilinan and Smith; 1994]. Second table contained the results obtained in the trials in which FOE Sulfonic acid was applied to test soils as a parent compound – studies by [Hellpointner; 1996], [Hellpointner; 2003], [Hein; 2013] and [Ströch and Junge; 2013].

Further analysing the data the Applicant stated that in case of the two soils used in the experiments with Flufenacet applied to soil – soils BBA 2.2 and Laacherhof AIII (both used in the study by [Kelley et al.; 1995]), the results for identical studies were available in the trials with FOE Sulfonic acid applied as parent compound (study by [Hellpointner; 1996]). For that reason the results were excluded from the data set. RMS however stated, having examined the data set, that the soils were similar but not identical. Additionally, the results were obtained in two separate studies. For that reason the results obtained in the study by [Kelley et al.; 1995] cannot be excluded from the data set on the basis of the justification provided by the Applicant. The Applicant also proposed to average the DT_{50} values, by calculating their geometric mean, obtained in soil Laacherhof AIII in studies by [Hellpointner; 1996] and [Hellpointner; 2003], and in soil Laacherhof AXXa in the same studies. The justification was not provided, but most probably it was based on the fact that the soils, bearing the same name were considered to be the same. RMS however, having analysed the data set, stated that the Applicant's proposal is not acceptable, because the soils for which averaging of the DT_{50} values was performed were not identical.

While soils bearing the name Laacherhof AIII were similar, belonging to the same textural class, but at the same time having different pH and OC, in case of the soil Laacherhof AXXa it was stated that the used soils not only differed in pH and OC, but also belonged to different textural classes.

Applicant also performed statistical analysis of the DT_{50} -data set, aimed on the identification of the would-be outliers. The analysis was performed in the same way as for Flufenacet and its results were presented in graphical form, reproduced below on figure B.8.1.1.2.1.1._CA-153. On their basis the Applicant stated that the DT_{50} values obtained in soils Hoefchen im Tal (study by [Kelley et al.; 1995]) and Howe, Indiana (study by [Pangilinan and Smith; 1994]), both having the value $DT_{50} = 1000$ days, should not be taken into account in selection of DT_{50} suitable for calculation of PEC_{SOIL} values, being outliers. RMS, having analysed the data set, came to similar conclusion with regard to these two values, but with different justification, presented further down this evaluation.

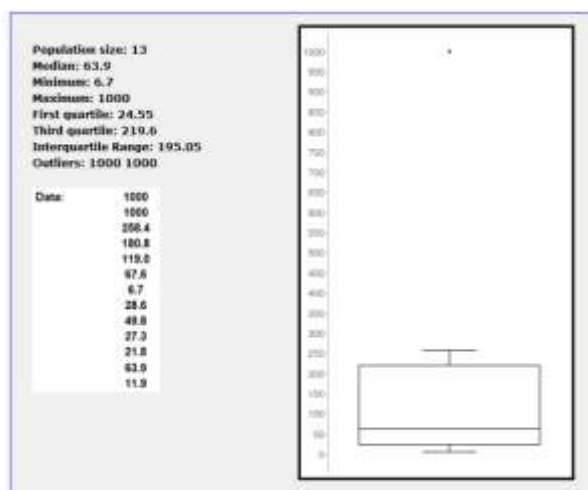

Figure B.8.1.1.2.1.1._CA-153: The results of the statistical analysis of the data set aimed on the identification of the outliers (copied from the study report).

Finally, the values proposed as definitive persistence kinetic endpoints (DT_{50} values) by the Applicant were compared with those found acceptable by the RMS. The results are presented below in the table B.8.1.1.2.1.1._CA-285. It shall be noted that in case of one trial – that on Laacherhof AIII in the study by [Hellpointner; 1996], the results of the repeated kinetic analysis demonstrated that it was not possible to obtain reliable kinetic fit. As a result RMS decided to replace the value by the mark “n. d.” – “not determined”. In case of the results of two studies – [Kelley et al; 1995] and [Pangilinan and Smith; 1994], the kinetic curve for FOE Sulfonic acid did not reach the decline phase. Therefore the default values $DT_{50} = 1000$ days were proposed in absence of those experimentally derived. It shall be noted however that, as they do not represent the reliable estimates of persistence of FOE Sulfonic acid in soil, they were not taken into account in determination of the DT_{50} value appropriate as input parameter in exposure assessment for the soil compartment and are presented here only for completeness. For that reason they are given in italics.

Table B.8.1.1.2.1.1_CA-285: The persistence kinetic endpoints – DT_{50} values, determined for FOE Sulfonic acid.

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	Kinetic model	DT_{50} [days]
			pH	OC [%]				
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	SFO	> 1000	SFO	> 1000
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	> 1000	SFO	> 1000
	Hoefchen im Tal	Silt loam	5.8	2.4	SFO	> 1000	SFO	> 1000
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	> 1000	SFO	> 1000
<i>Hellpointner; 1996</i>	BBA 2.1	Sand	5.3	0.57	SFO	258.4	SFO	318
	BBA 2.2	Loamy sand	6.3	2.48	SFO	180.8	SFO	211
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	234.9	SFO	n. d.
<i>Hellpointner; 2003</i>	Laacherhof AXXa	Sandy loam	6.3	1.47	SFO	62.3	SFO	62.31
	Laacherhof AIII	Silt loam	6.8	0.88	SFO	60.3	SFO	60.26
<i>Hein; 2013</i>	Laacherhof AXXa	Loamy sand	6.2	1.7	SFO	73.4	SFO	73.38
	Dollendorf II	Loam	7.0	4.6	SFO	6.7	SFO	6.71
	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	28.6	SFO	28.58
	Wurmweise	Sandy loam	5.0	1.8	SFO	49.8	SFO	49.77
<i>Ströch and Junge; 2013</i>	Hanscheider Hof	Loam	5.6	2.8	SFO	27.3	SFO	27.30
	Frankenforst	Silt loam	6.8	1.8	SFO	21.8	SFO	21.79
	LUFA 2.3	Sandy loam	6.8	1.1	SFO	63.9	SFO	63.87
	LUFA 6S	Clay	7.0	1.9	SFO	37.7	SFO	37.71

Conclusion:

As a result of the evaluation presented above RMS identified the $DT_{50} = 318$ days, determined in BBA 2.1 Sand soil (study by [Hellpointner; 1996]) as appropriate value to be used in the exposure assessment for soil compartment performed for FOE Sulfonic acid.

c) The persistence kinetic endpoints obtained for FOE Oxalate:

The data on the persistence of FOE Oxalate in soil were obtained in two studies with Flufenacet applied as parent compound and FOE Oxalate forming as one of the primary major degradation products – [Kelley et al.; 1995], and [Pangilinan and Smith; 1994]. The results of these studies were kinetically examined and the outcome presented in two study reports – [Reinken and Partsch; 2014] and [Reinken and Partsch; 2014a]. That analysis resulted in the set of four persistence kinetic endpoint determined in four test soils. RMS, having analysed the data, stated that in case of one soil it was not possible to determine the reliable kinetic endpoints, because the decline phase was not reached in course of the study. Therefore for that soil the value reported by the Applicant was replaced by the mark “n. d.” – “not determined”. The results of the comparative analysis of the Applicant’s persistence kinetic endpoints and those found acceptable by the RMS are presented below in the table B.8.1.1.2.1.1_CA-286.

Table B.8.1.1.2.1.1._CA-286: The persistence kinetic endpoints – DT_{50} values, determined for FOE Oxalate.

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	Kinetic model	DT_{50} [days]
			pH	OC [%]				
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	SFO	6.9	SFO	6.7
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	20.7	SFO	18.9
	Hoefchen im Tal	Silt loam	5.8	2.4	SFO	13.1	SFO	13.09
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	19.4	SFO	n. d.

Conclusion:

As a result of the evaluation presented above RMS identified the $DT_{50} = 18.9$ days, determined in Laacherhof AIII Silt loam soil (study by [Hellpointner; 1996]) as appropriate value to be used in the exposure assessment for soil compartment performed for FOE Sulfonic acid.

d) The persistence kinetic endpoints obtained for FOE Methylsulfone:

The data on the persistence of FOE Methylsulfone in soil were obtained in one study with Flufenacet applied as parent compound and FOE Methylsulfone forming as one of the primary major degradation products – [Kelley et al.; 1995], and in two additional studies in which FOE Methylsulfone was applied to soil as a parent compound – [Traub; 2012; 2013] and [Ströch and Junge; 2013a]. The results of the study by [Kelley et al.; 1995] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014]. The results obtained in the study by [Traub; 2012] were subjected to subsequent kinetic analysis, the results of which were presented in another study report by Reinken and Partsch – [Reinken and Partsch; 2014f]. The remaining study – [Ströch and Junge; 2013a], contain the appropriate kinetic analysis of the data.

That analysis resulted in the set of eleven persistence kinetic endpoints, determined in eleven test soils. The Applicant presenting the data set, initially divided it into two parts, presented separately in two tables. In one table were given the results obtained in the trials with Flufenacet applied as a parent compound – study [Kelley et al.; 1995]. Second table contained the results obtained in the trials in which FOE Methylsulfone was applied to test soils as a parent compound – studies by [Traub; 2012] and [Ströch and Junge; 2013a].

Applicant also performed statistical analysis of the DT_{50} -data set, aimed on the identification of the would-be outliers. The analysis was performed in the same way as for Flufenacet and its results were presented in graphical form, reproduced below on figure B.8.1.1.2.1.1._CA-154. On their basis the Applicant stated that the DT_{50} values obtained in soils BBA 2.2 and Hoefchen im Tal in the study by [Kelley et al.; 1995], both having the value $DT_{50} = 1000$ days, should not be considered in selection of DT_{50} suitable for calculation of PEC_{SOIL} values, being outliers. RMS, having analysed the data set came to similar conclusion with regard to these two values, but with different justification. In RMS's opinion the reason for not taking into account the kinetic endpoints reported for BBA 2.2 and Hoefchen im Tal soils is the fact that for these two soils the decline phase of the kinetic curve for FOE Methylsulfone was not reached, hence it cannot be stated whether the proposed kinetic endpoints can be considered the reliable estimates for the persistence of FOE Methylsulfone in those two soils.

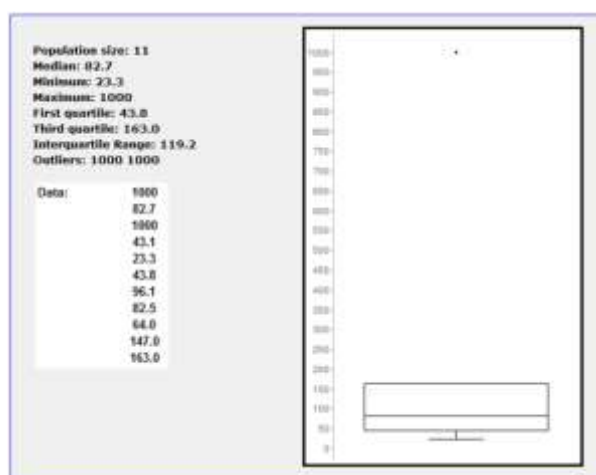

Figure B.8.1.1.2.1.1_CA-154: The results of the statistical analysis of the data set aimed on the identification of the outliers (copied from the study report).

Finally, the values proposed as definitive persistence kinetic endpoints (DT_{50} values) by the Applicant were compared with those found acceptable by the RMS. The results are presented below in the table B.8.1.1.2.1.1_CA-287. The kinetic endpoints for BBA 2.2 and Hoefchen im Tal soils are considered as not representing the reliable estimates of persistence of FOE Methylsulfone in soil. For that reason they were not taken into account in the determination of the DT_{50} value appropriate as input parameter in exposure assessment for the soil compartment and are presented here only for completeness. Therefore they are given in italics.

Table B.8.1.1.2.1.1_CA-287: The persistence kinetic endpoints – DT_{50} values, determined for FOE Methylsulfone.

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	Kinetic model	DT_{50} [days]
			pH	OC [%]				
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	SFO	> 1000	SFO	> 1000
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	82.7	SFO	174
	Hoefchen im Tal	Silt loam	5.8	2.4	SFO	> 1000	SFO	> 1000
<i>Traub; 2012</i>	Laacherhof AXXa	Loamy sand	6.2	1.7	SFO	43.1	SFO	43.14
	Dollendorf II	Loam	7.0	4.6	SFO	23.2	SFO	23.30
	Hoefchen Am Hohenseh 4a	Silt loam	6.1	2.0	SFO	43.8	SFO	43.84
	Laacherhof Wurmweise	Sandy loam	5.0	1.8	SFO	96.1	SFO	96.13
<i>Ströch and Junge; 2013a</i>	Hanscheider Hof	Loam	5.6	2.8	SFO	82.5	SFO	82.53
	Frankenforst	Silt loam	6.8	1.8	SFO	64.0	SFO	63.98
	LUFA 2.3	Sandy loam	6.8	1.1	SFO	147.0	SFO	146.78
	LUFA 6S	Clay	7.0	1.9	SFO	163.0	SFO	163.06

Conclusion:

As a result of the evaluation presented above RMS identified the $DT_{50} = 174$ days, determined in Laacherhof AIII Silt loam soil (study by [Kelley et al.; 1995]) as appropriate value to be used in the exposure assessment for soil compartment performed for FOE Methylsulfone.

e) The persistence kinetic endpoints obtained for FOE Thiadone:

The data on the persistence of FOE Thiadone in soil were obtained in three studies with Flufenacet applied as parent compound and FOE Thiadone forming as one of the primary major degradation products – [Pangilinan and Smith; 1994a], [Hein; 2012] and [Hein; 2012a], as well as in one additional study in which FOE Thiadone was applied to soil as a parent compound – [Lentz and Bloomberg; 1999]. The results of the study by [Pangilinan and Smith; 1994a] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014d], those obtained in the studies by [Hein; 2012] and [Hein; 2012a] in the study report by [Reinken and Partsch; 2014c] and finally those obtained in the study by [Lentz and Bloomberg; 1999] in the study report by [Reinken and Partsch; 2014g].

That analysis resulted in the set of seven persistence kinetic endpoints, determined in eight test soils. No reliable kinetic endpoint could be determined in soil Howe, Indiana (study by [Pangilinan and Smith; 1994a]), due to the poor results of the fitting. RMS however was able to derive the reliable persistence kinetic endpoint for that soil as well using the top-down approach.

The values proposed as definitive persistence kinetic endpoints (DT_{50} values) by the Applicant were compared with those found acceptable by the RMS. The results are presented below in the table B.8.1.1.2.1.1_CA-288.

Table B.8.1.1.2.1.1_CA-288: The persistence kinetic endpoints – DT_{50} values, determined for FOE Thiadone.

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	Kinetic model	DT_{50} [days]
			pH	OC [%]				
<i>Lentz and Bloomberg; 1999</i>	Iowa	Loamy sand	7.2	1.91	SFO	2.0	SFO	1.98
	Indiana	Sandy loam	6.5	1.28	SFO	1.4	SFO	1.40
	Nebraska	Silt loam	7.7	1.66	SFO	2.9	SFO	2.93
<i>Pangilinan and Smith; 1994a</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	n. d.	SFO	15.9
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	1.1	SFO	1.34
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	1.4	SFO	1.13
	Dollendorf II	Clay loam	7.2	5.3	SFO	2.8	SFO	2.84
	Laacherhof Wurmwiiese	Loam	5.4	2.2	SFO	2.0	SFO	1.99

Conclusion:

As a result of the evaluation presented above RMS identified the $DT_{50} = 15.9$ days, determined in Howe, Indiana Sandy loam soil (study by [Pangilinan and Smith; 1994a]), as appropriate value to be used in the exposure assessment for soil compartment performed for FOE Thiadone.

f) The persistence kinetic endpoints obtained for FOE 5043-Trifluoroethanesulfonic acid (TFESA):

The data on the persistence of FOE 5043-Trifluoroethanesulfonic acid in soil were obtained in two studies with Flufenacet applied as parent compound and FOE 5043-Trifluoroethanesulfonic acid forming as a secondary major degradation products – [Hein; 2012] and [Hein; 2012a]. The results of these studies were kinetically examined and the outcome presented in the study report by [Reinken and Partsch; 2014c].

That analysis resulted in the set of four persistence kinetic endpoint determined in four test soils. The values proposed as definitive persistence kinetic endpoints (DT_{50} values) by the Applicant were compared with those found acceptable by the RMS. The results are presented below in the table B.8.1.1.2.1.1_CA-289. It shall be noted that in case of two test soils – Dollendorf II Clay loam soil and Laachehof Wurmwiiese Loam soil, the Applicant's and RMS's values are significantly different. That is due to the fact that, because of the poor fitting results, RMS repeated the analysis using the top-down approach.

Table B.8.1.1.2.1.1._CA-289: The persistence kinetic endpoints – DT₅₀ values, determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA).

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT ₅₀ [days]	Kinetic model	DT ₅₀ [days]
			pH	OC [%]				
Hein; 2012	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	9.1	SFO	9.10
Hein; 2012a	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	4.5	SFO	4.48
	Dollendorf II	Clay loam	7.2	5.3	SFO	22.5	SFO	20.9
	Laacherhof Wurmweise	Loam	5.4	2.2	SFO	7.6	SFO	2.24

Conclusion:

As a result of the evaluation presented above RMS identified the **DT₅₀ = 20.9 days**, determined in Dollendorf II Clay loam soil (study by [Hein; 2012a]), as appropriate value to be used in the exposure assessment for soil compartment performed for FOE 5043-Trifluoroethanesulfonic acid (TFESA).

g) The persistence kinetic endpoints obtained for Trifluoroacetic acid (TFA):

The data on the persistence of Trifluoroacetic acid – TFA, were obtained in two studies Flufenacet applied as parent compound and TFA forming as secondary and ternary major degradation product – [Hein; 2012] and [Hein; 2012a], as well as in one additional study in which TFA was applied to soil as a parent compound – [Eckermann; 2012]. The results of the studies by [Hein; 2012] and [Hein; 2012a] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014c]. The kinetic analysis of the data obtained in the study by [Eckermann; 2012] was found incomplete by RMS, therefore repeated and the hence the reliable persistence kinetic endpoints reported here are those determined by the RMS.

The values proposed as definitive persistence kinetic endpoints (DT₅₀ values) by the Applicant were compared with those found acceptable by the RMS. The results are presented below in the table B.8.1.1.2.1.1._CA-277.

Table B.8.1.1.2.1.1._CA-290: The persistence kinetic endpoints – DT₅₀ values, determined for Trifluoroacetic acid – TFA.

Study	Test soil data				Results obtained by the Applicant		Results verified and accepted by RMS	
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT ₅₀ [days]	Kinetic model	DT ₅₀ [days]
			pH	OC [%]				
Hein; 2012	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	> 1000	SFO	> 1000
Hein; 2012a	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	> 1000	SFO	> 1000
	Dollendorf II	Clay loam	7.2	5.3	SFO	> 1000	SFO	> 1000
	Laacherhof Wurmweise	Loam	5.4	2.2	SFO	> 1000	SFO	> 1000
Eckermann; 2012	Laacher Hof AXXa	Sandy loam	6.2	1.6	SFO	> 1000	SFO	> 10000
	Dollendorf II	Clay loam	7.3	5.5	SFO	> 1000	SFO	> 10000
	Hoefchen Am Hohenseh 4a	Silt loam	6.4	2.4	SFO	> 1000	SFO	> 10000
	Laacher Hof Wurmweise	Sandy loam	5.1	1.9	SFO	> 1000	SFO	> 10000

Conclusion:

As a result of the evaluation presented above RMS identified the default **DT₅₀ = 10000 days** as appropriate value to be used in the exposure assessment for soil compartment performed for Trifluoroacetic acid. That extreme value is considered appropriate because not only the relevant study demonstrated no degradation of TFA in soil, but also the literature data indicate that the compound is extremely persistent in that compartment.

Study 24:

Report: Reinken G. Porschewski R., (2014): “Flufenacet Core PEC_{gw} FOCUS EU: Modelling Core Info Document for Groundwater Risk Assessment in Europe.”; Bayer CropScienceAG, Environmental Safety, Alfred-Nobel-Straße 50, 40789 Monheim, Germany, unpublished Report No. EnSa-13-1006; 2014. 02. 25; study reference number: M-478214-01-1;

Guidelines: Not specified, it was stated however that the assessment of the kinetic endpoints for Flufenacet and its major soil degradation products to select those suitable for calculating PEC_{GW} was performed to comply with the recommendations for modelling input selection given by the EU Commission, FOCUS and EFSA.

GLP: No, not applicable, modelling study

RMS comments: The study was performed as a supportive study to the main study presenting the results of the model exposure/risk assessment for the groundwater compartment, performed by the Applicant for Flufenacet and its major soil degradation products. It provides, for each compound of interest, the list of determined reliable soil DT₅₀ values and adsorption parameters (K_f, K_{fOC} and 1/n values), the analysis of the data sets aimed on the identification of potential outliers and identification, with justification, of the endpoints considered suitable in calculation of PEC_{GW} values, as well as their normalisation.

RMS evaluated the study and found it generally acceptable, although some of the conclusions drawn by the Applicant had to be modified as a result of the repeated kinetic analysis performed by the RMS. Also refined was the normalisation procedure – calculated correction fraction, presented by the Applicant. The study, although intended by the Applicant to be supportive for model risk assessment for the groundwater compartment is summarised here in its part dealing with the analysis of the kinetic endpoints derived for soil compartment. That is due to the fact that in RMS opinion the study in that area it is closely related to the issues presented in this section, summarising the results of all studies presented under the point B.8.1.1.2.1.1.

Summary:

The aim of the study was to provide a summary of modelling input values for Flufenacet and its major soil degradation products selected for PEC_{GW} calculations, in line with the recommendations given by EU Commission, FOCUS and EFSA. In the area of the degradation in soil it provided lists of the normalised kinetic endpoints – DT₅₀ values, together with the corresponding kinetic model, considered as appropriately representing degradation rate of Flufenacet and its major soil degradation products – FOE Sulfonic acid, FOE Oxalate, FOE Methylsulfone, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid (TFESA) and Trifluoroacetic acid (TFA) in aerobic soil. The normalisation of DT₅₀ values to the standard conditions – T = 20°C and soil moisture equal to FC (Field Capacity), was performed in line with the recommendations provided by the relevant EU Guidelines. The correction for temperature was performed using the recommended by EFSA Q₁₀ = 2.58. The normalisation factor f_T was calculated using the equation presented below (copied from the study report):

$$f_T = Q_{10}^{(T - T_{ref})/10}$$

The normalisation for the soil moisture was performed using the Walker equation presented below (copied from the study report) and Walker moisture exponent $\beta = 0.7$:

$$f_\theta = \begin{cases} \left(\frac{\theta}{\theta_{ref}} \right)^\beta & \theta \leq \theta_{ref} \\ 1 & \theta > \theta_{ref} \end{cases}$$

The results of the normalisation – correction factors calculated by the Applicant, are provided below in the table B.8.1.1.2.1.1_CA-291.

Table B.8.1.1.2.1.1_CA-291: The results of the normalisation procedure performed by the Applicant – calculated temperature and moisture correction factors.

Study	Test soil		Experimental conditions		Temperature normalisation		Moisture content normalisation					RMS evaluation – acceptability of the correction factor	
	Name ¹⁾	Textural class (USDA) ²⁾	T [°C]	Soil moist.	T [°C] ³⁾	Corr. factor	Experimental conditions [%]		Reference value - θ_{ef} at pF2 [%]		Corr. factor		
							MWHC	θ	measured	FOCUS

Footnotes to the table:

- 1) For the soil names the following abbreviations were used:
 - LH AIII: Laaaherhof AIII/Laacher Hof AIII;
 - HT: Hoefchen im Tal (Höfchen im Tal);
 - LH AXXa: Laacherhof AXXa/Laacher Hof AXXa;
 - HH: Hoefchen am Hohenseh 4a/ Höfchen am Hohenseh 4a;
 - DD: Dollendorf II;
 - LW: Laaaherhof Wurmwielse;
 - WW: Wurmwielse;
 - HaH: Hanscheider Hof;
 - FF: Frankenforst;
- 2) For the soil textural class the following abbreviations were used:
 - LS: Loamy sand;
 - SiL: Silt loam;
 - SaL: Sandy loam;
 - Cl: Clay;
 - Lo: Loam;
 - Sa: Sand;
 - CL: Clay loam.
- 3) Temperature reported by the Applicant

These values were verified by the RMS. The following things were stated:

- The normalisation for the temperature was not accepted in case of Howe Indiana soil in the study [Pangilinan and Smith; 1994a], because the Applicant used the wrong incubation temperature – $T = 20^{\circ}\text{C}$ instead of $T = 21^{\circ}\text{C}$ declared in the study and hence incorrectly assumed the correction factor of 1.00.
- In case of Howe, Indiana, Sandy loam soil for both experiments – by [Pangilinan and Smith; 1994] and [Pangilinan and Smith; 1994a], normalisation for the soil moisture cannot be accepted because the Applicant incorrectly stated that there was no soil moisture data available in the study. In fact in the study report were given both soil moisture content measured at the level of $\frac{1}{3}$ bar – 13.1%, and at 75% of $\frac{1}{3}$ bar – 8.95%. Therefore it was possible to carry out proper normalisation and hence it was not necessary to assume worst case conditions – 100% FC, as did the Applicant.
- In case of the study by [Lentz and Bloomberg; 1999] normalisation for the soil moisture content was carried out incorrectly: the Applicant as the values of soil moisture during the experiment used those determined at the level of $\frac{1}{3}$ bar instead of the values at 75% of $\frac{1}{3}$ bar – the actual soil moisture content during incubation. That in turn resulted in underestimated correction factors.
- The temperature normalisation performed for the studies [Hellpointner; 1999], [Hein; 2012], [Hein; 2012a] and [Traub; 2012] was not accepted by the RMS because of the inconsistency of the Applicant's approach. For these three studies the incubation temperature was set to $T = 20^{\circ}\text{C}$, while in fact the average incubation temperature was different: $T = 20.3^{\circ}\text{C}$ in case of the study by [Hellpointner; 1999], $T = 19.7^{\circ}\text{C}$ in case of the study by [Hein; 2012], $T = 19.8^{\circ}\text{C}$ in case of the study by [Hein; 2012a] and $T = 19.7^{\circ}\text{C}$ in case of the study by [Traub; 2012]. These deviations from the assumed temperature $T = 20 \pm 1^{\circ}\text{C}$ were minimal and it may be therefore stated that the correction for the temperature was not necessary, however the Applicant performed the temperature correction of the kinetic endpoints in case of three other studies – by [Hein; 2013], where the average $T = 19.6^{\circ}\text{C}$ and by [Ströch and Junge; 2013] and [Ströch and Junge; 2013a], for both of which the average $T = 19.9^{\circ}\text{C}$, so the difference between the assumed $T = 20^{\circ}\text{C}$ and the averaged measured incubation temperature was $<0.5^{\circ}\text{C}$, so within the assumed error margin $\pm 1.0^{\circ}\text{C}$. In RMS's opinion for none of these studies the normalisation for temperature was required, but to maintain the consistency of the approach the RMS decided to normalise for temperature the results of the studies by [Hellpointner; 1999], [Hein; 2012], [Hein; 2012a] and [Traub; 2012].
- No normalisation was performed for the experiment by [Eckermann; 2012], but that may be explained by the fact that it was not necessary since no degradation of the compound was observed in any test soil, so the default DT_{50} values were proposed, for which any normalisation would be meaningless.

The verified correction factors used in normalisation of the kinetic endpoints are provided below in the table B.8.1.1.2.1.1._CA-292.

Table B.8.1.1.2.1.1_CA-292: The results of the updated normalisation procedure performed by the RMS – temperature and moisture correction factors.

 - FF: Frankenforst;
- 2) For the soil textural class the following abbreviations were used:
 - LS: Loamy sand;
 - SiL: Silt loam;
 - SaL: Sandy loam;
 - Cl: Clay;
 - Lo: Loam;
 - Sa: Sand;
 - CL: Clay loam.

The correction factors presented above in the table B.8.1.1.2.1.1_CA-292 were subsequently used to normalise the DT_{50} values for GW and SW modelling.

The Applicant presented in the study report the determined kinetic formation fractions – ff for each degradation product and the normalised kinetic endpoints – individual DT_{50} values for each test soil and the calculated geomean values. RMS noticed that the normalised values were determined using the persistence DT_{50} values, identical with those characterised in the previously summarised **Study 23**. As the RMS changed the conclusions of that study, also the results obtained there by the Applicant changed. Therefore RMS decided not to present the values obtained by the Applicant, even for the comparative purposes, in order to not overburden the Assessment Report.

As an introduction to the whole analysis the conceptual compartmental scheme of transformation of Flufenacet in aerobic soil was presented, shown below on figure B.8.1.1.2.1.1_CA-155.

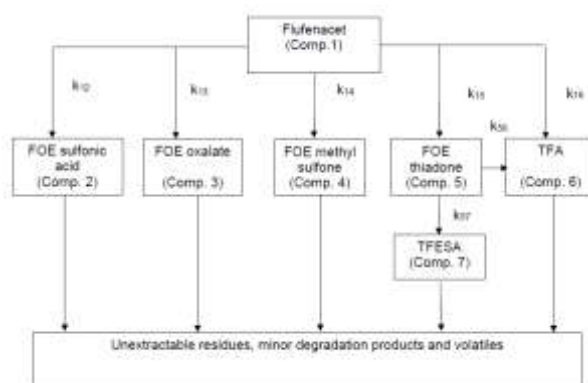

Figure B.8.1.1.2.1.1_CA-155: The conceptual compartmental scheme of transformation of Flufenacet in aerobic soil (copied from the study report).

Next are presented the results of the normalisation of DT_{50} values for each compound and, for the degradation products, the determined kinetic formation fractions ff . To maintain the consistency between the two summaries, the RMS used exactly the same order of presenting the data for each individual compound as in the previous summary (**Study 23**).

a) The kinetic endpoints determined for Flufenacet:

The degradation of Flufenacet in aerobic soil was examined in six studies: [Kelley et al.; 1995], [Pangilinan and Smith; 1994], [Pangilinan and Smith; 1994a], [Hellpointner; 1999], [Hein; 2012] and [Hein; 2012a]. The kinetic analysis of the results obtained in these studies was performed and its results presented by Reinken and Partsch in five study reports, of which three were found to contain relevant kinetic endpoints – [Reinken and Partsch; 2014], [Reinken and Partsch; 2014c] and [Reinken and Partsch; 2014d]. That analysis resulted in the set of ten pairs of persistence kinetic endpoints – DT_{50} and DT_{90} values, determined in nine test soils. The DT_{50}

values representing persistence were subsequently normalised in order to obtain the modelling DT_{50} values. All of them are given below in the table B.8.1.1.2.1.1._CA-293. It shall be noted that while in case of Howe Indiana soil two DT_{50} values are available for the same soil incubated under the same conditions, these values cannot be averaged, because they were determined in two separate studies, differing substantially in analytical protocol (soil processing and extracts quantitative analysis). As a result, the values cannot be regarded as replicates for the same soil but rather as separate values.

The Applicant rejected both sets of kinetic endpoints obtained in Howe, Indiana, Sandy loam soil. The kinetic endpoints obtained in the study by [Pangilinan and Smith; 1994] were rejected from the data set as outliers already at initial stage and not taken at all into consideration for the selection of DT_{50} values for PEC_{GW} calculations. That conclusion was supported by the results of the statistical analysis, the results of which are presented in graphical form below, on figure B.8.1.1.2.1.1._CA-156. Such approach is however inconsistent, because the values determined for degradation products – FOE Sulfonic acid and FOE Oxalate, were included into the data set undergoing further statistical analysis. The results of the normalisation showed that the value was in good agreement with other DT_{50} values, therefore there is no reason for not including it into the data set.

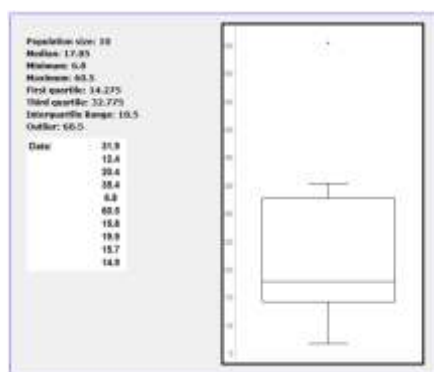

Figure B.8.1.1.2.1.1._CA-156: The results of the initial statistical analysis of the data set aimed on the identification of the outliers (copied from the study report).

Applicant also stated that the second set of kinetic endpoints obtained in Howe, Indiana, Sandy loam soil, in the study by [Pangilinan and Smith; 1994a] should be considered as an outlier and not taken into account in calculating the geomean DT_{50} value to be used in GW modelling. RMS however did not agree with that approach, moreover because no justification was provided and the results of the statistical analysis, presented above on figure B.8.1.1.2.1.1._CA-156, did not demonstrate that the value significantly differed from the other values within the data set.

Finally, it was noticed that the Applicant averaged two DT_{50} values obtained in Laacherhof AXXa soil before calculating the overall geomean normalised DT_{50} value. However, that approach is not acceptable, since the two Laacherhof AXXa soils bear a common name, but are different in many other aspects – one Laacherhof AXXa soil is a Sandy loam, having pH = 6.1 and OC = 1.41, while the other is a Loamy sand, although having the same pH = 6.1, but different OC = 2.4. Additionally, the values were derived using the data coming from two separate studies, having different analytical protocol with regard to sample processing and analysing.

As a result, the values cannot be considered replicates for the same soil, but should be used as individual values in calculating the averaged kinetic endpoint.

As signalled above, the resulting ultimate data set is presented below in the table B.8.1.1.2.1.1._CA-293.

Table B.8.1.1.2.1.1_CA-293: The persistence and modelling kinetic endpoints – DT₅₀ and DT₉₀ values, determined for Flufenacet.

Study	Test soil data				Persistence kinetic endpoints			Kinetic endpoints recommended for modelling
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT ₅₀ [days]	DT ₉₀ [days]	DT ₅₀ [days]
			pH	OC [%]				
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	SFO	31.9	106.1	31.9
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	16.9	56.0	13.86
	Hoefchen im Tal	Silt loam	5.8	2.4	SFO	20.44	67.90	20.44
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	32.21	107.0	20.90
<i>Pangilinan and Smith; 1994a</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	57.63	191.42	37.40
<i>Hellpointner; 1999</i>	Laacherhof AXXa	Sandy loam	6.1	1.41	SFO	7.35	24.42	7.04
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	15.84	52.61	15.36
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	19.85	65.93	19.45
	Dollendorf II	Clay loam	7.2	5.3	SFO	16.30	54.18	15.49
	Laacherhof Wurmweise	Loam	5.4	2.2	SFO	14.91	49.54	14.61
Geomean (n = 10)						20.23	67.20	17.89
Median (n = 10)						18.38	60.97	17.47

The report also contained the data on the soil sorption of Flufenacet, which are beyond the scope of this summary therefore not presented here, and on the kinetic formation fractions determined for the degradation products of Flufenacet. In case of these values RMS decided to present and evaluate them in the relevant sections of this summary, dealing individually with each degradation product.

Conclusion:

As a result of the evaluation presented above RMS determined the normalised geomean **DT₅₀ = 17.89 days**, value for Flufenacet, recommended to be used in GW (and SW) model exposure assessment. Also the median normalised **DT₅₀ = 17.47 days** was calculated, which can be alternatively used for the same purpose.

b) The kinetic endpoints determined for FOE Sulfonic acid:

The data on the persistence of FOE Sulfonic acid in soil were obtained in two studies with Flufenacet applied as parent compound and FOE Sulfonic acid forming as one of the primary major degradation products – [Kelley et al.; 1995] and [Pangilinan and Smith; 1994], and in four additional studies in which FOE Sulfonic acid was applied to soil as a parent compound – [Hellpointner; 1996], [Hellpointner; 2003], [Hein; 2013] and [Ströch and Junge; 2013]. The results of the studies by [Kelley et al.; 1995], [Pangilinan and Smith; 1994] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014]. The results obtained in the studies by [Hellpointner; 1996] and [Hellpointner; 2003] were subjected to subsequent kinetic analysis, the results of which were presented in another study report by Reinken and Partsch – [Reinken and Partsch; 2014e]. The two remaining studies – [Hein; 2013] and [Ströch and Junge; 2013], contain the appropriate kinetic analysis of the data.

That analysis resulted in the set of seventeen persistence kinetic endpoint determined in seventeen test soils. The Applicant presenting the data set, initially divided it into two parts, presented separately in two tables. In one table were given the results obtained in the studies with Flufenacet applied as a parent compound – studies by [Kelley et al.; 1995] and [Pangilinan and Smith; 1994]. Second table contained the results obtained in studies in which FOE Sulfonic acid was applied to test soils as a parent compound – studies by [Hellpointner; 1996], [Hellpointner; 2003], [Hein; 2013] and [Ströch and Junge; 2013].

Further analysing the data the Applicant stated that in case of the two soils used in the experiments with Flufenacet applied to soil – soils BBA 2.2 and Laacherhof AIII (both used in the study by [Kelley et al.; 1995]) the results for identical soils were available in the trials with FOE Sulfonic acid applied as parent compound (study by [Hellpointner; 1996]). For that reason the results were excluded from the data set. RMS however stated, having examined the data set, that the soils were similar but not identical. Additionally, the results were obtained in two separate studies. For that reason the results obtained in the study by [Kelley et al.; 1995] cannot be excluded from the data base on the basis of the justification provided by the Applicant. The Applicant also proposed to average the DT_{50} values, by calculating their geometric mean, obtained in soil Laacherhof AIII in studies by [Hellpointner; 1996] and [Hellpointner; 2003] and in soil Laacherhof AXXa in the same studies. The justification was not provided, but most probably it was based on the fact that the soils, bearing the same name should be the same. RMS however, having analysed the data set, stated that the Applicant's proposal is not acceptable, because the soils for which averaging of the DT_{50} values was performed were not identical. While soils bearing name Laacherhof AIII were similar, belonging to the same textural class, but at the same time having different pH and OC, in case of the soil Laacherhof AXXa it was stated that the used soil samples not only differed in pH and OC, but also belonged to different textural classes.

Applicant also performed statistical analysis of the DT_{50} -data set aimed on the identification of the would-be outliers. The analysis was performed in the same way as for Flufenacet and its results presented in graphical form, reproduced below on figure B.8.1.1.2.1.1_CA-157. On their basis the Applicant stated that the DT_{50} values obtained in soils Hoefchen im Tal (study by [Kelley et al.; 1995]) and Howe, Indiana (study by [Pangilinan and Smith; 1994]), both having the value $DT_{50} = 1000$ days, should not be considered in selection of DT_{50} suitable for calculation of PEC_{GW} values, being outliers. RMS having analysed the data set came to similar conclusion with regard to these two values, but with different justification, presented further down this evaluation.

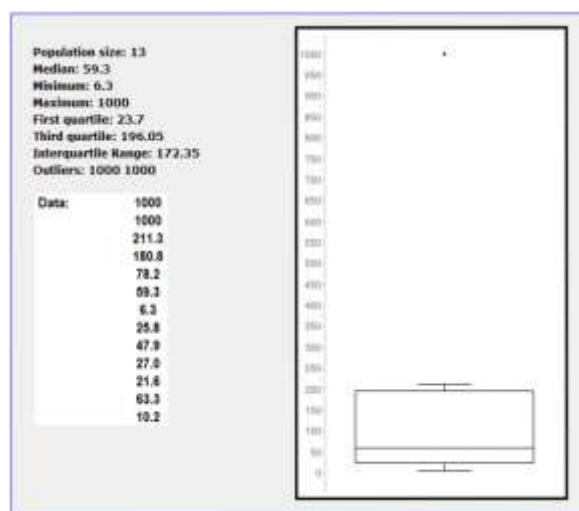

Figure B.8.1.1.2.1.1_CA-157: The results of the statistical analysis of the data set aimed on the identification of the outliers (copied from the study report).

RMS decided not to include the kinetic endpoints obtained as a result of the kinetic examination of the data coming from the studies by [Kelley et al; 1995] and [Pangilinan and Smith; 1994]. That is due to the fact that the decline phase for FOE Sulfonic acid was not reached in any of the test soils used in these studies. Therefore, although the persistence kinetic endpoints were proposed, set to the default value $DT_{50}/DT_{90} > 1000$ days, they cannot be considered as reliable and were given only for completeness. For that reason RMS decided not to present the results for these studies in the summary table presenting the persistence and modelling kinetic endpoints, given below as table B.8.1.1.2.1.1_CA-294. Also the whole data set for soil Laacherhof AIII in the study by [Hellpointner; 1996] was not presented in that table. That was due to the fact that in the repeated kinetic analysis performed by the RMS it was not possible to obtain reliable kinetic fit and hence kinetic endpoints.

Table B.8.1.1.2.1.1._CA-294: The persistence and modelling kinetic endpoints – DT₅₀ and DT₉₀ values, determined for FOE Sulfonic acid.

Study	Test soil data				Persistence kinetic endpoints			Kinetic endpoints recommended for modelling
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT ₅₀ [days]	DT ₉₀ [days]	DT ₅₀ [days]
			pH	OC [%]				
<i>Hellpointner; 1996</i>	BBA 2.1	Sand	5.3	0.57	SFO	318	1060	260.76
	BBA 2.2	Loamy sand	6.3	2.48	SFO	211	701	211.00
<i>Hellpointner; 2003</i>	Laacherhof AXXa	Sandy loam	6.3	1.47	SFO	62.31	206.99	49.85
	Laacherhof AIII	Silt loam	6.8	0.88	SFO	60.26	200.18	40.37
<i>Hein; 2013</i>	Laacherhof AXXa	Loamy sand	6.2	1.7	SFO	73.38	243.77	70.44
	Dollendorf II	Loam	7.0	4.6	SFO	6.71	22.30	6.25
	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	28.58	94.95	25.79
	Wurmwielse	Sandy loam	5.0	1.8	SFO	49.77	165.32	47.78
<i>Ströch and Junge; 2013</i>	Hanscheider Hof	Loam	5.6	2.8	SFO	27.30	90.70	27.03
	Frankenforst	Silt loam	6.8	1.8	SFO	21.79	72.39	21.57
	LUFA 2.3	Sandy loam	6.8	1.1	SFO	63.87	212.61	63.23
	LUFA 6S	Clay	7.0	1.9	SFO	37.71	125.28	32.11
Geomean (n = 12)						50.15	166.67	45.11
Median (n = 12)						55.02	182.75	44.08

In addition the Applicant presented also the normalised kinetic endpoints derived for FOE Sulfonic acid from field dissipation studies. These values will be dealt with separately, under the point B.8.1.1.2.2.1. – Soil dissipation studies.

The study report also provided the kinetic formation fractions determined for FOE Sulfonic acid. These are presented, together with the respective values considered reliable by the RMS, below in the table B.8.1.1.2.1.1._CA-295.

Table B.8.1.1.2.1.1._CA-295: The kinetic formation fraction values – *ff*, determined by the Applicant and verified by the RMS.

Study	Test soil data				Kinetic formation fractions - <i>ff</i>		
	Soil name	Soil type (USDA)	Key soil properties		Value proposed by the Applicant	Value accepted by RMS	Precursor
			pH	OC [%]			
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	0.257	0.257	Flufenacet
	Laacherhof AIII	Silt loam	7.3	0.9	0.259	0.272	Flufenacet
	Hoefchen im Tal	Silt loam	5.8	2.4	0.143	0.143	Flufenacet
<i>Pangilinan and Smith; 1994</i>	Howe, Indiana	Sandy loam	6.2	0.35	0.108	0.108	Flufenacet
Arithmetic mean (n = 4)						0.195	Flufenacet

The report also contained the data on the soil sorption of FOE Sulfonic acid. As they are however beyond the scope of this summary they were not presented here.

Conclusion:

As a result of the evaluation presented above RMS determined the normalised geomean **DT₅₀ = 45.11 days**, value for FOE Sulfonic acid, recommended to be used in GW (and SW) model exposure assessment. Also the median normalised **DT₅₀ = 44.08 days** was calculated, which can be alternatively used for the same purpose.

The kinetic formation fraction recommended to be used in GW model exposure assessment is ***ff* = 0.195**.

c) The kinetic endpoints determined for FOE Oxalate:

The data on the persistence of FOE Oxalate in soil were obtained in two studies with Flufenacet applied as parent compound and FOE Oxalate forming as one of the primary major degradation products – [Kelley et al.; 1995], and [Pangilinan and Smith; 1994]. The results of these studies were kinetically examined and the outcome presented in two study reports – [Reinken and Partsch; 2014] and [Reinken and Partsch; 2014a]. That analysis resulted in the set of four persistence kinetic endpoint determined in four test soils. RMS having analysed the data stated that in case of Howe, Indiana, Sandy loam soil used in the study by [Pangilinan and Smith; 1994], it was not possible to determine the reliable kinetic endpoints as the decline phase was not reached in course of the study. Therefore the whole data set was for that soil was removed from the summary table. The summary table presenting the persistence and modelling kinetic endpoints for FOE Oxalate is given below as table B.8.1.1.2.1.1_CA-296. Although the geomean values were calculated for all kinetic endpoints, they are not recommended to be used in modelling, because the data base consists of only three individual values, therefore it may not be considered fully representative.

Table B.8.1.1.2.1.1_CA-296: The persistence and modelling kinetic endpoints – DT_{50} and DT_{90} values, determined for FOE Oxalate.

Study	Test soil data				Persistence kinetic endpoints			Kinetic endpoints recommended for modelling
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	DT_{90} [days]	DT_{50} [days]
			pH	OC [%]				
Kelley et al.; 1995	BBA 2.2	Loamy sand	6.2	2.58	SFO	6.9	22.80	6.9
	Laacherhof AIII	Silt loam	7.3	0.9	SFO	18.9	62.90	15.5
	Hoefchen im Tal	Silt loam	5.8	2.4	SFO	13.09	43.48	13.09
Geomean (n = 3)						11.83	39.65	11.08

The study report also provided the kinetic formation fractions determined for FOE Oxalate. These are presented, together with the respective values considered reliable by the RMS, below in the table B.8.1.1.2.1.1_CA-297.

Table B.8.1.1.2.1.1_CA-297: The kinetic formation fraction values – ff , determined by the Applicant and verified by the RMS.

Study	Test soil data				Kinetic formation fractions - ff		
	Soil name	Soil type (USDA)	Key soil properties		Value proposed by the Applicant	Value accepted by RMS	Precursor
			pH	OC [%]			
Kelley et al.; 1995	BBA 2.2	Loamy sand	6.2	2.58	0.448	0.448	Flufenacet
	Laacherhof AIII	Silt loam	7.3	0.9	0.375	0.422	Flufenacet
	Hoefchen im Tal	Silt loam	5.8	2.4	0.350	0.350	Flufenacet
Pangilinan and Smith; 1994	Howe, Indiana	Sandy loam	6.2	0.35	0.484	0.484	Flufenacet
Arithmetic mean (n = 4)						0.426	Flufenacet

Conclusion:

As a result of the evaluation presented above RMS stated that it was possible to determine the normalised geomean $DT_{50} = 11.08$ days, value for FOE Oxalate, recommended to be used in GW (and SW) model exposure assessment. However, it shall be pointed out that because the supporting data base consisted of only three values, more conservative value – the longest normalised $DT_{50} = 15.5$ days, may also be used for that purpose.

The kinetic formation fraction recommended to be used in GW model exposure assessment is $ff = 0.426$.

d) The kinetic endpoints determined for FOE Methylsulfone:

The data on the persistence of FOE Methylsulfone in soil were obtained in one study with Flufenacet applied as parent compound and FOE Methylsulfone forming as one of the primary major degradation products – [Kelley et al.; 1995], and in two additional studies in which FOE Methylsulfone was applied to soil as a parent compound – [Traub; 2012; 2013] and [Ströch and Junge; 2013a]. The results of the study by [Kelley et al.; 1995] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014]. The results obtained in the study by [Traub; 2012] were subjected to subsequent kinetic analysis, the results of which were presented in another study report by Reinken and Partsch – [Reinken and Partsch; 2014f]. The remaining study – [Ströch and Junge; 2013a], contain the appropriate kinetic analysis of the data.

That analysis resulted in the set of eleven persistence kinetic endpoint determined in eleven test soils. The Applicant presenting the data set, initially divided it into two parts, presented separately in two tables. In one table were given the results obtained in the studies with Flufenacet applied as a parent compound – study [Kelley et al.; 1995]. Second table contained the results obtained in studies in which FOE Methylsulfone was applied to test soils as a parent compound – studies by [Traub; 2012] and [Ströch and Junge; 2013a].

Applicant also performed statistical analysis of the DT₅₀-data set aimed on the identification of the would-be outliers. The analysis was performed in the same way as for Flufenacet and its results were presented in graphical form, reproduced below on figure B.8.1.1.2.1.1._CA-158. On their basis the Applicant stated that the DT₅₀ values obtained in soils BBA 2.2 and Hoefchen im Tal in the study by [Kelley et al.; 1995], both having the value DT₅₀ = 1000 days, should not be considered in selection of DT₅₀ suitable for calculation of PEC_{GW} values, being outliers. RMS having analysed the data set came to similar conclusion with regard to these two values, but with different justification. In RMS's opinion the reason for not taking into account the kinetic endpoints reported for BBA 2.2 and Hoefchen im Tal soils is the fact that for these two soils the decline phase of the kinetic curve for FOE Methylsulfone was not reached, hence it cannot be stated whether the proposed kinetic endpoints can be considered as reliable estimates for the persistence of FOE Methylsulfone in those two soils. As a results the data for these two soils were removed from the summary table presenting the persistence (not normalised) and modelling (normalised) kinetic endpoints for FOE Methylsulfone.

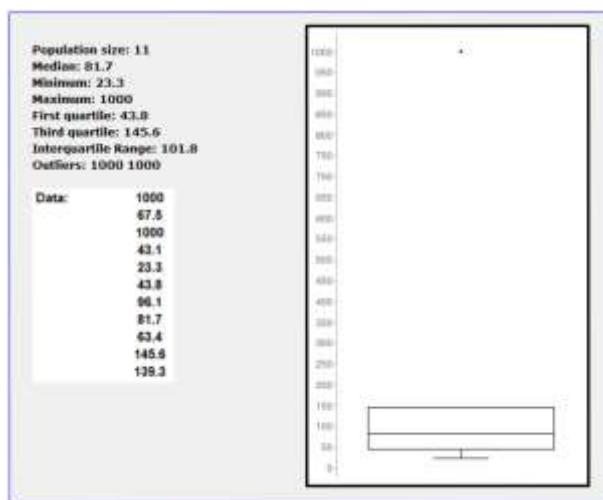

Figure B.8.1.1.2.1.1._CA-158: The results of the statistical analysis of the data set aimed on the identification of the outliers (copied from the study report).

The summary table presenting the persistence and modelling kinetic endpoints for FOE Methylsulfone is given below as table B.8.1.1.2.1.1._CA-298.

Table B.8.1.1.2.1.1._CA-298: The persistence and modelling kinetic endpoints – DT₅₀ and DT₉₀ values, determined for FOE Methylsulfone.

Study	Test soil data				Persistence kinetic endpoints			Kinetic endpoints recommended for modelling
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT ₅₀ [days]	DT ₉₀ [days]	DT ₅₀ [days]
			pH	OC [%]				
<i>Kelley et al.; 1995</i>	Laacherhof AIII	Silt loam	7.3	0.9	SFO	174	576	142.68
<i>Traub; 2012</i>	Laacherhof AXXa	Loamy sand	6.2	1.7	SFO	43.14	143.3	41.85
	Dollendorf II	Loam	7.0	4.6	SFO	23.30	77.41	22.60
	Hoefchen Am Hohenseh 4a	Silt loam	6.1	2.0	SFO	43.84	145.6	42.52
	Laacherhof Wurmwise	Sandy loam	5.0	1.8	SFO	96.13	319.32	93.25
<i>Ströch and Junge; 2013a</i>	Hanscheider Hof	Loam	5.6	2.8	SFO	82.53	274.14	81.70
	Frankenforst	Silt loam	6.8	1.8	SFO	63.98	212.53	63.34
	LUFA 2.3	Sandy loam	6.8	1.1	SFO	146.78	487.60	145.31
	LUFA 6S	Clay	7.0	1.9	SFO	163.06	541.68	138.83
Geomean (n = 9)						76.82	255.08	72.57
Median (n = 9)						82.53	274.14	81.7

The study report also provided the kinetic formation fractions determined for FOE Methylsulfone. These are presented, together with the respective values considered reliable by the RMS, below in the table B.8.1.1.2.1.1._CA-299.

Table B.8.1.1.2.1.1._CA-299: The kinetic formation fraction values – *ff*, determined by the Applicant and verified by the RMS.

Study	Test soil data				Kinetic formation fractions - <i>ff</i>		
	Soil name	Soil type (USDA)	Key soil properties		Value proposed by the Applicant	Value accepted by RMS	Precursor
			pH	OC [%]			
<i>Kelley et al.; 1995</i>	BBA 2.2	Loamy sand	6.2	2.58	0.061	0.061	Flufenacet
	Laacherhof AIII	Silt loam	7.3	0.9	0.087	0.096	Flufenacet
	Hoefchen im Tal	Silt loam	5.8	2.4	0.051	0.051	Flufenacet
Arithmetic mean (n = 3)						0.069	Flufenacet

Conclusion:

As a result of the evaluation presented above RMS determined the normalised geomean **DT₅₀ = 72.57 days**, value for FOE Methylsulfone, recommended to be used in GW (and SW) model exposure assessment. Also the median normalised **DT₅₀ = 81.70 days** was calculated, which can be alternatively used for the same purpose.

The kinetic formation fraction recommended to be used in GW model exposure assessment is ***ff* = 0.069**.

e) The kinetic endpoints determined for FOE Thiadone:

The data on the persistence of FOE Thiadone in soil were obtained in three studies with Flufenacet applied as parent compound and FOE Thiadone forming as one of the primary major degradation products – [Pangilinan and Smith; 1994a], [Hein; 2012] and [Hein; 2012a], as well as in one additional study in which FOE Thiadone was applied to soil as a parent compound – [Lentz and Bloomberg; 1999]. The results of the study by [Pangilinan and Smith; 1994a] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014d], those obtained in the studies by [Hein; 2012] and [Hein; 2012a] in the study report by [Reinken and Partsch; 2014c] and finally those obtained in the study by [Lentz and Bloomberg; 1999] in the study report by [Reinken and Partsch; 2014g].

That analysis resulted in the set of seven persistence kinetic endpoint determined in eight test soils. No reliable kinetic endpoint could be determined in soil Howe, Indiana (study by [Pangilinan and Smith; 1994a]) due to the poor results of the fitting. RMS however was able to derive the reliable persistence kinetic endpoint for that soil

as well, using the top-down approach. The summary table presenting the persistence and modelling kinetic endpoints for FOE Thiadone is given below as table B.8.1.1.2.1.1._CA-300.

Table B.8.1.1.2.1.1._CA-300: The persistence and modelling kinetic endpoints – DT_{50} and DT_{90} values, determined for FOE Thiadone.

Study	Test soil data				Persistence kinetic endpoints			Kinetic endpoints recommended for modelling
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	DT_{90} [days]	DT_{50} [days]
			pH	OC [%]				
<i>Lentz and Bloomberg; 1999</i>	Iowa	Loamy sand	7.2	1.91	SFO	1.98	6.59	1.27
	Indiana	Sandy loam	6.5	1.28	SFO	1.40	4.66	0.90
	Nebraska	Silt loam	7.7	1.66	SFO	2.93	9.74	2.29
<i>Pangilinan and Smith; 1994a</i>	Howe, Indiana	Sandy loam	6.2	0.35	SFO	15.9	52.9	10.32
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	1.13	3.77	1.10
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	1.36	4.53	1.33
	Dollendorf II	Clay loam	7.2	5.3	SFO	2.84	9.45	2.70
	Lacherhof Wurmweise	Loam	5.4	2.2	SFO	1.99	6.60	1.95
Geomean (n = 8)						2.41	8.00	1.95
Median (n = 8)						1.99	6.60	1.64

The study report also provided the kinetic formation fractions determined for FOE Thiadone. These are presented, together with the respective values considered reliable by the RMS, below in the table B.8.1.1.2.1.1._CA-301.

Table B.8.1.1.2.1.1._CA-301: The kinetic formation fraction values – ff , determined by the Applicant and verified by the RMS.

Study	Test soil data				Kinetic formation fractions - ff		
	Soil name	Soil type (USDA)	Key soil properties		Value proposed by the Applicant	Value accepted by RMS	Precursor
			pH	OC [%]			
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	0.913	0.913	Flufenacet
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	0.524	0.524	Flufenacet
	Dollendorf II	Clay loam	7.2	5.3	0.438	0.438	Flufenacet
	Lacherhof Wurmweise	Loam	5.4	2.2	0.405	0.404	Flufenacet
Arithmetic mean (n = 4)						0.570	Flufenacet

Conclusion:

As a result of the evaluation presented above RMS determined the normalised geomean $DT_{50} = 1.95$ days, value for FOE Thiadone, recommended to be used in GW (and SW) model exposure assessment. Also the median normalised $DT_{50} = 1.64$ days was calculated, which can be alternatively used for the same purpose.

The kinetic formation fraction recommended to be used in GW model exposure assessment is $ff = 0.570$.

- f) The kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA):

The data on the persistence of FOE 5043-Trifluoroethanesulfonic acid in soil were obtained in two studies with Flufenacet applied as parent compound and FOE 5043-Trifluoroethanesulfonic acid forming as a secondary major degradation products – [Hein; 2012] and [Hein; 2012a]. The results of these studies were kinetically examined and the outcome presented in the study report by [Reinken and Partsch; 2014c].

That analysis resulted in the set of four persistence kinetic endpoint determined in four test soils. It shall be noted that in case of two test soils – Dollendorf II Clay loam soil and Laacherhof Wurmweise Loam soil the Applicant's and RMS's values are significantly different. That was due to the fact that, because of the poor

fitting results RMS repeated the analysis using the top-down approach. The summary table presenting the persistence and modelling kinetic endpoints for FOE 5043-Trifluoroethanesulfonic acid (TFESA) is given below as table B.8.1.1.2.1.1._CA-302.

Table B.8.1.1.2.1.1._CA-302: The persistence and modelling kinetic endpoints – DT_{50} and DT_{90} values, determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA).

Study	Test soil data				Persistence kinetic endpoints			Kinetic endpoints recommended for modelling
	Soil name	Soil type (USDA)	Key soil properties		Kinetic model	DT_{50} [days]	DT_{90} [days]	DT_{50} [days]
			pH	OC [%]				
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	SFO	9.10	30.23	8.83
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	SFO	4.48	14.87	4.39
	Dollendorf II	Clay loam	7.2	5.3	SFO	20.9	69.5	19.87
	Laacherhof Wurmweise	Loam	5.4	2.2	SFO	2.24	7.45	2.19
Geomean (n = 4)						6.61	21.96	6.41

The study report also provided the kinetic formation fractions determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA). These are presented, together with the respective values considered reliable by the RMS, below in the table B.8.1.1.2.1.1._CA-303.

Table B.8.1.1.2.1.1._CA-303: The kinetic formation fraction values – ff , determined by the Applicant and verified by the RMS.

Study	Test soil data				Kinetic formation fractions - ff		
	Soil name	Soil type (USDA)	Key soil properties		Value proposed by the Applicant	Value accepted by RMS	Precursor
			pH	OC [%]			
<i>Hein; 2012</i>	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	0.264	0.264	FOE Thiadone
<i>Hein; 2012a</i>	Laacherhof AXXa	Loamy sand	6.1	2.4	0.534	0.534	FOE Thiadone
	Dollendorf II	Clay loam	7.2	5.3	0.422	0.422	FOE Thiadone
	Laacherhof Wurmweise	Loam	5.4	2.2	0.655	0.655	FOE Thiadone
Arithmetic mean (n = 4)						0.469	FOE Thiadone

Conclusion:

As a result of the evaluation presented above RMS determined the normalised geomean $DT_{50} = 6.41$ days, value for FOE 5043-Trifluoroethanesulfonic acid (TFESA), recommended to be used in GW (and SW) model exposure assessment.

The kinetic formation fraction recommended to be used in GW model exposure assessment is $ff = 0.469$.

g) The kinetic endpoints determined for Trifluoroacetic acid (TFA):

The data on the persistence of Trifluoroacetic acid – TFA, were obtained in two studies Flufenacet applied as parent compound and TFA forming as secondary and ternary major degradation product – [Hein; 2012] and [Hein; 2012a], as well as in one additional study in which TFA was applied to soil as a parent compound – [Eckermann; 2012]. The results of the studies by [Hein; 2012] and [Hein; 2012a] were kinetically examined and the outcome presented in the study report [Reinken and Partsch; 2014c]. The kinetic analysis of the data obtained in the study by [Eckermann; 2012] was found incomplete by RMS, therefore repeated and the hence the reliable persistence kinetic endpoints reported here are those determined by the RMS. The results showed that no degradation was observed, so the default values were set to represent the persistence of TFA in soil. These are: $DT_{50} = 10000$ days and $DT_{90} = 10000$ days.

The values as default require no normalisation. Therefore the value recommended for modelling should be **DT₅₀ = 10000 days**, but because the FOCUS models do not accept such value, the normalised value proposed for modelling is **DT₅₀ = 1000 days**.

The study report also provided the kinetic formation fractions determined for TFA. These are presented, together with the respective values considered reliable by the RMS, below in the table B.8.1.1.2.1.1._CA-304.

Table B.8.1.1.2.1.1._CA-304: The kinetic formation fraction values –*ff*, determined by the Applicant and verified by the RMS.

Study	Test soil data				Kinetic formation fractions - <i>ff</i>		
	Soil name	Soil type (USDA)	Key soil properties		Value proposed by the Applicant	Value accepted by RMS	Precursor
			pH	OC [%]			
Hein; 2012	Hoefchen am Hohenseh 4a	Silt loam	6.7	2.5	0.087	0.087	Flufenacet
					0.736	0.736	FOE Thiadone

Conclusion:

As a result of the evaluation presented above RMS proposed to use the default **DT₅₀ = 1000 days**, as a value for Trifluoroacetic acid (TFA) recommended to be used in GW (and SW) model exposure assessment. The kinetic formation fraction values recommended to be used in GW model exposure assessment are ***ff* = 0.430** for the compound formed from Flufenacet and ***ff* = 0.531** for the compound formed from FOE Thiadone.

Study 25:

Report: Reinken G. Porschewski R., (2014): “Flufenacet Core PEC_{sw} FOCUS EU: Modelling Core Info Document for Standard FOCUS 1-2 and STEP 3-4 Surface Water Exposure Assessment in Europe.”; Bayer CropScienceAG, Environmental Safety, Alfred-Nobel-Straße 50, 40789 Monheim, Germany, unpublished Report No. EnSa-13-1008; 2014. 02. 25; study reference number: M-478438-01-1;

Guidelines: Not specified, it was stated however that the assessment of the kinetic endpoints for Flufenacet and its major soil degradation products to select those suitable for calculating PEC_{SW} and PEC_{SED} values was performed to comply with the recommendations for modelling input selection given by the EU Commission, FOCUS and EFSA.

GLP: No, not applicable, modelling study

RMS comments: The study was performed as a supportive study to the main study presenting the results of the model exposure assessment for the surface water compartment performed by the Applicant for Flufenacet and its major soil degradation products. It provides for each compound of interest the list of determined reliable soil and aquatic (water and sediment) DT₅₀ values as well as adsorption parameters (K_f, K_{foc} and 1/n values), the analysis of the data sets aimed on the identification of potential outliers and identification, with justification, of the endpoints considered suitable in calculation of PEC_{SW} and PEC_{SED} values.

RMS evaluated the study and found it acceptable, although some of the conclusions drawn by the Applicant had to be modified as a result of the repeated kinetic analysis performed by the RMS. The study was intended by the Applicant to be supportive for model risk assessment for the surface water compartment. It shall be pointed out that in the area of the determination of soil DT₅₀ values appropriate for modelling the study overlaps with the preceding study (**Study 24**). For that reason, in order not to overburden the report, RMS decided not to provide its summary.

Additionally the search of the open literature resulted in identifying two papers containing the data relevant for the determination of the rate of degradation of Flufenacet in soil.

Study 26:

Report: Gupta S., Gajbhiye V. T., Agnihotri N. P. (2001): “Adsorption-Desorption, Persistence and Leaching Behavior of Flufenacet in Alluvial Soil of India.”; Division of Agricultural Chemicals, Indian Agricultural Research Institute, New Delhi 110 012, India; published study - published in: “Bulletin of Environmental Contamination and Toxicology”, vol 66, 2001, pp 9-16.

Guidelines: : None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper

RMS comments: The paper presents the results of the examination of soil equilibrium sorption (determination of Freundlich sorption isotherms), mobility in soil profile (column leaching experiment) and persistence in aerobic and anaerobic soil, for Flufenacet. The experiments were performed using one test soil. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with the OECD 307 guideline for soil persistence, OECD 106 Guideline for examining batch sorption and OECD 312 for column leaching. The level of details was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below, in this section of the Assessment Report for its part examining the persistence of Flufenacet in soil under laboratory conditions. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and conformatory to the endpoints provided by the regulatory studies submitted by the Applicant, and should not be used as a source of regulatory endpoints.

Summary:

The Editor has not provided the abstract for that publication. However the paper contained the introduction, clearly outlining the aims and scope of the research activity described in it, which may be considered a summary of the study. Due to the copyright restrictions, RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the mobility and persistence of Flufenacet in soil. The test soil used in the experiment was an agricultural soil, of the type of inceptisol, having the following physicochemical properties:

- **particle size distribution:** 64.7% sand, 15.6% silt and 19.7% clay;
- **soil texture class:** Sandy loam;
- **pH:** 7.1;
- **OC:** 0.34%;
- **Moisture content at FC (field capacity):** 20%.

The soil used in the experiment was freshly sampled from the top 15-cm layer of the fields of Indian Agricultural Research Institute in New Delhi, India. It was then air-dried and sieved through 2-mm mesh screen before being used.

The test compound was analytical grade Flufenacet, having a purity of > 99.5%, provided by M/s Bayer India Ltd. It was applied to the test soil in form of aqueous solution in 0.01 N CaCl₂, prepared from the stock solution of Flufenacet in acetone, having a concentration of 0.5 mg/mL.

The persistence of Flufenacet in aerobic soil was examined for two application doses – 1 µg Flufenacet/g soil (d. w.) and 10 µg Flufenacet/g soil (d. w.). To obtain that level, initially 200-g portions of the dry test soil were treated with the test compound at the level 100 µg Flufenacet/g soil (d. w.). Next the treated soil was mixed thoroughly with the appropriate amount of untreated soil to obtain the target application level of either 1 µg Flufenacet/g soil (d. w.) or 10 µg Flufenacet/g soil (d. w.). The 20-g portions of so prepared test soil were weighed to beakers and brought to the designated level of moisture content (FC) by addition of the appropriate

amount of distilled water. That level of soil moisture was maintained throughout the study by daily controlling and adjusting it, when necessary.

The samples were incubated for up to 90 days at constant temperature $T = 25 \pm 1^\circ\text{C}$. At designated time points: DAT (Days After Treatment) 0, 3, 6, 10, 14, 29, 45, 60 and 90, triplicate samples were taken for the analysis.

Alongside treated samples the non-treated control samples were set and maintained in the same way as treated samples.

Additionally the experiment was performed on submerged soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil (d. w.). The test soil samples were treated in the same way as described above for the experiment with aerobic samplers. Next, before being placed in incubation chamber, the samples were flooded with water added to each beaker in such amount to give 3-cm layer above the soil surface. That level was maintained throughout the whole incubation period, lasting also up to 90 days. The sampling points were the same as for aerobic samples. Although it was not called so, in RMS's opinion that variant of the experiment represents the examination of persistence of flufenacet in anaerobic soil.

At sampling soil samples incubated under aerobic conditions were air-dried at room temperature, mixed with 0.2 mL of liquid NH_3 and left for ~3 hours. After that period 0.5-g portions of activated florisil and charcoal were mixed with each soil sample, the so prepared mixture dry-packed into the 50-cm long glass column having a diameter of 2.5 cm, containing at the bottom 2-cm layer of anhydrous Na_2SO_4 . The so prepared columns were eluted using 125 mL of acetone-hexane (1:9) mixture. Extract was concentrated to dryness, residues reconstituted in n-hexane and analysed using GLC-ECD chromatography. The LOD of the analytical method was $0.005\ \mu\text{g/L}$.

The submerged samples were processed by extracting them repeatedly with acetone. After extraction the organic solvent was evaporated and the remaining aqueous phase extracted with three 30-mL portions of dichloromethane. The organic phase was collected, remnants of water removed by passing the whole volume through anhydrous Na_2SO_4 , and evaporated to dryness. The residue was reconstituted in n-hexane and analysed using GLC-ECD. The LOD of the analytical method was $0.005\ \mu\text{g/g}$.

The results of the analysis – the concentration of the test compound in soil as a function of time, given in $\mu\text{g/g}$ and as a % decrease of DAT-0 level, for each variant of the experiment are presented below in the table B.8.1.1.2.1.1._CA-305.

Table B.8.1.1.2.1.1._CA-305: The numerical results of the experiment

Time point – DAT (Days After Treatment)	Results obtained for:					
	Aerobic soil treated at the level $1\ \mu\text{g}$ Flufenacet/g soil		Aerobic soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil		Submerged (anaerobic) soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil	
	Concentration of flufenacet [$\mu\text{g/g}$]	% decrease of concentration comparing to DAT 0 amount	Concentration of flufenacet [$\mu\text{g/g}$]	% decrease of concentration comparing to DAT 0 amount	Concentration of flufenacet [$\mu\text{g/g}$]	% decrease of concentration comparing to DAT 0 amount
0	0.87	0.0	8.13	0.0	8.13	0.0
3	0.67	23.7	7.67	6.8	6.49	20.0
6	0.58	34.0	6.49	20.1	4.79	41.1
10	0.50	42.7	5.80	28.7	4.03	50.4
14	0.46	47.7	5.40	33.6	3.77	53.6
29	0.16	81.4	2.76	66.0	3.09	62.0
45	0.05	94.2	0.99	87.8	1.88	76.9
60	0.01	98.6	0.23	97.2	1.20	85.2
90	<LOD	not given	0.09	98.8	0.37	95.5

The obtained results were subjected to the kinetic analysis using linear-regression-1st order kinetics model. The obtained kinetic curves were not presented in the paper, instead the regression equations were given together with the calculated half-lives.

The parameters of the kinetic curves were as follows:

- for aerobic soil treated at the level $1\ \mu\text{g}$ Flufenacet/g soil the regression equation was $Y = 0.019 - 0.0323 X$, with correlation coefficient $r = 0.99$;
- for aerobic soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil the regression equation was $Y = 0.979 - 0.0231 X$, with correlation coefficient $r = 0.99$;
- for submerged (anaerobic) soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil the regression equation was $Y = 0.626 - 0.134 X$, with correlation coefficient $r = 0.99$.

The calculated half-lives, for convenience marked as DT_{50} were following:

- for aerobic soil treated at the level $1\ \mu\text{g}$ Flufenacet/g soil the $\text{DT}_{50} = 9.3$ days;
- for aerobic soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil the $\text{DT}_{50} = 13.0$ days;
- for submerged (anaerobic) soil treated at the level $10\ \mu\text{g}$ Flufenacet/g soil the $\text{DT}_{50} = 22.5$ days.

The authors stated that the rate of degradation in aerobic soil treated at different fortification levels was initially slower than in anaerobic soil, but later that trend reversed, what was postulated to be due to the strong sorption of the test compound to alluvial soil.

RMS noted that the kinetic endpoints were determined for the incubation temperature higher than the standard recommended $T = 20^{\circ}\text{C}$. Therefore for the comparative purpose the kinetic endpoints were normalised to standard conditions. The normalisation for soil moisture content was not performed as in case of aerobic soils they were incubated at the reference level – FC level, while for anaerobic/submerged soils such procedure is not necessary.

The results of the normalisation are presented below:

- for aerobic soil treated at the level 1 μg Flufenacet/g soil the $\text{DT}_{50} = 14.3$ days;
- for aerobic soil treated at the level 10 μg Flufenacet/g soil the $\text{DT}_{50} = 20.4$ days;
- for submerged (anaerobic) soil treated at the level 10 μg Flufenacet/g soil the $\text{DT}_{50} = 35.3$ days.

RMS comments:

The obtained kinetic endpoints are within the range of the values obtained for Flufenacet in regulatory studies. However, because of the method of their derivation, as well as due to the fact that the test soil is a non-EU soil, nor it is representative for the EU agricultural soils, they shall be considered only as indicative and not used as regulatory endpoints.

Study 27:

Report: Suman Gupta, Vijay T. Gajbhiye (2002): “Effect of concentration, moisture and soil type on the dissipation of flufenacet from soil.”; Division of Agricultural Chemicals, Indian Agricultural Research Institute, New Delhi 110012, India; published study - published in: “Chemosphere”, vol 47, 2002, pp 901 - 906.

Guidelines: None declared as this is an open-source study, therefore not submitted for the regulatory purposes.

GLP: no, not applicable – peer-reviewed scientific paper;

RMS comments: The paper presents the results of the examination of persistence of Flufenacet in soil under various experimental conditions. The experiment was performed on three Indian agricultural soils, incubated under either aerobic or anaerobic (submerged) conditions. In case of aerobic soil rate of degradation was examined for two fortification levels. Although in the paper it was not indicated that the experiments were performed in line with any relevant guidelines, it can be stated that the study protocol generally complied with the OECD 307 Guideline. The level of detail was sufficient to evaluate the study for its validity. The study may be considered valid, and therefore is summarised below. However, RMS is of the opinion that the results it provides may be regarded only as supplementary and conformatory to the endpoints provided by the regulatory studies submitted by the Applicant and should not be used as a source of regulatory endpoints.

Summary:

The paper contains an abstract, outlining the aims of the experiment and its key results, which was made available on-line. However, due to the copyright restrictions RMS could not present it here and the readers are kindly asked to consult the relevant document. Instead, below is presented the extended summary prepared by the RMS.

Extended summary prepared by RMS:

The aim of the study was to examine the persistence of Flufenacet in agricultural soils incubated in the laboratory, either under aerobic or anaerobic conditions. The examination was performed on three soils, representing different regions of India. Their characteristic is provided below in the table B.8.1.1.2.1.1._CA-306. They were freshly sampled from the top 15-cm layer of the cultivated of the three locations: Dehli, Ranchi and Nagpur. After sampling they were air-dried, ground, sieved through 2-mm sieve and stored in plastic containers until being used.

Table B.8.1.1.2.1.1._CA-306: The characteristic of the test soils used in the experiment

Parameter		Soil		
		<i>Delhi</i>	<i>Ranchi</i>	<i>Nagpur</i>
Soil type		Inceptisol	Ultisol	Vertisol
Soil textural type (reported in the study)		Sandy loam	Sandy loam	Clayley
Soil type (USDA; determined by RMS)		US Loamy sand	US Sandy clay loam	US Clay
Particle size distribution	Sand [%]	77.5	60.0	40.0
	Silt [%]	17.5	8.7	16.3
	Clay [%]	5.0	31.3	43.7
pH value (medium not specified)		7.69	5.54	8.25
Organic carbon content (OC) [%]		0.501	0.042	0.399
Organic matter content (OM) [%]		0.864	0.072	0.688
Cation Exchange Capacity – CEC [mEq/100g]		6.95	3.86	13.69
Water holding capacity	a Field Capacity (FC) [%]	20	17	30

The test compound was a non-radiolabelled Flufenacet, having a chemical purity of > 99.5%, supplied by Bayer India Ltd. It was used in form of a stock solution in acetone, having a concentration 1.0 mg/mL, if necessary further diluted using distilled hexane.

The persistence of Flufenacet in aerobic soil was examined for two application doses – 1 µg Flufenacet/g soil (d.w.) and 10 µg Flufenacet/g soil (d. w.). To obtain that level, initially 200-g portions of the dry test soils were treated with the test compound at the level 100 µg Flufenacet/g soil (d. w.). Next the treated soils were mixed thoroughly with the appropriate amount of adequate untreated soils to obtain the target application level of either 1 µg Flufenacet/g soil (d. w.) or 10 µg Flufenacet/g soil (d. w.). The 10-g portions of so prepared test soils were weighed into beakers and brought to the designated level of moisture content (FC) by addition of the appropriate amount of distilled water. That level of soil moisture was maintained throughout the study by daily controlling and adjusting it, when necessary.

The samples were incubated for up to 90 days at constant temperature $T = 25 \pm 1^\circ\text{C}$. The sampling dates used in the experiment were not specified, but as the paper refers on several instances to the earlier study by the same authors, summarised above, it is possible that they were the same.

Alongside treated samples the non-treated control samples were set and maintained it the same way as treated samples.

Additionally the experiment was performed on submerged soil treated at the level 10 µg Flufenacet/g soil (d. w.). The samples of the test soils were treated in the same way as described above for the experiment with aerobic soils. Next, before being placed in incubation chamber, samples were flooded with water added to each beaker in such amount to give 3-cm layer above the soil surface. That level was maintained throughout the whole incubation period, lasting also up to 90 days. The sampling points were the same as for aerobic samples. Although it was not called so, in RMS's opinion that variant of the experiment represents the examination of persistence of flufenacet in anaerobic soil.

At sampling soil samples incubated under aerobic conditions were air-dried at room temperature, mixed with 0.2 mL of liquid NH_3 and left for ~3 hours. After that period 0.5-g portions of activated florasil and charcoal were mixed with each soil sample, the so prepared mixture dry-packed into the 50-cm long glass column having a diameter of 2.5 cm, containing at the bottom 2-cm layer of anhydrous Na_2SO_4 . The so prepared columns were eluted using 150 mL of acetone-hexane (1:9) mixture. Extract was concentrated to dryness, residues reconstituted n-hexane and analysed using GC-ECD chromatography.

The submerged samples were processed by extracting them repeatedly with acetone. After extraction the organic solvent was evaporated and the remaining aqueous phase extracted with three 30-mL portions of dichloromethane. The organic phase was collected, remnants of water removed by passing the whole volume through anhydrous Na_2SO_4 and evaporated to dryness. The residue was reconstituted in n-hexane and analysed using GC-ECD.

The detailed numerical results of the study were not provided. Instead they were given in graphical form. In the study it was stated that the recovery levels were acceptable, all above 80% on DAT 0, so the residue data were not corrected for the recovery. In samples treated at the level 1 µg Flufenacet/g soil the initial recovery was on the level 81 – 87% and in samples treated at the level of 10 µg Flufenacet/g soil 89 – 102%.

Therefore the initial concentration measured in three test soils treated at the level of 1 µg Flufenacet/g soil were in range 0.793 – 0.905 µg/g soil and in case of soils treated at the level of 10 µg Flufenacet/g soil they were in range 7.53 – 8.13 µg/g soil.

The dissipation followed 1st order kinetics. It was stated that it was concentration-dependent: in soils treated at the level of 1 µg Flufenacet/g soil on day 60th after treatment 96 – 100% of the initial dose disappeared from three

test soils, while for the treatment level of 10 µg Flufenacet/g soil for the same time period that value was lower – 65 – 97%. The influence of aerobic or anaerobic conditions (in paper referred to as influence of soil moisture) on the rate of dissipation of Flufenacet from the test soils was less pronounced. Finally it was stated that the physicochemical properties of test soils had a substantial influence on the rate of degradation of Flufenacet in soil. It was stated that the positive correlation was observed between the determined DT_{50} values and soil clay content, what in turn was attributed to higher adsorption capacity. No significant correlation was observed between the determined DT_{50} and both soil pH and OM content. However, in case of that last parameter RMS noted that in all test soils the OC/OM content was low, lower than that recommended in the relevant guidelines.

The obtained results were subjected to the kinetic analysis using linear-regression 1st order kinetics model. The obtained kinetic curves were not presented in the paper, instead the regression equations were given together with the calculated half-lives.

For Delhi test soil the parameters of the kinetic curves were as follows:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the regression equation was **$Y = -0.0143 - 0.0299 X$** , with correlation coefficient **$r = 0.99$** ;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the regression equation was **$Y = 0.9792 - 0.0231 X$** , with correlation coefficient **$r = 0.99$** ;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the regression equation was **$Y = 0.8302 - 0.0135 X$** , with correlation coefficient **$r = 0.99$** ;

The calculated half-lives, for convenience marked as DT_{50} , were following:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the **$DT_{50} = 10.1$ days**;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 13.0$ days**;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 22.3$ days**.

For Ranchi test soil the parameters of the kinetic curves were as follows:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the regression equation was **$Y = -0.1353 - 0.0286 X$** , with correlation coefficient **$r = 0.99$** ;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the regression equation was **$Y = 0.8537 - 0.0141 X$** , with correlation coefficient **$r = 0.99$** ;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the regression equation was **$Y = 0.8414 - 0.0125 X$** , with correlation coefficient **$r = 0.99$** ;

The calculated half-lives, for convenience marked as DT_{50} , were following:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the **$DT_{50} = 10.5$ days**;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 21.3$ days**;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 24.1$ days**.

For Nagpur test soil the parameters of the kinetic curves were as follows:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the regression equation was **$Y = -0.1651 - 0.0097 X$** , with correlation coefficient **$r = 0.99$** ;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the regression equation was **$Y = 0.8451 - 0.0103 X$** , with correlation coefficient **$r = 0.94$** ;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the regression equation was **$Y = 0.8633 - 0.0100 X$** , with correlation coefficient **$r = 0.93$** ;

The calculated half-lives, for convenience marked as DT_{50} , were following:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the **$DT_{50} = 31.0$ days**;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 29.2$ days**;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 30.1$ days**.

RMS noted that the kinetic endpoints were determined for the incubation temperature higher than the standard recommended $T = 20^{\circ}\text{C}$. Therefore for the comparative purpose the kinetic endpoints were normalised to standard conditions. The normalisation for soil moisture content was not performed as in case of aerobic soils they were incubated at the reference level – FC level, while for anaerobic/submerged soils such procedure is not necessary.

The results of the normalisation in Delhi soil were following:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the **$DT_{50} = 15.8$ days**;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 20.4$ days**;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the **$DT_{50} = 35.0$ days**.

The results of the normalisation in Ranchi soil were following:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the **DT₅₀ = 16.5 days**;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the **DT₅₀ = 33.4 days**;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the **DT₅₀ = 37.8 days**.

The results of the normalisation in Nagpur soil were following:

- for aerobic soil treated at the level 1 µg Flufenacet/g soil the **DT₅₀ = 48.6 days**;
- for aerobic soil treated at the level 10 µg Flufenacet/g soil the **DT₅₀ = 45.8 days**;
- for submerged (anaerobic) soil treated at the level 10 µg Flufenacet/g soil the **DT₅₀ = 47.2 days**.

RMS comments:

The obtained kinetic endpoints are within the range of the values obtained for Flufenacet in regulatory studies. However, because of the method of their derivation, as well as due to the fact that the test soils are the non-EU soils or representative for the EU agricultural conditions, they shall be considered only as indicative and not used as regulatory endpoints.

Summary – Rate of degradation of Flufenacet and its degradation products in aerobic soil:

The degradation kinetics of Flufenacet in aerobic soil was extensively examined by the Applicant and its results presented in 26 study reports, of which 24 were found by the RMS acceptable and relevant for the current assessment. Additionally two literature studies were identified by the RMS which also provided the data on the degradation kinetics of Flufenacet in aerobic soils. These reports were found by the RMS relevant as supplementary source of data, however not suitable for deriving the regulatory endpoints.

The key results for each of the evaluated compounds are presented below, in tabularised form, individually for each of the test compounds.

Additionally RMS presented the obtained data in form of the tables recommended in the current template for the List of End Points.

a) Kinetic endpoints determined for Flufenacet:

The degradation kinetics of Flufenacet in aerobic soil was examined in ten trials using nine soils. One of the test soils – Howe, Indiana, Sandy loam soil, was used in two trials in which was used Flufenacet differently radiolabelled (either in phenyl ring or in C2 position of thiadiazole moiety), but the resulting kinetic endpoints cannot be averaged prior to calculating the overall geomean because they were derived in two separate studies, significantly differing in sample processing method.

The persistence (best-fit) kinetic endpoints obtained for Flufenacet are presented below in the table B.8.1.1.2.1.1._CA-307. The modelling endpoints are given in the table B.8.1.1.2.1.1._CA-308.

Table B.8.1.1.2.1.1._CA-307: The persistence kinetic endpoints determined for Flufenacet in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints	
Soil name	Soil type (USDA)	OC	pH			χ^2 error	Visual fit ¹⁾ /R ²	Param.	Value	DT ₅₀ [days]	DT ₉₀ [days]

For GW and SW model exposure assessment the **geomean $DT_{50} = 17.89$ days** and **geomean $k = 0.0387$ [days⁻¹]** are the kinetic endpoints recommended as input parameters.

b) Kinetic endpoints determined for FOE Sulfonic acid:

The degradation kinetics of FOE Sulfonic acid in aerobic soil was examined in seventeen trials on the same number of the test soils. The experiments were performed in two variants – four trials with soils treated with Flufenacet (active substance) and the remaining thirteen trials with soils treated with FOE Sulfonic acid.

The performed kinetic analysis resulted in a data base consisting of twelve reliable kinetic endpoints, all determined in trials in which the test soils were treated with FOE Sulfonic acid. In case of the experiments on soils treated with Flufenacet it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Sulfonic acid in soil because decline of that compound was not observed. As a result, the default values – $DT_{50} = 1000$ days and $DT_{90} > 1000$ days, were proposed for these trials. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate

normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fractions for FOE Sulfonic acid, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

In case of the kinetic analysis of the data obtained in Laacherhof IIIA Silt loam soil in the study by [Hellpointner; 1996], it was not possible to obtain a reliable kinetic fit and hence kinetic endpoints. For that reason the trial was removed from both summary table presenting persistence and modelling endpoints.

The persistence (best-fit) kinetic endpoints obtained for FOE Sulfonic acid are presented below in the table B.8.1.1.2.1.1._CA-309. The modelling endpoints are given in the table B.8.1.1.2.1.1._CA-310.

Table B.8.1.1.2.1.1._CA-309: The persistence kinetic endpoints determined for FOE Sulfonic acid in aerobic soil.

Arithmetic mean for ff (n = 4)												0.195

Footnotes to the table:

- 1) Measured in:
 - CaCl₂/water for values marked a);
 - distilled water for results marked b);
 - (0.01M) CaCl₂ for results marked c);
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) Value not determined – the decline phase not reached;
- 4) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **geomean DT₅₀ = 45.11 days** and **geomean k = 0.0154 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended **ff** value is **ff = 0.195** (arithmetic mean) for Flufenacet as a precursor.

c) Kinetic endpoints determined for FOE Oxalate:

The degradation kinetics of FOE Oxalate in aerobic soil was examined in four trials on the same number of the test soils. The experiments were performed with soils treated with Flufenacet (active substance).

The performed kinetic analysis resulted in a data base consisting of three reliable kinetic endpoints. In case of the experiment in Howe, Indiana, Sandy loam soil it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Oxalate because the decline of that compound was not observed. As a result,

the default values – $DT_{50} = 1000$ days and $DT_{90} > 1000$ days, were proposed for that trial. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fraction for FOE Oxalate, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

The persistence (best-fit) kinetic endpoints obtained for FOE Oxalate are presented below in the table B.8.1.1.2.1.1._CA-311. The modelling endpoints are given in the table B.8.1.1.2.1.1._CA-312.

Table B.8.1.1.2.1.1._CA-311: The persistence kinetic endpoints determined for FOE Oxalate in aerobic soil.

- 3) Value not determined – the decline phase not reached;

For GW and SW model exposure assessment the **geomean DT₅₀ = 11.08 days** and **geomean k = 0.0639 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended **ff** value is **ff = 0.426** (arithmetic mean) for Flufenacet as a precursor.

d) Kinetic endpoints determined for FOE Methylsulfone:

The degradation kinetics of FOE Methylsulfone in aerobic soil was examined in eleven trials using the same number of the test soils. The experiments were performed in two variants – three trials with soils treated with Flufenacet (active substance) and the remaining eight trials with soils treated with FOE Methylsulfone.

The performed kinetic analysis resulted in a data base consisting of nine reliable kinetic endpoints, one with soil treated with Flufenacet as a precursor of FOE Methylsulfone and remaining eight with soils treated with FOE Methylsulfone. In case of two trials on soils treated with Flufenacet – BBA 2.2 Loamy sand soil and Hoefchen im Tal Silt loam soil, it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Methylsulfone in soil, because decline of that compound was not observed. As a result, the default values – $DT_{50} = 1000$ days and $DT_{90} > 1000$ days, were proposed for these trials. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fractions for FOE Methylsulfone, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

The persistence (best-fit) kinetic endpoints obtained for FOE Methylsulfone are presented below in the table B.8.1.1.2.1.1._CA-313. The modelling endpoints are given in the table B.8.1.1.2.1.1._CA-314.

Table B.8.1.1.2.1.1._CA-313: The persistence kinetic endpoints determined for FOE Methylsulfone in aerobic soil.

For GW and SW model exposure assessment the **median DT₅₀ = 81.70 days** and **median *k* = 0.00848 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.070** (arithmetic mean) for Flufenacet as a precursor.

e) Kinetic endpoints determined for FOE Thiadone:

The degradation kinetics of FOE Thiadone in aerobic soil was examined in eight trials using the equal number of the test soils. The experiments were performed in two variants – five trials with soils treated with Flufenacet (active substance) and the remaining eight trials with soils treated with FOE Methylsulfone.

The performed kinetic analysis resulted in a data base consisting of eight reliable kinetic endpoints, four with soil treated with Flufenacet as a precursor of FOE Thiadone and three with soils treated with FOE Thiadone. In case of one trial on soil treated with Flufenacet – Howe, Indiana Sandy loam soil, it was not possible to obtain reliable fit for FOE Thiadone in combination with the parent compound. Such fit however was obtained when the data were kinetically analysed for FOE Thiadone alone using the top-down approach. That solution however implied that no reliable value for kinetic formation fraction in that trial could be obtained and reported. RMS decided not to report the default value $ff = 1.00$, proposed by the Applicant. The persistence (best-fit) kinetic endpoints obtained for FOE Thiadone are presented below in the table B.8.1.1.2.1.1_CA-315. The modelling endpoints are given in the table B.8.1.1.2.1.1_CA-316.

Table B.8.1.1.2.1.1_CA-315: The persistence kinetic endpoints determined for FOE Thiadone in aerobic soil.

- 6) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **geomean DT₅₀ = 1.95 days** and **geomean *k* = 0.3557 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.570** (arithmetic mean) for Flufenacet as a precursor.

f) Kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA):

The degradation kinetics of FOE 5043-Trifluoroethanesulfonic acid (TFESA) in aerobic soil was examined in four trials using the equal number of the test soils. The experiments were performed with soils treated with Flufenacet (active substance).

The performed kinetic analysis resulted in a data base consisting of four reliable kinetic endpoints. In case of two trials – on the Dollendorf II Clay loam soil and Laacherhof Wurm-wiese Loam soil it was not possible to obtain reliable kinetic fits for the whole transformation scheme, therefore the top-down approach was used. RMS however decided to keep the determined values of kinetic formation fraction *ff*. The persistence (best-fit) kinetic endpoints obtained for FOE 5043-Trifluoroethanesulfonic acid (TFESA) are presented below in the table B.8.1.1.2.1.1_CA-317. The modelling endpoints are given in the table B.8.1.1.2.1.1_CA-318.

Table B.8.1.1.2.1.1_CA-317: The persistence kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints

Arithmetic mean for ff (n = 3)												0.469

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂;
 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

The DT₅₀ = **20.9 days** value, determined in Dollendorf II Clay loam soil was identified as appropriate input parameter for soil exposure assessment.

Table B.8.1.1.2.1.1_CA-318: The modelling kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints		
Soil name	Soil type (USDA)	OC	pH ¹⁾			χ^2 error	Vis. fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]	Kinetic formation fraction ff
Hoefchen Am Hohenseh 4a;	Silt loam	2.5	6.7	19.1 ⁰ C; 55% MWHC	SFO	5.85	G	k	0.0785	8.83	29.32	0.264
Laacherhof AXXa;	Loamy sand	2.4	6.1	19.9 ⁰ C; 55% MWHC	SFO	18.25	G	k	0.1579	4.39	14.57	0.534
Dollendorf II;	Clay loam	5.3	7.2	19.9 ⁰ C; 55% MWHC	SFO	4.31	G	k	0.0349	19.87	66.01	0.422
Laacherhof Wurm-wiese;	Loam	2.2	5.4	19.9 ⁰ C; 55% MWHC	SFO	12.3	G	k	0.3165	2.19	7.30	0.655
Geometric mean (n = 4)									0.1082	6.41	21.30	----
Arithmetic mean for ff (n = 3)												0.469

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂;
 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

For GW and SW model exposure assessment the **geomean DT₅₀ = 6.41 days** and **geomean k = 0.1082 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended ff value is **ff = 0.469** (arithmetic mean) for FOE Thiadone as a precursor.

g) Kinetic endpoints determined for Trifluoroacetic acid (TFA):

The degradation kinetics of Trifluoroacetic acid (TFA) in aerobic soil was examined in eight trials using the equal number of the test soils. The experiments were performed in two variants – four trials with soils treated with Flufenacet (active substance) and the remaining four trials with soils treated with TFA.

Due to the high persistence of the test compound – TFA, in none of the test soils it was possible to obtain the reliable kinetic endpoints. For that reason the default values were proposed.

Due to the difference between the modelling tools, for the persistence endpoints two sets of the default values were provided. For trials on test soils treated with Flufenacet as precursor of TFA, where the analysis performed by the Applicant was accepted, the default kinetic endpoints were: **DT₅₀ = 1000 days** and **DT₉₀ > 1000 days**. In case however of the trials with TFA applied as parent compound, for which RMS had to repeat the kinetic analysis, the kinetic endpoints were: **DT₅₀ = 10000 days** and **DT₉₀ > 10000 days** – the values returned by the applied tool. RMS considers these defaults to be representative for the persistence of TFA in soil, as that indicated the results of the examination of the fate of TFA in environment presented in the open-source literature.

However for modelling the recommended input value is **DT₅₀ = 1000 days**, because of the constraints of the current modelling tools. It shall be noted that due to the nature of the determined endpoint – a default value, its normalisation was not performed as not necessary.

For TFA a set for two kinetic formation fraction values were determined – one for formation of TFA from Flufenacet and the second for its formation from FOE Thiadone.

The persistence (best-fit) kinetic endpoints obtained for TFA are presented below in the table B.8.1.1.2.1.1._CA-319. The modelling endpoints are given in the table B.8.1.1.2.1.1._CA-320.

Table B.8.1.1.2.1.1._CA-319: The persistence kinetic endpoints determined for Trifluoroacetic acid (TFA) in aerobic soil.

- 4) ff_1 – kinetic formation fraction for formation of TFA from Flufenacet; ff_2 – kinetic formation fraction for formation of TFA from FOE Thiadone.

For GW and SW model exposure assessment the default **DT₅₀ = 1000 days** is a kinetic endpoint recommended as input parameter. The corresponding recommended ff values are $ff_1 = 0.430$ (arithmetic mean) for Flufenacet as a precursor and $ff_2 = 0.531$ (arithmetic mean) for FOE Thiadone as a precursor.

The kinetic endpoints identified by RMS as appropriate to be used in model exposure assessment for soil, groundwater and surface water compartments are summarised below in the table B.8.1.1.2.1.1_CA-321. For completeness also the maximum concentrations observed in soils are provided. That table will be directly transferred to the List of EndPoints.

Table B.8.1.1.2.1.1._CA-321: The kinetic endpoints determined in laboratory studies on aerobic soils, recommended to be used in model exposure assessment for soil, groundwater and surface water compartments.

Compound	Compartment	Recommended endpoints					
		Maximum observed in soil		Kinetic formation fraction - <i>ff</i>		Persistence in soil – <i>DT</i> ₅₀ value	
		Observed soil maximum [%]	Remark	<i>ff</i>	Remark	<i>DT</i> ₅₀ [days]	Remark
Flufenacet	Soil	Not applicable	Not applicable – parent compound	----	Not applicable – parent compound	57.6	Longest not normalised lab value
	Groundwater			----		17.89	Normalised lab geomean value
	Surface Water			----		17.89	Normalised lab geomean value
FOE Sulfonic acid	Soil	26.5	Recommended for simple modelling ¹⁾	0.272	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	318	Longest not normalised lab value
	Groundwater	----	Not applicable	0.195	Precursor: flufenacet;	45.11	Normalised lab geomean value
	Surface Water	26.5	To be used in calculations at Steps 1 and 2	0.195	Precursor: flufenacet; to be used in Step 3-4 assessment	45.11	Normalised lab geomean value
FOE Oxalate	Soil	26.3	Recommended for simple modelling ¹⁾	0.484	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	18.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.426	Precursor: flufenacet;	11.08	Normalised lab geomean value
	Surface Water	26.3	To be used in calculations at Steps 1 and 2	0.426	Precursor: flufenacet; to be used in Step 3-4 assessment	11.08	Normalised lab geomean value
FOE Methylsulfone	Soil	6.6	Recommended for simple modelling ¹⁾	0.096	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	174	Longest not normalised lab value
	Groundwater	----	Not applicable	0.070	Precursor: flufenacet;	81.70	Normalised lab median value
	Surface Water	6.6	To be used in calculations at Steps 1 and 2	0.070	Precursor: flufenacet; to be used in Step 3-4 assessment	81.70	Normalised lab median value
FOE Thiadone	Soil	5.8	Recommended for simple modelling ¹⁾	0.913	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	15.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.570	Precursor: flufenacet;	1.95	Normalised lab geomean value
	Surface Water	5.8	To be used in calculations at Steps 1 and 2	0.570	Precursor: flufenacet; to be used in Step 3-4 assessment	1.95	Normalised lab geomean value
FOE 5043-Trifluoroethane-sulfonic acid	Soil	6.0	Recommended for simple modelling ¹⁾	0.655	Precursor: Thiadone; highest <i>ff</i> , to be used in complex modelling ²⁾	20.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.469	Precursor: Thiadone;	6.41	Normalised lab geomean value
	Surface Water	6.0	To be used in calculations at Steps 1 and 2	0.469	Precursor: Thiadone; to be used in Step 3-4 assessment	6.41	Normalised lab geomean value
Trifluoroacetic acid (TFA)	Soil	81.5	Recommended for simple modelling ¹⁾	0.430	Precursor: flufenacet; average <i>ff</i> , to be used in complex modelling ^{2, 3)}	10000	Longest lab value (default)
				0.531	Precursor: Thiadone; average <i>ff</i> , to be used in complex modelling ^{2, 3)}		
	Groundwater	----	Not applicable	0.430	Precursor: flufenacet;	1000	FOCUS default for non-degrading compounds
				0.531	Precursor: Thiadone;		
	Surface Water	81.5	To be used in calculations at Steps 1 and 2	0.430	Precursor: flufenacet; to be used in Step 3-4 assessment	1000	FOCUS default for non-degrading compounds
				0.531	Precursor: Thiadone; to be used in Step 3-4 assessment		

Footnotes to the table:

- 1) By the term “simple modelling” are understood calculations performed using simple models with metabolites applied as parent;
- 2) The term “complex models” concerns calculations performed using more sophisticated tools, e.g. ESCAPE, in which metabolites are calculated as formed from their precursor (parent compound or preceding degradation product);
- 3) For that compound, due to the complex formation scheme, average *ff* values are proposed to be used in complex soil exposure assessment with the average *ff* for Thiadone to be used in case it becomes necessary to recalculate the value to obtain the bet formation of TFA in that process (as if from parent).

Additionally all kinetic endpoints determined in laboratory studies for aerobic soil are given below in format recommended for presenting the data in the current EU List of EndPoints.

Rate of degradation in soil (aerobic) laboratory studies active substance (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.2.1.1 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.1.1)

Parent - Flufenacet	Dark aerobic conditions						
	Soil type	OC [%]	pH ^{a)}	t. °C / % MWHC	DT ₅₀ /DT ₉₀ (d)	DT ₅₀ (d) 20 °C pF2/10kPa ^{b)}	St. (X ²) Method of calculation

B.8.1.1.2.1.2. – Anaerobic degradation

Degradation of Flufenacet in soil under anaerobic conditions was examined in two newly submitted studies, both summarised under the point B.8.1.1.2. of this report as **Study 1** and **Study 2**.

Study 1, [Pangilinan and Smith; 1995], examined the degradation of [Phenyl-U-¹⁴C]Flufenacet in one soil incubated under anaerobic conditions. The study report contained the results of the kinetic analysis of the data for Flufenacet, performed however not in line with the recommendations of the FOCUS Kinetics Work Group [FOCUS; 2006] – the fitting was done using linear regression and the statistical evaluation of the fit, except r^2 value, was not provided. For that reason RMS decided not to present them in the Renewal Assessment Report.

Study 2, [Heinemann; 2012], examined the degradation of [Thiadiazole-5-¹⁴C]Flufenacet in two soils incubated under anaerobic conditions. The study report also contained the results of the kinetic evaluation of the data obtained for Flufenacet. The kinetic analysis was performed in line with the recommendations of the FOCUS Kinetics Work Group [FOCUS; 2006]. The study report contains however only results of the fitting obtained using DFOP kinetic model, most probably returning the best fit. As such, the results of the kinetic examination of the data cannot be considered complete. Therefore RMS decided not to present them, moreover because more detailed kinetic analysis of the same data is available in the new study report, specifically aimed on the kinetic examination of the data obtained in the studies listed above, summarised below as **Study 1**.

Additionally two open-source literature reports provided additional data on the degradation kinetics of Flufenacet in anaerobic soil. The studies were summarised under the preceeding point – B.8.1.1.2.1.1. as **Study 27** and **Study 28**, therefore the RMS decided not to provide their summaries in this section. The results will however be provided in the part summarising the results of the degradation of Flufenacet in soil under anaerobic conditions.

Study 1:

Report: Reinken G., Partsch S., Bolekhan A., (2014): “Kinetic evaluation of the Degradation of Flufenacet and its Degradation Products under Anaerobic Soil Conditions in Laboratory According to FOCUS Kinetics Using the KinGUI 2 Tool.”; Bayer CropScience AG, Environmental Safety, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; unpublished study Report No. EnSa-13-0971; 2014. 02. 28; study reference number: M-478213-02-1;.

Guidelines: the study was declared to be performed following the guidance of the FOCUS Kinetics Work Group given in:

- FOCUS, 2006: “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.”; Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 2.0, 434 pp.;
- FOCUS, 2011: “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Version 1.0, Nov. 23, 2011.

No deviations were stated.

GLP: No, not required, as the study is a modelling study.

RMS comments: The study was verified and it was found acceptable. It is summarised below.

Summary:

The aim of the study was the kinetic analysis, performed in line with recommendations of FOCUS Kinetics Work Group, of the data obtained in two studies examining the degradation of Flufenacet in soil under anaerobic conditions in order to:

- a) determine the persistence of Flufenacet and its degradation products by deriving the appropriate kinetic endpoints;
- b) derive the kinetic endpoints – DT₅₀ values, suitable for use in model calculations.

The data used in this study came from two studies examining the degradation of Flufenacet in soil under anaerobic conditions – [Pangilinan and Smith; 1995] (**Study 1**) and [Heinemann; 2012] (**Study 2**), summarised in details under the point B.8.1.1.2. of this report. The examination was performed using three soils, the characteristic of which is provided below in the table B.8.1.1.2.1.2._CA-1.

Table B.8.1.1.2.1.2._CA-1: The characteristic of soil used in examination of the degradation of Flufenacet in soil under anaerobic conditions.

Parameter	Study/test soil		
	Pangilinan & Smith; 1995	Heinemann; 2012	
	Howe	Hoefchen am Hohenseh 4a	Dollendorf II
Soil origin	Indiana, USA	Burscheid, Germany	Blankenheim, Germany
Soil type (USDA)	Sandy loam	Silt loam	Loam
Particle size distribution	Sand [%]	73.5	22
	Silt [%]	19.1	62
	Clay [%]	7.5	16
pH value (in H ₂ O, 1:1)	6.2	6.3	7.1
pH value (in CaCl ₂)	5.6	6.1	7.0
Organic carbon content (C _{org}) [%]	0.35	2.0	4.6
Cation Exchange Capacity – CEC [mEq/100g]	6.5	11.1	19.5
Water holding capacity at ½ bar	13.1 %	20.9 g H ₂ O/100 g soil	35.1 g H ₂ O/100 g soil
Bulk density (disturbed) [g/cm ³]	1.37	1.09	1.03

The test substance used in the study by [Pangilinan and Smith; 1995] was [Phenyl-U-¹⁴C]Flufenacet applied to soil at a rate of 1.03 mg/kg soil. The treated soil samples were incubated in the dark at T = 21 ± 1 °C, firstly for 30 days under aerobic conditions, followed by 180-days incubation under anaerobic conditions. The test soil was demonstrated to be fully biologically viable throughout both aerobic and anaerobic incubation phases.

For the purpose of the kinetic evaluation only the data obtained during anaerobic phase were used. These are presented below, in the table B.8.1.1.2.1.2._CA-2. The averages of the two replicates are given, as only those were reported in the source study report.

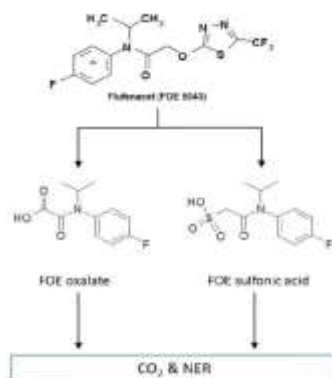

Table B.8.1.1.2.1.2._CA-2: The data obtained during anaerobic incubation period in the study by [Pangilinan and Smith; 1995].

Time point – DASF ¹⁾ [days]	Concentration in % AR of:		
	Flufenacet ²⁾	FOE Oxalate ²⁾	FOE Sulfonic acid ²⁾
0	69.0	11.2	6.6
15	60.3	12.2	6.1
30	55.6	14.5	5.3
67	52.0	10.9	4.7
123	44.2	11.4	5.0
180	39.0	9.9	4.5

Footnotes to the table:

- 1) DASF – Days after Soil Flooding;
 2) Values are averages of the two replicates.

These values were inserted, after being processed following recommendations given by FOCUS Kinetics Work Group (FOCUS; 2006, 2011), into the kinetic modelling tool – KinGUI 2 developed by Bayer. The assumed transformation pathway is shown below on figure B.8.1.1.2.1.2._CA-1.

**Figure B.8.1.1.2.1.2._CA-1:** The assumed transformation pathway of [Phenyl-U-¹⁴C] Flufenacet in anaerobic soil used in the kinetic examination of the data from the study by Pangilinan and Smith [1995] (copied from the study's report).

The test substance used in the study by [Heinemann; 2012] was [Thiadiazole-5-¹⁴C]Flufenacet applied to soil at a rate (nominal) 1.6 mg/kg soil (d. w.). The treated soil samples were incubated in the dark at $T = 20 \pm 2^{\circ}\text{C}$, firstly for 15 days under aerobic conditions, followed by 120-days incubation under anaerobic conditions. The test soils were demonstrated to be fully biologically viable throughout both aerobic and anaerobic incubation periods.

For the purpose of the kinetic evaluation only the data obtained during anaerobic phase were used. These are presented below, in the table B.8.1.1.2.1.2._CA-3.

Table B.8.1.1.2.1.2._CA-3: The data obtained during anaerobic incubation period in the study by Heinemann [2012].

Test soil	Time point – DASF ¹⁾ [days]	Concentration in % AR of:							
		Flufenacet		FOE Thiadone		FOE 5043-Trifluoroethane-sulfonic acid		Trifluoroacetic acid

	14	17.6	18.7	11.4	11.6	0.7	0.6	52.9	53.6
	20	17.8	13.9	12.5	11.2	< LOD	< LOD	51.4	51.1
	33	10.9	10.3	9.9	7.5	0.7	0.8	51.1	54.2
	62	3.1 ⁴⁾	12.1	15.8 ⁴⁾	7.7	0.7 ⁴⁾	0.7	114.6 ⁴⁾	47.3
	90	4.4	4.5	6.3	4.3	< LOD	< LOD	51.5	54.9
	120	3.1	3.1	2.2	3.2	1.2	1.2	49.8	53.3

Footnotes to the table:

- 1) DASF – Days After Soil Flooding;
- 2) Replicate 1;
- 3) Replicate 2;
- 4) It was indicated in the study report that mass balance in this sample was not achieved, hence the values were not considered in the kinetic analysis.

These values were inserted, after being processed following recommendations given by FOCUS Kinetics Work Group (FOCUS; 2006, 2011), into the kinetic modelling tool – KinGUI 2 developed by Bayer. The assumed transformation pathway is shown below on figure B.8.1.1.2.1.2._CA-2.

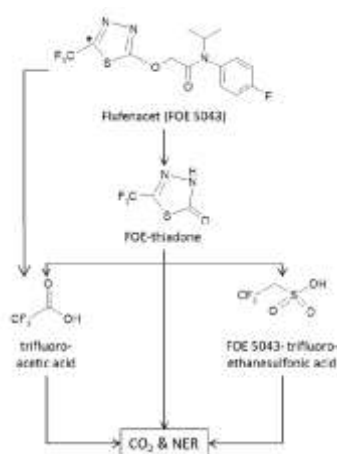

Figure B.8.1.1.2.1.2._CA-2: The assumed transformation pathway of [thiadiazole-5-¹⁴C] Flufenacet in anaerobic soil used in the kinetic examination of the data from the study by Heinemann [2012] (copied from the study's report).

The kinetic analysis of the data presented in the tables B.8.1.1.2.1.2._CA-2 and B.8.1.1.2.1.2._CA-3 consisted of the following three steps:

- **Step 1:** pre-processing of the reported soil residue values;
- **Step 2:** Kinetic evaluation of the pre-processed data using KinGUI 2 kinetic modelling tool;
- **Step 3:** Evaluation of the results of the kinetic analysis performed at **Step 2**, selection of the appropriate kinetic model and persistence kinetic endpoints as well as those recommended for modelling.

The pre-processing of data generally followed the procedure recommended by FOCUS [2006, 2011] for parent and metabolite data. Its initial step was the elimination of the data obtained during aerobic pre-incubation phase, setting the Day 0 of the anaerobic phase as the initial time point and residues measured then as initial concentration.

In case of the results of the study by [Pangilinan and Smith; 1995] the only available results were the averages of the two replicates, so these were used as input values in the kinetic analysis.

In case of the results obtained by [Heinemann; 2012] the values obtained for the individual replicates were available for both test soils. These were used singularly as input data for each time point.

The values were checked for consistency and clear outliers. Whenever lack of consistency or the fact of the data being an outlier was stated, such values were removed from the data set and that was clearly indicated. It concerned in particular one of DASF-62 replicates (Rep. 1) in Dollendorf II soil, where the mass balance was out of a Guideline recovery range of 90 – 110% AR.

Apart from the corrections listed above, the pre-processing of the data followed the procedure outlined below:

- values for day 0 after flooding (DASF-0) were set to measured value;
- values between LOD and LOQ were set to measured values;
- all samples <LOD were set to ½ LOD or after the first non-detect, to zero in case no detects appeared later on.

The pre-processed data used in the kinetic fitting are presented above in two separate tables – Table B.8.1.1.2.1.2._CA-4 for the results of the study by [Pangilinan and Smith; 1995] and B.8.1.1.2.1.2._CA-5 for those obtained by [Heinemann; 2012].

Table B.8.1.1.2.1.2._CA-4: The pre-processed data from the by [Pangilinan and Smith; 1995] used in the kinetic evaluation.

Time point – DASF ¹⁾ [days]	Concentration in % AR of:		
	<i>Flufenacet</i> ²⁾	<i>FOE Oxalate</i> ²⁾	<i>FOE Sulfonic acid</i> ²⁾
0	69.0	11.2	6.6

	62	NaN ⁴⁾	12.1	NaN ⁴⁾	7.7	NaN ⁴⁾	NaN ⁴⁾	NaN ⁴⁾	47.3
	90	4.4	4.5	6.3	4.3	NaN ⁴⁾	NaN ⁴⁾	51.5	54.9
	120	3.1	3.1	2.2	3.2	1.2	1.2	49.8	53.3

Footnotes to the table:

- 1) DASF – Days After Soil Flooding;
- 2) Replicate 1;
- 3) Replicate 2;
- 4) NaN – “Not a Number” – KinGUI default setting when numbers are not available.

The pre-processed data were inserted into the KinGUI ver. 2 modelling tool, developed by Bayer, and kinetically analysed in a sequential procedure consisting of two steps. Firstly the data for parent compound were kinetically examined. Next those for the degradation products were added, and the whole data set kinetically re-examined using the conceptual transformation schemes presented above on figures B.8.1.1.2.1.2._CA-1 (data from [Pangilinan and Smith; 1995]) and B.8.1.1.2.1.2._CA-2 (data from [Heinemann; 2012]). For the parent compound – Flufenacet, all four available kinetic models – SFO, FOMC, DFOP and HS, were tested at first stage. At the next step, after addition of the data for the degradation products, only the model identified as returning the best fit was tested. The data for the degradation products were kinetically examined using solely SFO model. The kinetic fitting was performed using IRLS (Iteratively Reweighted Nonlinear Least Squares) algorithm as optimisation method.

The results of the kinetic analysis were evaluated for their acceptability. The following parameters were evaluated:

- visual acceptability of the fit – examination of coefficient of determination – r^2 , and residual plot;
- statistical acceptability of the fit by means of χ^2 test;
- the significance of the calculated kinetic parameters – t-test.

The 4-step procedure was applied here that followed the recommendations given by FOCUS [2006, 2011].

Results and their discussion:

The results of the kinetic analysis of the data is presented below, separately for each of the test soils used in the examination of the degradation of Flufenacet in soil under anaerobic conditions. The assessment is fully based on the results obtained by the Applicant and presented in the study report.

- 1) Results of the kinetic examination of the data obtained in soil **Howe (Indiana, USA)** for [Phenyl-U-¹⁴C] Flufenacet (study by [Pangilinan and Smith; 1995]):

The results of the kinetic examination of the data are presented below. First are presented the results of the kinetic examination of the data for parent only. The results of the kinetic examination of the data for the parent compound and degradation products are presented further down.

a) Results of the fitting of the data for parent compound only:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.2_CA-6 and in the graphical form on figure B.8.1.1.2.1.2_CA-3. For convenience the results for all kinetic models tested are presented together.

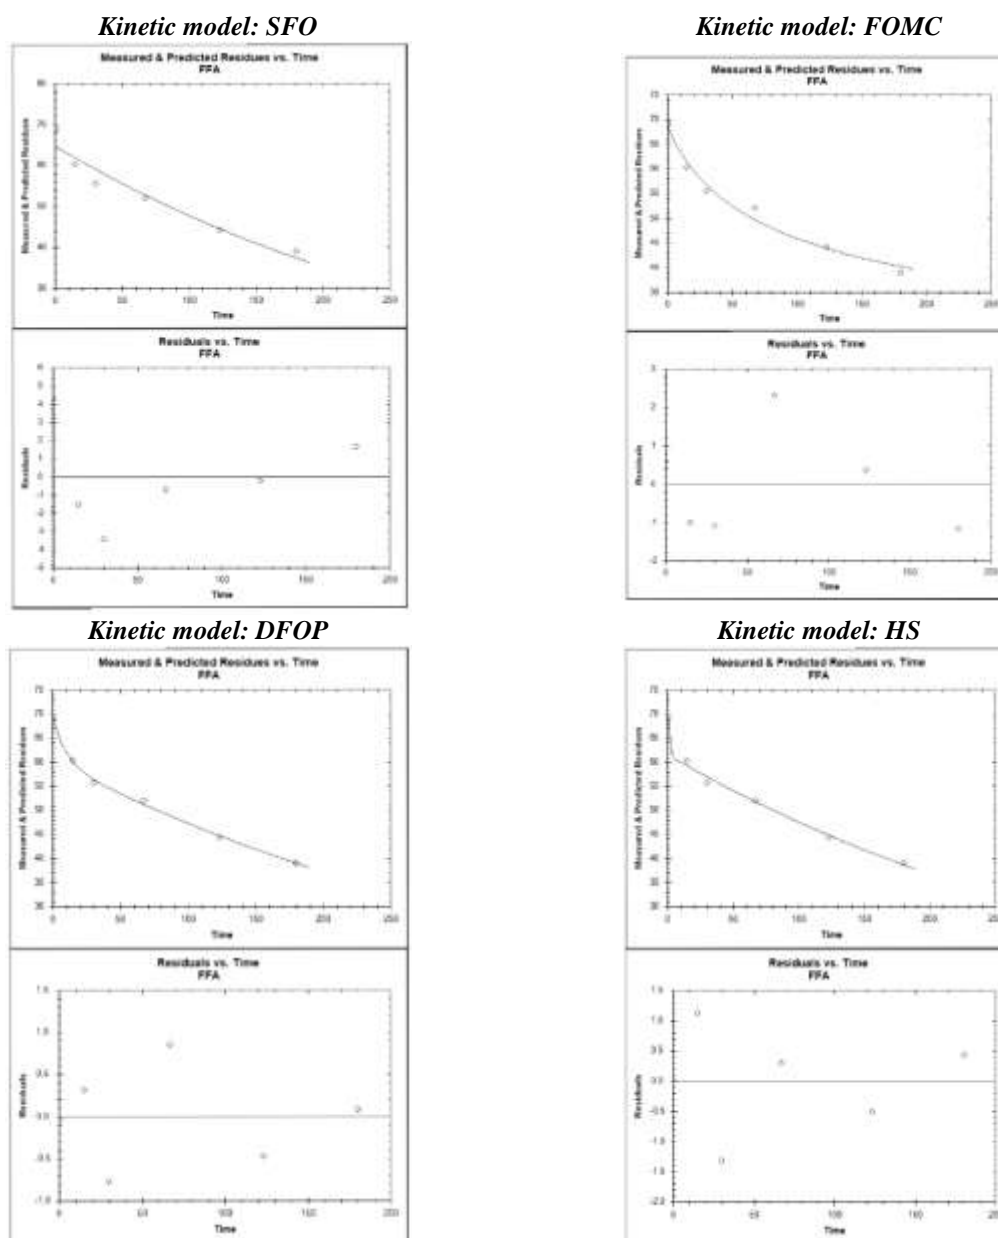

Figure B.8.1.1.2.1.2_CA-3: The graphical results of the kinetic analysis (copied from the study report).

Table B.8.1.1.2.1.2._CA-6: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment ¹⁾
				Lower	Upper

	t _b	3.903	0.9170	2.106	5.701	0.02550		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Also the kinetic endpoints – DT₅₀ and DT₉₀ values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.2._CA-7.

Table B.8.1.1.2.1.2._CA-7: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
Flufenacet	DT ₅₀ [days]	277.00	346.31	229.63	222.90
	DT ₉₀ [days]	754.09	1263.14	895.64	842.93

Evaluation:

On the basis of the obtained results the Applicant proposed to consider SFO and DFOP kinetic fits in the further analysis. That proposal was based on the fact that although SFO fit was visually and statistically acceptable, it returned worse fit than FOMC model. FOMC fit however was visually, but not statistically, acceptable (CI for β contained zero). Both DFOP and HS models returned visually and statistically acceptable fits, that for DFOP being however superior. For that reason the Applicant proposed DFOP fit as returning the best-fit results and as such should be used for deriving trigger endpoints.

RMS having examined the SFO fit stated that the decline curve was not well fitted to the experimental points, especially in its initial phase. Also the residuals were not randomly distributed and their level was higher in comparison to that observed for DFOP fit. For that reason RMS's proposal is to consider DFOP fit, visually acceptable and statistically reliable, suitable for deriving both persistence and modelling endpoints.

b) Results of the fitting of the data for parent compound and degradation products:

As a next step proposed by the Applicant the data for the parent compound were kinetically examined together with those for the degradation products using the best-fit kinetic model identified for the parent compound.

For the experiment on Sandy loam soil (Howe, Indiana, USA) with the [Phenyl-U-¹⁴C]Flufenacet, Applicant tested two options:

- SFO for parent compound (Flufenacet) and SFO for the degradation products to derive modelling endpoints – **Option 1**;
- DFOP for parent compound (Flufenacet) and SFO for the degradation products to obtain the persistence endpoints – **Option 2**.

The results of both fittings are presented below.

Option 1: SFO (Parent) – SFO (Metabolites) fitting:

The results of the fitting are presented below in graphical form on the figure B.8.1.1.2.1.2._CA-4 and in numerical form in the table B.8.1.1.2.1.2._CA-8.

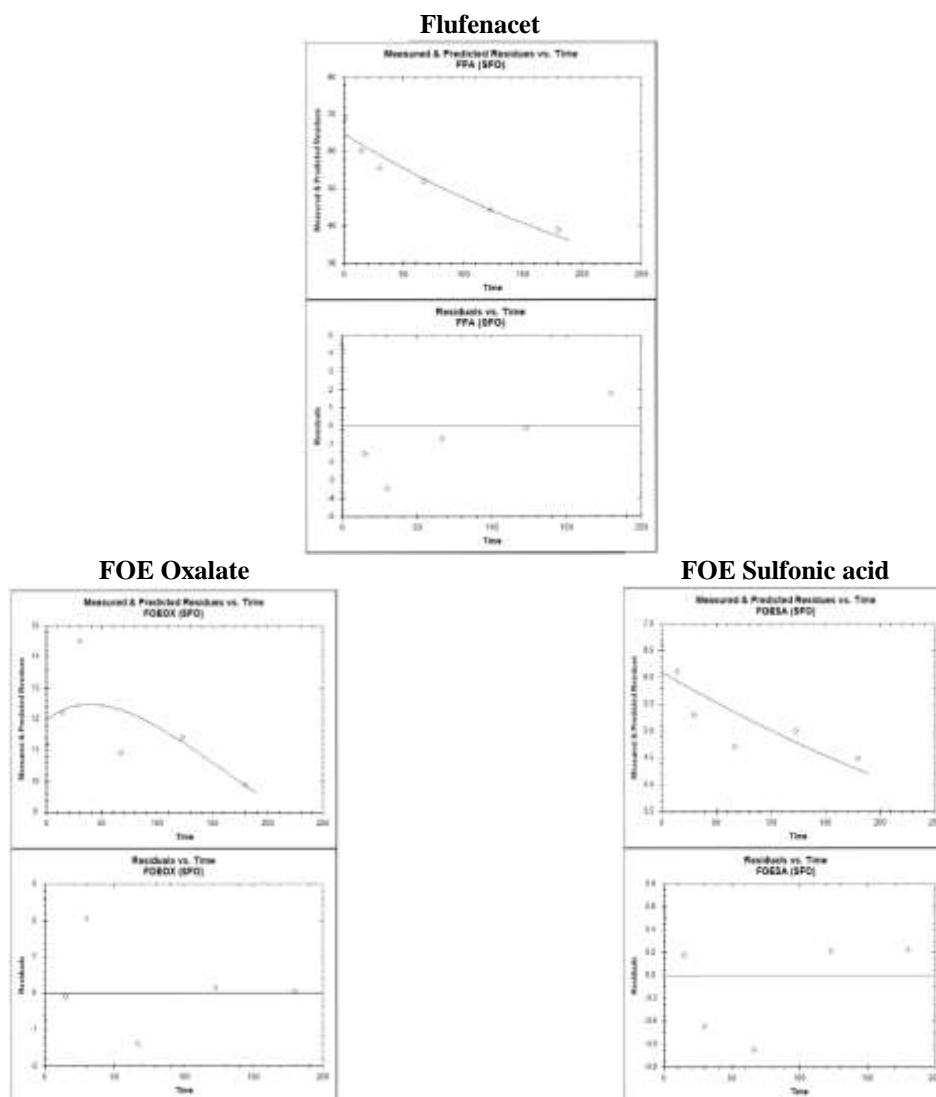

Figure B.8.1.1.2.1.2._CA-4: The graphical results of the kinetic fitting of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid using SFO for Flufenacet (copied from the study report).

Table B.8.1.1.2.1.2_CA-9: The numerical results of the kinetic fitting of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid using SFO for Flufenacet.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	Visual assessment ¹⁾
					Lower	Upper			
Flufenacet	SFO	M_0	64.78	2.13	60.61	68.96	1.71 E-11	3.65	Acceptable fit

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant;
- 2) Value not reported, not calculated by the modelling tool.

Evaluation:

The combination SFO-SFO did not return fully reliable kinetic endpoints for parent compound and its degradation products. The addition of the data for FOE Oxalate and FOE Sulfonic acid did not significantly influence the results of the fitting for the parent compound. The results of the fitting for both degradation products showed that neither for FOE Oxalate nor FOE Sulfonic acid the acceptable kinetic fit can be found. The Applicant indicated that the fit for FOE Oxalate was poor, but the fit for FOE Sulfonic acid was considered acceptable. RMS however is of the opinion that both fits are poor and as such cannot be used to derive the reliable kinetic endpoints. The distribution of the experimental points suggests that, at least for FOE Sulfonic acid the sound fit may be found, probably using the kinetic model other than SFO, when the fitting is performed applying the top-down approach. Similar solution may be applicable to FOE Oxalate.

RMS also decided not to present the kinetic endpoints resulting from that fitting.

Option 2: DFOP (Parent) – SFO (Metabolites) fitting:

The results of the fitting are presented below in graphical form on the figure B.8.1.1.2.1.2._CA-5 and in numerical form in the table B.8.1.1.2.1.2._CA-10.

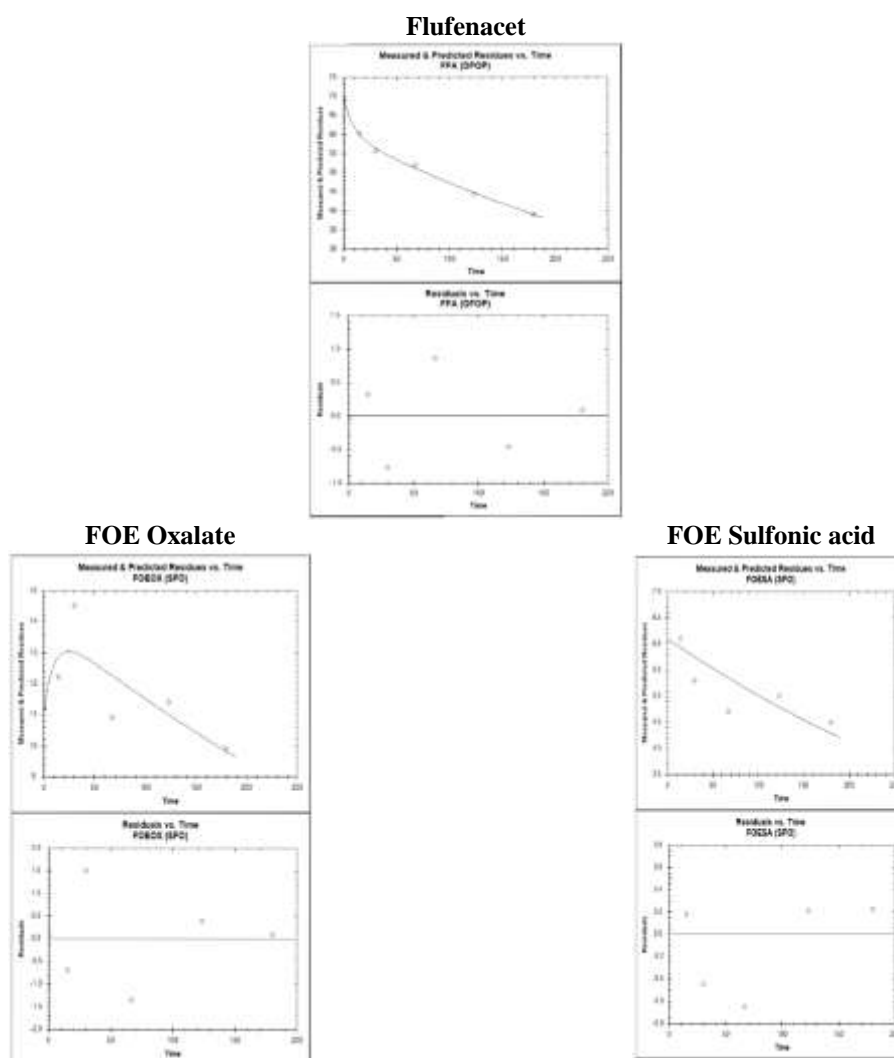

Figure B.8.1.1.2.1.2._CA-5: The graphical results of the kinetic fitting of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid using DFOP for Flufenacet (copied from the study report).

Table B.8.1.1.2.1.2_CA-10: The numerical results of the kinetic fitting of the data for Flufenacet, FOE Oxalate and FOE Acetic acid using SFO for Flufenacet.

		ff	5.03 E-8	0.161	----	----	----		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant;

Evaluation:

The DFOP model returned superior fit for Flufenacet in comparison to that obtained with SFO also when the data for the degradation products were added. That conforms the conclusion drawn by the RMS during the evaluation of the fitting results for parent alone. For the degradation products the results of the kinetic fitting cannot be considered reliable. Although some improvement was observed, especially for FOE Oxalate, the fits cannot be considered acceptable – in RMS's opinion the results of their visual assessment show that they poorly represent the distribution of the data points.

However, as it has been already stated when the SFO-SFO fitting option was evaluated, the distribution of the experimental points suggests that, at least for FOE Sulfonic acid the sound fit may be found, probably using the kinetic model other than SFO, when the fitting is performed applying the top-down approach. Similar solution may be applicable to FOE Oxalate.

RMS also decided not to present the kinetic endpoints resulting from that fitting. That is due to the fact that for parent compound these do not significantly differ from the results obtained for the parent fitted alone using DFOP kinetic model, whereas the kinetic endpoints for both degradation products cannot be considered fully reliable.

Additionally RMS performed the additional kinetic analysis of the data obtained for FOE Oxalate and FOE Sulfonic acid using the top-down approach. This was done using CAKE ver. 3.1 modelling tool, developed by Tessella Inc., separately for each degradation product. To maintain the consistency with the kinetic analysis performed by the Applicant, the kinetic fitting was performed using IRLS (Iteratively Reweighted Nonlinear Least Squares) algorithm as optimisation method. The input data used in the repeated kinetic examination are presented below, in the table B.8.1.1.2.1.2_CA-11.

Table B.8.1.1.2.1.2_CA-11: The input data used in the repeated kinetic examination performed for FOE Oxalate and FOE Sulfonic acid using the top-down approach.

Data for FOE Oxalate:		Data for FOE Sulfonic acid:	
Time point	Concentration of the compound	Time point	Concentration of the compound
DASF [days]	[% AR]	DASF [days]	[% AR]
30	14.5	0	6.6
67	10.9	15	6.1
123	11.4	30	5.3
180	9.9	67	4.7
		123	5.0
		180	4.5

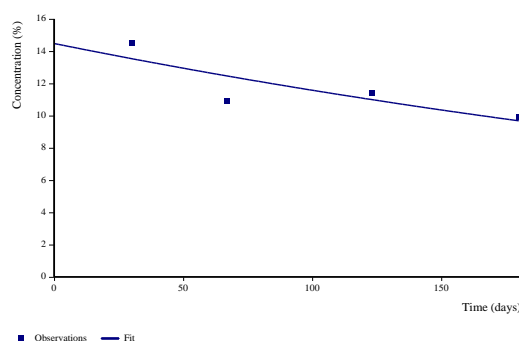

The preliminary analysis of the data showed that for FOE Oxalate, due to the limited number of data points (only four), it was possible to perform the kinetic analysis using solely SFO kinetic model. In case of FOE Sulfonic acid the number of data points was sufficient to perform the kinetic analysis using all four kinetic models. The results of the kinetic fitting are presented below.

The results of the kinetic fitting of the data for FOE Oxalate:

The results of the fitting are presented below in graphical form on the figure B.8.1.1.2.1.2._CA-6 and in numerical form in the table B.8.1.1.2.1.2._CA-12.

FOE Oxalate – SFO model

Observations and Fitted Model:

Residuals:

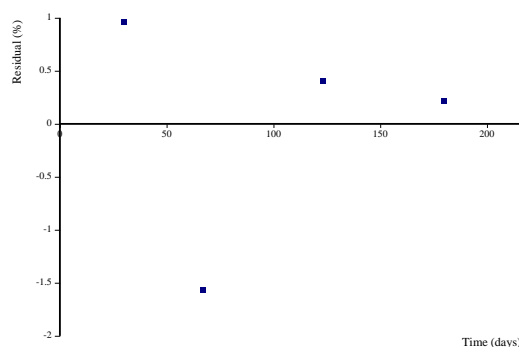

Figure B.8.1.1.2.1.2._CA-6: The graphical results of the kinetic fitting of the data for FOE Oxalate using SFO kinetic model.

Table B.8.1.1.2.1.2._CA-12: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	14.48	1.55	7.82	21.13	n. c. ¹⁾	6.62	0.697 Intermediate fit
	k	0.002233	0.001049	-0.002282	0.007	0.08359		

Footnotes to the table:

1) Value not calculated by the modelling tool.

The kinetic endpoints calculated by the model are following: $DT_{50} = 310$ days, $DT_{90} = 1030$ days.

Evaluation:

The results of the kinetic re-evaluation of the data for FOE Oxalate using the top-down approach showed that no significant improvement of the kinetic fit, in comparison to the results obtained by the Applicant, was achieved. The fit, although statistically acceptable, is only intermediate according to the results of its visual assessment. It was also noticed that the calculated degradation rate constant is not fully reliable – the *Prob. > t* is higher than the recommended highest value 0.05, but lower than 0.1. Therefore the calculated kinetic endpoints – DT_{50} and DT_{90} values may be considered only as indicative with regard to the persistence of FOE Oxalate in anaerobic soil.

The results of the kinetic fitting of the data for FOE Sulfonic acid:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.2._CA-13 and in the graphical form on figure B.8.1.1.2.1.2_CA-7. For convenience the results for all kinetic models tested are presented together.

	t_b	47.58	14.27	-13.8	109.0	n. c. ¹⁾		

Footnotes to the table:

1) Value not calculated by the modelling tool.

Evaluation:

The results of the kinetic re-evaluation of the data show that the reliable fit was obtained only with SFO kinetic model. That fit, although only intermediate, as demonstrated the results of its visual inspection, was both visually and statistically acceptable. Also the calculated kinetic parameter – the rate constant k was reliable, as demonstrated the results of the t-test.

All tested bi-phasic models – FOMC, DFOP and HS, returned fits superior to that obtained with SFO, both visually and statistically, but none of them returned fully reliable kinetic parameters.

As a result, SFO model should be considered as returning the best fit and hence the determined with it kinetic endpoints – **DT₅₀ = 352 days** and **DT₉₀ = 1170 days** as representative for the determining of the persistence of that compound in anaerobic soil. However, as it has been stated for FOE Oxalate, because of the deficiencies displayed by the fit, the results should be considered as indicative.

Conclusions:

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Oxalate and FOE Sulfonic acid, obtained for Sandy loam (Howe) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic sandy loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling. That conclusion is drawn by the RMS and is different from the Applicant's proposal – to consider the SFO kinetic model as a source of the kinetic endpoints appropriate for modelling. That conclusion is based on the fact that DFOP fit was superior to SFO both when the fitting was performed for the parent compound alone and for the parent and degradation products.
- It was not possible to obtain the reliable kinetic fit for either of the degradation products – FOE Oxalate and FOE Sulfonic acid kinetically examined together with parent. Slightly better results were obtained when the data for these two compounds were fitted alone using the top-down approach. In both cases SFO was identified as returning visually and statistically reliable fits with reliable parameters. RMS however is of the opinion that the kinetic endpoints derived from those fits should be considered indicative with regard to the persistence of both compounds in anaerobic sandy loam soil and cannot be further used to derive any modelling endpoints. It shall be also noted that it was not possible to derive reliable kinetic formation fractions for either FOE Oxalate or FOE Sulfonic acid.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: DT₅₀ = 229.63 days, DT₉₀ = 895.64 days, DFOP model ($k_1 = 0.9976 \text{ days}^{-1}$, $k_2 = 2.416 \text{ E-3 days}^{-1}$, $g = 0.1291$);
- Flufenacet, modelling endpoints not normalised: $k = 2.416 \text{ E-3 [days}^{-1}]$, DT₅₀ = 286.90 days, DT₉₀ = 953.06 days, SFO (slow phase DFOP);
- Flufenacet, modelling endpoints normalized for temperature: $k = 2.205 \text{ E-3 [days}^{-1}]$, DT₅₀ = 314.35 days, DT₉₀ = 1044.26 days, SFO (slow phase DFOP);

-
- FOE Oxalate, persistence endpoints (indicative): $DT_{50} = 310$ days, $DT_{90} = 1030$ days, SFO model – top-down approach ($k = 0.002233 \text{ days}^{-1}$);
 - FOE Sulfonic acid, persistence endpoints (indicative): $DT_{50} = 352$ days, $DT_{90} = 1170$ days, SFO model – top-down approach ($k_I = 0.001986 \text{ days}^{-1}$).

- 2) Results of the kinetic examination of the data obtained in soil **Hoefchen am Hohenseh 4a (Germany)** for [Thiadiazole-5-¹⁴C] Flufenacet (study by [Heinemann; 2012]):

The results of the kinetic examination of the data are presented below. First are presented the results of the kinetic examination of the data for parent only. The results of the kinetic examination of the data for the parent compound and degradation products are presented further down.

- a) Results of the fitting of the data for parent compound only:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.2_CA-14 and in the graphical form on figure B.8.1.1.2.1.2_CA-8. For convenience the results for all kinetic models tested are presented together.

	t _b	12.87	1.707	9.527	16.220	1.36 E-6		

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Also the kinetic endpoints – DT₅₀ and DT₉₀ values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.2._CA-15.

Table B.8.1.1.2.1.2._CA-15: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
Flufenacet	DT ₅₀ [days]	34.23	22.73	22.67	25.15
	DT ₉₀ [days]	113.69	262.22	160.72	148.67

Evaluation:

On the basis of the obtained results the Applicant stated that the SFO model returned statistically acceptable and reliable with regard to kinetic parameters, but visually poor fit. All tested bi-phasic models returned fits superior to SFO, both visually and statistically. In addition the kinetic parameters determined using those models were fully reliable.

Further analysis of the bi-phasic models showed that DFOP returned the best fit. Therefore the Applicant proposed to use that model for parent in kinetic examination the data set for Flufenacet and its degradation products. RMS accepted that proposal, noticing at the same time that the decline curve obtained with SFO model was rather well fitted to the experimental data, and the only problem were high and not randomly distributed residuals, the probable reason for qualifying the fit as poor by the Applicant.

b) Results of the fitting of the data for parent compound and degradation products:

As a next step proposed by the Applicant the data for the parent compound were kinetically examined together with those for the degradation products using the best-fit kinetic model identified for the parent compound.

The results of the fitting are presented below in graphical form on the figure B.8.1.1.2.1.2._CA-9 and in numerical form in the table B.8.1.1.2.1.2._CA-16.

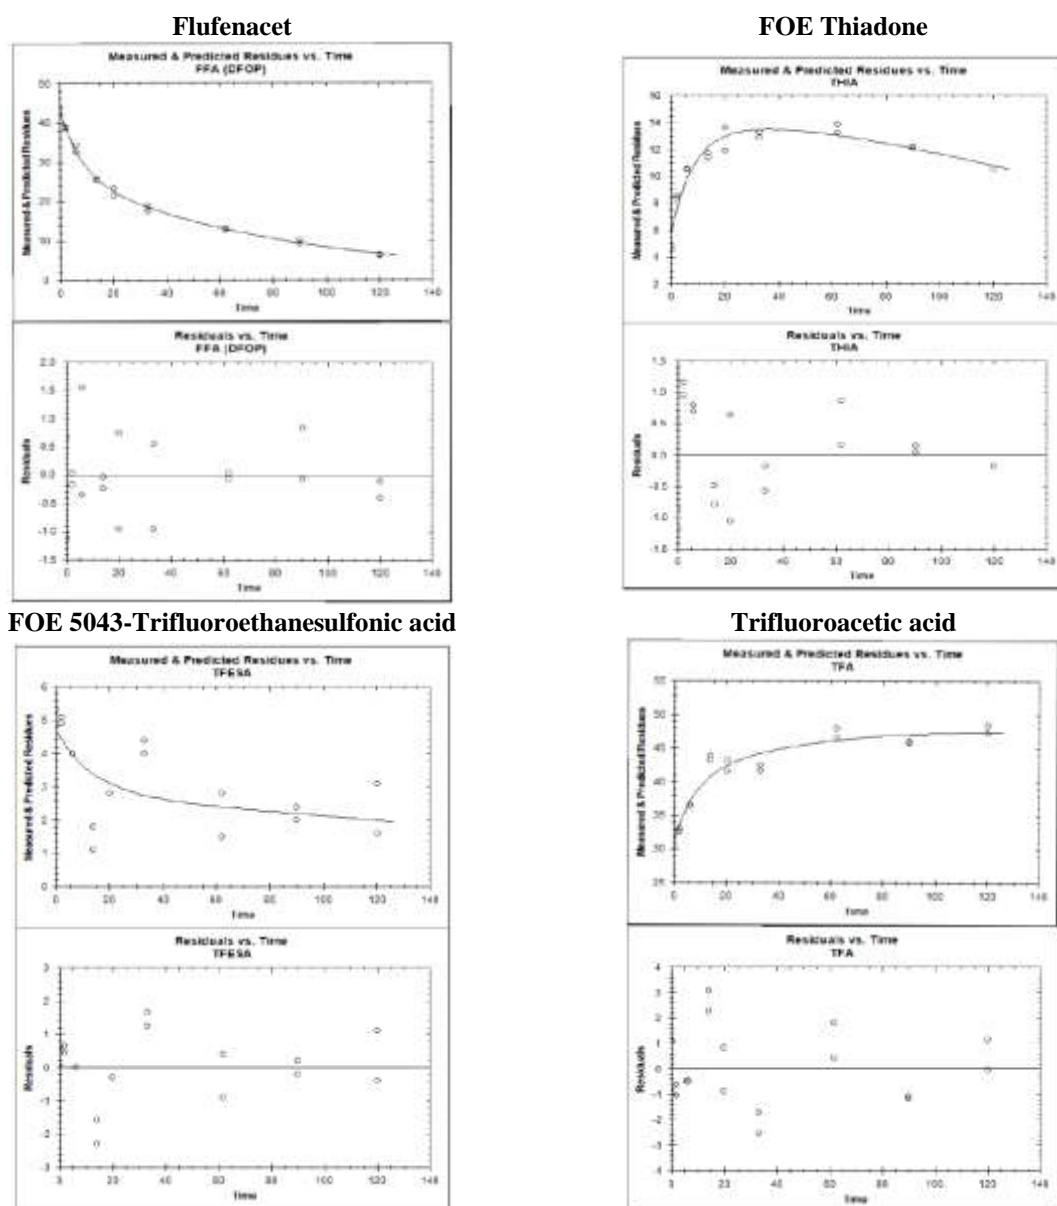

Figure B.8.1.1.2.1.2._CA-9: The graphical results of the kinetic fitting of the data for Flufenacet, FOE Thiadone, FOE 5043-Trifluoroethanesulfonic acid and Trifluoroacetic acid (copied from the study report).

- 6) Formed from FOE Thiadone.

Evaluation:

The fitting of the data for the parent compound together with those for the degradation products using the combination DFOP (parent) – SFO (metabolites) resulted in some statistical worsening of the fit for Flufenacet in comparison to the situation when this compound was fitted alone using DFOP model. It shall be pointed out however that this worsening was minimal. Applicant stated that visually and statistically good fits were obtained for FOE Thiadone and Trifluoroacetic acid, while that for FOE 5043-Trifluoroethanesulfonic acid was poor both visually and statistically.

RMS noted that there were the discrepancies in the results of the fitting reported in the main text of the study report and those presented in appendices, generated by the modelling tool. Therefore the whole assessment is based on the results presented in the source KinGUI report.

In RMS's opinion the results of the fitting show that it was possible to obtain the robust fit for Flufenacet and FOE Thiadone. For both compounds the determined kinetic parameters are reliable.

In case of Trifluoroacetic acid the obtained fit is visually and statistically acceptable, but the determined rate constant *k* is not reliable, according to the results of the t-test. That may be due to the fact that the decline phase was not achieved and it is even doubtful, from the distribution of the experimental points, that the maximum concentration was reached. As a result the kinetic endpoints – DT₅₀ and DT₉₀ values calculated by the modelling tool, bear a significant level of uncertainty. Therefore the RMS would like to propose to use, instead of the values calculated by the modelling tool, the default values – DT₅₀ = 1000 days and DT₉₀ > 1000 days.

In case of the third degradation product, for which the kinetic assessment was performed – FOE-5043 Trifluoroethanesulfonic acid, it was not possible to obtain acceptable kinetic fit and hence reliable kinetic parameters. That may be due to the fact that the concentrations of that compound recorded in the test system (soil and overlying it water) during anaerobic incubation phase were very low and scattered. That in turn may indicate that in anaerobic soil FOE-5043 Trifluoroethanesulfonic acid is a transient, rapidly degrading compound.

Conclusions:

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid, obtained for Silt loam (Hoefchen am Hohenseh 4 a) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic Silt loam soil;

- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling.
- It was possible to obtain reliable kinetic fit and kinetic endpoints for FOE Thiadone;
- Although it was possible to obtain reliable kinetic fit for Trifluoroacetic acid, the reliable kinetic parameters describing degradation of that compound could not be derived due to the fact that the decline phase was not reached. Therefore RMS proposed to use the default DT_{50} and DT_{90} values instead of those calculated by the model;
- It was not possible to obtain the reliable kinetic fit for FOE 5043-Trifluoroethanesulfonic acid, therefore for that compound no reliable kinetic endpoints are available. RMS attributed that to the low concentrations of the compound recorded in the test system and their significant scattering, what may indicate that the compound of concern is transient and rapidly degrades in anaerobic silt loam soil.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 22.66$ days, $DT_{90} = 156.90$ days, DFOP model ($k_1 = 0.1214$ days⁻¹, $k_2 = 0.01162$ days⁻¹, $g = 0.3810$);
- Flufenacet, modelling endpoints: $k = 0.01162$ [days⁻¹], $DT_{50} = 59.65$ days, $DT_{90} = 198.16$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
- FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 97.04$ days, $DT_{90} = 322.30$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
- Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
- FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.

- 3) Results of the kinetic examination of the data obtained in soil **Dollendorf II (Germany)** for [Thiadiazole-5-¹⁴C] Flufenacet (study by [Heinemann; 2012]):

The results of the kinetic examination of the data are presented below. First are presented the results of the kinetic examination of the data for parent only. The results of the kinetic examination of the data for the parent compound and degradation products are presented further down.

- Results of the fitting of the data for parent compound only:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.2_CA-17 and in the graphical form on figure B.8.1.1.2.1.2_CA-10. For convenience the results for all kinetic models tested are presented together.

Footnotes to the table:

1) Visual assessment of the kinetic curve as proposed by the Applicant.

Also the kinetic endpoints – DT₅₀ and DT₉₀ values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.2._CA-18.

Table B.8.1.1.2.1.2._CA-18: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
Flufenacet	DT ₅₀ [days]	23.83	14.91	14.98	15.44
	DT ₉₀ [days]	79.16	194.86	111.05	115.22

Evaluation:

On the basis of the obtained results the Applicant stated that the SFO model did not return the fit statistically and visually acceptable. All tested bi-phasic models returned fits superior to SFO, both visually and statistically. However FOMC fit returned kinetic parameters that were not reliable – the CI for β passed through zero. DFOP and HS returned fits visually and statistically acceptable with reliable kinetic parameters. It was stated that DFOP was better than HS - χ^2 error was lower as well as residuals. It was determined that the distribution of residuals was very alike for both kinetic models. As a result Applicant indicated DFOP as returning the best fit for the parent and that model was used for kinetic fitting the of the data for parent when they were kinetically examined with those for the degradation products.

RMS accepted that proposal, on the basis of the overall weight of evidence, although it was noticed that the reliability of k₁ in DFOP model was rising some concerns.

- Results of the fitting of the data for parent compound and degradation products:

As a next step proposed by the Applicant the data for the parent compound were kinetically examined together with those for the degradation products using the best-fit kinetic model identified for the parent compound.

The results of the fitting are presented below in graphical form on the figure B.8.1.1.2.1.2._CA-11 and in numerical form in the table B.8.1.1.2.1.2._CA-19.

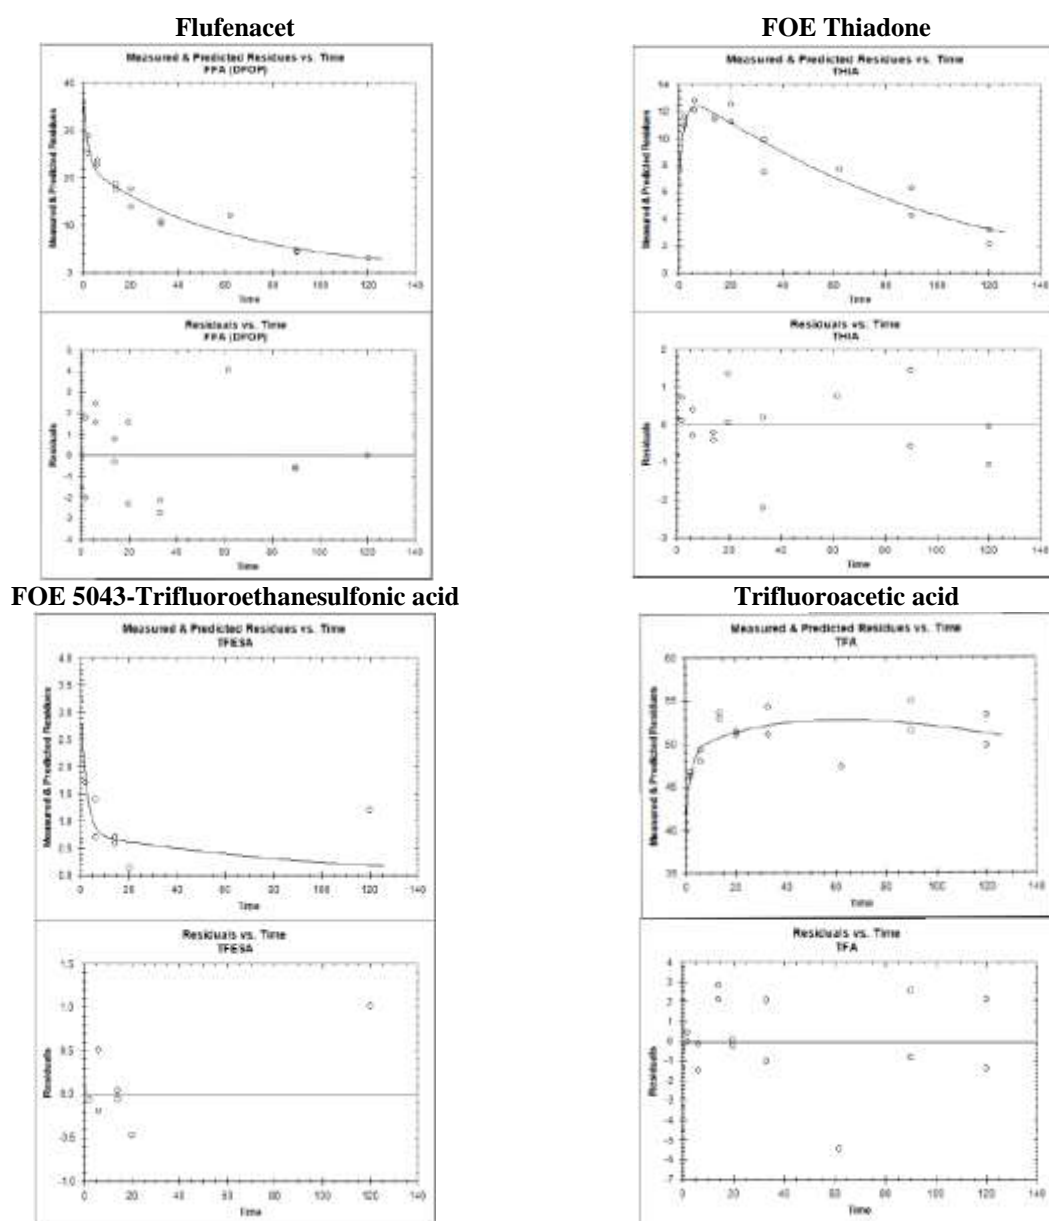

Figure B.8.1.1.2.1.2. CA-11: The graphical results of the kinetic fitting of the data for Flufenacet, FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid (copied from the study report).

Table B.8.1.1.2.1.2_CA-19: The numerical results of the kinetic fitting of the data for Flufenacet, FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid.

Footnotes to the table:

- 1) Visual assessment of the kinetic curve as proposed by the Applicant;
- 2) Not calculated by the modelling tool;
- 3) Formed from Flufenacet;
- 4) Formed from FOE Thiadone;
- 5) Formed from Flufenacet;
- 6) Formed from FOE Thiadone.

Evaluation:

The fitting of the data for the parent compound together with those for the degradation products using the combination DFOP (parent) – SFO (metabolites) resulted in some improvement of the fit for Flufenacet, especially in the area of the reliability of kinetic parameters derived (namely k_1). shall be pointed out however that this worsening was minimal. Applicant stated that visually and statistically good fits was obtained for FOE Thiadone. That for Trifluoroacetic acid was visually and statistically acceptable, while that for FOE 5043-Trifluoroethanesulfonic acid was visually, but not statistically, acceptable.

RMS noted that there were the discrepancies in the results of the fitting reported in the main text of the study report and those presented in appendices presenting the report generated by the modelling tool. Therefore the whole assessment is based on the results presented in the source KinGUI report.

In RMS's opinion the results of the fitting show that it was possible to obtain the robust fit for Flufenacet and FOE Thiadone. For both compounds the determined kinetic parameters are reliable.

In case of Trifluoroacetic acid the obtained fit is visually and statistically acceptable, but the determined rate constant k is not reliable, according to the results of the t-test. That may be due to the fact that although the maximum and subsequent decline phase was reached, it was very flat, indicating that the degradation may take longer than estimated by the modelling tool. Therefore the kinetic endpoints – DT₅₀ and DT₉₀ values calculated by the modelling tool bear a significant level of uncertainty. As a result the RMS would like to propose to use, instead of the values calculated by the modelling tool, the default values – DT₅₀ = 1000 days and DT₉₀ > 1000 days.

In case of the third degradation product, for which the kinetic assessment was performed – FOE-5043 Trifluoroethanesulfonic acid, it was not possible to obtain statistically acceptable kinetic fit and hence reliable kinetic parameters. That may be due to the fact that the concentrations of that compound recorded in the test system (soil and overlying it water) during anaerobic incubation phase were very low. That in turn may indicate that FOE-5043 Trifluoroethanesulfonic acid is a transient, rapidly degrading compound.

Conclusions:

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid, obtained for Loam (Dollendorf II) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic Silt loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling.
- It was possible to obtain reliable kinetic fit and kinetic endpoints for FOE Thiadone;
- Although it was possible to obtain reliable kinetic fit for Trifluoroacetic acid, the reliable kinetic parameters describing degradation of that compound could not be derived due to the fact that the well pronounced decline phase was not reached. Therefore RMS proposed to use the default DT_{50} and DT_{90} values instead of those calculated by the model;
- It was not possible to obtain the reliable kinetic fit for FOE 5043-Trifluoroethanesulfonic acid, therefore for that compound no reliable kinetic endpoints are available. RMS attributed that to the low concentrations of the compound recorded in the test system and their significant scattering, what may indicate that the compound of concern is transient and rapidly degrades in anaerobic silt loam soil.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 13.51$ days, $DT_{90} = 110.02$ days, DFOP model ($k_1 = 0.4756$ days⁻¹, $k_2 = 0.0167$ days⁻¹, $g = 0.3745$);
- Flufenacet, modelling endpoints not normalised: $k = 0.0167$ [days⁻¹], $DT_{50} = 41.51$ days, $DT_{90} = 137.88$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
- FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 33.90$ days, $DT_{90} = 112.60$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
- Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
- FOE-5043 Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.

Final conclusion of the study:

The determination of the kinetic parameters of the process of degradation of Flufenacet in anaerobic soil was performed for the results obtained in two studies, on three soils using the test compound radiolabelled in two different positions:

- uniformly in phenyl ring (one test soil);
- in C5 position of thiadiazole moiety (two test soils).

The key results are presented below, individually for each test soil.

- a) The key results obtained for Sandy loam (Howe) soil treated with [Phenyl-¹⁴C]Flufenacet (study by [Pangilinan and Smith; 1995]):

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 229.63$ days, $DT_{90} = 895.64$ days, DFOP model ($k_1 = 0.9976$ days⁻¹, $k_2 = 2.416 \text{ E-}3$ days⁻¹, $g = 0.1291$);
- Flufenacet, modelling endpoints not normalised: $k = 2.416 \text{ E-}3$ [days⁻¹], $DT_{50} = 286.90$ days, $DT_{90} = 953.06$ days, SFO (slow phase DFOP);
- Flufenacet, modelling endpoints normalized for temperature: $k = 2.205 \text{ E-}3$ [days⁻¹], $DT_{50} = 314.35$ days, $DT_{90} = 1044.26$ days, SFO (slow phase DFOP);
- FOE Oxalate, persistence endpoints (indicative): $DT_{50} = 311$ days, $DT_{90} = 1030$ days, SFO model – top-down approach ($k = 0.002233$ days⁻¹);
- FOE Sulfonic acid, persistence endpoints (indicative): $DT_{50} = 352$ days, $DT_{90} = 1170$ days, SFO model – top-down approach ($k_1 = 0.001986$ days⁻¹).

- b) The key results obtained for Silt loam (Hoefchen am Hohenseh 4a) soil treated with [Thiadiazole-5-¹⁴C] Flufenacet (study by [Heinemann; 2012]):

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 22.66$ days, $DT_{90} = 156.90$ days, DFOP model ($k_1 = 0.1214$ days⁻¹, $k_2 = 0.01162$ days⁻¹, $g = 0.3810$);

- Flufenacet, modelling endpoints: $k = 0.01162$ [days⁻¹], $DT_{50} = 59.65$ days, $DT_{90} = 198.16$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
 - FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 97.04$ days, $DT_{90} = 322.30$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
 - Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
 - FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.
- c) The key results obtained for Loam (Dollendorf II) soil treated with [Thiadiazole-5-¹⁴C]Flufenacet (study by [Heinemann; 2012]):

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 13.51$ days, $DT_{90} = 110.02$ days, DFOP model ($k_1 = 0.4756$ days⁻¹, $k_2 = 0.0167$ days⁻¹, $g = 0.3745$);
- Flufenacet, modelling endpoints not normalised: $k = 0.0167$ [days⁻¹], $DT_{50} = 41.51$ days, $DT_{90} = 137.88$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
- FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 33.90$ days, $DT_{90} = 112.60$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
- Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
- FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.

These results are also presented below in format recommended currently for EU List of End Points

Rate of degradation in soil (anaerobic) laboratory studies active substance (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.2.1.3 and Regulation (EU) N° 284/2013, Annex Part A, point 9.1.1.1)

Additionally the results of the determination of the rate of degradation of Flufenacet in anaerobic soils incubated under controlled (laboratory) conditions were provided by two literature studies, summarised under the point B.8.1.1.2.1.1. as **Study 27** and **Study 28**. Below, in the table B.8.1.1.2.1.2._CA-20 are given the key results obtained in these two studies. As already indicated, these results may be considered only as indicative and were not used to derive the regulatory endpoints.

Table B.8.1.1.2.1.2._CA-20: The key results of the relevant publications examining the rate of degradation of Flufenacet in anaerobic (submerged) soils.

B.8.1.1.2.1.3. – Soil photolysis

Two studies were submitted examining the issue of phototransformation of Flufenacet on the soil surface. One of them was aimed on the determination of route and rate of soil photolysis of Flufenacet, the other examined the phototransformation on the soil surface of FOE Thiadone – the degradation product of Flufenacet. Both studies were summarized, as **Study 1** and **Study 2** respectively, under the point B.8.1.1.1.3. of this Renewal Assessment Report. The summaries contain also the key results of the kinetic analysis of the results, performed by the RMS in line with the recommendations of FOCUS Kinetics Guidance Document (FOCUS 2006). The kinetic analysis was repeated because that presented in the study reports did not comply with the current standards set by the Guidance Document referred to above. The detailed kinetic analysis of the results is presented below, separately for each study.

Study 1 examined the photodegradation of Flufenacet, radiolabelled uniformly within the phenyl ring, on one soil. The detailed results of the kinetic evaluation of its results are presented below.

Study 1:

Report: Kasper A. M., Shadrick B. A., (1995): “Photolysis of [Phenyl- ^{14}C] FOE 5043 on Sandy Loam.”; Bayer Corporation (formerly Miles Inc.), Agriculture Division, P. O. Box 4913, Kansas City, Missouri 64120-0013, USA; study No. F3082101/F3082102 (Bayer); unpublished Miles Report No. MR 106247; 22 June 1995; study reference number: M-002145-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-3, Soil Photolysis Study.

GLP: Yes

RMS comments: The study, submitted already for the purpose of the first authorisation in the EU, was re-evaluated for the purpose of the current assessment and found acceptable for its part related to the determination of the route of degradation of Flufenacet on the soil surface when exposed to sunlight. It is summarised under the point B.8.1.1.1.3. of this Renewal Assessment Report. However, in its part dealing with rate of degradation it was stated not compliant with the provisions of the current Guidelines, namely FOCUS Kinetics Guidance document. For that reason RMS repeated the kinetic assessment of the data, the results of which are presented in the summary below.

Summary:

The aim of the study was to examine photodegradation of Flufenacet on soil surface through:

- a. determining the half-life of that compound when exposed to artificial sunlight;
- b. identifying the transformation pattern, and in particular the degradation products formed in amounts greater than 10% AR.

The analysis of the kinetic assessment of the results presented in the study report showed that:

- it was performed using linear regression method, not recommended any more by the current guidelines;
- no statistical evaluation of the fit, as recommended by FOCUS Kinetics, was provided, the only statistical parameter being correlation coefficient r ; RMS noticed that it was due to the fact that the kinetic analysis of the data, as well as a whole study, pre-dated the introduction of FOCUS Kinetics;
- for both irradiated samples and dark control samples fitting was performed using the Natural Sunlight Days as time points; the approach may be justified in case of irradiated samples as it relates the results to would-be exposure of the test compound to the sunlight on the soil surface for well defined conditions, but it is not for dark control samples, because it artificially overestimate the kinetic parameters – k , DT_{50} and DT_{90} values.

All that taken into account RMS decided to repeat the kinetic analysis. It was performed following recommendations given by FOCUS Kinetics Workgroup (FOCUS; 2006), using the KinGUI 1.1 tool developed by Bayer CropScience.

The input data used in the evaluation are presented below in the table B.8.1.1.2.1.3._CA-1. In case of irradiated samples the analysis was performed twice – firstly using the real time points from the study – Suntest

days, then using converted time points – Natural Sunlight Days. For the dark control samples the kinetic analysis was performed using solely the real time points from the study – Suntest days, for the reason given above.

Table B.8.1.1.2.1.3._CA-1: The input data used in the kinetic analysis

Irradiated sample			Dark control sample	
Time point [days]		Concentration of Flufenacet [% AR]	Time point [days]	Concentration of Flufenacet [% AR]
Suntest days (real time point)	Natural Sunlight Days (converted time point)		Suntest days (real time point)	
0.00	0.0	98.4	0.00	98.4

The results of the kinetic analysis are presented below.

- a) results of the kinetic analysis of the data for irradiated sample and real time points:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.3._CA-2 and in the graphical form on figure B.8.1.1.2.1.3_CA-1. For convenience the results for all kinetic models tested are presented together.

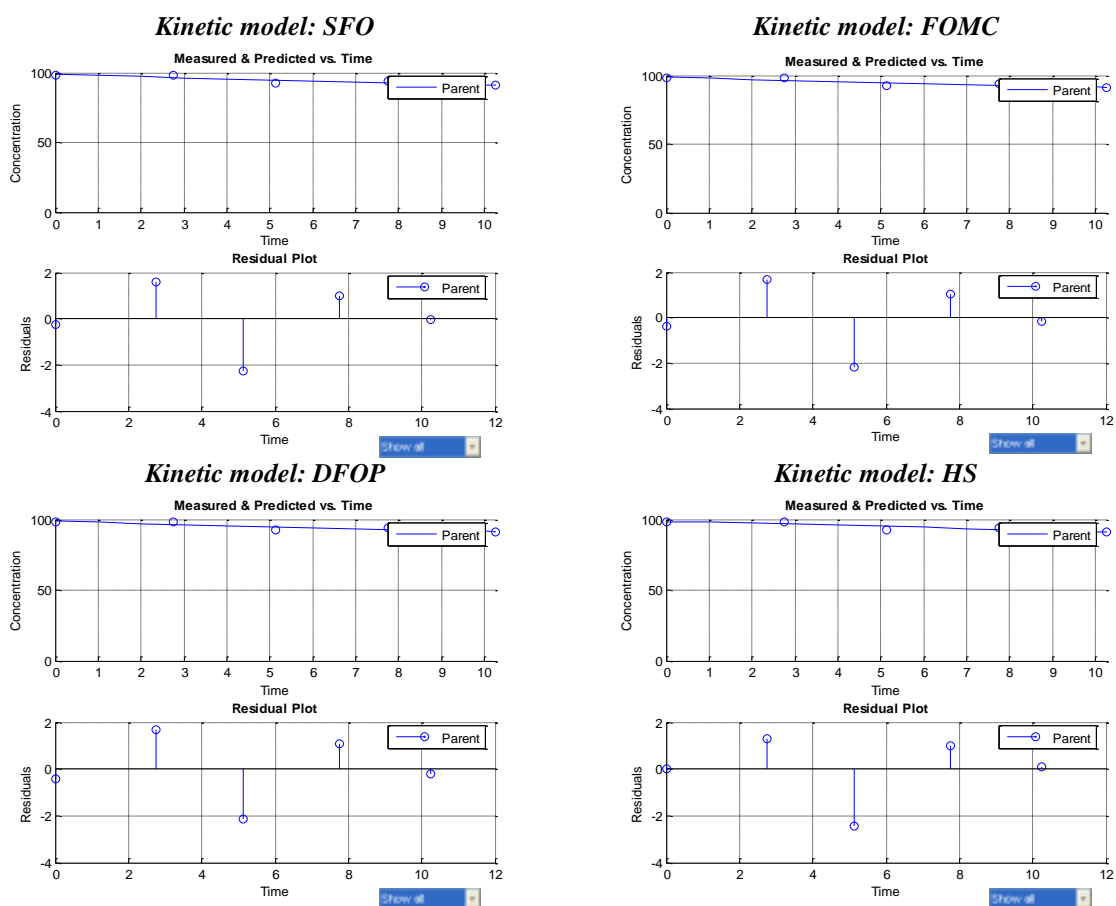

Figure B.8.1.1.2.1.3._CA-1: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.3._CA-2: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2
				Lower	Upper			
SFO	M_0	98.670	1.355	94.359	102.982	----	1.116	0.796
	k	0.0076	0.0022	5.3 E-4	0.0148	0.0209

	α	0.3032	2.7929	-11.7138	12.3201	0.4617		
	β	34.7810	362.7821	<-1000	>1000	0.4662		
DFOP	M_0	98.821	2.934	61.545	136.098	----	1.585	0.798
	k_1	0.0437	10.4171	-132.3184	132.4058	0.4987		
	k_2	9.5 E-4	1.9303	-24.5263	24.5282	0.4998		
	g	0.1866	81.5933	<-1000	>1000	0.4993		
HS	M_0	98.405	2.918	61.205	135.605	----	1.574	0.800
	k_1	0.0042	0.0235	-0.2945	0.3030	0.4436		
	k_2	0.0083	0.0055	-0.0623	0.0788	0.1885		
	t_b	0.1802	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾		

Footnotes to the table:

1) n. c. = not calculated by the model;

Also the kinetic endpoints – DT₅₀ and DT₉₀ values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.3_CA-3.

Table B.8.1.1.2.1.3._CA-3: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
Flufenacet	DT ₅₀ [days]	90.72	307.43	512.70	84.88
	DT ₉₀ [days]	301.36	> 1000	> 1000	279.91

Evaluation:

The results of the kinetic analysis show that only SFO model returned reliable results. That may be due to the very low level of degradation of Flufenacet observed during the experiment combined with short incubation/irradiation period (~10% degradation within ~10 days).

b) results of the kinetic analysis of the data for irradiated sample and Natural Sunlight days as time points:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.3._CA-4 and in the graphical form on figure B.8.1.1.2.1.3_CA-2. For convenience the results for all kinetic models tested are presented together.

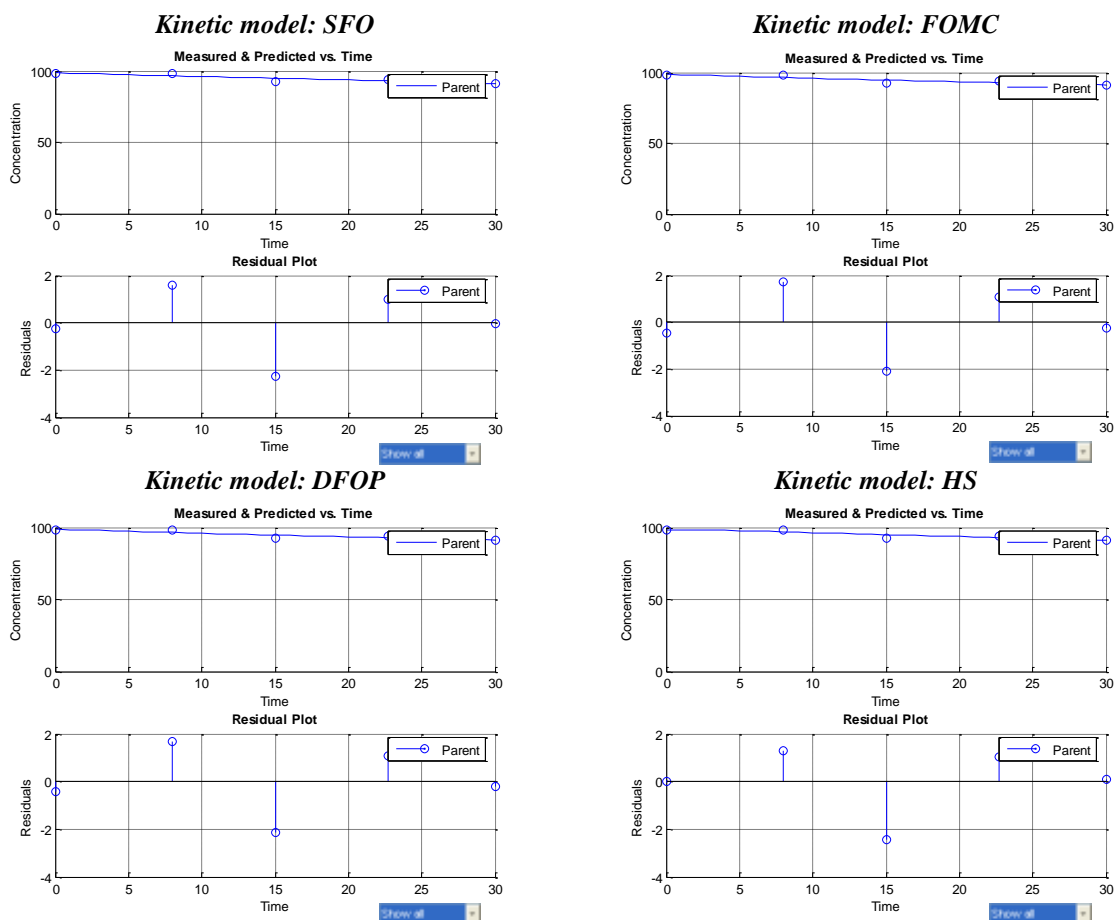

Figure B.8.1.1.2.1.3_CA-2: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.3_CA-4: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2
				Lower	Upper			
SFO	M_0	98.665	1.352	94.362	102.969	----	1.116	0.796
	k	0.0026	7.6 E-4	1.8 E-4	0.0050	0.0209

	α	0.1735	0.9236	-3.8003	4.1472	0.4342		
	β	52.7870	347.3942	<-1000	> 1000	0.4466		
DFOP	M_0	98.815	2.932	61.566	136.064	----	1.583	0.798
	k_1	0.0193	3.8466	-48.8558	48.8944	0.4984		
	k_2	9.2 E-4	0.3866	-4.9113	4.9131	0.4992		
	g	0.1161	42.3086	-537.4655	537.6978	0.4991		
HS	M_0	98.405	2.927	61.219	135.591	----	1.574	0.801
	k_1	0.0028	0.0019	-0.0212	0.0268	0.1886		
	k_2	8.5 E-4	94.0534	<-1000	> 1000	> 1000		
	t_b	3.6083	> 10000	<-1000	> 1000	0.5000		

Also the kinetic endpoints – DT_{50} and DT_{90} values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.3._CA-5.

Table B.8.1.1.2.1.3._CA-5: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested for Flufenacet			
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>	<i>HS</i>
<i>Flufenacet</i>	DT_{50} [days]	265.67	> 1000	618.16	249.26
	DT_{90} [days]	882.55	> 1000	> 1000	822.19

Evaluation:

The results of the kinetic analysis show that only SFO model returned reliable results. That may be due to the very low level of degradation of Flufenacet observed during the experiment combined with short actual incubation/irradiation period (~10% degradation within ~10 days).

c) results of the kinetic analysis of the data for the dark control sample (real time points):

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.3._CA-6 and in the graphical form on figure B.8.1.1.2.1.3_CA-3. For convenience the results for all kinetic models tested are presented together.

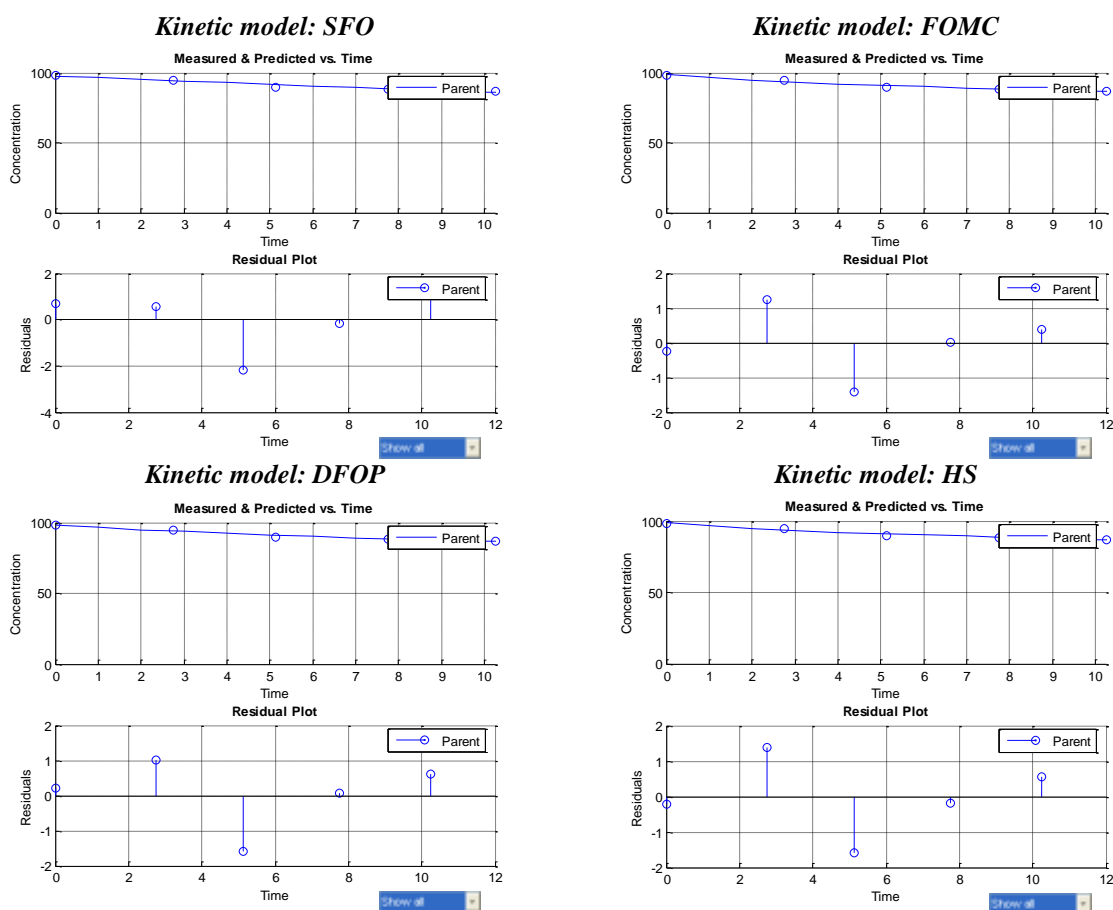

Figure B.8.1.1.2.1.3._CA-3: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.3._CA-6: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2
				Lower	Upper			
SFO	M_0	97.723	1.2143	93.859	101.587	----	1.027	0.923
	k	0.0124	0.0021	0.0059	0.0189	0.0046

	α	0.1106	0.1002	-0.3203	0.5416	0.1922		
	β	4.7131	7.0065	-25.4334	34.8595	0.2852		
DFOP	M_0	98.189	1.988	72.935	123.442	----	1.109	0.957
	k_1	0.0885	1.9700	-24.9431	25.1201	0.4857		
	k_2	2.3 E-4	0.3150	-4.0021	4.0021	0.5000		
	g	0.1980	7.0235	-89.0444	89.4405	0.4910		
HS	M_0	98.608	2.16	70.827	126.388	----	1.218	0.947
	k_1	0.0189	0.0102	-0.1109	0.1486	0.1580		
	k_2	0.0098	0.0048	-0.0514	0.0710	0.1454		
	t_b	3.214	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾		

Footnotes to the table:

1) n. c. = not calculated by the model;

Also the kinetic endpoints – DT_{50} and DT_{90} values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.3._CA-7.

Table B.8.1.1.2.1.3._CA-7: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested for Flufenacet			
		SFO	FOMC	DFOP	HS
Flufenacet	DT_{50} [days]	55.90	> 1000	> 1000	67.80
	DT_{90} [days]	185.68	> 1000	> 1000	232.12

Evaluation:

The results of the kinetic analysis show that only SFO model returned reliable results. That may be due to the very low level of degradation of Flufenacet observed during the experiment, combined with short actual incubation/irradiation period (~10% degradation within ~10 days).

The data obtained for degradation products were not kinetically evaluated because of very low concentrations and/or the due to the fact that the decline phase was not reached at the end of incubation/irradiation period.

Results and their discussion:

The final set of the kinetic endpoints obtained for Flufenacet in the study examining its photolysis on the soil surface is presented below in the table B.8.1.1.2.1.3._CA-8.

Table B.8.1.1.2.1.3._CA-8: the definitive set of the kinetic endpoints obtained in the study.

Determined parameter	Results obtained for:		
	Dark control samples	Irradiated samples	
		Values not corrected (Suntest days)	Values corrected for summer sunlight intensity (Natural sunlight days) ¹⁾
Rate constant k [days ⁻¹]	0.0124	0.076	0.0026
DT_{50} [days]	55.90	90.72	265.67
DT_{90} [days]	185.68	301.36	882.55
Kinetic model	SFO	SFO	SFO

Footnotes to the table:

1) values calculated for conditions representative for summer sunny day in Phoenix, AZ, USA – longitude: 33° 27' N

On their basis it can be stated that Flufenacet is not expected to degrade in soil via its photolysis on the soil surface.

Conclusion:

The results clearly demonstrate that the degradation of Flufenacet was slower in irradiated samples than in the dark control. On that basis it can be stated that Flufenacet is not prone to the photolysis on the soil surface, hence soil photolysis will not be a relevant mechanism of degradation of Flufenacet in soil.

Second study – **Study 2**, was submitted to further examine the photolysis of Flufenacet on the soil surface, by determining the route and rate of photodegradation of FOE Thiadone – the primary degradation product of Flufenacet within the thiadiazole moiety.

The details of the kinetic analysis of its results are provided below.

Study 2:

Report: Lentz N. R., Bloomberg A. M., (2001): “Soil Photolysis of Thiadone on Loamy Sand (A Metabolite of FOE 5043).”; Ricerca LLC, Department of Environmental and Metabolic Fate, 7528 Auburn Road, Painesville, Ohio 44077, USA (performing laboratory) *for* Bayer Corporation, Agriculture Division, P. O. Box 4913, Kansas City, MO 64120, USA; Ricerca document No. 7410-0055-EF-001, study No. F3082103 (Bayer); Bayer Report No. 108721; 21 June 2001; study reference number: M-106297-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 161-3, Soil Photolysis Study.

GLP: Yes;

RMS comments: This is a newly submitted study, evaluated for the purpose of the current assessment and found acceptable for its part related to the determination of the route of degradation of FOE Thiadone on the soil surface when exposed to sunlight. It is summarised under the point B.8.1.1.1.3. of this Renewal Assessment Report. However, in its part dealing with rate of degradation it was stated not compliant with the provisions of the current Guidelines, namely FOCUS Kinetics Guidance document. For that reason RMS repeated the kinetic assessment of the data, the results of which are presented in the summary below.

Summary:

The aim of the study was to examine photodegradation of FOE Thiadone – the metabolite of Flufenacet, on the soil surface through:

- a) determining the half-life of that compound when exposed to artificial sunlight;
- b) identifying the transformation pattern, and in particular the degradation products formed in amounts greater than 10% AR.

The analysis of the kinetic assessment of the results presented in the study report showed that:

- it was performed using linear regression method, not recommended any more by the current guidelines;
- no statistical evaluation of the fit, as recommended by FOCUS Kinetics was provided, the only statistical parameter being coefficient of determination – R^2 ; RMS noted that it was due to the fact that the kinetic analysis of the data, as well as a whole study, pre-dated the introduction of FOCUS Kinetics.

All that taken into account RMS decided to repeat the kinetic analysis. It was performed following recommendations given by FOCUS Kinetics Workgroup (FOCUS; 2006), using the KinGUI 1.1 tool developed by Bayer CropScience. Only the data for FOE Thiadone were used. That was due to the fact that the concentrations of the only identified degradation product – propionic acid conjugate of FOE Thiadone, were too low to return a robust kinetic fit, in particular for irradiated samples.

The input data used in the evaluation are presented below in the table B.8.1.1.2.1.3._CA-9. In the analysis the average values were used.

Table B.8.1.1.2.1.3._CA-9: The data for FOE Thiadone used in the kinetic examination performed by RMS.

Time point	Concentration of FOE Thiadone in:					
	<i>Irradiated samples</i>			<i>Dark control samples</i>		
	Replicate 1	Replicate 2	Average	Replicate 1	Replicate 2	Average
Day 0	96.52	96.92	96.7	96.52	96.92	96.7
Day 0.5	74.22	84.03	79.2	85.08	82.10	83.6
Day 1	76.95	77.53	77.3	79.12	76.98	78.1
Day 2	52.80	51.65	52.3	67.66	63.64	65.7
Day 3	42.77	53.50	48.2	65.13	54.34	59.8
Day 5	35.51	34.67	35.2	47.31	34.82	41.1
Day 7	21.65	21.48	21.6	22.61	34.91	28.9
Day 10	11.13	13.85	12.5	21.80	14.71	18.3
Day 14	6.30	7.94	7.2	12.41	13.94	13.3

The results of the kinetic analysis are presented below, separately for irradiated samples and the dark control.

a) results of the kinetic analysis of the data for the irradiated samples:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.3._CA-10 and in the graphical form on figure B.8.1.1.2.1.3_CA-4. For convenience the results for all kinetic models tested are presented together.

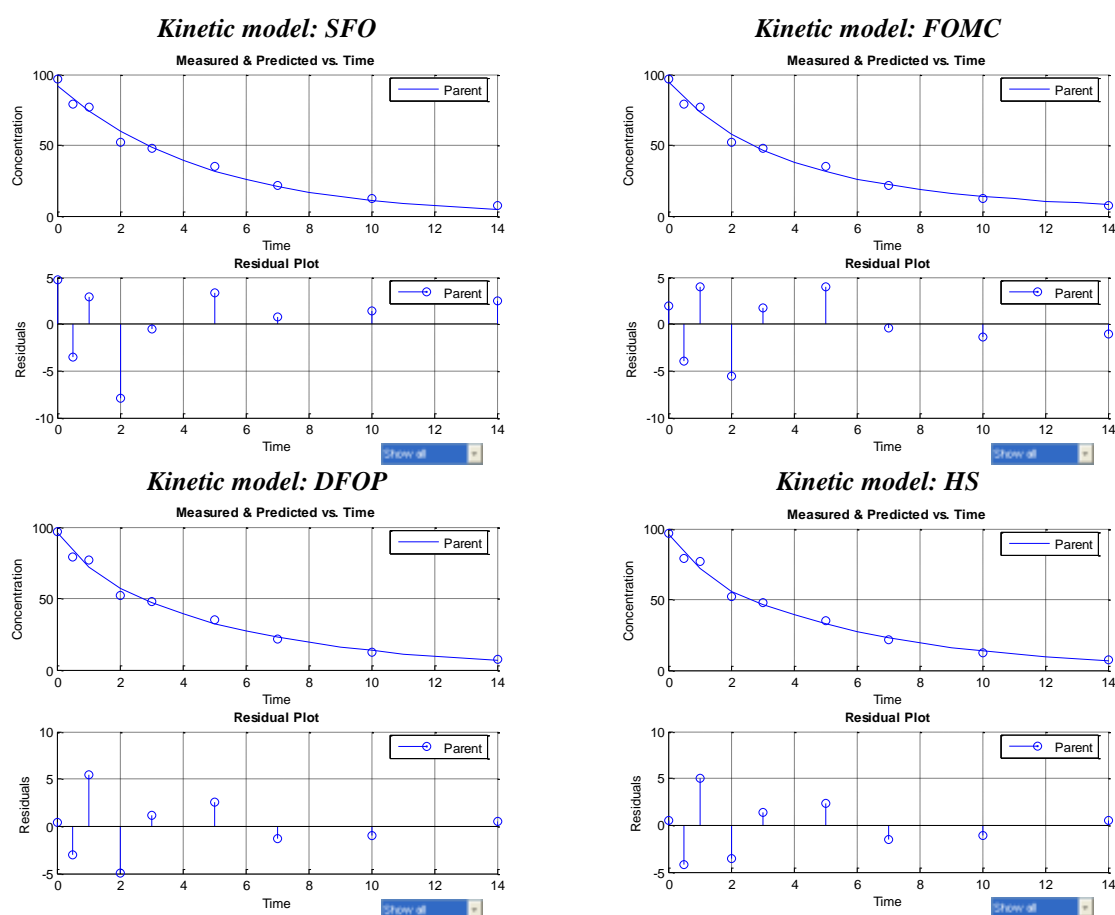

Figure B.8.1.1.2.1.3._CA-4: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.3._CA-10: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2
				Lower	Upper			
SFO	M_0	92.000	2.887	85.174	98.826	----	6.250	0.985
	k	0.2120	0.0162	0.1736	0.2503	1.8 E-6

	α	3.0248	1.8721	-1.5561	7.6058	0.0786		
	β	11.2741	8.5879	-9.7398	32.2881	0.1186		
DFOP	M_0	96.250	3.767	86.567	105.933	----	5.428	0.991
	k_1	1.0775	1.2470	-2.1279	4.2830	0.2135		
	k_2	0.1762	0.0352	0.0852	0.2668	0.0021		
	g	0.1840	0.1656	-0.2416	0.6095	0.1585		
HS	M_0	96.132	3.033	88.334	103.930	----	5.123	0.992
	k_1	0.2853	0.0332	0.2024	0.3681	1.5 E-4		
	k_2	0.1765	0.0203	0.1243	0.2288	1.7 E-4		
	t_b	1.7469	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾		

Footnotes to the table:

1) n. c. = not calculated by the model;

Also the kinetic endpoints – DT_{50} and DT_{90} values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.3._CA-11.

Table B.8.1.1.2.1.3._CA-11: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		SFO	FOMC	DFOP	HS
FOE Thiadone	DT_{50} [days]	3.27	2.90	2.87	2.85
	DT_{90} [days]	10.86	12.86	11.91	11.96

Evaluation:

The results of the kinetic analysis show that only SFO model returned reliable results. In case of FOMC and DFOP the lack of reliability was stated for the calculated kinetic parameters. For HS calculated kinetic parameters were reliable, but there was no statistical evaluation of t_b , and for that reason the kinetic fit cannot be considered acceptable.

b) results of the kinetic analysis of the data for the dark control samples:

The obtained results are presented below in the numerical form in table B.8.1.1.2.1.3._CA-12 and in the graphical form on figure B.8.1.1.2.1.3_CA-5. For convenience, as presented data are for a single compound – Flufenacet, the results for all kinetic models tested are presented together.

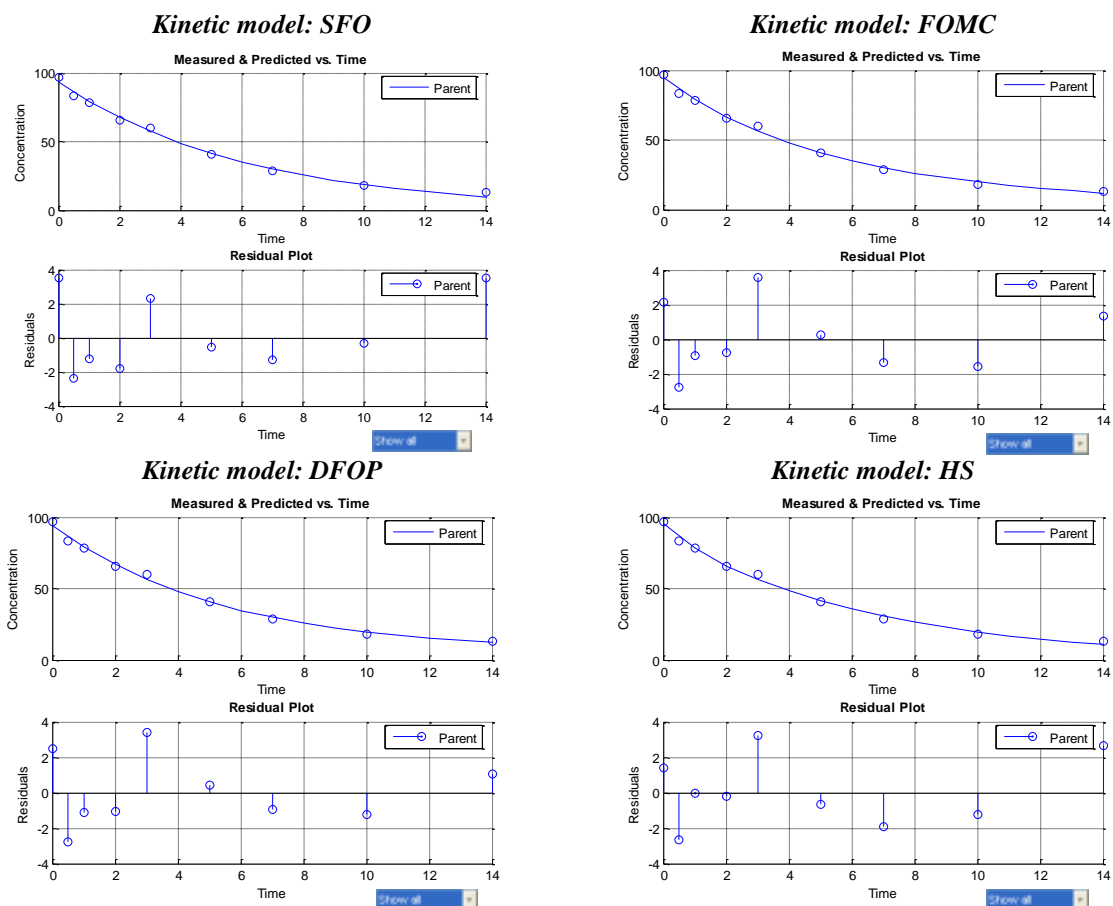

Figure B.8.1.1.2.1.3_CA-5: The graphical results of the kinetic analysis.

Table B.8.1.1.2.1.3_CA-12: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Statistical evaluation of the fit

	k_2	0.0056	0.4264	-1.0904	1.1016	0.4950		
	g	0.9328	0.5191	-0.4017	2.2673	0.0661		
HS	M_0	95.274	2.923	89.379	101.169	----	3.162	0.996
	k_1	0.1985	0.0320	0.1163	0.2807	7.9 E-4		
	k_2	0.1519	0.0095	0.1275	0.1764	8.8 E-6		
	t_b	1.3690	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾	n. c. ¹⁾		

Footnotes to the table:

1) n. c. = not calculated by the model;

Also the kinetic endpoints – DT₅₀ and DT₉₀ values for each of the kinetic models were calculated. These are presented below in the table B.8.1.1.2.1.3_CA-13.

Table B.8.1.1.2.1.3_CA-13: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested			
		<i>SFO</i>	<i>FOMC</i>	<i>DFOP</i>	<i>HS</i>
<i>FOE Thiadone</i>	DT ₅₀ [days]	4.30	4.07	4.09	4.13
	DT ₉₀ [days]	14.29	15.96	16.98	14.73

Evaluation:

The results of the kinetic analysis show that only SFO model returned reliable results. In case of FOMC and DFOP the lack of reliability was stated for the calculated kinetic parameters. For HS calculated kinetic parameters were reliable, but there was no statistical evaluation of t_b, and for that reason the kinetic fit cannot be considered acceptable.

Results and their discussion:

The final set of the kinetic endpoints obtained for FOE Thiadone in the study examining its photolysis on the soil surface is presented below in the table B.8.1.1.2.1.3_CA-14.

Table B.8.1.1.2.1.3_CA-14: The definitive set of the kinetic endpoints obtained in the study.

Determined parameter	Results obtained for:	
	<i>Dark control samples</i>	<i>Irradiated samples</i>
Rate constant <i>k</i> [days ⁻¹]	0.1612	0.2120
DT ₅₀ [days]	4.30	3.27
DT ₉₀ [days]	14.29	10.86
Kinetic model	SFO	SFO

The results demonstrate that photolysis on the soil surface may contribute to degradation of FOE Thiadone in soil.

The net rate constant of the photolysis will be:

$$k_{\text{photolysis}} = k_{\text{irrad}} - k_{\text{dark control}} = 0.2120 - 0.1612 = 0.0508 [\text{days}^{-1}].$$

The resulting kinetic endpoints calculated using that value are: **DT₅₀ = 13.64 days** and **DT₉₀ = 45.33 days**.

Conclusion:

The results demonstrate that the photolysis on the soil surface might contribute to the degradation of FOE Thiadone in soil, if only that compound had been found on the soil surface in any substantial amounts. However, such possibility is minimal, because Flufenacet is photolytically stable, hence FOE Thiadone cannot be formed on the soil surface as a result of soil photolysis and, as aerobic metabolite is expected to be formed in deeper soil layers. On that basis it can be stated that soil photolysis will not be a relevant degradation mechanism of FOE Thiadone in soil, even though that compound is prone to it. As a result, the calculated kinetic endpoints will not be presented in the List of EndPoints nor further used in the exposure/risk assessment.

Summary – Rate of photodegradation of Flufenacet and its degradation products on the soil surface:

The photolysis of Flufenacet on the soil surface was examined in one experiment using one soil. Its results were kinetically examined, in line with the recommendations given by FOCUS [2006], by the RMS. The final set of the kinetic endpoints obtained for Flufenacet as a result of that examination is presented below in the table B.8.1.1.2.1.3._CA-15.

Table B.8.1.1.2.1.3._CA-15: The definitive set of the kinetic endpoints obtained for Flufenacet in the study examining soil photolysis of that compound.

Determined parameter	Results obtained for:		
	Dark control samples	Irradiated samples	
		Values not corrected (Suntest days)	Values corrected for summer sunlight intensity (Natural sunlight days) ¹⁾
Rate constant k [days ⁻¹]	0.0124	0.076	0.0026
DT_{50} [days]	55.90	90.72	265.67
DT_{90} [days]	185.68	301.36	882.55
Kinetic model	SFO	SFO	SFO

Footnotes to the table:

1) values calculated for conditions representative for summer sunny day in Phoenix, AZ, USA – longitude: 33° 27' N

On their basis it can be stated that Flufenacet is not expected to degrade in soil via its photolysis on the soil surface.

The conclusion drawn by the RMS from the study on the basis of the results presented above was following: “The results clearly demonstrate that the degradation of Flufenacet was slower in irradiated samples than in the dark control. On that basis it can be stated that Flufenacet is not prone to the photolysis on the soil surface, hence soil photolysis will not be a relevant mechanism of degradation of Flufenacet in soil.”

None of the degradation products of Flufenacet requiring further assessment were formed in that study, so the kinetic analysis for them was not performed. However, for one the major soil degradation product of Flufenacet – FOE Thiadone the photodegradation of that compound on the soil surface was examined in a separate study. The results were kinetically examined by the RMS and the definitive data set is presented below in the table B.8.1.1.2.1.3._CA-16.

Table B.8.1.1.2.1.3._CA-16: The definitive set of the kinetic endpoints obtained for FOE Thiadone in the study examining its photolysis on the soil surface.

Determined parameter	Results obtained for:	
	Dark control samples	Irradiated samples
Rate constant k [days ⁻¹]	0.1612	0.2120
DT_{50} [days]	4.30	3.27
DT_{90} [days]	14.29	10.86
Kinetic model	SFO	SFO

The results demonstrate that photolysis on the soil surface might contribute to degradation of FOE Thiadone in soil.

The net rate constant of the photolysis will be:

$$k_{\text{photolysis}} = k_{\text{irrad}} - k_{\text{dark control}} = 0.2120 - 0.1612 = 0.0508 \text{ [days}^{-1}\text{]}.$$

The resulting kinetic endpoints calculated using that value are: $DT_{50} = 13.64$ days and $DT_{90} = 45.33$ days.

At the same time it shall be pointed out however that the probability that that compound would be found on the soil surface in any substantial amounts is minimal. For that reason the process should be considered to have minimal relevance in the overall transformation of Flufenacet in soil.

The key results of the kinetic examination of the data obtained in the studies on the soil photolysis of Flufenacet are presented below in format of the new EU LoEP.

Rate of degradation on soil (photolysis) laboratory active substance (Regulation (EU) N° 283/2013, Annex Part A, point 7.1.1.3)

Parent	Soil photolysis					
Soil type	OC	pH ^{a)}	t. °C / % MWHC	DT ₅₀ / DT ₉₀ (d) calculated at 27°C	St. (x ²)	Method of calculation
US Sandy loam	0.67%	6.4	T = 25 ± 1°C; 75% of 1/3 bar (75% FC)	DT ₅₀ = 265.67 d; DT ₉₀ = 882.55 d.; Calculated at 33° 27' N (Phoenix, AZ; USA)	1.03	SFO, non-linear regression, OLS

^{a)} Measured in: medium for performing measurements not given

B.8.1.1.2.1.4. – Summary: rate of degradation, laboratory studies

Below are presented the key results of the kinetic examination of the data on the degradation of in soil obtained in the laboratory.

Aerobic degradation in biologically viable soil:

The degradation kinetics of Flufenacet in aerobic soil was extensively examined by the Applicant and its results presented in 26 study reports, of which 24 were found by the RMS acceptable and relevant for the current assessment. Additionally two literature studies were identified by the RMS which also provided the data on the degradation kinetics of Flufenacet in aerobic soils. These reports were found by the RMS relevant as supplementary source of data, however not suitable for deriving the regulatory endpoints.

The key results for each of the evaluated compounds are presented below, in tabularised form, individually for each of the test compounds.

a) Kinetic endpoints determined for Flufenacet:

The degradation kinetics of Flufenacet in aerobic soil was examined in ten trials using nine soils. One of the test soils – Howe, Indiana, Sandy loam soil, was used in two trials in which was used Flufenacet differently radiolabelled (either in phenyl ring or in C2 position of thiadiazole moiety), but the resulting kinetic endpoints cannot be averaged prior to calculating the overall geomean because they were derived in two separate studies, significantly differing in sample processing method.

The persistence (best-fit) kinetic endpoints obtained for Flufenacet are presented below in the table B.8.1.1.2.1.4._CA-1. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-2.

Table B.8.1.1.2.1.4._CA-1: The persistence kinetic endpoints determined for Flufenacet in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints

Geometric mean (n = 10)									0.0387	17.89	59.42
Median (n = 10)									0.0402	17.47	58.05

Footnotes to the table:

- 1) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 2) Declared to be measured in CaCl₂/Water;
- 3) Measured in distilled water;
- 4) Measured in CaCl₂

For GW and SW model exposure assessment the **geomean DT₅₀ = 17.89 days** and **geomean *k* = 0.0387 [days⁻¹]** are the kinetic endpoints recommended as input parameters.

b) Kinetic endpoints determined for FOE Sulfonic acid:

The degradation kinetics of FOE Sulfonic acid in aerobic soil was examined in seventeen trials on the same number of the test soils. The experiments were performed in two variants – four trials with soils treated with Flufenacet (active substance) and the remaining thirteen trials with soils treated with FOE Sulfonic acid.

The performed kinetic analysis resulted in a data base consisting of twelve reliable kinetic endpoints, all determined in trials in which the test soils were treated with FOE Sulfonic acid. In case of the experiments on soils treated with Flufenacet it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Sulfonic acid in soil because decline of that compound was not observed. As a result, the default values – DT₅₀ = 1000 days and DT₉₀ > 1000 days, were proposed for these trials. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fractions for

FOE Sulfonic acid, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

In case of the kinetic analysis of the data obtained in Laacherhof IIIA Silt loam soil in the study by [Hellpointner; 1996], it was not possible to obtain a reliable kinetic fit and hence kinetic endpoints. For that reason the trial was removed from both summary table presenting persistence and modelling endpoints.

The persistence (best-fit) kinetic endpoints obtained for FOE Sulfonic acid are presented below in the table B.8.1.1.2.1.4._CA-3. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-4.

Table B.8.1.1.2.1.4._CA-3: The persistence kinetic endpoints determined for FOE Sulfonic acid in aerobic soil.

Arithmetic mean for <i>ff</i> (n = 4)												0.195

Footnotes to the table:

- 1) Measured in:
 - CaCl₂/water for values marked a);
 - distilled water for results marked b);
 - (0.01M) CaCl₂ for results marked c);
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) Value not determined – the decline phase not reached;
- 4) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **geomean DT₅₀ = 45.11 days** and **geomean *k* = 0.0154 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.195** (arithmetic mean) for Flufenacet as a precursor.

c) Kinetic endpoints determined for FOE Oxalate:

The degradation kinetics of FOE Oxalate in aerobic soil was examined in four trials on the same number of the test soils. The experiments were performed with soils treated with Flufenacet (active substance).

The performed kinetic analysis resulted in a data base consisting of three reliable kinetic endpoints. In case of the experiment in Howe, Indiana, Sandy loam soil it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Oxalate because the decline of that compound was not observed. As a result, the default values – DT₅₀ = 1000 days and DT₉₀ > 1000 days, were proposed for that trial. These values, due to

their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fraction for FOE Oxalate, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

The persistence (best-fit) kinetic endpoints obtained for FOE Oxalate are presented below in the table B.8.1.1.2.1.4._CA-5. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-6.

Table B.8.1.1.2.1.4._CA-5: The persistence kinetic endpoints determined for FOE Oxalate in aerobic soil.

Howe, Indiana;	Sandy loam	0.35	6.2 ^{b)}	21 ⁰ C; 75% of 1/3 bar	SFO	3.99	G	k	n. d. ³⁾	n. d. ³⁾	n. d. ³⁾	0.484
Geometric mean (n = 3)									0.0639	11.08	37.12	----
Arithmetic mean for ff (n = 4)												0.426

Footnotes to the table:

- 1) Measured in:
- CaCl₂/water for values marked a);
- distilled water for results marked b);
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) Value not determined – the decline phase not reached;

For GW and SW model exposure assessment the **geomean DT₅₀ = 11.08 days** and **geomean k = 0.0639 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended ff value is **ff = 0.426** (arithmetic mean) for Flufenacet as a precursor.

d) Kinetic endpoints determined for FOE Methylsulfone:

The degradation kinetics of FOE Methylsulfone in aerobic soil was examined in eleven trials using the same number of the test soils. The experiments were performed in two variants – three trials with soils treated with Flufenacet (active substance) and the remaining eight trials with soils treated with FOE Methylsulfone.

The performed kinetic analysis resulted in a data base consisting of nine reliable kinetic endpoints, one with soil treated with Flufenacet as a precursor of FOE Methylsulfone and remaining eight with soils treated with FOE Methylsulfone. In case of two trials on soils treated with Flufenacet – BBA 2.2 Loamy sand soil and Hoefchen im Tal Silt loam soil, it was not possible to obtain reliable kinetic endpoints characterising degradation of FOE Methylsulfone in soil, because decline of that compound was not observed. As a result, the default values – $DT_{50} = 1000$ days and $DT_{90} > 1000$ days, were proposed for these trials. These values, due to their nature and uncertainty related to them, were not used either as input parameters in soil exposure assessment or to calculate normalised mean values used subsequently in GW/SW exposure assessment. They are however provided in the table presenting the persistence endpoints, as with them are associated reliable kinetic formation fractions for FOE Methylsulfone, recommended to be used in GW exposure assessment. RMS however decided not to provide them in the table presenting the kinetic endpoints recommended for modelling.

The persistence (best-fit) kinetic endpoints obtained for FOE Methylsulfone are presented below in the table B.8.1.1.2.1.4._CA-7. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-8.

Table B.8.1.1.2.1.4._CA-7: The persistence kinetic endpoints determined for FOE Methylsulfone in aerobic soil.

Arithmetic mean for <i>ff</i> (n = 3)												0.070

Footnotes to the table:

- 1) Measured in:
 - CaCl₂/water for values marked a);
 - (0.01M) CaCl₂ for results marked b);
- 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;
- 3) Value not determined – the decline phase not reached;
- 4) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **median DT₅₀ = 81.70 days** and **median *k* = 0.00848 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.070** (arithmetic mean) for Flufenacet as a precursor.

e) Kinetic endpoints determined for FOE Thiadone:

The degradation kinetics of FOE Thiadone in aerobic soil was examined in eight trials using the equal number of the test soils. The experiments were performed in two variants – five trials with soils treated with Flufenacet (active substance) and the remaining eight trials with soils treated with FOE Methylsulfone.

The performed kinetic analysis resulted in a data base consisting of eight reliable kinetic endpoints, four with soil treated with Flufenacet as a precursor of FOE Thiadone and three with soils treated with FOE Thiadone. In case of one trial on soil treated with Flufenacet – Howe, Indiana Sandy loam soil, it was not possible to obtain reliable fit for FOE Thiadone in combination with the parent compound. Such fit however was obtained when the data were kinetically analysed for FOE Thiadone alone using the top-down approach. That solution however implied that no reliable value for kinetic formation fraction in that trial could be obtained and reported. RMS decided not to report the default value *ff* = 1.00, proposed by the Applicant. The persistence (best-fit) kinetic

endpoints obtained for FOE Thiadone are presented below in the table B.8.1.1.2.1.4._CA-9. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-10.

Table B.8.1.1.2.1.4._CA-9: The persistence kinetic endpoints determined for FOE Thiadone in aerobic soil.

- 6) Value not available – the test compound applied as parent.

For GW and SW model exposure assessment the **geomean DT₅₀ = 1.95 days** and **geomean *k* = 0.3557 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.570** (arithmetic mean) for Flufenacet as a precursor.

f) Kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid (TFESA):

The degradation kinetics of FOE 5043-Trifluoroethanesulfonic acid (TFESA) in aerobic soil was examined in four trials using the equal number of the test soils. The experiments were performed with soils treated with Flufenacet (active substance).

The performed kinetic analysis resulted in a data base consisting of four reliable kinetic endpoints. In case of two trials – on the Dollendorf II Clay loam soil and Laacherhof Wurm-wiese Loam soil it was not possible to obtain reliable kinetic fits for the whole transformation scheme, therefore the top-down approach was used. RMS however decided to keep the determined values of kinetic formation fraction *ff*. The persistence (best-fit) kinetic endpoints obtained for FOE 5043-Trifluoroethanesulfonic acid (TFESA) are presented below in the table B.8.1.1.2.1.4._CA-11. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-12.

Table B.8.1.1.2.1.4_CA-11: The persistence kinetic endpoints determined for FOE 5043-Trifluoroethanesulfonic acid in aerobic soil.

Soil		Soil properties		Incubation conditions	Kinetic model	Evaluation of the fit		Kinetic parameters		Kinetic endpoints		
Soil name	Soil type (USDA)	OC	pH ¹⁾			χ^2 error	Vis. fit ²⁾	Par.	Value	DT ₅₀ [days]	DT ₉₀ [days]	Kinetic formation fraction <i>ff</i>

Geometric mean (n = 4)									0.1082	6.41	21.30	----
Arithmetic mean for <i>ff</i> (n = 3)												0.469

Footnotes to the table:

- 1) Measured in 0.01M CaCl₂;
 2) The abbreviations used to describe the visual fit: G. – good, A. – acceptable, P. – poor;

For GW and SW model exposure assessment the **geomean DT₅₀ = 6.41 days** and **geomean *k* = 0.1082 [days⁻¹]** are the kinetic endpoints recommended as input parameters. The corresponding recommended *ff* value is ***ff* = 0.469** (arithmetic mean) for FOE Thiadone as a precursor.

g) Kinetic endpoints determined for Trifluoroacetic acid (TFA):

The degradation kinetics of Trifluoroacetic acid (TFA) in aerobic soil was examined in eight trials using the equal number of the test soils. The experiments were performed in two variants – four trials with soils treated with Flufenacet (active substance) and the remaining four trials with soils treated with TFA.

Due to the high persistence of the test compound – TFA, in none of the test soils it was possible to obtain the reliable kinetic endpoints. For that reason the default values were proposed.

Due to the difference between the modelling tools, for the persistence endpoints two sets of the default values were provided. For trials on test soils treated with Flufenacet as precursor of TFA, where the analysis performed by the Applicant was accepted, the default kinetic endpoints were: **DT₅₀ = 1000 days** and **DT₉₀ > 1000 days**. In case however of the trials with TFA applied as parent compound, for which RMS had to repeat the kinetic analysis, the kinetic endpoints were: **DT₅₀ = 10000 days** and **DT₉₀ > 10000 days** – the values returned by the applied tool. RMS considers these defaults to be representative for the persistence of TFA in soil, as that indicated the results of the examination of the fate of TFA in environment presented in the open-source literature.

However for modelling the recommended input value is **DT₅₀ = 1000 days**, because of the constraints of the current modelling tools. It shall be noted that due to the nature of the determined endpoint – a default value, its normalisation was not performed as not necessary.

For TFA a set for two kinetic formation fraction values were determined – one for formation of TFA from Flufenacet and the second for its formation from FOE Thiadone.

The persistence (best-fit) kinetic endpoints obtained for TFA are presented below in the table B.8.1.1.2.1.4._CA-13. The modelling endpoints are given in the table B.8.1.1.2.1.4._CA-14.

Table B.8.1.1.2.1.4._CA-13: The persistence kinetic endpoints determined for Trifluoroacetic acid (TFA) in aerobic soil.

- 4) ff_1 – kinetic formation fraction for formation of TFA from Flufenacet; ff_2 – kinetic formation fraction for formation of TFA from FOE Thiadone.

For GW and SW model exposure assessment the default **DT₅₀ = 1000 days** is a kinetic endpoint recommended as input parameter. The corresponding recommended ff values are $ff_1 = 0.430$ (arithmetic mean) for Flufenacet as a precursor and $ff_2 = 0.531$ (arithmetic mean) for FOE Thiadone as a precursor.

The kinetic endpoints identified by RMS as appropriate to be used in model exposure assessment for soil, groundwater and surface water compartments are summarised below in the table B.8.1.1.2.1.4._CA-15. For completeness also the maximum concentrations observed in soils are provided. That table will be directly transferred to the List of EndPoints.

Table B.8.1.1.2.1.4._CA-15: The kinetic endpoints determined in laboratory studies on aerobic soils, recommended to be used in model exposure assessment for soil, groundwater and surface water compartments.

Compound	Compartment	Recommended endpoints					
		Maximum observed in soil		Kinetic formation fraction - <i>ff</i>		Persistence in soil – <i>DT</i> ₅₀ value	
		Observed soil maximum [%]	Remark	<i>ff</i>	Remark	<i>DT</i> ₅₀ [days]	Remark
Flufenacet	Soil	Not applicable	Not applicable – parent compound	----	Not applicable – parent compound	57.6	Longest not normalised lab value
	Groundwater			----		17.89	Normalised lab geomean value
	Surface Water			----		17.89	Normalised lab geomean value
FOE Sulfonic acid	Soil	26.5	Recommended for simple modelling ¹⁾	0.272	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	318	Longest not normalised lab value
	Groundwater	----	Not applicable	0.195	Precursor: flufenacet;	45.11	Normalised lab geomean value
	Surface Water	26.5	To be used in calculations at Steps 1 and 2	0.195	Precursor: flufenacet; to be used in Step 3-4 assessment	45.11	Normalised lab geomean value
FOE Oxalate	Soil	26.3	Recommended for simple modelling ¹⁾	0.484	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	18.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.426	Precursor: flufenacet;	11.08	Normalised lab geomean value
	Surface Water	26.3	To be used in calculations at Steps 1 and 2	0.426	Precursor: flufenacet; to be used in Step 3-4 assessment	11.08	Normalised lab geomean value
FOE Methylsulfone	Soil	6.6	Recommended for simple modelling ¹⁾	0.096	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	174	Longest not normalised lab value
	Groundwater	----	Not applicable	0.070	Precursor: flufenacet;	81.70	Normalised lab median value
	Surface Water	6.6	To be used in calculations at Steps 1 and 2	0.070	Precursor: flufenacet; to be used in Step 3-4 assessment	81.70	Normalised lab median value
FOE Thiadone	Soil	5.8	Recommended for simple modelling ¹⁾	0.913	Precursor: flufenacet; highest <i>ff</i> , to be used in complex modelling ²⁾	15.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.570	Precursor: flufenacet;	1.95	Normalised lab geomean value
	Surface Water	5.8	To be used in calculations at Steps 1 and 2	0.570	Precursor: flufenacet; to be used in Step 3-4 assessment	1.95	Normalised lab geomean value
FOE 5043-Trifluoroethane-sulfonic acid	Soil	6.0	Recommended for simple modelling ¹⁾	0.655	Precursor: Thiadone; highest <i>ff</i> , to be used in complex modelling ²⁾	20.9	Longest not normalised lab value
	Groundwater	----	Not applicable	0.469	Precursor: Thiadone;	6.41	Normalised lab geomean value
	Surface Water	6.0	To be used in calculations at Steps 1 and 2	0.469	Precursor: Thiadone; to be used in Step 3-4 assessment	6.41	Normalised lab geomean value
Trifluoroacetic acid (TFA)	Soil	81.5	Recommended for simple modelling ¹⁾	0.430	Precursor: flufenacet; average <i>ff</i> , to be used in complex modelling ^{2, 3)}	10000	Longest lab value (default)
				0.531	Precursor: Thiadone; average <i>ff</i> , to be used in complex modelling ^{2, 3)}		
	Groundwater	----	Not applicable	0.430	Precursor: flufenacet;	1000	FOCUS default for non-degrading compounds
				0.531	Precursor: Thiadone;		
	Surface Water	81.5	To be used in calculations at Steps 1 and 2	0.430	Precursor: flufenacet; to be used in Step 3-4 assessment	1000	FOCUS default for non-degrading compounds
				0.531	Precursor: Thiadone; to be used in Step 3-4 assessment		

Footnotes to the table:

- 1) By the term “simple modelling” are understood calculations performed using simple models with metabolites applied as parent;
- 2) The term “complex models” concerns calculations performed using more sophisticated tools, e.g. ESCAPE, in which metabolites are calculated as formed from their precursor (parent compound or preceding degradation product);
- 3) For that compound, due to the complex formation scheme, average *ff* values are proposed to be used in complex soil exposure assessment with the average *ff* for Thiadone to be used in case it becomes necessary to recalculate the value to obtain the bet formation of TFA in that process (as if from parent).

Finally, the key results of the two literature studies examining the rate of degradation of Flufenacet in aerobic soil incubated under controlled – laboratory, conditions are presented below in the table B.8.1.1.2.1.4._CA-16. As already indicated, these results may be considered only as indicative and were not used to derive the regulatory endpoints.

Table B.8.1.1.2.1.4._CA-16: The key results of the relevant publications examining the rate of degradation of Flufenacet in aerobic soils.

Study	Test soil	Key soil properties			Incubation conditions		Fortification level [µg a. s./g soil]	Kinetic endpoints – DT ₅₀ [days]		Method of calculation

Anaerobic degradation:

The determination of the kinetic parameters of the process of degradation of Flufenacet in anaerobic soil was performed for the results obtained in two studies, on three soils using the test compound radiolabelled in two different positions:

- uniformly in phenyl ring (one test soil);
- in C5 position of thiadiazole moiety (two test soils).

The conclusions and key results are presented below, individually for each test soil.

- The conclusions and key results obtained for Sandy loam (Howe) soil treated with Phenyl-U-¹⁴C] Flufenacet (study by [Pangilinan and Smith; 1995]):

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Oxalate and FOE Sulfonic acid, obtained for Sandy loam (Howe) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic sandy loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling. That conclusion is drawn by the RMS and is different from the Applicant's proposal – to consider the SFO kinetic model as a source of the kinetic endpoints appropriate for modelling. That conclusion is based on the fact that DFOP fit was superior to SFO both when the fitting was performed for the parent compound alone and for the parent and degradation products.
- It was not possible to obtain the reliable kinetic fit for either of the degradation products – FOE Oxalate and FOE Sulfonic acid kinetically examined together with parent. Slightly better results were obtained when the data for these two compounds were fitted alone using the top-down approach. In both cases SFO was identified as returning visually and statistically reliable fits with reliable parameters. RMS however is of the opinion that the kinetic endpoints derived from those fits should be considered indicative with regard to the persistence of both compounds in anaerobic sandy loam soil and cannot be further used to derive any modelling endpoints. It shall be also noted that it was not possible to derive reliable kinetic formation fractions for either FOE Oxalate or FOE Sulfonic acid.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 229.63$ days, $DT_{90} = 895.64$ days, DFOP model ($k_1 = 0.9976$ days⁻¹, $k_2 = 2.416 \text{ E-}3$ days⁻¹, $g = 0.1291$);
- Flufenacet, modelling endpoints not normalised: $k = 2.416 \text{ E-}3$ [days⁻¹], $DT_{50} = 286.90$ days, $DT_{90} = 953.06$ days, SFO (slow phase DFOP);
- Flufenacet, modelling endpoints normalized for temperature: $k = 2.205 \text{ E-}3$ [days⁻¹], $DT_{50} = 314.35$ days, $DT_{90} = 1044.26$ days, SFO (slow phase DFOP);
- FOE Oxalate, persistence endpoints (indicative): $DT_{50} = 311$ days, $DT_{90} = 1030$ days, SFO model – top-down approach ($k = 0.002233$ days⁻¹);
- FOE Sulfonic acid, persistence endpoints (indicative): $DT_{50} = 352$ days, $DT_{90} = 1170$ days, SFO model – top-down approach ($k_1 = 0.001986$ days⁻¹).

- The conclusions and key results obtained for Silt loam (Hoefchen am Hohenseh 4a) soil treated with [Thiadiazole-5-¹⁴C]Flufenacet (study by [Heinemann; 2012]):

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid, obtained for Silt loam (Hoefchen am Hohenseh 4 a) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic Silt loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling.
- It was possible to obtain reliable kinetic fit and kinetic endpoints for FOE Thiadone;
- Although it was possible to obtain reliable kinetic fit for Trifluoroacetic acid, the reliable kinetic parameters describing degradation of that compound could not be derived due to the fact that the decline

phase was not reached. Therefore RMS proposed to use the default DT_{50} and DT_{90} values instead of those calculated by the model;

- It was not possible to obtain the reliable kinetic fit for FOE 5043-Trifluoroethanesulfonic acid, therefore for that compound no reliable kinetic endpoints are available. RMS attributed that to the low concentrations of the compound recorded in the test system and their significant scattering, what may indicate that the compound of concern is transient and rapidly degrades in anaerobic silt loam soil.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 22.66$ days, $DT_{90} = 156.90$ days, DFOP model ($k_1 = 0.1214$ days⁻¹, $k_2 = 0.01162$ days⁻¹, $g = 0.3810$);
- Flufenacet, modelling endpoints: $k = 0.01162$ [days⁻¹], $DT_{50} = 59.65$ days, $DT_{90} = 198.16$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
- FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 97.04$ days, $DT_{90} = 322.30$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
- Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
- FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.

- The conclusions and key results obtained for Loam (Dollendorf II) soil treated with [Thiadiazole-5-¹⁴C] Flufenacet (study by [Heinemann; 2012]):

The kinetic analysis of the data for Flufenacet and its major degradation products – FOE Thiadone, FOE-5043 Trifluoroethanesulfonic acid and Trifluoroacetic acid, obtained for Loam (Dollendorf II) soil incubated under anaerobic conditions demonstrated that:

- The degradation of Flufenacet in that soil was most adequately described by DFOP kinetic model. Therefore that model should be considered as providing the kinetic endpoints describing the persistence of Flufenacet in anaerobic Silt loam soil;
- DFOP kinetic model – its slow phase, should be also considered as providing the kinetic endpoints appropriate for modelling.
- It was possible to obtain reliable kinetic fit and kinetic endpoints for FOE Thiadone;
- Although it was possible to obtain reliable kinetic fit for Trifluoroacetic acid, the reliable kinetic parameters describing degradation of that compound could not be derived due to the fact that the well pronounced decline phase was not reached. Therefore RMS proposed to use the default DT_{50} and DT_{90} values instead of those calculated by the model;
- It was not possible to obtain the reliable kinetic fit for FOE 5043-Trifluoroethanesulfonic acid, therefore for that compound no reliable kinetic endpoints are available. RMS attributed that to the low concentrations of the compound recorded in the test system and their significant scattering, what may indicate that the compound of concern is transient and rapidly degrades in anaerobic silt loam soil.

The proposed set of the kinetic endpoints derived from that study is following:

- Flufenacet, persistence endpoints: $DT_{50} = 13.51$ days, $DT_{90} = 110.02$ days, DFOP model ($k_1 = 0.4756$ days⁻¹, $k_2 = 0.0167$ days⁻¹, $g = 0.3745$);
- Flufenacet, modelling endpoints not normalised: $k = 0.0167$ [days⁻¹], $DT_{50} = 41.51$ days, $DT_{90} = 137.88$ days, SFO (slow phase DFOP), normalisation was not required as the experiment was carried out at $T = 20^{\circ}\text{C}$ and the correction for soil moisture was not necessary (soil was permanently flooded);
- FOE Thiadone, persistence and modelling endpoints: $DT_{50} = 97.04$ days, $DT_{90} = 322.30$ days, $ff = 0.425$ (from parent compound), SFO model ($k = 0.0071$ days⁻¹);
- Trifluoroacetic acid persistence endpoints (indicative): $DT_{50} = 1000$ days, $DT_{90} > 1000$ days, $ff = 0.575$ (from parent compound), SFO model;
- FOE 5043-Trifluoroethanesulfonic acid: it was not possible to derive reliable kinetic endpoints.

Additionally the results of the determination of the rate of degradation of Flufenacet in anaerobic soils incubated under controlled (laboratory) conditions were provided by two literature studies, summarised under the point B.8.1.1.2.1.1. as **Study 27** and **Study 28**. The key results obtained in these two studies with regard to the rate of degradation of Flufenacet in anaerobic soils are provided in the table B.8.1.1.2.1.4._CA-17. As already indicated, these results may be considered only as indicative and were not used to derive the regulatory endpoints.

Table B.8.1.1.2.1.4._CA-17: The key results of the relevant publications examining the rate of degradation of Flufenacet in anaerobic (submerged) soils.

Study	Test soil	Key soil properties			Incubation conditions		Fortification level [µg a. s./g soil]	Kinetic endpoints – DT ₅₀ [days]		Method of calculation
		Soil type (USDA)	pH	OC [%]	T [°C]	Soil moisture		T=25°C; FC	T=20°C; FC	
<i>Gupta, Gajbhiye, Agnihotri [2001]</i>	Sandy loam	Sandy loam	7.1	0.34	25	FC	10	22.5	35.3	1 st order, linear regression, r =0.99

Soil photolysis:

The photolysis of Flufenacet on the soil surface was examined in one experiment using one soil. Its results were kinetically examined, in line with the recommendations given by FOCUS [2006], by the RMS. The final set of the kinetic endpoints obtained for Flufenacet as a result of that examination is presented below in the table B.8.1.1.2.1.4._CA-18.

Table B.8.1.1.2.1.4._CA-18: The definitive set of the kinetic endpoints obtained for Flufenacet in the study examining soil photolysis of that compound.

Determined parameter	Results obtained for:		
	Dark control samples	Irradiated samples	
		Values not corrected (Suntest days)	Values corrected for summer sunlight intensity (Natural sunlight days) ¹⁾
<i>Rate constant k [days⁻¹]</i>	0.0124	0.076	0.0026
<i>DT₅₀ [days]</i>	55.90	90.72	265.67
<i>DT₉₀ [days]</i>	185.68	301.36	882.55
<i>Kinetic model</i>	SFO	SFO	SFO

Footnotes to the table:

1) values calculated for conditions representative for summer sunny day in Phoenix, AZ, USA – longitude: 33° 27' N

On their basis it can be stated that Flufenacet is not expected to degrade in soil via its photolysis on the soil surface.

The conclusion drawn by the RMS from the study on the basis of the results presented above was following: “The results clearly demonstrate that the degradation of Flufenacet was slower in irradiated samples than in the dark control. On that basis it can be stated that Flufenacet is not prone to the photolysis on the soil surface, hence soil photolysis will not be a relevant mechanism of degradation of Flufenacet in soil.”.

None of the degradation products of Flufenacet requiring further assessment were formed in that study, so the kinetic analysis for them was not performed. However, for one the major soil degradation product of Flufenacet – FOE Thiadone the photodegradation of that compound on the soil surface was examined in a separate study. The results were kinetically examined by the RMS and the definitive data set is presented below in the table B.8.1.1.2.1.4._CA-19.

Table B.8.1.1.2.1.4._CA-19: The definitive set of the kinetic endpoints obtained for FOE Thiadone in the study examining its photolysis on the soil surface.

Determined parameter	Results obtained for:	
	<i>Dark control samples</i>	<i>Irradiated samples</i>
Rate constant k [days ⁻¹]	0.1612	0.2120
DT ₅₀ [days]	4.30	3.27
DT ₉₀ [days]	14.29	10.86
Kinetic model	SFO	SFO

The results demonstrate that photolysis on the soil surface might contribute to degradation of FOE Thiadone in soil.

The net rate constant of the photolysis will be:

$$k_{\text{photolysis}} = k_{\text{irrad}} - k_{\text{dark control}} = 0.2120 - 0.1612 = 0.0508 \text{ [days}^{-1}\text{]}.$$

The resulting kinetic endpoints calculated using that value are: **DT₅₀ = 13.64 days** and **DT₉₀ = 45.33 days**.

At the same time it shall be pointed out however that the probability that that compound would be found on the soil surface in any substantial amounts is minimal. For that reason the process should be considered to have minimal relevance in the overall transformation of Flufenacet in soil.

B.8.1.1.2.2. – Field studies

To cover this data requirement the Applicant submitted seven study reports, of which five examined the soil dissipation of Flufenacet. Two additional studies were aimed on the examination of the storage stability of Flufenacet and its seven soil degradation products in freezed soil. All they are summarised below under the point B.8.1.1.2.2.1. No studies examining the issues of soil residues (data point B.8.1.1.2.2.2.) and soil accumulation (data point B.8.1.1.2.2.3.) were submitted. In case of soil accumulation studies the Applicant gave the justification for their non-submission. No such justification was provided in case of soil residue studies. Still applicable, however, is the justification for not performing them presented in the Assessment Report prepared by the then-RMS – France, for the previous authorisation of Flufenacet in the EU.

B.8.1.1.2.2.1. – Soil dissipation studies

The Applicant submitted four study reports presenting the results of the examination of dissipation of Flufenacet in soil under field conditions. These studies are the existing studies, already used in the previous evaluation of Flufenacet for its authorisation in the EU. They were then found acceptable by the RMS – France and used to derive regulatory endpoints characterising persistence of Flufenacet in soil under field conditions. For the purpose of the present assessment they were evaluated by the RMS – Poland and summarised below as **Studies 1-4**. They contain the kinetic analysis of the results, but it cannot be considered acceptable, being not in line with the recommendations of the current Guidelines, primarily FOCUS Kinetics GD [FOCUS; 2006]. For that reason the RMS performed own kinetic analysis of the data, aimed on the identification of the best-fit kinetic model for Flufenacet and detected degradation products, and the determination of the persistence kinetic endpoints.

The Applicant submitted two other studies, also evaluated for the previous authorisation of Flufenacet in the EU. They presented the results of the examination of storage stability of Flufenacet and its seven degradation products in frozen soil. These studies, being closely related to the four studies examining field dissipation of Flufenacet, are summarised as **Study 5** and **Study 6** immediately after the **Studies 1-4**. They precede the kinetic analysis of the results obtained in **Studies 1-4**.

Finally, the Applicant submitted a new study, summarised as **Study 7**, presenting the results of the kinetic examination of the results of the **Studies 1-4** to determine the modelling kinetic endpoints for Flufenacet and FOE Sulfonic acid.

Additionally the literature search resulted in the identification of three open-source publication identified as relevant for the purpose of the current assessment as source of the supplementary data. They will be summarised at the end of this section as **Studies 8-10**.

Study 1:

Report: Sommer H., (1995): “Dissipation of FOE 5043 in Soil under Field Conditions (Germany, France).” Bayer AG, Crop Protection Business Group, Crop Protection-Development, Institute for Metabolism Research & Residue Analysis, D-51368 Leverkusen-Baywerk, Germany (performing laboratory) *for* Bayer Corporation, Agriculture Division, P. O. Box 4913, Hawthorne Road, Kansas City, MO 64120-0013, USA; Study Report RA-2112/93; Bayer Report No. 107724; 1 September 1995; study reference number: M-002172-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guideline IV-4.1, (1986);
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (Supplemental).

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by inclusion of the compound into the Annex I of the Directive 91/414/EEC. Its brief summary can be found under the point B.7.1.2.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. Assessing it, as well as other three similar studies, the RMS stated that it was acceptable, although at the same time indicated that the study was not triggered, and hence required according to the provisions of the Commission Directive 95/36/EC of the 14th July 1994, amending the Council Directive 91/414/EEC. It was however required according to the provisions of the German BBA guideline for assessing Plant Protection Products, part IV, 4.1.

For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- Lynch M. R., editor, (1995): “Procedures for assessing the environmental fate and ecotoxicology of pesticides.”, SETAC; chapter 3.1. – Soil dissipation study;
- NAFTA Guidance Document for Conducting Terrestrial Field Dissipation Studies, 31 March 2006;
- US EPA Fate, Transport and Transformation Test Guidelines, OPPTS Guideline 835.6100 – Terrestrial Field Dissipation;

Additionally, in the area of the kinetic assessment of the results, it was evaluated for the compliance with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS, 2011: “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Version 1.0, Nov. 23, 2011.

The following deviations from the Guidelines cited above were stated:

- The history of the test fields over 5 years preceding the trials was not provided, therefore it is not possible to state whether Flufenacet or other plant protection products belonging to the same group – oxyacetamides, acetamides or amides, were used there during that period;
- The analytical method used in the study was generally adequately characterised, with exception of the instrumental methods used for identification and quantitation of the test compounds. That was indicated solely to be HPLC-MS/MS. However, as the method was declared to be a validated method, it was probably very similar or the same as used in other studies aimed on the determination of the route and rate of degradation of Flufenacet in soil;
- The characteristic of the trial plots was very limited – only the area was provided without the plot’s dimension (width, length) and other physical features usually required, such as the plot’s slope;
- The soil cores were sampled to the depth of 50 cm, while the relevant Guidelines recommend 1-metre deep sampling;
- The kinetic analysis of the results was performed according to Timme and Frehse, the method not compliant with the currently recommended procedure for kinetic evaluation of the data;

- The study report contains the weather data, but reported, for the first 30 days in 7-days intervals, and afterwards in ~30 days intervals; additionally average monthly values and average monthly values of many years are given, what may substantially complicate the normalisation procedure;
- The analysis in the area of degradation products was performed only for the metabolites formed by the degradation within the phenyl moiety – FOE Oxalate, FOE Alcohol, and FOE Sulfonic acid; the would-be fate of Flufenacet within the thiadiazole moiety was not examined.

Despite these deficiencies RMS found the study acceptable and possible to be used for the regulatory purposes, at least as a source of the data characterising persistence of Flufenacet and its selected major soil degradation products in soil under field conditions. The study is summarised below.

Summary:

The aim of the study was to examine the dissipation of Flufenacet and formation and fate of its degradation products in soil under field conditions. The experiment was carried out on eight trial locations, in Germany (four locations) and in France (four locations – two in northern France and two other in southern France). It was performed on bare fields – German trials, and cropped fields - French trials. The characteristic of trial sites is presented below in two tables – table B.8.1.1.2.2.1._CA-1 for German trials and B.8.1.1.2.2.1._CA-2 for French trials.

Table B.8.1.2.2.1._CA-1: The characteristic of the German trial sites.

Footnotes to the table:

1) For that trial soil textural class was determined only using DIN 19682;

2) In the study report the trial bore the name "Laacherhof", but to maintain the consistency with the former DAR and other reports RMS renamed it "Monheim";

3) In the study report the trial bore the name "Höfchen", but to maintain the consistency with the former DAR and other reports RMS renamed it "Burscheid".

	Application dose of formulated product	10 kg/ha	2 L/ha	12 kg/ha	4 L/ha

The Test Substance – Flufenacet formulated as FOE 5043 60 WG, was applied at spring to either still bare soil or, in case of one French trial – Laudun 30251/1, soil already having 10%-plant cover (sunflower). Prior to the application from each trial site 50-cm soil cores were sampled for the characterisation of the soil on the test plot.

After application 50-cm soil cores were taken from each test field at pre-designated time point. The sampling points were statistically distributed over the plot to get the representative samples. The cores were taken using a pushing sampling system – Wacker Hammer. The first samples – DAT 0 samples (DAT stands for “Days After Treatment”), were taken directly after application, immediately after drying of the spray film. For that time point, as well as for the last time point, two types of soil cores were sampled for the further analysis – treated samples and control samples (from the non-treated plots). For the remaining time points only the cores from the treated plots were samples. At each sampling interval 20 cores were taken from the treated plot and 10 (for German trial sites) or 20 (for French trial sites) from the control, untreated, plot. The sampled cores were deep-frozen ($T < -18^{\circ}\text{C}$) on the sampling site and on the day of sampling. In that state they were shipped to the laboratory for further analysis. The sampling protocol for each trial site is presented below, in tables B.8.1.1.2.2.1_CA-4 and B.8.1.1.2.2.1_CA-5 for German trials and in tables B.8.1.1.2.2.1_CA-6 and B.8.1.1.2.2.1_CA-7 for French trials. The deep-frozen samples were stored for 2-181 days, depending on the trial and sample, before being processed.

In the laboratory the cores were cut into 10 cm segments and segments from the same layer were milled and homogenised. A part of such sample, further called laboratory samples, was used in the analysis, performed using the internal analytical method developed by Bachlechner and Allemendinger. It consisted of a cold-solvent extraction followed by the qualitative and quantitative analysis using HPLC-MS/MS technique.

The cold-solvent extraction looked as follows: soil samples were extracted by shaking for 60 minutes on mechanic shaker with 100 mL of 0.1N HCl/CH₃CN (1:1) solution. The liquid phase was decanted and purified by filtration. 40 mL of filtrate was concentrated to 5 mL on TurboVap and brought to the volume of 10 mL with 0.4 mL of 37% HCl_{aq}, followed by the appropriate amount of distilled water. After centrifugation the solution was analysed by HPLC-MS/MS. RMS noticed that the used extraction method was almost identical to that described in the open-source publication by [Lam, McKinney and Clay; 2002], summarised as **Study 8** under the point B.8.1.1.1.1. of this Renewal Assessment Report. This may indicate that it may be considered fully appropriate for the purpose it was used for.

The identification and quantitation was performed using HPLC-MS/MS method in comparison to internal standards – deuterised derivatives of the analytes, added after extraction. The qualitative and quantitative analysis was performed for the following compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The method was validated and controlled by determining the procedural recoveries for each of the test compounds in range 10 – 600 µg/kg. They were following:

- for Flufenacet the mean recovery was 89.6% with RSD = 6.2%;
- for FOE Alcohol the mean recovery was 94.3% with RSD = 4.3%;
- for FOE Oxalate the mean recovery was 96.6% with RSD = 7.9%;
- for FOE Sulfonic acid the mean recovery was 102% with RSD = 3.8%.

The performance of the method was also determined in terms of LOD = 3 µg/kg and LOQ = 10 µg/kg. These values were relevant for each compound of interest.

Additionally were determined the procedural recovery rates for each analysed compound and each trial site. The results are presented in the table B.8.1.1.2.2.1_CA-8. They were used to verify the integrity of the analysis of residues.

The verification of the application rate was performed for each trial site using 0-10 cm layers of sampled soil cores. The resulting values were the averages of four replicates. They were compared to the theoretical concentrations of Flufenacet in soil, calculated using the following assumptions: the compound was evenly distributed in 0-10cm layer and the soil density was 1.5 g/cm³. The theoretical concentrations of the test compound were therefore following:

- for the application rate of 480 g/ha it was **320 µg/kg**;
- for the application rate of 600 g/ha it was **400 µg/kg**.

The detailed results of the verification of application rate for each trial are provided in the table B.8.1.1.2.2.1_CA-9.

The main results of the study are presented in tabularised form further down this summary (tables B.8.1.1.2.2.1_CA-10 – B.8.1.1.2.2.1_CA-19). Finally, on figures B.8.1.1.2.2.1_CA-1 – B.8.1.1.2.2.1_CA-8 are presented the weather data as they were provided in the study report.

<i>St. Etienne du Gres (30253/8); South France</i>	600	400	280	70.0

Below are presented the results of the study: the concentrations in [$\mu\text{g/kg}$] of Flufenacet and its degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, in soil for each trial. The results for German trial sites are presented in five tables. Table B.8.1.1.2.2.1._CA-10 provides the values obtained in samples from the control plots. Next, in tables B.8.1.1.2.2.1._CA-11 – B.8.1.1.2.2.1._CA-14, are provided the values for the treated plots, individually for each trial site. The values are given only for the the layers down to 30-cm depth. That was due to the fact that in case of Flufenacet the measurable residues – above the LOQ = 10 $\mu\text{g/kg}$, were found predominantly in the top layer 0-10 cm, and sporadically in the lower 10-20-cm layer. In the layer 20-30 cm Flufenacet was not detected, so in the study report it was stated that deeper its concentrations were also below the LOD = 3 $\mu\text{g/kg}$.

In case of the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, their residues, if detected, were found in the top 0-10 cm layer. In the lower layers – 10-20 cm and 20-30 cm these compounds, if detected, were in amounts < LOQ (10 $\mu\text{g/kg}$). Additionally it was stated that in almost all cases they were < LOD (3 $\mu\text{g/kg}$), so in fact were not detected in deeper soil layers.

As a result the layers 30-40 cm and 40-50 cm were not analysed and consequently not taken into account in tables reporting the results.

Table B.8.1.1.2.2.1._CA-10: The results of the determination of the concentrations of the test compounds in samples from control (untreated) plots obtained in German trials.

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for that layer the values for two or, more commonly, one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

Table B.8.1.1.2.2.1_CA-12: The results of the determination of the concentrations of the test compounds in samples from treated plot obtained in the German trial Kirchlauter (30162/0).

Footnotes to the table:

1) For that layer usually the values for two replicates were reported;

2) for that layer the values for two or, more commonly, one replicate were reported;

3) <10 = values below the LOQ = 10 µg/kg soil;

4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.

5) No value.

6) For this time point, for the parent compound and FOE Sulfonic acid eight replicates were analysed. Each value is reported in the individual cell; RMS decided not to alter the general outline of the reporting table.

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for that layer the values for two or, more commonly, one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

The results for French trial sites are presented in five table. Table B.8.1.1.2.2.1._CA-15 is summarising the values obtained in samples from the control plots. The tables - B.8.1.1.2.2.1._CA-16 – B.8.1.1.2.2.1._CA-19 provide the results for the treated plots, individually for each trial site. The values are given only for the the layers down to 30-cm depth. That was due to the fact that in case of Flufenacet the measurable residues – above the LOQ = 10 µg/kg, were found predominantly in the top layer 0-10 cm, and sporadically in the lower 10-20-cm layer. In the layer 20-30 cm Flufenacet was not detected, so in the study report it was stated that its concentrations there were below the LOD = 3 µg/kg.

In case of the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, their residues, if detected, were found in the top 0-10 cm layer. In the lower layers – 10-20 cm and 20-30 cm these compounds, if detected, were in amounts < LOQ (10 µg/kg). Additionally it was stated that in almost all cases they were < LOD (3 µg/kg), so in fact were not detected in deeper soil layers.

As a result the layers 30-40 cm and 40-50 cm were not analysed and consequently not taken into account in tables reporting the results.

Table B.8.1.1.2.2.1._CA-15: The results of the determination of the concentrations of the test compounds in samples from control (untreated) plots obtained in French trials.

Results obtained for the trial: Fresne-L'Archeveque, North France (30248/1)

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for that layer the values for two or, more commonly, one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil;
- 5) No value;
- 6) The values for Flufenacet for that soil layer and that time point were lower than the LOQ = 10 µg/kg soil, so they were not taken into account in the further analysis.

The weather data for each trial site provided by the study report are presented below on figures B.8.1.1.2.2.1._CA-1 – B.8.1.1.2.2.1._CA-8.

Figure B.8.1.1.2.2.1_CA-8: The weather data presented in the study report for the South French trial site St. Etienne du Gres (30253/8); copied from the study report.

The results of the study were kinetically examined. It was stated that due to the fact that for the degradation products – FOE Oxalate and FOE Sulfonic acid, only in few samples from the layer 0-10 cm the concentrations were above the LOQ = 10 µg/kg soil (d. w.), while for FOE Alcohol the values were generally < LOQ, it was not possible to perform the kinetic examination of the data. Therefore only for the data obtained for Flufenacet kinetic analysis was performed.

The kinetic examination of the data was carried out using Timme and Frehse method. As that method of the kinetic analysis is not any longer considered valid for the regulatory purposes in the EU, RMS decided not to present its results in the summary. Instead the results will be kinetically evaluated, in line with the recommendations of the FOCUS Kineitcs Guidance Document [FOCUS; 2006], further down this Renewal Assessment Report.

Study 2:

Report: Sommer H., (1995): “Dissipation of FOE 5043 in Soil under Field Conditions (Germany).”; Bayer AG, Crop Protection Business Group, Crop Protection-Development, Institute for Metabolism Research & Residue Analysis, D-51368 Leverkusen-Baywerk, Germany (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Hawthorne Road, Kansas City, MO 64120-0013, USA; Study Report No. RA-2116/93; Bayer Report No. 107722; 5 October 1995; study reference number: M-002171-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guideline IV-4.1, (1986);
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (Supplemental).

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by inclusion of the compound into the Annex I of the Directive 91/414/EEC. Its brief summary can be found under the point B.7.1.2.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. Assessing it, as well as other three similar studies, the RMS stated that it was acceptable, although at the same time indicated that the study was not triggered, and hence required, according to the provisions of the Commission Directive 95/36/EC of the 14th July 1994, amending the Council Directive 91/414/EEC. It was however required according to the provisions of the German BBA guideline for assessing Plant Protection Products, part IV, 4.1.

For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- Lynch M. R., editor, (1995): “Procedures for assessing the environmental fate and ecotoxicology of pesticides.”, SETAC; chapter 3.1. – Soil dissipation study;
- NAFTA Guidance Document for Conducting Terrestrial Field Dissipation Studies, 31 March 2006;
- US EPA Fate, Transport and Transformation Test Guidelines, OPPTS Guideline 835.6100 – Terrestrial Field Dissipation;

Additionally, in the area of the kinetic assessment of the results, it was evaluated for the compliance with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS, 2011: “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Version 1.0, Nov. 23, 2011.

The following deviations from the Guidelines cited above were stated:

- The history of the test fields over 5 years preceding the trials was not provided, therefore it is not possible to state whether Flufenacet or other plant protection products belonging to the same group – oxyacetamides, acetamides or amides, were used there during that period;
- The analytical method used in the study was generally adequately characterised, with exception of the instrumental methods used for identification and quantitation of the test compounds. That was indicated solely to be HPLC-MS/MS. However, as the method was declared to be a validated method, it was probably very similar or the same as used in other studies aimed on the determination of the route and rate of degradation of Flufenacet in soil;
- The characteristic of the trial plots was very limited – only the area was provided without the plot’s dimension (width, length) and other physical features usually required, such as the plot’s slope;
- The soil cores were sampled to the depth of 50 cm, while the relevant Guidelines recommend 1-metre deep sampling;
- The kinetic analysis of the results was performed according to Timme and Frehse, the method not compliant with the currently recommended procedure for kinetic evaluation of the data;

- The study report contains the weather data, but reported, for the first 30 days in 7-days intervals, and afterwards in ~30 days intervals; additionally average monthly values and average monthly values of many years are given, what may substantially complicate the normalisation procedure;
- The analysis in the area of degradation products was performed only for the metabolites formed by the degradation within the phenyl moiety – FOE Oxalate, FOE Alcohol, and FOE Sulfonic acid; the would-be fate of Flufenacet within the thiadiazole moiety was not examined.

Despite these deficiencies RMS found the study acceptable and possible to be used for the regulatory purposes, at least as a source of the data characterising persistence of Flufenacet and its selected major soil degradation products in soil under field conditions. The study is summarised below.

Summary:

The aim of the study was to examine the dissipation of Flufenacet and formation and fate of its degradation products in soil under field conditions. The experiment was carried out on two trial locations in Germany. It was performed on bare fields. The characteristic of trial sites is presented below in the table B.8.1.1.2.2.1._CA-20.

Table B.8.1.2.2.1._CA-20: The characteristic of the trial sites.

The Test Substance – Flufenacet formulated as FOE 5043 60 WG, was applied in autumn to the bare soil. Prior to the application from each trial site 50-cm soil cores were sampled for the characterisation of the soil on the test plot.

After application 50-cm soil cores were taken from each test field at pre-designated time point. The sampling points were statistically distributed over the plot to get the representative samples. The cores were taken using a pushing sampling system – Wacker Hammer. The first samples – DAT 0 samples (DAT stands for “Days After Treatment”), were taken directly after application, immediately after drying of the spray film. For that time point, as well as for the last time point, two types of soil cores were sampled for the further analysis – treated samples and control samples (from the non-treated plots). For the remaining time points only the cores from the treated plots were samples. At each sampling interval 20 cores were sampled from the treated plot and 10 or 20 from the control. The sampled cores were deep-frozen ($T < -18^{\circ}\text{C}$) on the sampling site on the day of sampling and in that state shipped to the laboratory for further analysis. The sampling protocol for each trial site is presented below, in the table B.8.1.1.2.2.1._CA-21. The deep-frozen samples were stored for up to 365 days before being processed.

In the laboratory the cores were cut into 10 cm segments and segments of one layer, further called laboratory samples, were milled and homogenised. A part of such sample was used in the analysis, performed using the internal analytical method developed by Bachlechner and Allemendinger. It consisted of cold-solvent extraction followed by the quantitative analysis using HPLC-MS/MS technique.

The cold-solvent extraction looked as follows: soil samples were extracted by shaking for 60 minutes on mechanic shaker with 100 mL of 0.1N HCl/CH₃CN (1:1) solution. The liquid phase was decanted and purified by filtration. 40 mL of filtrate was concentrated to 5 mL on TurboVap and brought to the volume of 10 mL with first 0.4 mL of 37% HCl_{aq} followed by the appropriate amount of distilled water. After centrifugation it was analysed by HPLC-MS/MS. RMS noticed that the used extraction method was almost identical to that described in the open-source publication by [Lam, McKinney and Clay; 2002], summarised as **Study 8** under the point B.8.1.1.1.1. of this Renewal Assessment Report. This may indicate that it may be considered fully appropriate for the purpose it was used for.

The identification and quantitation was performed using HPLC-MS/MS method in comparison to internal standards – deuterised derivatives of the analytes, added after extraction. The qualitative and quantitative analysis was performed for the following compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The method was validated and controlled by determining the procedural recoveries for each of the test compounds in range 10 – 600 µg/kg. They were following:

- for Flufenacet the mean recovery was 89.6% with RSD = 6.2%;
- for FOE Alcohol the mean recovery was 94.3% with RSD = 4.3%;
- for FOE Oxalate the mean recovery was 96.6% with RSD = 7.9%;
- for FOE Sulfonic acid the mean recovery was 102% with RSD = 3.8%.

The performance of the method was also determined in terms of LOD = 3 µg/kg and LOQ = 10 µg/kg. These values were relevant for all analytes.

Additionally were determined the recovery rates during analyses for each analysed compound and each trial site. The results are presented in the table B.8.1.1.2.2.1._CA-22. They were used to verify the integrity of the analysis of residues.

The verification of the application rate was performed for each trial site using 0-10 cm layers of sampled soil cores. The resulting values were the averages of four replicates. They were compared to the theoretical concentrations of Flufenacet in soil calculated using the following assumptions: the compound was evenly distributed in 0-10cm layer and the soil density was 1.5 g/cm³. The theoretical concentration of the test compound for the application rate of 240 g Flufenacet/ha was **160 µg/kg soil**.

The detailed results of the verification of application rate for each trial are provided in the table B.8.1.1.2.2.1._CA-23.

The results of the analysis are presented in tabularised form further down this summary (tables B.8.1.1.2.2.1._CA-24 – B.8.1.1.2.2.1._CA-26). Finally, on figures B.8.1.1.2.2.1._CA-9 and B.8.1.1.2.2.1._CA-10 are presented the weather data as they were provided in the study report.

Next table – B.8.1.1.2.2.1._CA-22 provides the results of the determination of recovery rates for each analyte during analyses. It is followed by the table B.8.1.1.2.2.1._CA-23 presenting the results of the verification of the application rate for each trial site.

Table B.8.1.1.2.2.1._CA-22: The results of the verification of the recovery rates for each analyte during the analysis of the collected samples.

Compound	Parameter	Results for the trial:	
		Burscheid (30499/9)	Monheim (30500/6)
<i>Flufenacet</i>	Recovery rate [%]	83.0	87.4
	RSD [%]	8.8	3.1
	Number of experiments	8	8
<i>FOE Alcohol</i>	Recovery rate [%]	84.7	86.5
	RSD [%]	4.3	3.6
	Number of experiments	8	8
<i>FOE Oxalate</i>	Recovery rate [%]	77.6	80.0
	RSD [%]	3.7	3.1
	Number of experiments	8	8
<i>FOE Sulfonic acid</i>	Recovery rate [%]	94.0	96.0
	RSD [%]	3.0	3.5
	Number of experiments	8	8

Table B.8.1.1.2.2.1._CA-23: The results of the verification of the application rate for each trial site.

Trial	Application rate [g Flufenacet/ha]	Theoretical DAT-0 concentration of Flufenacet in top 10-cm soil layer [µg/kg soil]	Measured DAT-0 concentration of Flufenacet in top 10-cm soil layer [µg/kg soil]	Measured DAT-0 concentration of Flufenacet in top soil as % of Theoretical concentration
Burscheid (30499/9)	240	160	141	88.1
Monheim (30500/6)	240	160	101	63.1

Below are presented the results of the study – the concentrations in [µg/kg] of Flufenacet and its degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, in soil for each trial. The results are presented in three tables – table B.8.1.1.2.2.1._CA-24, summarising the values obtained in samples from the control plots, and then for the treated plots individually for each trial in tables B.8.1.1.2.2.1._CA-25 and B.8.1.1.2.2.1._CA-26. The values are given only for the the layers down to 30-cm depth. That was due to the fact that in case of Flufenacet the measurable residues – above the LOQ = 10 µg/kg, were found predominantly in the top layer 0-10 cm, and sporadically in the lower 10-20-cm layer. In the layer 20-30 cm Flufenacet was not detected, so in the study report it was stated that its concentrations there were below the LOD = 3 µg/kg.

In case of the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, their residues, if detected, were found in the top 0-10 cm layer. In the lower layers – 10-20 cm and 20-30 cm these compounds, if detected, were in amounts < LOQ (10 µg/kg). Additionally it was stated that in almost all cases they were < LOD (3 µg/kg), so in fact were not detected in deeper soil layers.

As a result the layers 30-40 cm and 40-50 cm were not analysed and consequently not taken into account in tables reporting the results.

Table B.8.1.1.2.2.1_CA-24: The results of the determination of the concentrations of the test compounds in samples from control (untreated) plots obtained in the trials.

Results obtained for the trial: Burscheid (30499/9)

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for that layer the values for two or, more commonly, one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

Table B.8.1.1.2.2.1_CA-26: The results of the determination of the concentrations of the test compounds in samples from treated plot obtained in the German trial Monheim (30500/6).

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for that layer the values for two or, more commonly, one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

The weather data for each trial site provided by the study report are presented below on figures B.8.1.1.2.2.1._CA-9 and B.8.1.1.2.2.1._CA-10.

Figure B.8.1.1.2.2.1._CA-10: The weather data presented in the study report for the German trial site Monheim (30500/6); copied from the study report.

The results of the study were kinetically examined. It was stated that due to the fact that for the degradation products – FOE Oxalate and FOE Sulfonic acid, only in few samples from the layer 0-10 cm the concentrations were above the LOQ = 10 µg/kg soil (d. w.), while for FOE Alcohol the values were generally < LOQ, it was not possible to perform the kinetic examination of the data. Therefore only for the data obtained for Flufenacet kinetic analysis was performed.

The kinetic examination of the data was carried out using Timme and Frehse method. As that method of the kinetic analysis is not any longer considered valid for the regulatory purposes in the EU, RMS decided not to present its results in the summary. Instead the results will be kinetically evaluated, in line with the recommendations of the FOCUS Kineitics Guidance Document [FOCUS; 2006], further down this Renewal Assessment Report.

Study 3:

Report: Sommer H., (1995): “Dissipation of FOE 5043 in Soil under Field Conditions (France).” Bayer AG, Crop Protection Business Group, Crop Protection-Development, Institute for Metabolism Research & Residue Analysis, D-51368 Leverkusen-Baywerk, Germany (performing laboratory) for Bayer Corporation, Agriculture Division, P. O. Box 4913, Hawthorne Road, Kansas City, MO 64120-0013, USA; Study Report No. RA-2051/93; Bayer Report No. 107723; 6 October 1995; study reference number: M-002169-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guideline IV-4.1, (1986);
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (Supplemental).

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by inclusion of the compound into the Annex I of the Directive 91/414/EEC. Its brief summary can be found under the point B.7.1.2.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. Assessing it, as well as other three similar studies, the RMS stated that it was acceptable, although at the same time indicated that the study was not triggered, and hence required, according to the provisions of the Commission Directive 95/36/EC of the 14th July 1994, amending the Council Directive 91/414/EEC. It was however required according to the provisions of the German BBA guideline for assessing Plant Protection Products, part IV, 4.1.

For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- Lynch M. R., editor, (1995): “Procedures for assessing the environmental fate and ecotoxicology of pesticides.”, SETAC; chapter 3.1. – Soil dissipation study;
- NAFTA Guidance Document for Conducting Terrestrial Field Dissipation Studies, 31 March 2006;
- US EPA Fate, Transport and Transformation Test Guidelines, OPPTS Guideline 835.6100 – Terrestrial Field Dissipation;

Additionally, in the area of the kinetic assessment of the results, it was evaluated for the compliance with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS, 2011: “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Version 1.0, Nov. 23, 2011.

The following deviations from the Guidelines cited above were stated:

- The history of the test fields over 5 years preceding the trials was not provided, therefore it is not possible to state whether flufenacet or other plant protection products belonging to the same group – oxyacetamides, acetamides or amides, were used there during that period;
- The analytical method used in the study was generally adequately characterised, with exception of the instrumental methods used for identification and quantitation of the test compounds. That was indicated solely to be HPLC-MS/MS. However, as the method was declared to be a validated method, it was probably very similar or the same as used in other studies aimed on the determination of the route of degradation of Flufenacet in soil;
- The characteristics of the trial plots was very limited – only the area was provided without the plot’s dimension (width, length) and other physical features usually required, such as the plot’s slope;
- The soil cores were sampled to the depth of 50 cm, while the relevant Guidelines recommend 1-metre deep sampling;
- The kinetic analysis of the results was performed according to Timme and Frehse, the method not compliant with the currently recommended procedure for kinetic evaluation of the data;

- The study report contains the weather data, but reported, for the first 30 days in 7-days intervals, and afterwards in ~30 days intervals; additionally average monthly values and average monthly values of many years are given, what may substantially complicate the normalisation procedure;
- The analysis in the area of degradation products was performed only for the metabolites formed by the degradation within the phenyl moiety – FOE Oxalate, FOE Alcohol, and FOE Sulfonic acid; the would-be fate of Flufenacet within the thiadiazole moiety was not examined.

Despite these deficiencies RMS found the study acceptable, and possible to be used for the regulatory purposes, at least as a source of the data characterising persistence of Flufenacet and its selected major soil degradation products in soil under field conditions. The study is summarised below.

Summary:

The aim of the study was to examine the dissipation of Flufenacet and formation and fate of its degradation products in soil under field conditions. The experiment was carried out on two trial locations in France – one in Northern France (Fresne-L'Archeveque) and another in Southern France (Saussay-la-Campagne). It was performed on cropped fields, covered with winter wheat. The characteristic of trial sites is presented below in the table B.8.1.1.2.2.1._CA-27.

Table B.8.1.2.2.1._CA-27: The characteristic of the trial sites.

Information			Trial:

The information provided in the study report on the use of the Plant Protection Products other than the test compound in the trials is given below in the table B.8.1.1.2.2.1._CA-28.

Table B.8.1.1.2.2.1._CA-28: The information on the use of other Plant Protection Products in the trials.

Trial site	Pesticide applied	Parameter			
		Date of the treatment	PPP data		
			Name of the formulation	Type of formulation	Application rate of formulated product
<i>Saussay-la-Campagne (30254/6), Southern France</i>	Pesticide 1	26/03/1994	Cycocel	460 SL	2.0 [L/ha]
	Pesticide 2	15/04/1994	Sponsor	250+250 EC	1.5 [L/ha]
	Pesticide 3	29/04/1994	Terpal	305 + 155 SL	0.8 [L/ha]
	Pesticide 4	10/05/1994	Alto Mayor	80 + 350 EC	0.6 [L/ha]
	Pesticide 5	10/05/1994	Karate	80 EC	0.25 [L/ha]
	Pesticide 6	30/05/1994	Sirius	75 + 300 SC	2.0 [L/ha]
	Pesticide 7	30/05/1994	Tracker	108 EC	0.07 [L/ha]
<i>Fresne-L'Archeveque (30455/7); Northern France</i>	Pesticide 1	26/03/1994	Cycocel	460 SL	2.0 [L/ha]
	Pesticide 2	19/04/1994	Horizon	280 EW	0.6 [L/ha]
	Pesticide 3	31/05/1994	Opus	125 SC	0.4 [L/ha]
	Pesticide 4	31/05/1994	Planete Aster	250 SC	0.25 [L/ha]
	Pesticide 5	16/06/1994	Karate	80 EC	0.125 [L/ha]

The Test Substance – Flufenacet formulated as FOE 5043 60 WG, was applied in early spring to the soil covered with winter wheat sown on the previous autumn. Prior to the application from each trial site 50-cm soil cores were sampled for the characterisation of the soil on the test plot.

After application 50-cm soil cores were taken from each test field at pre-designated time point. The locations of sampling points were statistically distributed over the plot to get the representative samples. The cores were taken using a pushing sampling system – Wacker Hammer. The first samples – DAT 0 samples (DAT stands for “Days After Treatment”), were taken directly after application, immediately after drying of the spray film. For that time point, as well as for the last time point two types of soil cores were sampled for the further analysis – treated samples and control samples (from the non-treated plots). For the remaining time points only the cores from the treated plots were samples. At each sampling interval 20 cores were sampled from the treated plot and another 20 from the control. Additionally on DAT 0 samples were taken from the 0-10cm layer using the RA-piercer. The sampled cores were deep-frozen ($T < -18^{\circ}\text{C}$) on the sampling site on the day of sampling and in that state shipped to the laboratory for further analysis. The sampling protocol for each trial site is presented below, in the table B.8.1.1.2.2.1._CA-29. The deep-frozen samples were stored for up to ~500 days before being processed.

In the laboratory the cores were cut into 10 cm segments and segments of one layer, further called laboratory samples, were milled and homogenised. A part of such sample was used in the analysis, performed using the internal analytical method developed by Bachlechner and Allemendinger. It consisted of cold-solvent extraction followed by the quantitative analysis using HPLC-MS/MS technique.

The cold-solvent extraction looked as follows: soil samples were extracted by shaking for 60 minutes on mechanic shaker, with 100 mL of 0.1N HCl/CH₃CN (1:1) solution. The liquid phase was decanted and purified by filtration. 40 mL of filtrate was concentrated to 5 mL on TurboVap and brought to the volume of 10 mL with first 0.4 mL of 37% HCl_{aq} followed by the appropriate amount of distilled water. After centrifugation it was analysed by HPLC-MS/MS. RMS noticed that the used extraction method was almost identical to that described in the open-source publication by [Lam, McKinney and Clay; 2002], summarised as **Study 8** under the point B.8.1.1.1.1. of this Renewal Assessment Report. This may indicate that it may be considered fully appropriate for the purpose it was used for.

The identification and quantitation was performed using HPLC-MS/MS method in comparison to internal standards – deuterised derivatives of the analytes, added after extraction. The qualitative and quantitative analysis was performed for the following compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The method was validated and controlled by determining the procedural recoveries for each of the test compounds in range 10 – 600 µg/kg. They were following:

- for Flufenacet the mean recovery was 89.6% with RSD = 6.2%;
- for FOE Alcohol the mean recovery was 94.3% with RSD = 4.3%;
- for FOE Oxalate the mean recovery was 96.6% with RSD = 7.9%;
- for FOE Sulfonic acid the mean recovery was 102% with RSD = 3.8%.

The performance of the method was also determined in terms of LOD = 3 µg/kg and LOQ = 10 µg/kg. These values were relevant for all analytes.

Additionally were determined the recovery rates during analyses for each analysed compound and each trial site. The results are presented in the table B.8.1.1.2.2.1._CA-30. They were used to verify the integrity of the analysis of residues.

The verification of the application rate was performed for each trial site using 0-10 cm layers of sampled soil cores. The resulting values were the averages of four replicates. They were compared to the theoretical concentrations of Flufenacet in soil, calculated using the following assumptions: the compound was evenly distributed in 0-10cm layer and the soil density was 1.5 g/cm³. The theoretical concentration of the test compound, for the application rate of 240 g Flufenacet/ha was **160 µg/kg soil**.

The detailed results of the verification of application rate for each trial are provided in the table B.8.1.1.2.2.1._CA-31.

The results of the analysis are presented in tabularised form further down this summary (tables B.8.1.1.2.2.1._CA-32 – B.8.1.1.2.2.1._CA-34/34a). Finally, on figures B.8.1.1.2.2.1._CA-11 and B.8.1.1.2.2.1._CA-12 are presented the weather data as they were provided in the study report.

Table B.8.1.1.2.2.1._CA-29: The sampling data for the French trials Saussay-la-Campagne and Fresne-L'Archeveque.

Trial: Saussay-la-Campagne (30254/6), Southern France					Trial: Fresne-L'Archeveque (30455/7), Northern France

Footnotes to the table:

- 1) For this time point samples taken using RA-piercer were analysed, because the soil cores taken using Wacker Hammer were not available for the analysis – they were damaged during transport;

Next table – B.8.1.1.2.2.1._CA-30 provides the results of the determination of recovery rates for each analyte during analyses. It is followed by the table B.8.1.1.2.2.1._CA-31 presenting the results of the verification of the application rate for each trial site.

Table B.8.1.1.2.2.1._CA-30: The results of the verification of the recovery rates for each analyte during the analysis of the collected samples.

Compound	Parameter	Results for the trial:	
		Saussay-la-Campagne (30254/6), Southern France	Fresne-L'Archeveque (30455/7), Northern France
Flufenacet	Recovery rate [%]	92.8	88.0
	RSD [%]	8.2	13.9
FOE Alcohol	Recovery rate [%]	88.5	86.4
	RSD [%]	9.8	4.4
FOE Oxalate	Recovery rate [%]	97.2	96.3
	RSD [%]	8.1	7.5
FOE Sulfonic acid	Recovery rate [%]	88.5	93.9
	RSD [%]	5.3	15.9

Table B.8.1.1.2.2.1._CA-31: The results of the verification of the application rate for each trial site.

Trial	Application rate [g Flufenacet/ha]	Theoretical DAT-0 concentration of Flufenacet in top 10-cm soil layer [µg/kg soil]	Measured DAT-0 concentration of Flufenacet in top 10-cm soil layer [µg/kg soil]	Measured DAT-0 concentration of Flufenacet in top soil as % of Theoretical concentration
Saussay-la-Campagne (30254/6), Southern France	240	160	115	71.9
Fresne-L'Archeveque (30455/7), Northern France	240	160	93.0	58.1

Below are presented the results of the study – the concentrations in [µg/kg] of Flufenacet and its degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, in soil for each trial. The results are presented in three tables – table B.8.1.1.2.2.1._CA-32, summarising the values obtained in samples from the control plots, and then for the treated plots individually for each trial in tables B.8.1.1.2.2.1._CA-33/33a and B.8.1.1.2.2.1._CA-34/34a. The values are given for the the layers down to 50-cm depth.

In case of the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, their residues, if detected, were found in the top 0-10 cm layer. In the lower layers – 10-20 cm, 20-30 cm, 30-40 cm and 40-50 cm, these compounds, if detected, were in amounts < LOQ (10 µg/kg). Additionally it was stated that in almost all cases they were < LOD (3 µg/kg), so in fact were not detected in deeper soil layers.

Table B.8.1.1.2.2.1._CA-32: The results of the determination of the concentrations of the test compounds in samples from control (untreated) plots obtained in the trials.

Results obtained for the trial: Saussay-la-Campagne (30254/6)

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for these layers the values one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

Figure B.8.1.1.2.2.1._CA-12: The weather data presented in the study report for the North French trial site Fresno-L'Archeveque (30455/7); copied from the study report.

The results of the study were kinetically examined. It was stated that due to the fact that for the degradation products – FOE Oxalate and FOE Sulfonic acid, only in few samples from the layer 0-10 cm the concentrations were above the LOQ = 10 µg/kg soil (d. w.), while for FOE Alcohol the values were generally < LOQ, it was not possible to perform the kinetic examination of the data. Therefore only for the data obtained for Flufenacet kinetic analysis was performed.

The kinetic examination of the data was carried out using Timme and Frehse method. As that method of the kinetic analysis is not any longer considered valid for the regulatory purposes in the EU, RMS decided not to present its results in the summary. Instead the results will be kinetically evaluated, in line with the recommendations of the FOCUS Kineitics Guidance Document [FOCUS; 2006], further down this Renewal Assessment Report.

Study 4:

Report: Sommer H., (1995): “Dissipation of FOE 5043 in Soil under Field Conditions (France, Italy).”; Bayer AG, Crop Protection Business Group, Crop Protection-Development, Institute for Metabolism Research & Residue Analysis, D-51368 Leverkusen-Baywerk, Germany (performing laboratory) *for* Bayer Corporation, Agriculture Division, P. O. Box 4913, Hawthorne Road, Kansas City, MO 64120-0013, USA; Study Report No. RA-2019/94; Bayer Report No. 107721; 23 November 1995; study reference number: M-002175-01-2;

Guidelines: The study was performed to comply with the following Guidelines:

- BBA Guideline IV-4.1, (1986);
- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (Supplemental).

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by inclusion of the compound into the Annex I of the Directive 91/414/EEC. Its brief summary can be found under the point B.7.1.2.2., in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. Assessing it, as well as other three similar studies, the RMS stated that it was acceptable, although at the same time indicated that the study was not triggered, and hence required, according to the provisions of the Commission Directive 95/36/EC of the 14th July 1994, amending the Council Directive 91/414/EEC. It was however required according to the provisions of the German BBA guideline for assessing Plant Protection Products, part IV, 4.1.

For the purpose of the current assessment the study was evaluated for its compliance with the following guidelines:

- Lynch M. R., editor, (1995): “Procedures for assessing the environmental fate and ecotoxicology of pesticides.”, SETAC; chapter 3.1. – Soil dissipation study;
- NAFTA Guidance Document for Conducting Terrestrial Field Dissipation Studies, 31 March 2006;
- US EPA Fate, Transport and Transformation Test Guidelines, OPPTS Guideline 835.6100 – Terrestrial Field Dissipation;

Additionally, in the area of the kinetic assessment of the results, it was evaluated for the compliance with the following Guidelines:

- FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference SANCO/10058/2005 version 2.0, 434 pp.;
- FOCUS, 2011: “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Version 1.0, Nov. 23, 2011.

The following deviations from the Guidelines cited above were stated:

- The history of the test fields over 5 years preceding the trials was not provided, therefore it is not possible to state whether flufenacet or other plant protection products belonging to the same group – oxyacetamides, acetamides or amides, were used there during that period;
- The analytical method used in the study was generally adequately characterised, with exception of the instrumental methods used for identification and quantitation of the test compounds. That was indicated solely to be HPLC-MS/MS. However, as the method was declared to be a validated method, it was probably very similar or the same as used in other studies aimed on the determination of the route of degradation of Flufenacet in soil;
- The characteristics of the trial plots was very limited – only the area was provided without the plot’s dimension (width, length) and other physical features usually required, such as the plot’s slope;
- The soil cores were sampled to the depth of 50 cm, while the relevant Guidelines recommend 1-metre deep sampling;
- The kinetic analysis of the results was performed according to Timme and Frehse, the method not compliant with the currently recommended procedure for kinetic evaluation of the data;

- The study report contains the weather data, but reported, for the first 30 days in 7-days intervals, and afterwards in ~30 days intervals; additionally average montly values and average monthly values of many years are given, what may substantially complicate the normalisation procedure;
- The analysis in the area of degradation products was performed only for the metabolites formed by the degradation within the phenyl moiety – FOE Oxalate, FOE Alcohol, and FOE Sulfonic acid; the would-be fate of Flufenacet within the thiadiazole moiety was not examined.

Despite these deficiencies RMS found the study acceptable, and possible to be used for the regulatory purposes, at least as a source of the data characterising persistence of Flufenacet and its selected major soil degradation products in soil under field conditions. The study is summarised below.

Summary:

The aim of the study was to examine the dissipation of Flufenacet and formation and fate of its degradation products in soil under field conditions. The experiment was carried out on four trial locations, in southern France (two locations) and in Italy (two locations). It was performed on cropped fields, covered with either sunflower (French trials) or soybean (Italian trials). The characteristic of trial sites is presented below in the table B.8.1.1.2.2.1._CA-35.

Table B.8.1.2.2.1._CA-35: The characteristic of the trial sites.

The Test Substance – Flufenacet formulated as FOE 5043 60 WG, was applied at spring, shortly after sowing of the crop. Prior to the application from each trial site 50-cm soil cores were sampled for the characterisation of the soil on the test plot.

After application 50-cm soil cores, having a diameter 49.0, 49.5 or 50 mm (depending on soil properties on sampling date) were taken from each test field at pre-designated time point. The locations of sampling points were statistically distributed over the plot to get the representative samples. The cores were taken using a pushing sampling system – Wacker Hammer. The first samples – DAT 0 samples (DAT stands for “Days After Treatment”), were taken directly after application, immediately after drying of the spray film. For that time point, as well as for the last time point two types of soil cores were sampled for the further analysis – treated samples and control samples (from the non-treated plots). For the remaining time points only the cores from the treated plots were samples. At each sampling interval 20 cores were sampled from the treated plot and 20 from the control, untreated, plot. The sampled cores were deep-frozen ($T < -18^{\circ}\text{C}$) on the sampling site on the day of sampling and in that state shipped to the laboratory for further analysis. The sampling protocol for each trial site is presented below, in tables B.8.1.1.2.2.1._CA-36 for French trials and B.8.1.1.2.2.1._CA-37 for Italian trials. The deep-frozen samples were stored for up to ~500 days, depending on the trial and sample, before being processed.

In the laboratory the cores were cut into 10 cm segments and segments of one layer, further called laboratory samples, milled and homogenised. A part of such sample was used in the analysis, performed using the internal analytical method developed by Bachlechner and Allemendinger. It consisted of cold-solvent extraction followed by the quantitative analysis using HPLC-MS/MS technique.

The cold-solvent extraction looked as follows: soil samples were extracted by shaking for 60 minutes on mechanic shaker, with 100 mL of 0.1N HCl/CH₃CN (1:1) solution. The liquid phase was decanted and purified by filtration. 40 mL of filtrate was concentrated to 5 mL on TurboVap and brought to the volume of 10 mL with first 0.4 mL of 37% HCl_{aq} followed by the appropriate amount of distilled water. After centrifugation it was analysed by HPLC-MS/MS. RMS noticed that the used extraction method was almost identical to that described in the open-source publication by [Lam, McKinney and Clay; 2002], summarised as **Study 8** under the point B.8.1.1.1.1. of this Renewal Assessment Report. This may indicate that it may be considered fully appropriate for the purpose it was used for.

The identification and quantitation was performed using HPLC-MS/MS method in comparison to internal standards – deuterised derivatives of the analytes, added after extraction. The qualitative and quantitative analysis was performed for the following compounds: Flufenacet, FOE Alcohol, FOE Oxalate and FOE Sulfonic acid.

The method was validated and controlled by determining the procedural recoveries for each of the test compounds in range 10 – 600 µg/kg. They were following:

- for Flufenacet the mean recovery was 89.6% with RSD = 6.2%;
- for FOE Alcohol the mean recovery was 94.3% with RSD = 4.3%;
- for FOE Oxalate the mean recovery was 96.6% with RSD = 7.9%;
- for FOE Sulfonic acid the mean recovery was 102% with RSD = 3.8%.

The performance of the method was also determined in terms of LOD = 3 µg/kg and LOQ = 10 µg/kg. These values were relevant for all analytes.

Additionally were determined the recovery rates during analyses for each analysed compound and each trial site. The results are presented in the table B.8.1.1.2.2.1._CA-38. They were used to verify the integrity of the analysis of residues.

The verification of the application rate was performed for each trial site using 0-10 cm layers of sampled soil cores. The resulting values were the averages of four replicates. They were compared to the theoretical concentrations of Flufenacet in soil calculated using the following assumptions: the compound was evenly distributed in 0-10cm layer and the soil density was 1.5 g/cm³. The theoretical concentration of the test compound, for the application rate of 600 g Flufenacet/ha was **400 µg/kg soil**. The detailed results of the verification of application rate for each trial are provided in the table B.8.1.1.2.2.1._CA-39.

The results of the analysis are presented in tabularised form further down this summary (tables B.8.1.1.2.2.1._CA-40 – B.8.1.1.2.2.1._CA-45/45a). Finally, on figures B.8.1.1.2.2.1._CA-13 – B.8.1.1.2.2.1._CA-16 are presented the weather data as they were provided in the study report.

Next table – B.8.1.1.2.2.1._CA-38 provides the results of the determination of recovery rates for each analyte during analyses. It is followed by the table B.8.1.1.2.2.1._CA-39 presenting the results of the verification of the application rate for each trial site.

Table B.8.1.1.2.2.1._CA-38: The results of the verification of the recovery rates for each analyte during the analysis of the collected samples.

Compound	Parameter	Results for the trial:			
		<i>Laudun (40163/3) South France</i>	<i>St. Etienne du Gres (40164/1) South France</i>	<i>Ravenna (40494/2) Italy</i>	<i>S. Romualdo (40495/0) Italy</i>
<i>Flufenacet</i>	Recovery rate [%]	85.8	83.3	92.2	84.7
	RSD [%]	9.11	7.94	4.03	9.33
	Number of experiments	10	8	8	10
<i>FOE Alcohol</i>	Recovery rate [%]	87.1	85.8	90.3	85.6
	RSD [%]	4.43	1.78	8.18	9.07
	Number of experiments	10	8	8	10
<i>FOE Oxalate</i>	Recovery rate [%]	97.8	97.4	101	99.1
	RSD [%]	5.22	4.74	5.54	6.48
	Number of experiments	10	8	8	10
<i>FOE Sulfonic acid</i>	Recovery rate [%]	96.2	95.0	112	103
	RSD [%]	7.57	4.86	7.04	4.44
	Number of experiments	10	8	8	10

Table B.8.1.1.2.2.1._CA-39: The results of the verification of the application rate for each trial site.

Trial	Application rate [g Flufenacet/ha]	Theoretical DAT-0 concentration of Flufenacet in top 10-cm soil layer [µg/kg soil]	Measured DAT-0 concentration of Flufenacet in top 10-cm soil layer [µg/kg soil]	Measured DAT-0 concentration of Flufenacet in top soil as % of Theoretical concentration
<i>Laudun (40163/3); South France</i>	600	400	202	50.5
<i>St. Etienne du Gres (40164/1); South France</i>	600	400	227	56.8
<i>Ravenna (40494/2) Italy</i>	600	400	345	86.3
<i>S. Romualdo (40495/0) Italy</i>	600	400	345	86.3

Below are presented the results of the study – the concentrations in [µg/kg] of Flufenacet and its degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, in soil for each trial. The results are presented in five tables – table B.8.1.1.2.2.1._CA-40, summarising the values obtained in samples from the control plots, and for then for the treated plots individually for each trial in tables: B.8.1.1.2.2.1._CA-41/41a for Laudun, B.8.1.1.2.2.1._CA-42/42a for St Etienne du Gres, B.8.1.1.2.2.1._CA-43/43a for Ravenna and B.8.1.1.2.2.1._CA-44/44a for S. Romualdo. The values are given for the the layers down to 50-cm depth.

In case of the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, their residues, if detected, were found in the top 0-10 cm layer. In the lower layers – 10-20 cm, 20-30 cm, 30-40 cm and 40-50 cm, these compounds, if detected, were in amounts < LOQ (10 µg/kg). Additionally it was stated that in almost all cases they were < LOD (3 µg/kg), so in fact were not detected in deeper soil layers.

Table B.8.1.1.2.2.1_CA-40: The results of the determination of the concentrations of the test compounds in samples from control (untreated) plots.

Results obtained for the trial: Laudun (40163/3); South France

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for these layers the values one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value;
- 6) Due to the wrong labelling of samples after milling and homogenisation the samples from these two layers were mismatched – the residues from the layer 10-20 cm should be attributed to the layer 0-10 cm, while those for the layer 0-10 cm to the layer 10-20 cm.

Table B.8.1.1.2.2.1_CA-41a: The results of the determination of the concentrations of the test compounds in samples from treated plot obtained in the South French trial
Laudun (40163/3) – continued.

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for these layers the values one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

Table B.8.1.1.2.2.1_CA-42a: The results of the determination of the concentrations of the test compounds in samples from treated plot obtained in the South French trial
St. Etienne du Gres (40164/1) – continued.

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for these layers the values one replicate were reported;
- 3) <10 = values below the LOQ = 10 µg/kg soil;
- 4) n. d. = not detectable – the values below the LOD = 3 µg/kg soil.
- 5) No value.

Table B.8.1.1.2.2.1_CA-43a: The results of the determination of the concentrations of the test compounds in samples from treated plot obtained in the Italian trial Ravenna (40494/2) – continued.

Footnotes to the table:

- 1) for that layer usually the values for two replicates were reported;
- 2) for these layers the values one replicate were reported;
- 3) <10 = values below the LOQ = 10 $\mu\text{g/kg}$ soil;
- 4) n. d. = not detectable – the values below the LOD = 3 $\mu\text{g/kg}$ soil.
- 5) No value.

The weather data for each trial site provided by the study report are presented below on figures B.8.1.1.2.2.1_CA-13 – B.8.1.1.2.2.1_CA-16.

Figure B.8.1.1.2.2.1_CA-16: The weather data presented in the study report for the Italian trial site S. Romualdo (40495/0); copied from the study report.

The results of the study were kinetically examined. It was stated that due to the fact that for the degradation products – FOE Oxalate and FOE Sulfonic acid, only in few samples from the layer 0-10 cm the concentrations were above the LOQ = 10 µg/kg soil (d. w.), while for FOE Alcohol the values were generally < LOQ, it was not possible to perform the kinetic examination of the data. Therefore only for the data obtained for Flufenacet kinetic analysis was performed.

The kinetic examination of the data was carried out using Timme and Frehse method. As that method of the kinetic analysis is not any longer considered valid for the regulatory purposes in the EU, RMS decided not to present its results in the summary. Instead the results will be kinetically evaluated, in line with the recommendations of the FOCUS Kineitcs Guidance Document [FOCUS; 2006], further down this Renewal Assessment Report.

Study 5:

Report: Lin H, Green D. L., Fig P. S, (1995): “Freezer stability of [Phenyl-UL-¹⁴C]FOE 5043 in Soil.”; Agriculture Division, Miles Inc., Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120, USA; Miles Study No. F3132101, Miles Report No. 106231, 23 February 1995; study reference number: M-002201-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (Supplemental).

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by inclusion of the compound into the Annex I of the Directive 91/414/EEC.. Its brief summary can be found under the point B.7.1.2.2.4, in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. The study was then found acceptable. For the purpose of the current assessment RMS-Poland evaluated it and found it acceptable as a supplementary study to the studies on field dissipation summarised above as **Studies 1-4**, conforming the acceptability of the study in the area of handling the sampled soil cores before their processing. As such it is summarised below.

Summary:

The aim of the study was to examine the stability of Flufenacet in stored deep-frozen soil samples. That parameter was examined in soil samples stored frozen for up to 733 days (approx. two years). The experiment was performed with one soil – Howe, Iowa, Sandy loam soil, used in other experiments examining fate and behaviour of Flufenacet in soil. The characteristic of the test soil is provided below in the table B.8.1.1.2.2.1._CA-45.

Table B.8.1.1.2.2.1._CA-45: The characteristic of soil used in the study.

Parameter		Soil:	
		395	
Soil origin		Howe, Indiana, USA	
Soil type (USDA)		Sandy loam	
Particle size distribution	Sand [%]	72.5	
	Silt [%]	20.5	
	Clay [%]	7.5	
pH value (medium not reported)		6.1	
Organic matter content (OM) [%]		Not reported	
Organic carbon content (C _{org}) [%]		Not reported	
Cation Exchange Capacity – CEC [mEq/100g]		6.9	
Bulk density (disturbed) [g/cm ³]		1.31	
Moisture holding capacity at ½ bar [%]		14.8	
Available nutrients ¹⁾	Ca	1500 [lb/ac]	1680.929 [kg/ha]
	Mg	250 [lb/ac]	280.155 [kg/ha]
	Na	23 [lb/ac]	25.774 [kg/ha]
	K	156 [lb/ac]	174.817 [kg/ha]
	H	37 [lb/ac]	41.463 [kg/ha]
Percent base saturation	% Ca	54.3	
	% Mg	15.1	
	% Na	0.7	
	% K	2.9	
	% H	26.7	
Microbial activity [CPU/g soil]		3.1 E6	

Footnotes to the table:

1) In the study report only the values in [lb/ac] (US pound/US acre) were given. RMS recalculated them to kg/ha using the following assumptions:
1 kg = 0.4535 US pound and 1ha = 0.4046873 US acre.

The test soil was sieved through 2-mm sieve before being characterised.

At the beginning of the experiment 25-g (d.w.) aliquots of the test soil were weighed to fifty 2-oz (~59.14 mL) flint jars, serving as test vessels. Next, the moisture content of soil sample in each jar was adjusted to the level of 75% of 1/3 bar by addition of the appropriate amount of water. The amount of so prepared test vessels was such, to grant 25 samples treated with the test compound, 22 control samples and three blank samples. The treated

samples were used to examine the freezer storage stability and were treated at the beginning of the experiment with Flufenacet applied to each sample at the fortification level of 0.55 mg/kg soil. Control samples were stored alongside the treated samples, but unlike them were fortified with the test compound on sampling date, to provide the concurrent recovery data. Finally, blank samples were left untreated and were processed on DAT 0 (the beginning of the experiment) to check the background radioactivity in the test soil.

The treated samples were spiked with the test compound – [Phenyl-U-¹⁴C]Flufenacet, applied to each sample in form of a spiking acetonitrile-solution having a nominal concentration 110 ppm.

The test compound was radiolabelled flufenacet – [Phenyl-U-¹⁴C]Flufenacet having a specific activity of 66.5 mCi/mMole (406246 dpm/μg) and radiochemical purity of 99.5% when determined by HPLC (99.3% when determined by TLC). Its structural formula is presented below on figure B.8.1.1.2.2.1._CA-17. It was delivered as liquid sample in Vial C-584, further called a standard.

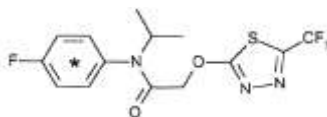

Figure B.8.1.1.2.2.1._CA-17: The structural formula of the test compound – [Phenyl-U-¹⁴C]Flufenacet; the asterisk denotes radiolabelling position (copied from the study report).

The spiking solution was prepared in a following way: first 84-μL of a standard was transferred from Vial C-584 and the original solvent evaporated under the gentle stream of N₂. Next the sample was reconstituted in 8.75 mL of acetonitrile (CH₃CN) to obtain a solution having a concentration 110 mg Flufenacet/L, further called **spiking solution**. Its radiochemical purity was verified by radio-HPLC and radio-TLC, while the concentration of the test compound by LSC.

On DAT-0 all treated samples were fortified with **spiking solution** applied in amount 0.125 mL to obtain the fortification level 0.55 mg Flufenacet/kg soil, and mixed thoroughly by shaking. In the study report it was stated that that fortification level corresponded to the maximum recommended application rate – 1 lb a. i./acre in the top 6-inch soil. When recalculated using standard assumptions – soil density $d = 1.5 \text{ g/cm}^3$ and the thickness of soil layer $l = 5 \text{ cm}$, that fortification level corresponded to the field application rate **A = 412.91 g Flufenacet/ha**.

After fortification all treated samples, except those labelled DAT-0 samples and blank samples which were both processed immediately after fortification of treated samples, and all control samples were placed in the walk-in freezer, set to the constant temperature $T = -23.9 \pm 2.5^\circ\text{C}$, and stored there for up to 733 days (24 months) of freezer storage, until being analysed. The sampling dates for treated samples were set to DAT (Days After Treatment) 0, 34, 92, 184, 365, 547 and 733. For the control samples the sampling intervals were set to 0 days, 1 month, 3 months, 6 months, 12 months 18 months and 24 months of freezer storage. At these sampling points triplicate samples of each type were removed from the freezer. Control samples were then treated with the test compound in exactly the same manner as described above for treated samples, to obtain the fortification level of 0.55 ppm. Next, all samples were processed by stir-extracting the whole soil aliquots with two 50-100 mL portions of CH₃CN/H₂O (9:1). Each extraction step lasted for 2-3 hours and was performed in a room temperature. The extracts were filtered, combined and concentrated to 10 mL by evaporation under vacuum at $T < 35^\circ\text{C}$. The concentrated extracts were analysed by LSC, HPLC and TLC.

Additionally, at 3-month intervals extracts of replicate samples were combined after routine LSC and chromatographic analyses and further analysed by GC-MS.

Extracted soil pellets were analysed, after combustion, for their radioactivity content.

The LSC analysis of sample extracts was performed using their 0.1 – 0.5 mL aliquots mixed with 15 mL of Ultima Gold liquid scintillation cocktail. It was used as quantitative analysis - to determine the radioactivity content in extracts.

The counting was performed using Packard Tricarb Scintillation Counter, model 4640. The performance parameters of the analysis were following:

- average volume of analysed sample was 0.2 mL,
- sample counting time was 5 minutes,
- the average background (BKGD) – 32 cpm,
- the minimum sensitivity was 4.15 E-4 ppm ,
- the Lowest Acceptable Gross Count Rate (LAGC) was 64 cpm,
- the Lowest Acceptable Net Count Rate (LANC) – 32 cpm,
- the greatest probable error GPE = 9.236%.

The analysis of extracted soil pellets was a quantitative analysis, aimed on the determination of the radioactivity retained by soil matrix. For that purpose 0.2-g aliquots of the extracted soil samples were oxidised. The formed $^{14}\text{CO}_2$ was absorbed in 15:5 mixture of Permafluor E and Carbo-sorb E and quantified using Packard Tricarb Scintillation Counter, model 4640. The performance parameters of the analysis were following:

- average mass of analysed sample was 0.2 g,
- sample counting time was 5 minutes,
- the average background (BKGD) – 32 cpm,
- the minimum sensitivity was 4.15 E-4 ppm ,
- the Lowest Acceptable Gross Count Rate (LAGC) was 64 cpm,
- the Lowest Acceptable Net Count Rate (LANC) – 32 cpm,
- the greatest probable error GPE = 9.236%.

Chromatographic analysis – HPLC and TLC was quantitative and qualitative analysis performed to identify the constituents of each extract and quantify them.

HPLC analysis was carried out using either Hewlett Packard 1090 or Shimadzu LC (SCL-6A) chromatographic station coupled with Raytest radioactivity detector (Ramona 90). Chromatographic separation was performed on 250 x 4.6 mm Zorbax ODS chromatographic column preceded by Spheri-5 guard column. It was carried out in a gradient mode presented below in the table B.8.1.1.2.2.1_CA-46. The flow rate of the mobile phase was set to 1.0 mL/min.

Table B.8.1.1.2.2.1_CA-46: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% CH_3COOH</i>	<i>Solvent B – Acetonitrile + 0.1% CH_3COOH</i>
0	100	0
2	100	0
7	75	25
27	25	75
32	0	0
40	0	0

The identification was performed by comparison of the retention times with those of the known standards.

The TLC analysis was performed on 20 x 20 cm, 0.25-mm-thick silica-gel plates. They were developed in a following solvent system: hexane/ethyl acetate (1:1). The non-radiolabelled standard was co-chromatographed and visualised under UV light. The developed TLC plates were radiographed using Kodak X-Omat AR films and scanned for quantitation using Ramona Rita-6800 radio-TLC analyser.

The GC-MS analysis was carried out on Hewlett Packard 5890 GC station coupled with Finnigan INCOS 50 quadrupole MS detector. The chromatographic separation was performed on GC capillary column DB-5, 15-m long, 0.25-mm i. d., 0.25- μm film thickness. The carrier gas was He at flow rate 1 mL/min. The GC oven programme was following:

- initial T = 80°C ;
- gradual increase to T = 250°C at rate $20^\circ\text{C}/\text{min}$.

The MS operated in EI mode. Scanned range was 50-400 amu at a rate 0.5 sec/scan.

The method was used to confirm the identity of Flufenacet in standard and spiking solutions as well as in control and treatment samples.

The results of the study are presented below.

Results and their discussion:

The analysis of the blank samples performed on DAT 0 showed that they contained no radioactivity, hence the test soil was free of radioactive contamination prior to the treatment.

The radiochemical purity of the spiking solution determined on DAT 0 was 97.4% when determined by HPLC and 97.7% when determined by TLC. The actual level radioactivity added to each treated sample was 5546310 dpm, corresponding to the fortification level 0.55 mg/kg soil (d. w.).

The numerical results of the experiment are presented below in the table B.8.1.1.2.2.1._CA-47.

Table B.8.1.1.2.2.1._CA-47: The numerical results of the determination of the storage stability of Flufenacet in frozen soil.

Additionally the obtained results – the concentrations of Flufenacet in treated soils in function of storage time, were presented in graphical form. For that purpose the concentrations of Flufenacet in extracts, determined using HPLC and TLC methods, were logarithmically transformed (by calculating Ln). Next, the trend line was plotted

using the linear regression. The results are presented below, on figure B.8.1.1.2.2.1._CA-18. These graphs clearly indicate no degradation of Flufenacet is stored frozen samples over the examined storage period.

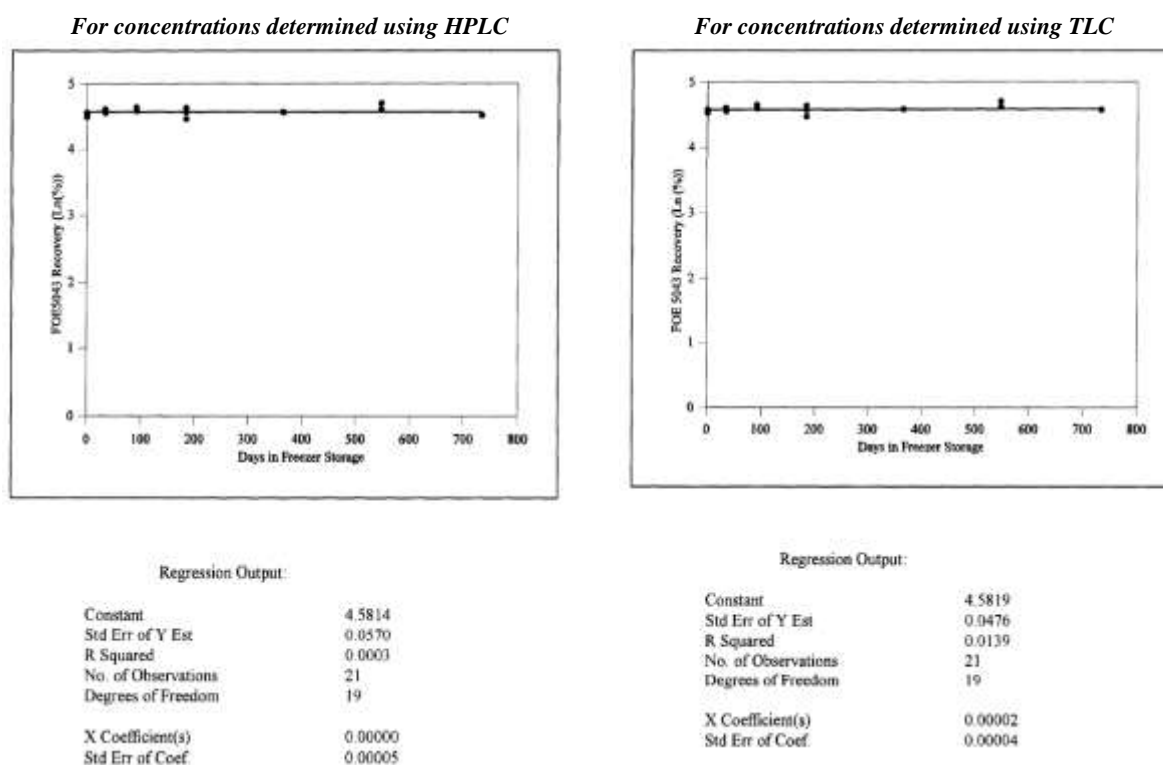

Figure B.8.1.1.2.2.1._CA-18: The results of the analysis of the change in concentration of Flufenacet in stored frozen soil samples in function of time (copied from the study report).

Conclusion:

On the basis of the obtained results it was stated that Flufenacet was stable in sandy loam soil stored in freezer conditions for at least two years.

Study 6:

Report: Lin H, Green D. L., Fig P. S, (1995): “Freezer stability of seven metabolites of [¹⁴C]FOE 5043 in Soil.”; Agriculture Division, Miles Inc., Research and Development Department, P. O. Box 4913, Kansas City, Missouri 64120, USA; Miles Study No. F3132102, Miles Report No. 106640, 26 June 1995; study reference number: M-002199-01-1;

Guidelines: The study was performed to comply with the following Guidelines:

- US. EPA Guidelines for Pesticide Registration, Subdivision N, Section 164-1, Terrestrial Field Dissipation (Supplemental).

GLP: Yes;

RMS comments: The study had been evaluated for the previous authorisation of Flufenacet in the EU, by inclusion of the compound into the Annex I of the Directive 91/414/EEC. Its brief summary can be found under the point B.7.1.2.2.4, in section B.7 of the Annex B to the Monograph prepared by the RMS – France, for Flufenacet. The study was then found acceptable. For the purpose of the current assessment RMS-Poland evaluated it and found it acceptable as a supplementary study to the studies on field dissipation summarised above as **Studies 1-4**, conforming the acceptability of the study in the area of handling the sampled soil cores before their processing. As such it is summarised below.

Summary:

The aim of the study was to examine the stability of seven degradation products of Flufenacet – FOE Alcohol, FOE Oxalate, FOE Sulfonic acid, FOE Methylsulfoxide, FOE Methylsulfone, FOE Thioglycolate sulfoxide and FOE Thiadone, in stored deep-frozen soil samples. That parameter was examined in soil samples stored frozen for up to 727 days (approx. two years). The experiment was performed with one soil – Howe, Iowa, Sandy loam soil, used in other experiments examining fate and behaviour of Flufenacet in soil. The characteristic of the test soil is provided below in the table B.8.1.1.2.2.1._CA-48.

Table B.8.1.1.2.2.1._CA-48: The characteristic of soil used in the study.

Parameter		Soil:	
		395	
Soil origin		Howe, Indiana, USA	
Soil type (USDA)		Sandy loam	
Particle size distribution	Sand [%]	70.7	
	Silt [%]	21.3	
	Clay [%]	8.0	
pH value (measured in water)		6.7	
Organic matter content (OM) [%]		1.8	
Organic carbon content (C _{org}) [%]		1.04	
Cation Exchange Capacity – CEC [mEq/100g]		9.9	
Bulk density (disturbed) [g/cm ³]		1.29	
Moisture holding capacity at ½ bar [%]		15.0	
Available nutrients ¹⁾	Ca	2300 [lb/ac]	2577.424 [kg/ha]
	Mg	370 [lb/ac]	414.629 [kg/ha]
	Na	26 [lb/ac]	29.136 [kg/ha]
	K	210 [lb/ac]	235.330 [kg/ha]
	H	46 [lb/ac]	51.548 [kg/ha]
	Olsen P	81 [lb/ac]	90.770
Percent base saturation	% Ca	57.9	
	% Mg	15.5	
	% Na	0.6	
	% K	2.7	
	% H	23.3	
Microbial activity [CPU/g soil]		3.0 E5	

Footnotes to the table:

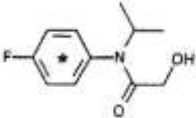

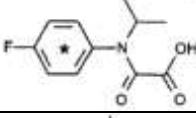

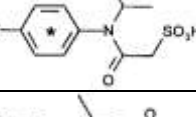

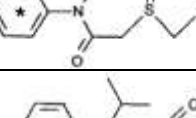

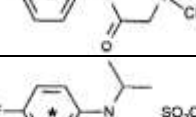

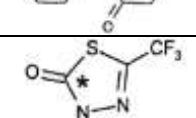

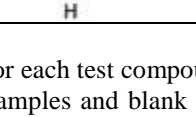

- 2) In the study report only the values in [lb/ac] (US pound/US acre) were given. RMS recalculated them to kg/ha using the following assumptions:
1 kg = 0.4535 US pound and 1ha = 0.4046873 US acre.

The test soil was kept in a bulk pit at the test facility, covered with alfalfa crop, until being used. Before being used the test soil was sieved through 2-mm sieve and its 25-g (d.w.) portions were weighed into fifty 2-oz (~59.14 mL) flint jars equipped with the Teflon-lined lids, serving as test vessels. Next, moisture content of soil

sample in each jar was adjusted to the level of 75% of 1/3 bar (11.25%) by addition of the appropriate amount of water. The amount of so prepared test vessels was such, to grant three replicates of treated samples for each test compound per each sampling point, the same number of the control samples and three blank samples.

Samples designated to be treated samples were fortified with the spiking solutions of the seven already listed radiolabelled test compounds. The spiking solutions were prepared individually for each of the test compounds, by dissolving the appropriate amount of the standard in acetonitrile/water (1:1) to obtain 11 mL of a solution having a concentration 62.5 ppm. The characteristic of each test compound – its structural formula with radiolabelling position marked by asterisk, radiochemical purity and specific activity determined by LSC for 0.2 ml of the spiking solution, is presented below in the table B.8.1.1.2.2.1._CA-49.

Table B.8.1.1.2.2.1._CA-49: The characteristic of the test compounds used in the study (structural formulas copied from their study report).

Compound	Structural formula	Sample code	Specific activity [mCi/mMole]	Radiochemical purity (measured) [%]
<i>FOE Alcohol</i>		C-581	11.8	97.6
<i>FOE Oxalate</i>		C-596	18.4	100.0
<i>FOE Sulfonic acid</i>		C-606	21	100.0
<i>FOE Thioglycolate sulfoxide</i>		C-608	21	100.0
<i>FOE Methylsulfoxide</i>		C-612	21	98.9
<i>FOE Methylsulfone</i>		C-613	21	98.4
<i>FOE Thiadone</i>		C-595	57	97.0

The fortification level for each test compound was set to 0.5 ppm. For each test compound an individual set of treated samples, control samples and blank samples was prepared. The treated samples were fortified with the given test compound, applied as a spiking solution in amount 0.2 mL, on DAT 0 (first day of storage period; DAT stands for Days After Treatment). The treated samples, except DAT 0 samples which were treated and analysed at application, were stored frozen – at $T = -25.2 \pm 0.4^\circ\text{C}$, for up to 24 months (DAT 715). At designated time points – on the 3rd, 6th, 12th, 18th and 24th month of frozen storage triplicate treated samples for each test compound were removed for further analysis. The exact sampling time points (DAT) may differ for each test compound. At the same time points for each test compound triplicate control samples were removed from freezer. These were treated with the given test compound, in exactly the same manner as treated samples, on the day of sampling. The control samples were not sampled on DAT 0. Instead the triplicate blank samples, set to determine the background soil radioactivity level were processed together with DAT-0 treated samples.

The samples collected at the given time point were processed in the following manner:

- firstly all samples were extracted with two 25-30 mL portions of $\text{CH}_3\text{CN}/0.1\text{N HCl}$ (1:1) in stir extraction carried out at room temperature; the extracts were combined and their 0.1-0.5 mL aliquots analysed for radioactivity content by LSC;

- extracts of samples treated with FOE Alcohol were directly analysed by HPLC because of the high specific activity ;
- extracts of samples treated with FOE Sulfonic acid were azeotropically concentrated (that was due to the fact that that compound is readily soluble in water, but its concentration in extract did not enable direct HPLC analysis); next the 20-mL aliquots of each concentrated extract were mixed with 90 mL of CH₃CN and the mixture was rotary-evaporated to approx. 1mL under vacuum and at T = 30-35⁰C; the so concentrated extracts were then analysed by HPLC;
- extracts from samples treated with remaning five test compounds were partitioned with two 20-mL portions of CH₂Cl₂ and radioactivity in aqueous and organosoluble (DCM) phases was quantified by LSC; next the DCM phase was dried under the gentle stream of nitrogen and reconstituted in 2 mL of either CH₃CN/H₂O (1:1) or water prior to HPLC analysis; in case of DCM phase from extracts of samples treated with FOE Thiadone in order to limit potential losses due to volatilisation 0.02 mL of 5% C₁₀H₁₁OH was added before solvent evaporation.

Extracted soil pellets were analysed, after combustion, for their radioactivity content by LSC.

The LSC analysis of sample extracts was performed using their 0.2 mL aliquots mixed with 15 mL of Ultima Gold liquid scintillation cocktail. It was used as quantitative analysis - to determine the radioactivity content in extracts.

The counting was performed using Packard Tricarb Scintillation Counter, model 4640. The performance parameters of the analysis were following:

- average volume of analysed sample was 0.2 mL,
- sample counting time was 5 minutes,
- the average background (BKGD) – 32 cpm,
- the minimum sensitivity was a compound-specific parameter and is provided further down the report,
- the Lowest Acceptable Gross Count Rate (LAGC) was 64 cpm,
- the Lowest Acceptable Net Count Rate (LANC) – 32 cpm,
- the greatest probable error GPE = 9.2%.

The minimum sensitivity determined for each test compound was following:

- for FOE Alcohol – 1.38 E-4 ppm;
- for FOE Oxalate – 9.68 E-4 ppm;
- for FOE Sulfonic acid – 9.93 E-4 ppm;
- for FOE Thioglycolate sulfoxide – 1.09 E-3 ppm;
- for FOE Methylsulfoxide – 9.28 E-4 ppm;
- for FOE Methylsulfone – 9.86 E-4 ppm;
- for FOE Thiadone – 2.26 E-4 ppm.

The analysis of extracted soil pellets was a quantitative analysis aimed on the determination of the radioactivity retained by soil matrix. For that purpose 0.2-g aliquots of the extracted soil samples were oxidised. The formed ¹⁴CO₂ was absorbed in a mixture of 15 mL Permafluor E and 5 mL Carbo-sorb E and quantified using Packard Tricarb Scintillation Counter, model 4640. The performance parameters of the analysis were following:

- average mass of analysed sample was 0.2 g,
- sample counting time was 5 minutes,
- the average background (BKGD) – 32 cpm,
- the minimum sensitivity was a compound-specific parameter, identical to the values presented above for liquid samples,
- the Lowest Acceptable Gross Count Rate (LAGC) was 64 cpm,
- the Lowest Acceptable Net Count Rate (LANC) – 32 cpm,
- the greatest probable error GPE = 9.2%.

Chromatographic – HPLC analysis was quantitative and qualitative analysis performed to identify the constituents of each extract and quantify them.

It was carried out using either Helwett Packard 1090 or Shimadzu LC (SCL-6A) chromatographic station coupled with Raytest radioactivity detector (Ramona 90). Chromatographic separation was performed on 305 x 7 mm Hamilton PRP-1 chromatographic column preceded by Hamilton PRP-1 guard column. It was carried out in a gradient mode presented below in the table B.8.1.1.2.2.1._CA-50. The flow rate of the mobile phase was set to 1.5 mL/min.

Table B.8.1.1.2.2.1._CA-50: The HPLC gradient mode used in the study.

Time [min]	Solvent ratio	
	<i>Solvent A – Water + 0.1% CH₃COOH</i>	<i>Solvent B – Acetonitrile + 0.1% CH₃COOH</i>
0	90	10
10	75	25
20	75	25
35	0	100
40	0	100

The identification was performed by comparison of the retention times with those of the known standards.

Additionally, for fractionated HPLC-eluates of the processed extracts of treated and control samples collected on the 18th month of freezer-storage, the LC-MS analysis was performed in order to identify the constituents. It was carried out on Varian 5040 HPLC coupled in-series to LB 505 Berthold flow-through radioactivity detector and Finnigan MAT 90 MS detector. The chromatographic separation was performed in a gradient mode on Hamilton PRP-1 (150 x 4.1 mm) HPLC column. The mobile phase consisted of CH₃OH – **Solvent 1**, and water – **Solvent 2**. Its composition changed linearly from 20% to 100% of **Solvent 1** during 20-minutes lasting elution. The flow rate of the mobile phase was 0.8 mL/min. 0.2 M CH₃COONH₄ was added post-column at a rate 0.2 mL/min. The MS detector operated in either positive- or negative-ion mode. The fragmentaric ions used for each test compound as identification factor are presented below in the table B.8.1.1.2.2.1._CA-51.

Table B.8.1.1.2.2.1._CA-51: LC/MS identification of the test compounds in the study.

Compound	Representative signals used in identification	
	<i>Position – m/z</i>	<i>Description</i>
FOE Alcohol	212	Protonated molecular ion [M+H] ⁺
FOE Sulfonic acid	274	Negative molecular ion [M – H] ⁻

FOE Thioglycolate sulfoxide	316	Protonated molecular ion [M+H] ⁺
	333	Ammonia adduct [M + NH ₄] ⁺
FOE Thiadone	171	Negative molecular ion [M – H] ⁻

The results of the study are presented below.

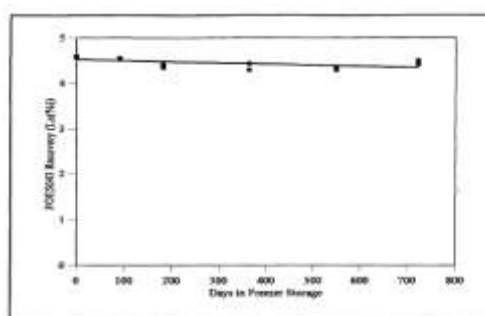

Results and their discussion:

The analysis of the blank samples performed on DAT 0 showed that they contained no radioactivity, hence the test soil was free of radioactive contamination prior to the treatment.

The numerical results of the experiment are presented below, individually for each test compound, in tables B.8.1.1.2.2.1._CA-52 – B.8.1.1.2.2.1._CA-58. The measured concentrations were logarithmically transformed (in form of ln) in order to determine the trend of decline in recovery and by that the rate of would-be degradation in stored frozen soil. These results are presented in graphical form individually for each compound, immediately after corresponding table, on figures B.8.1.1.2.2.1._CA-50 – B.8.1.1.2.2.1._CA-56.

Table B.8.1.1.2.2.1_CA-52: The numerical results of the determination of the storage stability of FOE Alcohol in frozen soil.

Sampling point		Type of sample	Replicate	Radioactivity recovered [% AR]

Figure B.8.1.1.2.2.1_CA-56: The graphical results of the determination of the storage stability of FOE Thiadone in frozen soil (copied from the study report).

Conclusions

On the basis of the obtained results following conclusions were drawn from the study:

- FOE Oxalate, FOE Sulfonic acid, FOE Thioglycolate sulfoxide, FOE Methylsulfoxide and FOE Methylsulfone were stable in stored frozen sandy loam soil throughout the 24-month test period;
- FOE Alcohol degraded slightly during the storage period, forming three unknown products; its extrapolated half-life in stored frozen sandy loam soil was 2748 days;
- In case of FOE Thiadone a significant decrease in concentration was observed during the storage period; it was attributed mainly to loss through volatilization and formation of bound residues; the extrapolated half-life for that compound in stored frozen sandy loam soil was 725 days.

In the Assessment Report for Flufenacet prepared by the RMS – France for the first authorisation of that compound in the EU, it was stated that the results of that study indicated that FOE Oxalate and FOE Sulfonic acid were stable in soil under frozen conditions for at least two years. No definitive conclusions were made with regard to the other degradation products undergoing that examination, but it may be stated that for all tested degradation products, except FOE Thiadone, their high stability in stored frozen soil for the period of two years was confirmed.

That also conforms that the results of the four field dissipation studies summarised above as **Studies 1-4** are fully reliable.

Kinetic examination of the obtained results

The results obtained in **Studies 1-4** were kinetically examined and the outcome of that examination was presented as an integral part of each study report. It was also presented in the Assessment Report prepared for the first authorisation of Flufenacet in the EU (by its inclusion into the Annex I of the Council Directive 91/414/EEC) by the then-RMS – France. Analysing that assessment the present RMS – Poland, stated that it did not comply with the current standards set for the kinetic evaluation of the data by the FOCUS Kineitics Guidance Document [FOCUS, 2006]. In all four study reports the kinetic analysis was declared to be performed in line with the method developed by Timme and Frehse. Additionally the best-fit kinetic model was determined only for the parent compound, while the data for the degradation products were not subjected to such analysis.

For the purpose of the present evaluation the Applicant focused on the kinetic analysis of the results aimed on the determination of the kinetic endpoints suitable for modelling exposure assessment for GW and SW compartments. It was presented in one study report summarised below as **Study 7**.

However no attempt was made by the Applicant to identify the best-fit model and to determine persistence endpoints for each trial. To fill that gap the RMS performed own kinetic analysis of the data obtained in field trials, in line with the recommendations given by FOCUS Workgroup on Degradation Kinetics [FOCUS 2006; FOCUS 2011]. At the same time the analysis was performed in such way to be compliant, as far as possible, with the kinetic evaluation of the data performed by the Applicant. That concerned mainly the pre-processing of the raw results in order to obtain the values subsequently used as input data for kinetic modelling tool.

The kinetic analysis of the data obtained in the field trials was a multi-step procedure, consisting of the following activities:

- **Step 1:** preliminary analysis of the data-sets obtained for each trial in order to determine for which compounds the kinetic analysis was possible;
- **Step 2:** pre-processing of the data identified as suitable for further kinetic assessment (detailed examination of the data sets for their suitability for kinetic assessment, calculation of the residue values for each sampling point, identification and elimination of the clear outliers, etc.);
- **Step 3:** kinetic examination of the pre-processed data sets following the recommendations given by FOCUS Workgroup on Degradation Kinetics [FOCUS 2006; FOCUS 2011];
- **Step 4:** presentation of the obtained results and conclusions.

The first step consisted on the preliminary analysis of the data obtained for each study and trial in order to identify those suitable for the kinetic examination. The general information on each study is provided below.

In the study No. 107724 [Sommer; 1995] the dissipation of Flufenacet was examined on eight trial sites – four located in Germany and another four in France. Each trial is briefly characterised below:

- **trial 30159/0, Breitenfelde:** performed in Germany, on bare soil, application rate 480 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30162/0, Kirchlauter:** performed in Germany, on bare soil, application rate 480 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30163/9, Monheim:** performed in Germany, on bare soil, application rate 480 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30164/7, Burscheid:** performed in Germany, on bare soil, application rate 480 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30248/1, Fresne-L'Archeveque:** performed in Northern France, on cropped soil (Maize), application rate 600 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30250/3, Fresne-L'Archeveque 1:** performed in Northern France, on cropped soil (Maize), application rate 600 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30251/1, Laudun:** performed in Southern France, on cropped soil (Sunflower), application rate 600 g Flufenacet/ha, spring application of the test compound in 1993;
- **trial 30253/8, St. Etienne du Gres:** performed in southern France, on cropped soil (Sunflower), application rate 600 g Flufenacet/ha, spring application of the test compound in 1993.

In the study No. 107722 [Sommer; 1995a] the dissipation of Flufenacet was examined on two trial sites, both located in Germany. Each trial is briefly characterised below:

- **trial 30499/9, Burscheid:** performed in Germany, on bare soil, application rate 240 g Flufenacet/ha, autumn application of the test compound in 1993;
- **trial 30500/6, Monheim:** performed in Germany, on bare soil, application rate 240 g Flufenacet/ha, autumn application of the test compound in 1993.

In the study No. 107723 [Sommer; 1995b] the dissipation of Flufenacet was examined on two trial sites, both located in France. Each trial is briefly characterised below:

- **trial 30254/6, Saussay-la-Campagne:** performed in Southern France, on cropped soil (winter wheat), application rate 240 g Flufenacet/ha, early spring application of the test compound in 1994;
- **trial 30455/7, Fresne-L'Archeveque:** performed in Northern France, on cropped soil (winter wheat), application rate 240 g Flufenacet/ha, early spring application of the test compound in 1994.

In the study No. 107721 [Sommer; 1995c] the dissipation of Flufenacet was examined on four trial sites – two located in France and another two in Italy. Each trial is briefly characterised below:

- **trial 40163/3, Laudun:** performed in Southern France, on cropped soil (Sunflower), application rate 600 g Flufenacet/ha, spring application of the test compound in 1994;
- **trial 40164/1, St. Etienne du Gres:** performed in Southern France, on cropped soil (Sunflower), application rate 600 g Flufenacet/ha, spring application of the test compound in 1994;
- **trial 40494/2, Ravenna:** performed in Italy, on cropped soil (Soybean), application rate 600 g Flufenacet/ha, spring application of the test compound in 1994;
- **trial 40495/0, S. Romualdo:** performed in Italy, on cropped soil (Soybean), application rate 600 g Flufenacet/ha, spring application of the test compound in 1994;

The results of the preliminary examination of the data sets from each trial are presented below, individually for each trial. RMS, deciding on the suitability of the data set for the given compound for kinetic analysis, used the criterion of whether it contained for at least one time point the values >LOQ. Therefore, if for the given compound in the given trial all values were <LOQ, even though some of them were still >LOD, such data sets were considered not suitable for further kinetic analysis, as the results of it would bear too high level of uncertainty (the results would be artificially set to pre-defined level without any guarantee that they may appropriately represent the real situation).

For the trial **30159/0, Breitenfelde** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for seven of nine time points, while for the remaining two they were <LOQ, but still >LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOQ and only for two time points >LOD;
- for FOE Sulfonic acid values >LOQ were recorded for two time points and >LOD for additional two time points;
- on that basis RMS stated that for this trial it was possible to perform the kinetic analysis for Flufenacet and it may be possible to perform such analysis also for FOE Sulfonic acid.

For the trial **30162/0, Kirchlauter** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided all nine time points;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOQ and for four time points were recorded those >LOD;
- for FOE Sulfonic acid there was no values >LOQ and for five time points were recorded those >LOD;
- on that basis RMS stated that for this trial it was possible to perform the kinetic analysis for Flufenacet only.

For the trial **30163/9, Monheim** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for all nine time points;
- for FOE Alcohol there was no values >LOQ and only for two time points the values >LOD were recorded;
- for FOE Oxalate there was no values >LOQ and only for two time points the values >LOD were recorded;
- for FOE Sulfonic acid there was no values >LOQ and only for four time points the values >LOD were recorded;
- on that basis RMS stated that for this trial it was possible to perform the kinetic analysis for Flufenacet only.

For the trial **30164/7, Burscheid** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for five of nine time points and additionally those >LOD but <LOQ were given for two time points;
- for FOE Alcohol the values >LOD were recorded for two time points and there was no results >LOQ;
- for FOE Oxalate there was no values >LOD;
- for FOE Sulfonic acid values there was no values >LOQ and only for two time points were recorded the values >LOD;
- on that basis RMS stated that for this trial it was possible to perform the kinetic analysis for Flufenacet only.

For the trial **30248/1, Fresne-L'Archeveque** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for all nine time points;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOQ and for five time points were recorded those >LOD;
- for FOE Sulfonic acid values >LOQ were recorded for four time points and additionally those >LOD for three time points; it shall be noted that in case of one of the time points with values >LOD recorded, one of them was >LOQ;
- on that basis RMS stated that for this trial it was possible to perform the kinetic analysis for Flufenacet and it might be possible to do that for FOE Sulfonic acid as well.

For the trial **30250/3, Fresne-L'Archeveque 1** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for all nine time points, while for the remaining two they were below LOQ, but still above LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate three time points the values were > LOQ and additionally for two two time points they were >LOD;
- for FOE Sulfonic acid values the values >LOQ were recorded for two time points and those >LOD for additional three time points, it shall be noted that for one of them, with the values predominantly > LOD, in one replicate the concentration was >LOQ;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet and it might be possible to perform such analysis also for FOE Oxalate and FOE Sulfonic acid.

For the trial **30251/1, Laudun** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were recorded for seven of nine time points, while for the remaining two they were <LOQ, but still >LOD;
- for FOE Alcohol for only one time point the residue values were >LOD, for the remaining eight being below that level;
- for FOE Oxalate for one time point the residue values were > LOQ and for additional three were reported as being <LOQ but >LOD;
- for FOE Sulfonic acid values >LOQ were recorded for three time points and those >LOD for additional two time points;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet and it might be possible to perform such analysis also for FOE Oxalate and FOE Sulfonic acid.

For the trial **30253/8, St. Etienne du Gres** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for seven of nine time points, while for the remaining two they were below LOQ, but still above LOD;
- for FOE Alcohol there were no values >LOQ and only for one time points the values >LOD were recorded;
- for FOE Oxalate there was no values >LOQ, but for five consecutive time points the values >LOD were recorded;
- for FOE Sulfonic acid values >LOQ were recorded for only one time point, but for the two time points preceding it and two immediately after it were recorded the values >LOD;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet and it might be possible to perform such analysis also for FOE Sulfonic acid.

For the trial **30499/9, Burscheid** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were provided for seven of nine time points and for one additional time points the recorded residue concentrations were >LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values > LOD;
- for FOE Sulfonic acid there was no values >LOQ, but for four consecutive time points the values >LOD were recorded;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet only.

For the trial **30500/6, Monheim** it was stated that:

- the residue data were provided for the soil layers down to 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were recorded provided for eight of nine time points;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOD;
- for FOE Sulfonic acid there was no values >LOD;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet only.

For the trial **30254/6, Saussay-la-Campagne** it was stated that:

- the residue data were provided for the soil layers down to 50 cm, but for the layers 20-30cm, 30-40 cm and 40-50 cm the values were provided for a single replicate and all were >LOD – for that reason, and also to maintain the consistency of the pre-processed data sets RMS decided to present the non-processed data only to the depth of 30 cm;
- the results were given for eight time points;
- for Flufenacet the measured values >LOQ were recorded only for three time points and additionally for the two following time points they were >LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOD;
- for FOE Sulfonic acid there was no values >LOD;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet only.

For the trial **30455/7, Fresne-L'Archeveque** it was stated that:

- the residue data were provided for the soil layers down to 50 cm, but for the layers 20-30cm, 30-40 cm and 40-50 cm the values were provided for a single replicate and all were >LOD – for that reason, and also to maintain the consistency of the pre-processed data sets RMS decided to present the non-processed data only to the depth of 30 cm;
- the results were given for seven time points;
- for Flufenacet the measured values >LOQ were recorded for only two time points and additionally for the two following time points the recorded residue values were >LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOD;
- for FOE Sulfonic acid there was no values >LOD;
- on that basis RMS stated that it might be possible to perform the kinetic analysis for Flufenacet, but even for that compound, due to very limited amount of data points, it would bear a significant level of uncertainty.

For the trial **40163/3, Laudun**, it was stated that:

- the residue data were provided for the soil layers down to 50 cm, but for the layers 20-30cm, 30-40 cm and 40-50 cm the values were provided for a single replicate and all were >LOD – for that reason, and also to maintain the consistency of the pre-processed data sets RMS decided to present the non-processed data only to the depth of 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were recorded for seven of nine time points and additionally one following point had residue concentrations >LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there were two time points with residue values >LOQ and additional four with those >LOD;
- for FOE Sulfonic acid there was one time point with values >LOQ and additional four with those >LOD;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet and it might be possible to perform such analysis also for FOE Oxalate and FOE Sulfonic acid.

For the trial **40164/1, St. Etienne du Gres** it was stated that:

- the residue data were provided for the soil layers down to 50 cm, but for the layers 20-30cm, 30-40 cm and 40-50 cm the values were provided for a single replicate and all were >LOD – for that reason, and also to maintain the consistency of the pre-processed data sets RMS decided to present the non-processed data only to the depth of 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were recorded for eight time points and additionally for the last time point they were >LOD;
- for FOE Alcohol there was no values >LOD;
- for FOE Oxalate there was no values >LOQ, but for five time points the values >LOD were recorded;
- for FOE Sulfonic acid the values >LOQ were recorded for two time points and those >LOD for additional two time points;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet and it might be possible to perform such analysis also for FOE Sulfonic acid.

For the trial **40494/2, Ravenna** it was stated that:

- the residue data were provided for the soil layers down to 50 cm, but for the layers 20-30cm, 30-40 cm and 40-50 cm the values were provided for a single replicate and all were >LOD – for that reason, and also to maintain the consistency of the pre-processed data sets RMS decided to present the non-processed data only to the depth of 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were recorded for eight time points and additionally for the last time point they were >LOD;
- for FOE Alcohol there was no values >LOQ and for only one time point the values >LOD were recorded;
- for FOE Oxalate there was no values >LOQ, but for three consecutive time points the values >LOD were recorded;
- for FOE Sulfonic acid the values >LOQ were recorded for three consecutive time points only and no other values >LOD were reported;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet and it might be possible to perform such analysis also for FOE Sulfonic acid.

For the trial **40495/0, S. Romualdo** it was stated that:

- the residue data were provided for the soil layers down to 50 cm, but for the layers 20-30cm, 30-40 cm and 40-50 cm the values were provided for a single replicate and all were >LOD – for that reason, and also to maintain the consistency of the pre-processed data sets RMS decided to present the non-processed data only to the depth of 30 cm;
- the results were given for nine time points;
- for Flufenacet the measured values >LOQ were recorded for all nine time points;
- for FOE Alcohol there was no values >LOQ, but for the two consecutive time points there were values >LOD;
- for FOE Oxalate there was no values >LOQ, but for four consecutive time points there were values >LOD;
- for FOE Sulfonic acid was no values >LOQ, but for four consecutive time points there were values >LOD;
- on that basis RMS stated that it was possible to perform the kinetic analysis for Flufenacet only.

The resulting data-sets determined for each trial site and subsequently used in the procedure of pre-processing the data are presented below in tables B.8.1.1.2.2.1._CA-59 – B.8.1.1.2.2.1._CA-68. For clarity the values were grouped into three sets:

- **set 1** presenting the results of eight trials identified as those for which it was possible to do the kinetic analysis solely for Flufenacet (tables B.8.1.1.2.2.1._CA-59 – B.8.1.1.2.2.1._CA-62);
- **set 2** presenting the results of four trials identified as those for which it was possible to perform the kinetic analysis of the data for Flufenacet and FOE Sulfonic acid (tables B.8.1.1.2.2.1._CA-63 and B.8.1.1.2.2.1._CA-65);
- **set 3** presenting the results of four trials identified as those for which it was possible to perform the kinetic analysis of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid (tables B.8.1.1.2.2.1._CA-66 – B.8.1.1.2.2.1._CA-68).

Table B.8.1.1.2.2.1._CA-59: The not processed residue data appropriate to be used in the kinetic analysis obtained in the trials: **30162/0 Kirchlauter** and **30163/9 Monheim**.

The not processed data set for the trial 30162/0, Kirchlauter (study [Sommer; 1995])

As a next step, the data were pre-processed in order to be used as input in kinetic assessment. The pre-processing procedure used here is the same as that used by the Applicant to prepare the input data for the kinetic assessment performed to derive modelling endpoints and presented immediately after this evaluation as **Study 7**.

For all trials were available the data obtained for the soil layers 0-10 cm, 10-20 cm and 20-30 cm. Additionally, for six trials, in which the active substance was applied in 1994 ([Sommer; 1995b], study report No. 107723, and [Sommer; 1995c], study report No. 107721) the values for two additional layers – 30-40 cm and 40-50 cm, were reported. However, in order to maintain the consistency of the assessment, only the layers down to 30 cm were analysed.

The Applicant analysing the obtained data sets with aim to derive from them modelling kinetic endpoints for Flufenacet and FOE sulfonic acid stated that the quantifiable residues - > LOQ (10 µg/kg soil d. w.), were found predominantly in the uppermost soil layer – 0-10 cm. As a result, the subsequent analysis focused on that layer.

For the pre-processing of the data two crucial experimental parameters were used: LOD = 3 µg/kg soil and LOQ = 10 µg/kg soil. The procedure, according to the Applicant, followed the recommendations given by FOCUS Work Group on Degradation Kinetics [Focus; 2005].

The following solutions were adopted:

- All values < LOQ (in the tables presenting the results they are given as “< 10”) were set to $\frac{1}{2}$ (LOD + LOQ) = 6.5 µg/kg soil – the value representing the mean of the interval between LOD and LOQ;
- All values < LOD (in the tables presenting the results given as “n. d.”), appearing immediately before or after either the measured concentrations, or the concentrations being <LOQ, were set to $\frac{1}{2}$ LOD = 1.5 µg/kg soil; in case of the the second and next appearances of the values <LOD, they were set to 0, unless they were followed by either the value < LOQ or a quantifiable residue concentration, or else, for the same time point, the residues in deeper layer were either at the level < LOQ or quantifiable;
- For the degradation products the DAT-0 concentrations were set to zero;
- Finally, the kinetic curve was cut off after the first value <LOD, unless it was followed by the value <LOQ or a quantifiable residue concentration.

For the deeper layers – 10-20 cm and 20-30 cm, for which the residue concentrations in the topmost layer were determined to be a quantifiable value or that <LOQ or else <LOD, but in course of subsequent pre-processing described above set to $\frac{1}{2}$ LOD = 1.5 µg/kg soil, the values <LOD were also set to that level – $\frac{1}{2}$ LOD = **1.5 µg/kg soil**. Such approach was considered by the Applicant to be conservative – the residues were expected to be overestimated.

As a next step for each layer the average values were calculated and then summed up to represent the concentration in 0-10 cm layer. These values were subjected to the kinetic analysis. The additional step was the analysis of the data in search of the outliers. That was done for the parent compound. In case the value that was a probable outlier was initially identified, it was further examined, by comparing it to its immediate predecessor. In case the difference between the two was greater than 20%, the preceding and following data points were also analysed in order to determine the general distribution of the data points. Additionally the value supposed to be an outlier was compared to the theoretical DAT-0 concentration of the test compound in the top soil. When the value was conformed to be a potential outlier, it was not used in the kinetic evaluation of the data set. In case of the data sets consisting of parent – Flufenacet, and degradation products – either only FOE Sulfonic acid or FOE Oxalate and FOE Sulfonic acid, when for Flufenacet the given data point was identified as outlier also the corresponding value(s) for degradation product(s) was/were not used in the kinetic assessment as being uncertain.

The resulting data sets for each trial site are presented below in the table(s) B.8.1.1.2.2.1._CA-69 – B.8.1.1.2.2.1._CA-71. The outliers were reported for completeness, but marked italics and not used in the kinetic assessment.

The data presented above in above in the tables B.8.1.1.2.2.1._CA-69 – B.8.1.1.2.2.1._CA-71 were then subjected to the kinetic analysis similar to that used for the determination of the persistence kinetic endpoints for the laboratory studies and described in section B.8.1.1.2.1.1., eg. in the summary of the **Study 3** on page 203. It is presented, with necessary modifications, below.

The whole assessment was carried out as a multistep procedure, presented below.

It consisted of the following steps:

- **Step 1:** the data for the parent compound were fitted using two kinetic models: SFO and FOMC and verified for passing the acceptance criteria (χ^2 -error and distribution of residuals); in case the SFO fit was found visually acceptable and statistically more appropriate than FOMC, it was selected as the best-fit model;
- **Step 2:** in case the SFO model was found not to be more appropriate than FOMC, it was refined in three-step procedure, by removing the outliers, fixing model parameters and data weighing, until the best fit was achieved;
- **Step 3:** if the **Step-2** fitting for SFO model still failed the χ^2 -error test, and FOMC was demonstrated to be more appropriate, the DFOP model was tested in order to determine if bi-phasic model is acceptable and if so, which one should be selected as returning the best fit;
- **Step 4:** once the best-fit model was identified, the data for the degradation products, if available were added to the data set and the kinetic analysis repeated using the identified best-fit model for Flufenacet (parent compound) and SFO for the degradation products.

The obtained results of the kinetic analysis were evaluated by means of a detailed statistical analysis comprising the following components:

- visual assessment of the fit;
- χ^2 -error statistics;
- t-test significance;
- correlation analysis.

It was carried out in line with the approach characterised in section B.8.1.1.2.1.1. in the summary of the **Study 2**, presented on page 169.

In the visual assessment of the fit the following elements were taken into consideration:

- the conformity of the fitted decline curve with measured residue concentrations;
- the distribution of the residuals, which should be random and not systematic;
- level of residuals, which should be as small as possible – in such case even if their distribution is rather systematic, the fit may be still qualified as acceptable.

Based on these criteria the obtained fit was classified as:

- **good fit**, when the conformity of the kinetic curve and measured residues was good, levels of residuals were low, they were randomly scattered and no obvious systematic deviation in residual plot was visible;
- **acceptable fit**, when the conformity of the kinetic curve and measured residues was acceptable, levels of residuals were medium and they were more-or-less randomly scattered, and the absolute level of residuals was low;
- **poor fit**, when the fitted decline curve significantly deviated from the measured residues and did not match the observed pattern, the level of residuals was high and they were clearly not randomly scattered around zero line.

The next component of the assessment is χ^2 -error statistics, for which the threshold value is set by the relevant Guidelines to 15%. However, as it was for the laboratory studies, it should not be considered to be an absolute cut-off criterion in case of the field dissipation studies, especially in case of the degradation products. That is due to the fact that that threshold value is strictly appropriate for optimal experimental conditions only, which are hardly expected to occur in case of field dissipation studies. For that reason in some cases, even though χ^2 -error >15%, the fit may be acceptable. Additionally, for degradation products it shall be pointed out that for them usually measurements in comparison to the mean of all measurements are low, what strongly influences the χ^2 test.

Another element of that analysis is the t-test. It is recommended that the t-test probability of 0.05, as sufficiently small, should be used as acceptability criterion. In case however of degradation products, or the results of field dissipation studies (as it is in this case), the *prob > t* value of 0.10 or even higher may be still acceptable.

In case of FOMC fit the additional acceptability criterion was the range of Confidence Intervals (CI). Whenever it passed through zero, such fit was considered unreliable. Such approach is consistently used by the RMS – Poland, in all kinetic evaluations performed.

All that was taken into account when the goodness of fit was assessed.

The processed data were kinetically examined using CAKE ver. 3.1 modelling tool, developed by Tessella. The optimisation was performed using IRLS (Iteratively Reweighed Nonlinear Least Squares) algorithm. The settings of the optimiser were the defaults of the tool:

- maximum iterations: 100,
- maximum reweighing: 10,
- SANN maximum iterations: 10000,
- convergence tolerance: 1 E-5,
- error variance tolerance: 1 E-5,
- extra solver: yes, if required.

The results of the fitting are presented below, individually for each trial.

1) Results of the kinetic examination of the data obtained in the trial *Breitenfelde, 30159/0, Germany* (Study No 107724, [Sommer; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-57 and in numerical form in the table B.8.1.1.2.2.1._CA-72. Additionally the table B.8.1.1.2.2.1._CA-73 provides the kinetic endpoints obtained with each of the kinetic models tested.

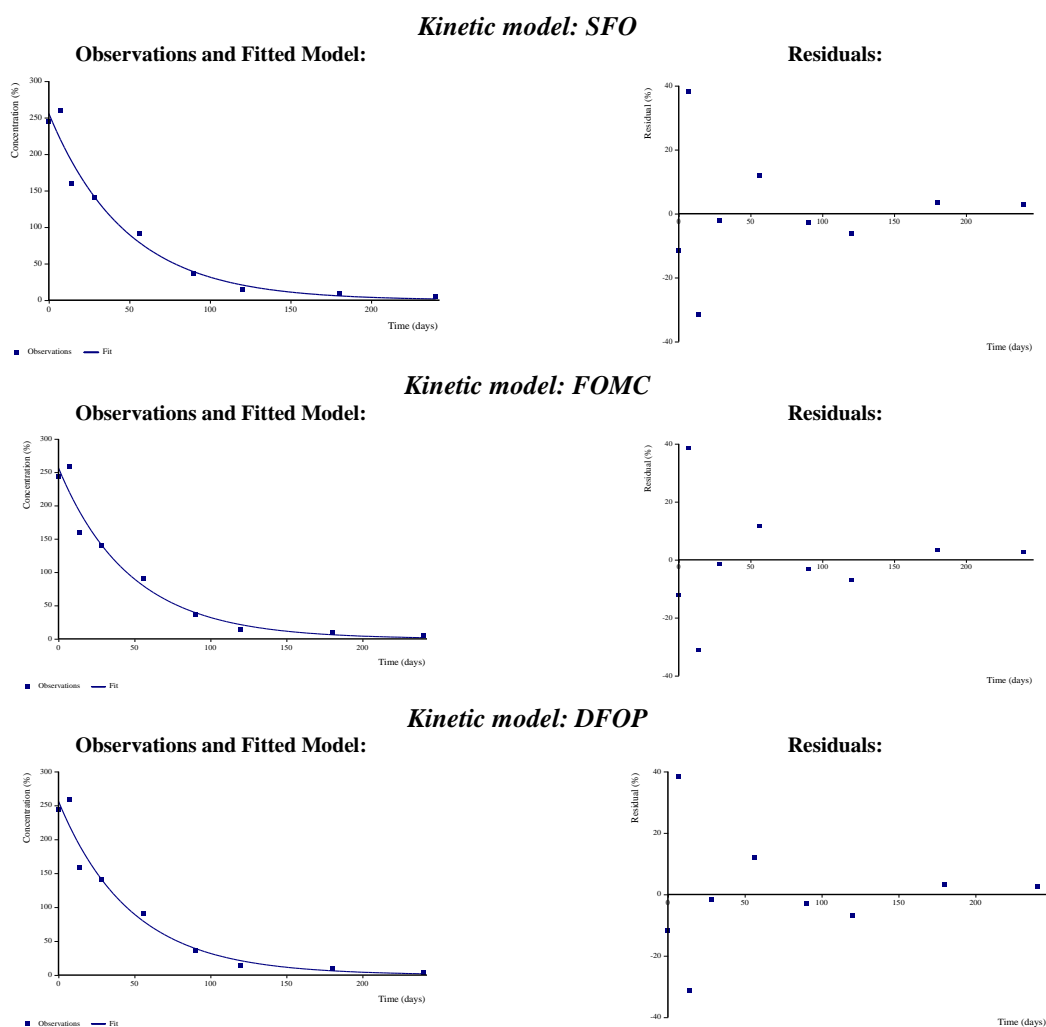

Figure B.8.1.1.2.2.1._CA-57: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-72: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	255.8	14.81	227.7	283.8	-----	13.3	0.9648; Acceptable fit
	k	0.02092	0.003042	0.01516	0.02669	1.18 E-4		
FOMC	M_0	256.1	18.09	221.0	291.3	-----	14.0	0.9648; Acceptable fit
	α	64.32	1510	-2866	3000	-----		
	β	3040	72100	-137000	143000	-----		
DFOP	M_0	256.5	22.7	210.7	302.2	-----	14.9	0.9648; Acceptable fit
	k_1	0.05167	2.135	-4.25	4.353	0.4908		
	k_2	0.02046	0.0246	-0.02911	0.0700	0.2217		
	g	0.0332	2.551	-5.107	5.174	not given		

Table B.8.1.1.2.2.1._CA-73: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	33.1	32.9	32.8
	DT ₉₀ [days]	110.0	111.0	111.0

The examination of the results showed that all three kinetic models returned visually and statistically acceptable fits, very similar one to another. The visual fit, although displaying good conformity with the experimental results, may be classified only as acceptable, because of the high level of residuals, which on the other hand are distributed randomly. However, neither the FOMC fit nor that obtained using DFOP model may be considered acceptable because of the lack of reliability of the kinetic parameters – in case of FOMC fit for both α and β the CI passes through zero, while for DFOP for both k_1 and k_2 the $prob > t$ was significantly higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet, and as such was used at the next stage of analysis.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1_CA-58 and in numerical form in the table B.8.1.1.2.2.1_CA-74. The fitting was performed for combination SFO-SFO.

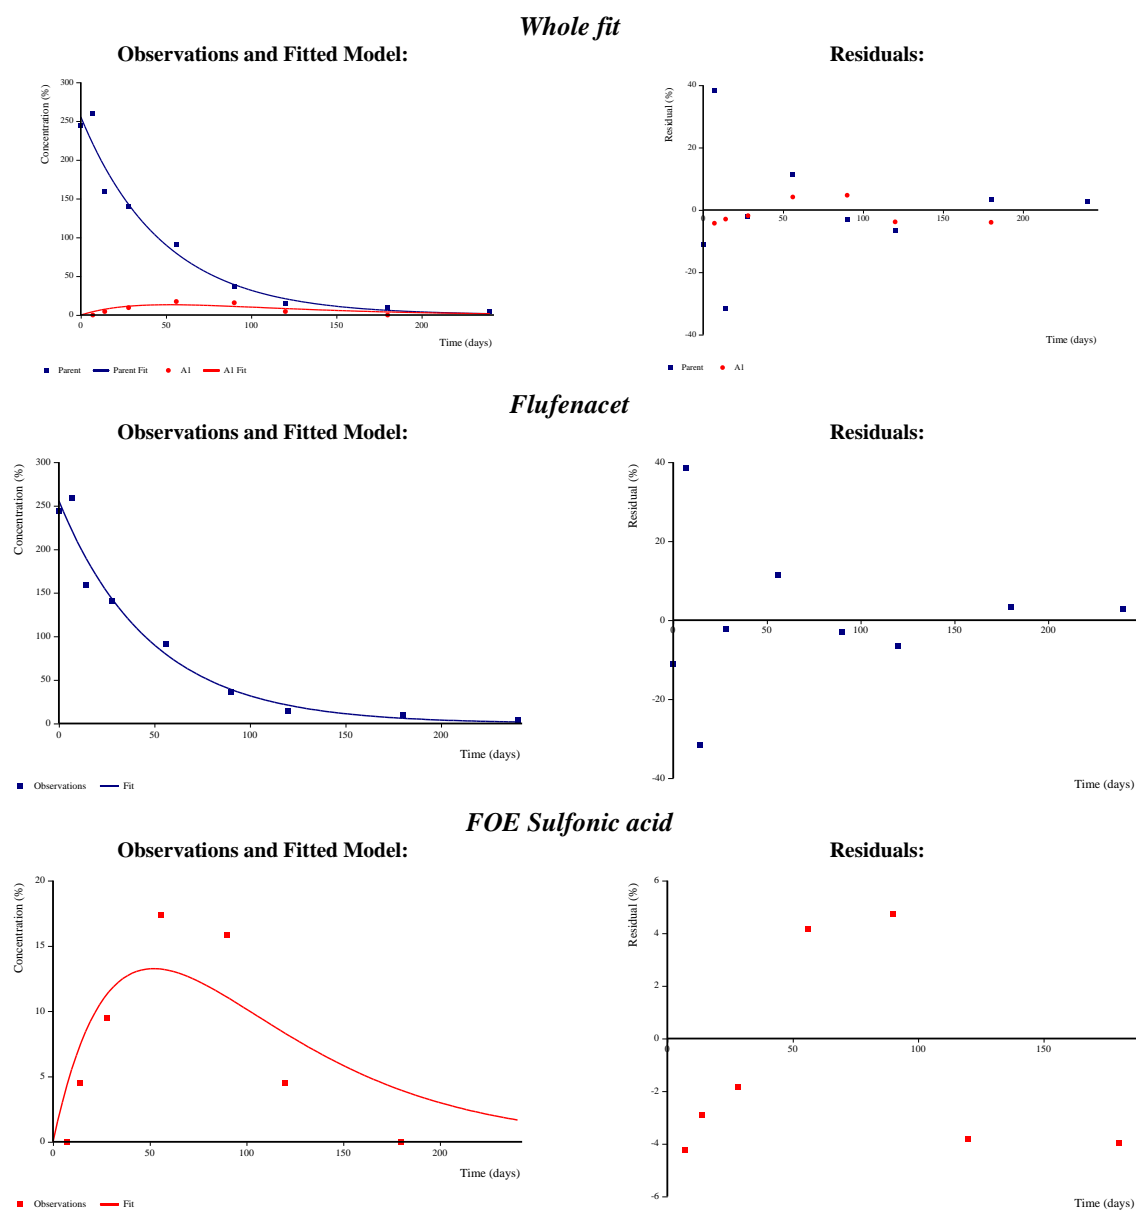

Figure B.8.1.1.2.2.1_CA-58: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Breitenfelde, 30159/0.

Table B.8.1.1.2.2.1._CA-74: The numerical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Breitenfelde, 30159/0.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	255.5	15.06	228.7	282.3	-----	13.3	0.9648; Acceptable fit
		k	0.02082	0.003083	0.01533	0.02632	1.02 E-5		
FOE Sulfonic acid	SFO	M ₀	0.0	-----	-----	-----	-----	40.6	0.8898; Poor fit
		k	0.0177	0.008983	0.001686	0.03371	0.03618		
		ff	0.1304	0.0495	0.04216	0.2186	-----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-75.

Table B.8.1.1.2.2.1._CA-75: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Sulfonic acid
DT ₅₀ [days]	33.3	39.2
DT ₉₀ [days]	111.0	130
Kinetic formation fraction ff	Not applicable – parent compound	0.1304 ± 0.049
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fit obtained for FOE Sulfonic acid cannot be considered acceptable, because of the high χ^2 error – 40.6%, and low conformity of the kinetic curve with the experimental results.

As a result, it cannot be stated that in that trial it was possible to obtain for FOE Sulfonic acid a reliable kinetic curve and hence assess adequately the persistence of that compound in the trial **Breitenfelde, 30159/0**.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were very similar to those for the parent fitted alone and no improvement of the fit was observed for the degradation product – FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Breitenfelde, 30159/0**, demonstrated that reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field conditions, were obtained only for the parent compound – Flufenacet. The kinetic model identified as returning the best fit was SFO.

For the degradation product subjected to the kinetic examination – FOE Sulfonic acid, it was not possible to obtain reliable kinetic fit and hence reliable kinetic endpoints representing the persistence of that compound on the trial site.

As a result, it can be stated that the reliable persistence kinetic endpoints for that trial may be determined for the parent compound – Flufenacet, when fitted alone. These values will be presented in the List of End Points.

2) Results of the kinetic examination of the data obtained for the trial *Kirchlauter, 30162/0, Germany* (Study No. 107724, [Sommer; 1995]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-59 and in numerical form in the table B.8.1.1.2.2.1._CA-76. Additionally the table B.8.1.1.2.2.1._CA-77 provides the kinetic endpoints obtained with each of the kinetic models tested.

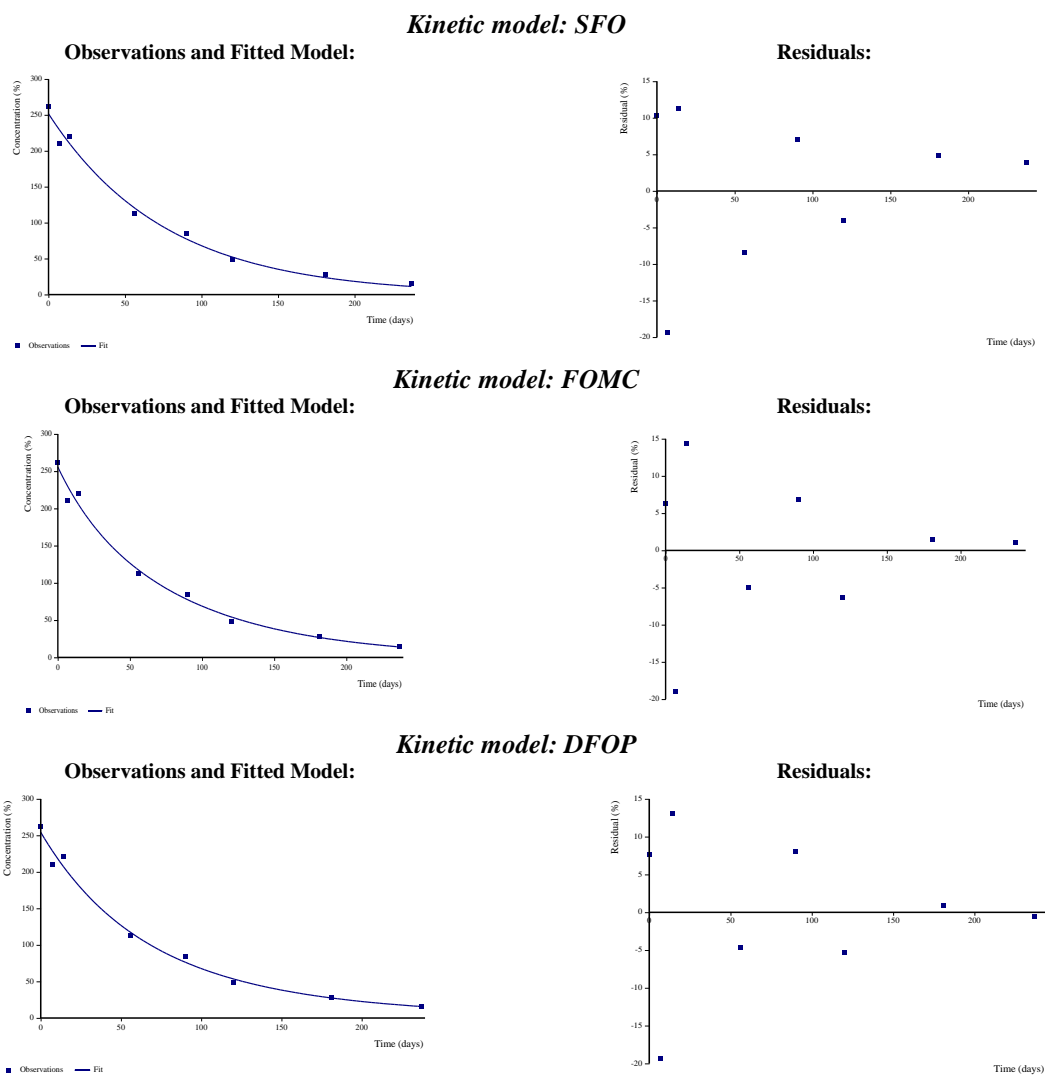

Figure B.8.1.1.2.2.1._CA-59: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-76: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	251.7	7.743	236.6	266.7	-----	6.43	0.988; Good fit
	k	0.0131	0.001011	0.01113	0.01506	6.53 E-6		
FOMC	M_0	254.4	9.347	235.6	273.2	-----	6.58	0.9888; Good fit
	α	6.373	10.0	-13.78	26.53	-----		
	β	433.2	760	-1098	1960	-----		
DFOP	M_0	255.7	15.27	223.2	288.3	-----	7.1	0.9888; Good fit
	k_1	0.03994	0.209	-0.4057	0.4855	0.4289		
	k_2	0.01148	0.008237	-0.006076	0.02904	0.1179		
	g	0.1607	0.9886	-1.947	2.268	not given		

Table B.8.1.1.2.2.1._CA-77: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	52.9	49.8	49.1
	DT ₉₀ [days]	176.0	189.0	185.0

The examination of the results showed that all three kinetic models returned visually and statistically good fits, very similar one to another. However, neither the FOMC fit nor that obtained using DFOP model may be considered acceptable because of the lack of reliability of the kinetic parameters – in case of FOMC fit for both α and β the CI passed through zero, while for DFOP for both k_1 and k_2 the $prob > t$ was higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Kirchlauter 30162/0**, demonstrated that kinetic model that returned reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field, conditions for the parent compound – Flufenacet, was SFO. Therefore the values obtained using that model will be presented in the List of End Points. The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed because of the lack of the appropriate data base for any of them.

3) Results of the kinetic examination of the data obtained for the trial *Monheim, 30163/9, Germany* (Study [Sommer; 1995]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-60 and in numerical form in the table B.8.1.1.2.2.1._CA-78. Additionally the table B.8.1.1.2.2.1._CA-79 provides the kinetic endpoints obtained with each of the kinetic models tested.

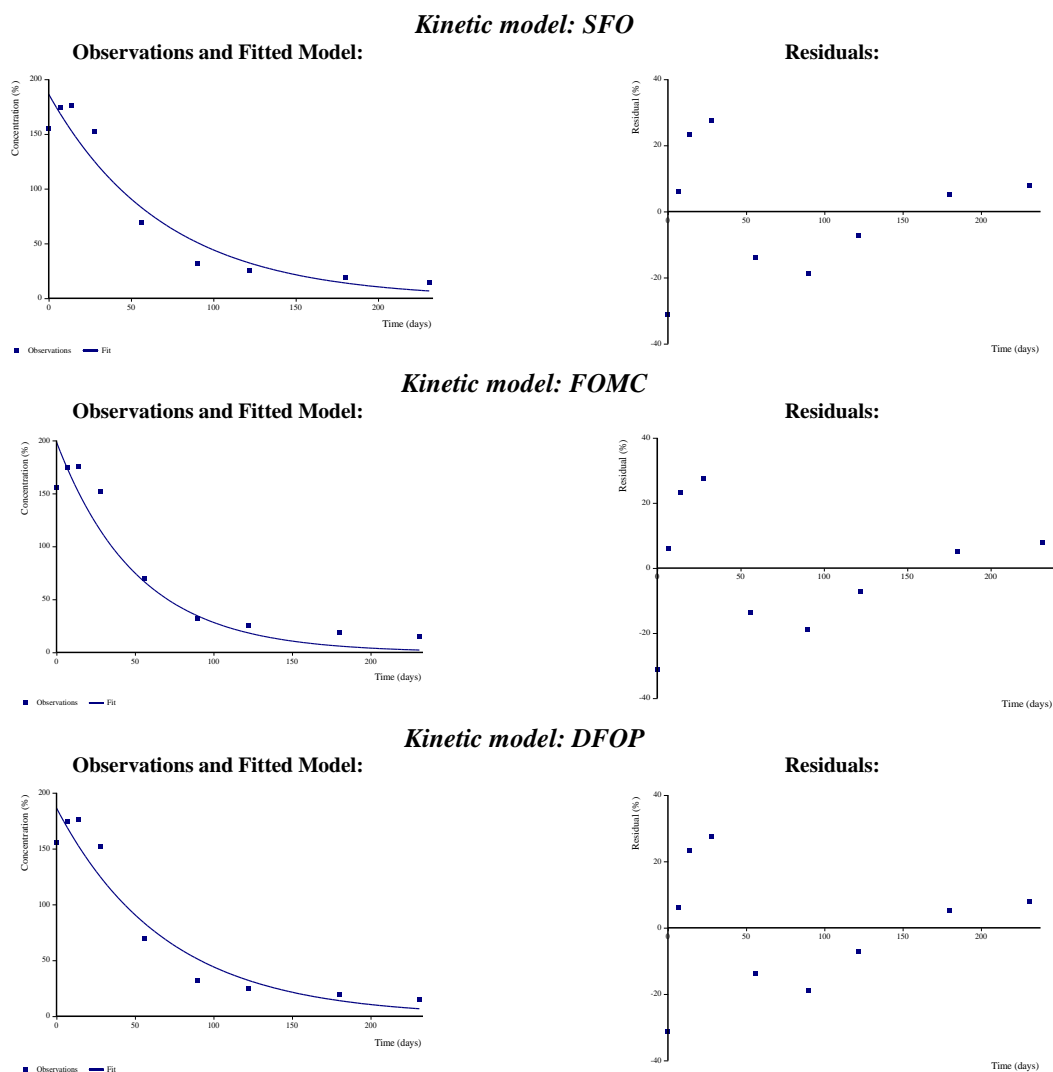

Figure B.8.1.1.2.2.1._CA-60: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-78: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	186.4	13.93	160.0	212.8	-----	16.1	0.9275; Acceptable fit
	k	0.0144	0.00272	0.009241	0.01955	5.67 E-4		
FOMC	M_0	198.6	17.66	164.3	232.9	-----	17.0	0.9648; Acceptable fit
	α	440.9	120.0	207.7	674.2	-----		
	β	22600	6450	10000	35100	-----		
DFOP	M_0	186.4	15.79	154.6	218.2	-----	18.1	0.9275; Acceptable fit
	k_1	0.01439	0.01655	-0.01896	0.04775	0.2121		
	k_2	0.0144	0.001542	0.01129	0.0175	1.19 E-4		
	g	0.08148	Not determined	Not determined	Not determined	not given		

Table B.8.1.1.2.2.1._CA-79: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	48.2	35.5	48.2
	DT ₉₀ [days]	160.0	118.0	160.0

The examination of the results showed that all three kinetic models returned visually acceptable fits, very similar one to another. The visual fit for all three models may be classified only as acceptable. That is due to the fact that although the correlation coefficient r was above 0.9, what indicated good conformity of the experimental points with the estimated kinetic curve, the visual inspection showed that it was not. Additionally the residuals were high, for some time points above the level $\pm 20\%$. On the other hand for all fits the residuals were randomly distributed.

As for their statistical acceptability, for all three kinetic models the χ^2 error was slightly above the threshold value of 15%, not surpassing however 20%. The lowest value was obtained for SFO model, the highest for DFOP kinetic fit, the sole of the three that cannot be considered acceptable because of the lack of reliability of the determined kinetic parameters. For that fit the $prob > t$ – for k_2 was higher than 0.1 and, because the covariance matrix could not have been created, it was not possible to calculate the error and CI values for parameter g . RMS also noticed that kinetic parameters k_1 and k_2 in DFOP fit were identical and the same as the kinetic parameter k determined using SFO kinetic model.

The fit obtained with FOMC model was visually almost identical to that obtained with SFO, but statistically worse - χ^2 error was higher than that for SFO (17.0% v/s 16.1% respectively). RMS also noticed that the kinetic parameters determined using FOMC model - α and β , although statistically reliable seem to be unrealistically high. Finally, it was noticed that DT₉₀ determined for FOMC fit was shorter than that determined using SFO model. That may suggest, taking into account the conceptual definition of FOMC model, that this model is not appropriate to characterise the kinetic behaviour of Flufenacet in the trial **Monheim, 30163/9**.

As a result it shall be stated that only SFO returned reliable fit and hence it should be considered as the best-fit model for the parent compound – Flufenacet.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Monheim, 30163/9**, demonstrated that for that trial SFO shall be considered as the best-fit model for Flufenacet. The results of the fitting – the determined kinetic endpoints, will be presented in the List of End Points.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for that trial due to the lack of the suitable data base for any of them.

4) Results of the kinetic examination of the data obtained for the trial *Burscheid, 30164/7, Germany* (Study No. 107724, [Sommer; 1995]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1_CA-61 and in numerical form in the table B.8.1.1.2.2.1_CA-80. Additionally the table B.8.1.1.2.2.1_CA-81 provides the kinetic endpoints obtained with each of the kinetic models tested.

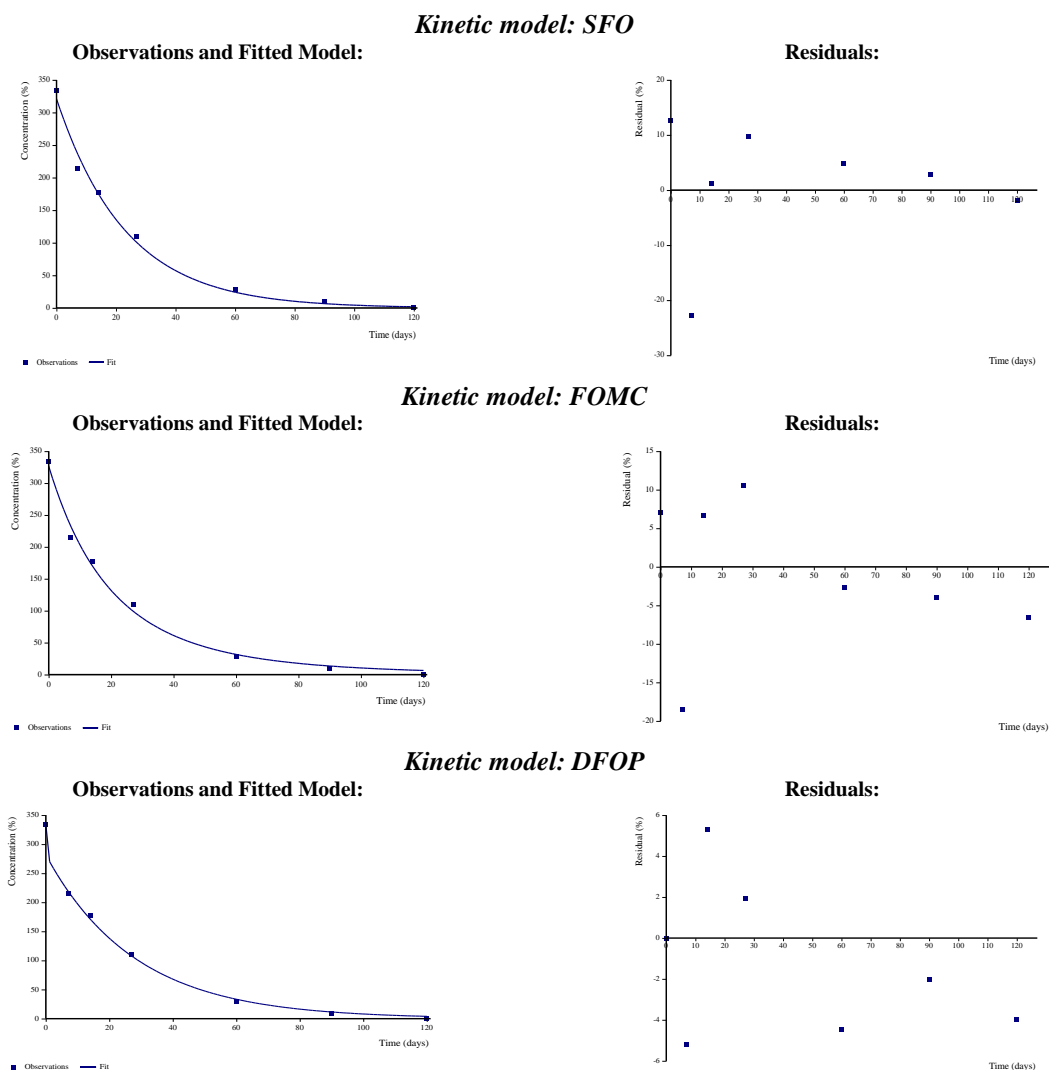

Figure B.8.1.1.2.2.1_CA-61: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-80: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	321.0	11.23	298.3	343.6	-----	6.83	0.9915; Good fit
	k	0.04309	0.003632	0.03577	0.05041	3.75 E-5		
FOMC	M_0	326.6	11.85	301.3	351.8	-----	6.43	0.9936; Good fit
	α	4.903	4.224	-4.144	13.95	-----		
	β	98.42	97.02	-108.4	305.2	-----		
DFOP	M_0	333.6	5.72	320.1	347.1	-----	2.85	0.9991; Good fit
	k_1	3.869	309.9	-725.3	733.1	0.4954		
	k_2	0.03551	0.002005	0.03079	0.040023	1.96 E-4		
	g	0.1569	0.3041	0.08531	0.2284	not given		

Table B.8.1.1.2.2.1._CA-81: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	16.1	14.9	14.7
	DT ₉₀ [days]	53.4	59.0	60.0

The examination of the results showed that all three kinetic models returned visually and statistically good fits, very similar one to another. The visual fits displayed good conformity with the experimental results and low level of residuals, randomly distributed. However, neither the FOMC fit nor that obtained using DFOP model may be considered acceptable because of the lack of reliability of the kinetic parameters – in case of FOMC fit for both α and β the CI passes through zero, while for DFOP for k_1 the $prob > t$ was significantly higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet in that trial.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Burscheid, 30164/7**, demonstrated that for that trial SFO shall be considered as the best-fit model for Flufenacet. The results of the fitting – the determined kinetic endpoints, will be presented in the List of End Points.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for this trial due to the lack of the suitable data base for any of them.

5) Results of the kinetic examination of the data obtained for the trial *Fresne-L'Archeveque, 30248/1, North France* (Study No. 107724, [Sommer; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-62 and in numerical form in the table B.8.1.1.2.2.1._CA-82. Additionally, the table B.8.1.1.2.2.1._CA-83 provides the kinetic endpoints obtained with each of the kinetic models tested.

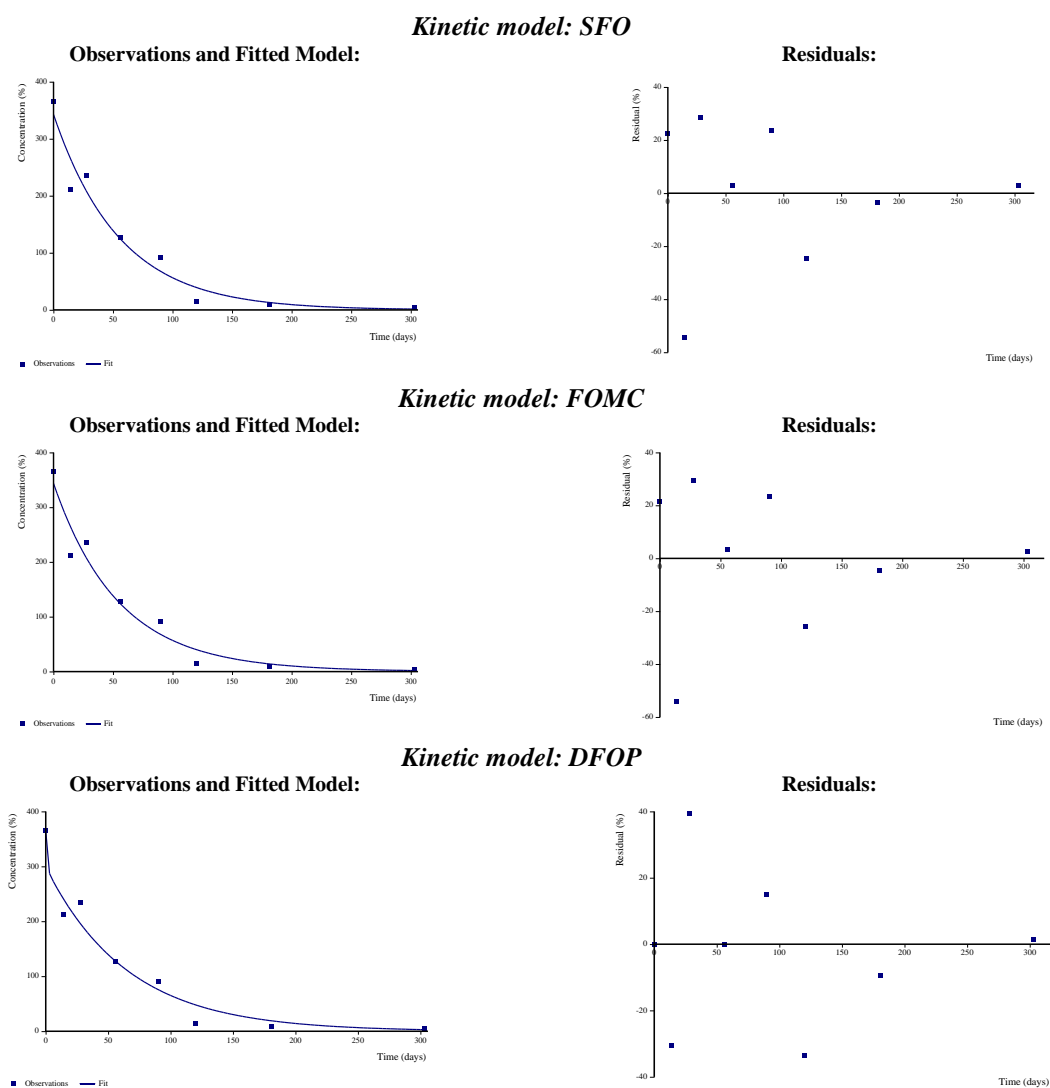

Figure B.8.1.1.2.2.1._CA-62: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-82: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	342.7	25.23	293.7	391.7	-----	15.8	0.9536; Acceptable fit
	k	0.01805	0.002917	0.01239	0.02372	4.10 E-4		
FOMC	M_0	343.6	30.6	282.0	405.3	-----	16.8	0.9537; Acceptable fit
	α	36.84	594.4	-1161.0	1240.0	-----		
	β	2000.0	32900	-62400	68200	-----		
DFOP	M_0	365.2	31.37	298.3	432.1	-----	15.4	0.9673; Acceptable fit
	k_1	1.243	174.8	-371.4	373.9	0.4973		
	k_2	0.01526	0.003287	0.008247	0.02226	0.004865		
	g	0.1811	0.1306	-0.09725	0.4595	not given		

Table B.8.1.1.2.2.1._CA-83: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	38.4	38.0	32.3
	DT ₉₀ [days]	128.0	129.0	138.0

The visual fit for all three models may be classified only as acceptable. That is due to the fact that although the correlation coefficient r was above 0.9, what indicated good conformity of the experimental points with the estimated kinetic curve, the visual inspection showed that it was not. Additionally the residuals were high, for some time points above the level $\pm 20\%$. On the other hand for all fits the residuals were randomly distributed.

As for their statistical acceptability, for all three kinetic models the χ^2 error was slightly above the threshold value of 15%, not surpassing however 17%. The lowest value was obtained for DFOP model, the highest for FOMC kinetic fit. At the same time it shall be noted that for all three kinetic fits the χ^2 error values were very close and in case of DFOP and SFO fits almost identical.

Additionally it was noticed that neither the FOMC fit nor that obtained using DFOP model may be considered acceptable because of the lack of reliability of the kinetic parameters – in case of FOMC fit for both α and β the CI passes through zero, while for DFOP for k_1 the $prob > t$ was significantly higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet and as such was used at the next stage of analysis.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-63 and in numerical form in the table B.8.1.1.2.2.1._CA-84. The fitting was performed for combination SFO-SFO.

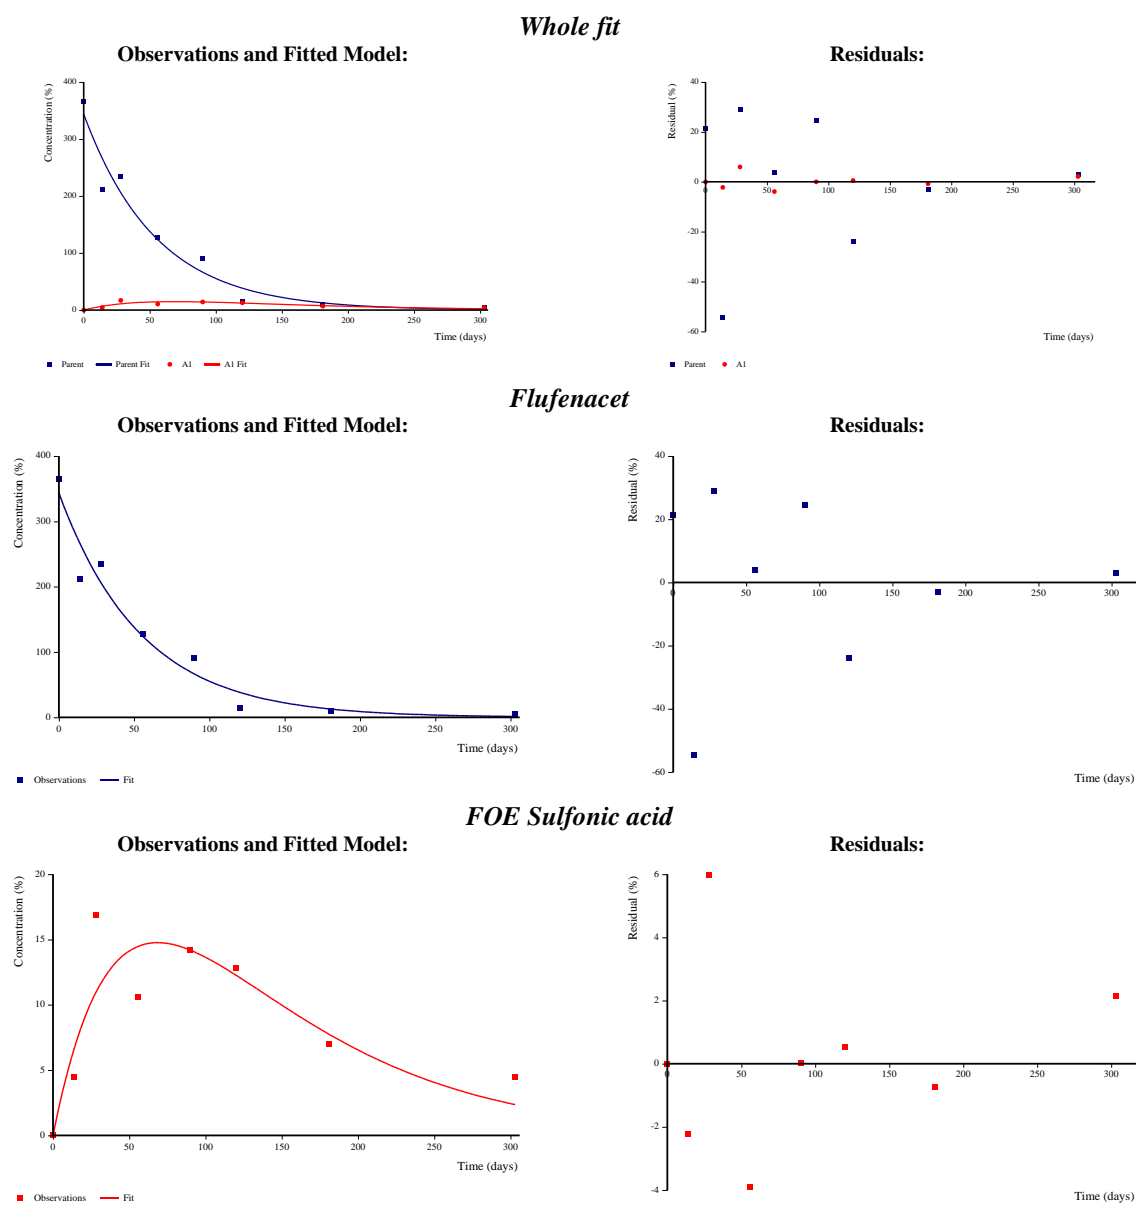

Figure B.8.1.1.2.2.1._CA-63: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Fresne-L'Archeveque, 30248/1.

Table B.8.1.1.2.2.1._CA-84: The numerical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Fresne-L'Archeveque, 30248/1.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	343.7	26.39	296.3	391.1	-----	15.8	0.9536
		k	0.01827	0.003069	0.01275	0.02378	4.79 E-5		Acceptable fit
FOE Sulfonic acid	SFO	M ₀	0.0	-----	-----	-----	-----	23.3	0.7441;
		k	0.01144	0.004436	0.003473	0.01941	0.01282		Acceptable fit
		ff	0.09409	0.02776	0.04423	0.1439	-----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-85.

Table B.8.1.1.2.2.1._CA-85: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Sulfonic acid
DT ₅₀ [days]	38.0	60.6
DT ₉₀ [days]	126.0	201
Kinetic formation fraction ff	Not applicable – parent compound	0.0941 ± 0.028
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fit obtained for FOE Sulfonic acid can also be considered acceptable, despite the χ^2 error > 15% (23.3%). That is due to the fact that the conformity of the kinetic curve with the experimental results may be classified as good, the residuals are low and randomly distributed.

As a result, it can be stated that in that trial it was possible to obtain reliable fits for Flufenacet and FOE Sulfonic acid using a combination SFO-SFO.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were very similar to those for the parent fitted alone and no improvement of the fit was observed for the degradation product – FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound would not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Fresne-L'Archeveque, 30248/1**, demonstrated that reliable fit, and hence reliable kinetic endpoints representing persistence in soil under realistic – field conditions, was obtained for both parent compound – Flufenacet and its degradation product – FOE Sulfonic acid when the combination of the kinetic models SFO-SFO was used. The kinetic endpoints resulting from this kinetic assessment will be presented in the List of End Points as persistence kinetic endpoints for Flufenacet and FOE Sulfonic acid in the trial **Fresne-L'Archeveque, 30248/1**.

6) Results of the kinetic examination of the data obtained for the trial *Fresne-L'Archeveque 1, 30250/3, North France* (Study No. 107724, [Sommer; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-64 and in numerical form in the table B.8.1.1.2.2.1._CA-86. Additionally the table B.8.1.1.2.2.1._CA-87 provides the kinetic endpoints obtained with each of the kinetic models tested.

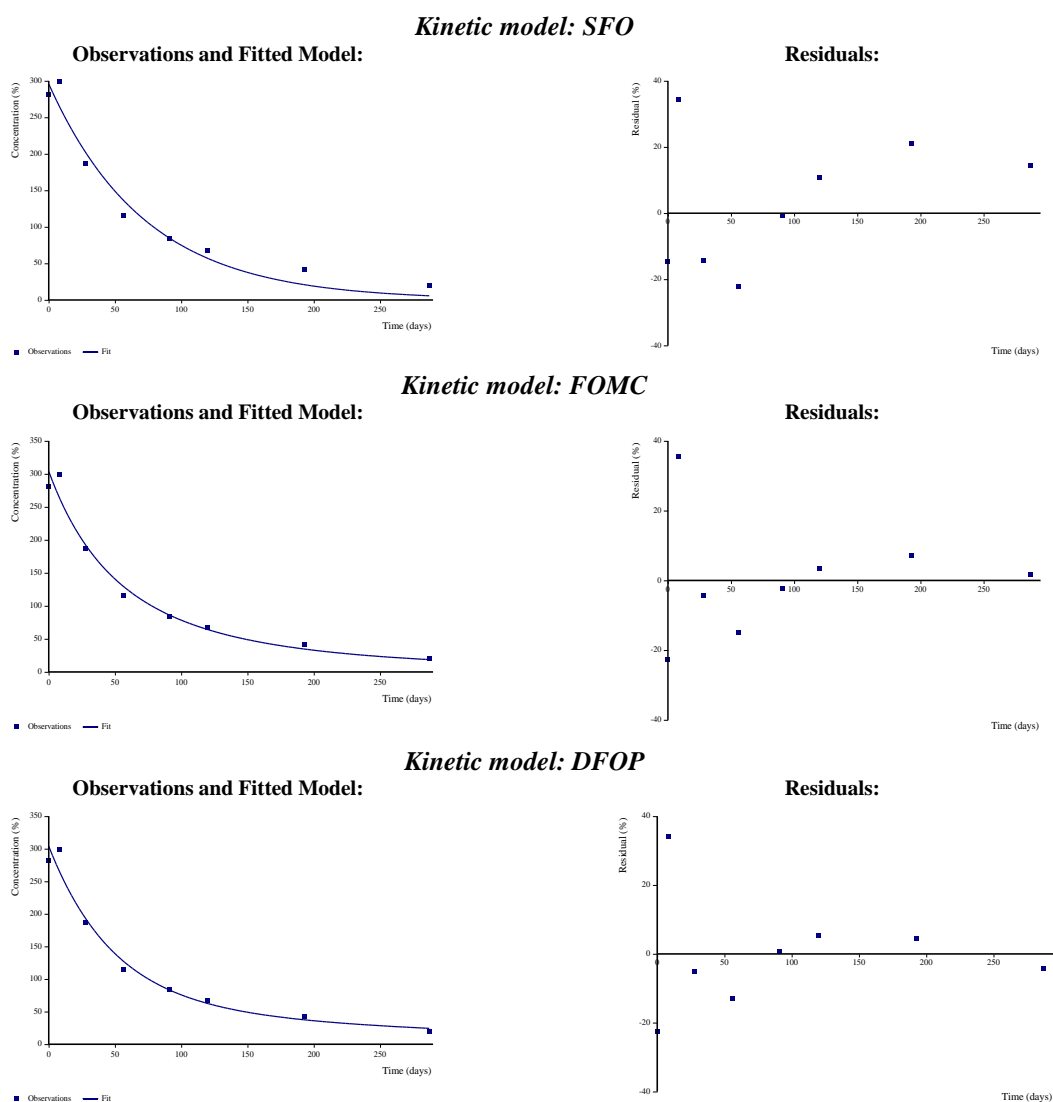

Figure B.8.1.1.2.2.1._CA-64: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-86: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	296.0	16.16	264.6	327.4	-----	11.0	0.9681; Acceptable fit
	k	0.01374	0.001757	0.01032	0.01715	1.15 E-4		
FOMC	M_0	304.0	17.55	268.7	339.4	-----	10.0	0.9741; Acceptable fit
	α	2.448	2.117	-1.819	6.714	-----		
	β	135.2	152.0	-171.1	441.4	-----		
DFOP	M_0	304.0	18.76	264.0	344.0	-----	10.4	0.9761; Acceptable fit
	k_1	0.02088	0.01564	-0.01247	0.05423	0.1264		
	k_2	0.003541	0.01107	-0.02005	0.02713	0.3825		
	g	0.7834	0.5767	-0.4461	2.013	not given		

Table B.8.1.1.2.2.1._CA-87: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	50.5	44.2	43.7
	DT ₉₀ [days]	168.0	211.0	235.0

The examination of the results showed that all three kinetic models returned visually acceptable and statistically reliable – for all three models the χ^2 error was < 15%. The fits were similar one to another. In case of the SFO model the visual fit was classified as acceptable, despite the fact that correlation coefficient $r > 0.9$, what suggested a good conformity of the estimated kinetic curve and experimental points. In reality the kinetic curve did not represent well the distribution of the experimental points. Additionally some of the residuals were high and their distribution, especially for later time points, not random.

For FOMC and DFOP fits the conformity of the estimated kinetic curve and experimental points was better, what was also reflected in lower χ^2 error and higher correlation coefficient r . However, the residuals for these two fits were very similar to those determined for the SFO fit, both in terms of their values and their spatial distribution.

At the same time it shall be stated that neither FOMC nor DFOP may be considered acceptable, due to the lack of reliability of the kinetic parameters – in case of FOMC fit for both α and β the CI passes through zero, while for DFOP for both k_1 and k_2 the $prob > t$ was higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet, and as such was used at the next stage of analysis.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-65 and in numerical form in the table B.8.1.1.2.2.1._CA-88. The fitting was performed for combination SFO-SFO-SFO. In the modelling tool A1 was used to denominate FOE Oxalate and B1 – FOE Sulfonic acid.

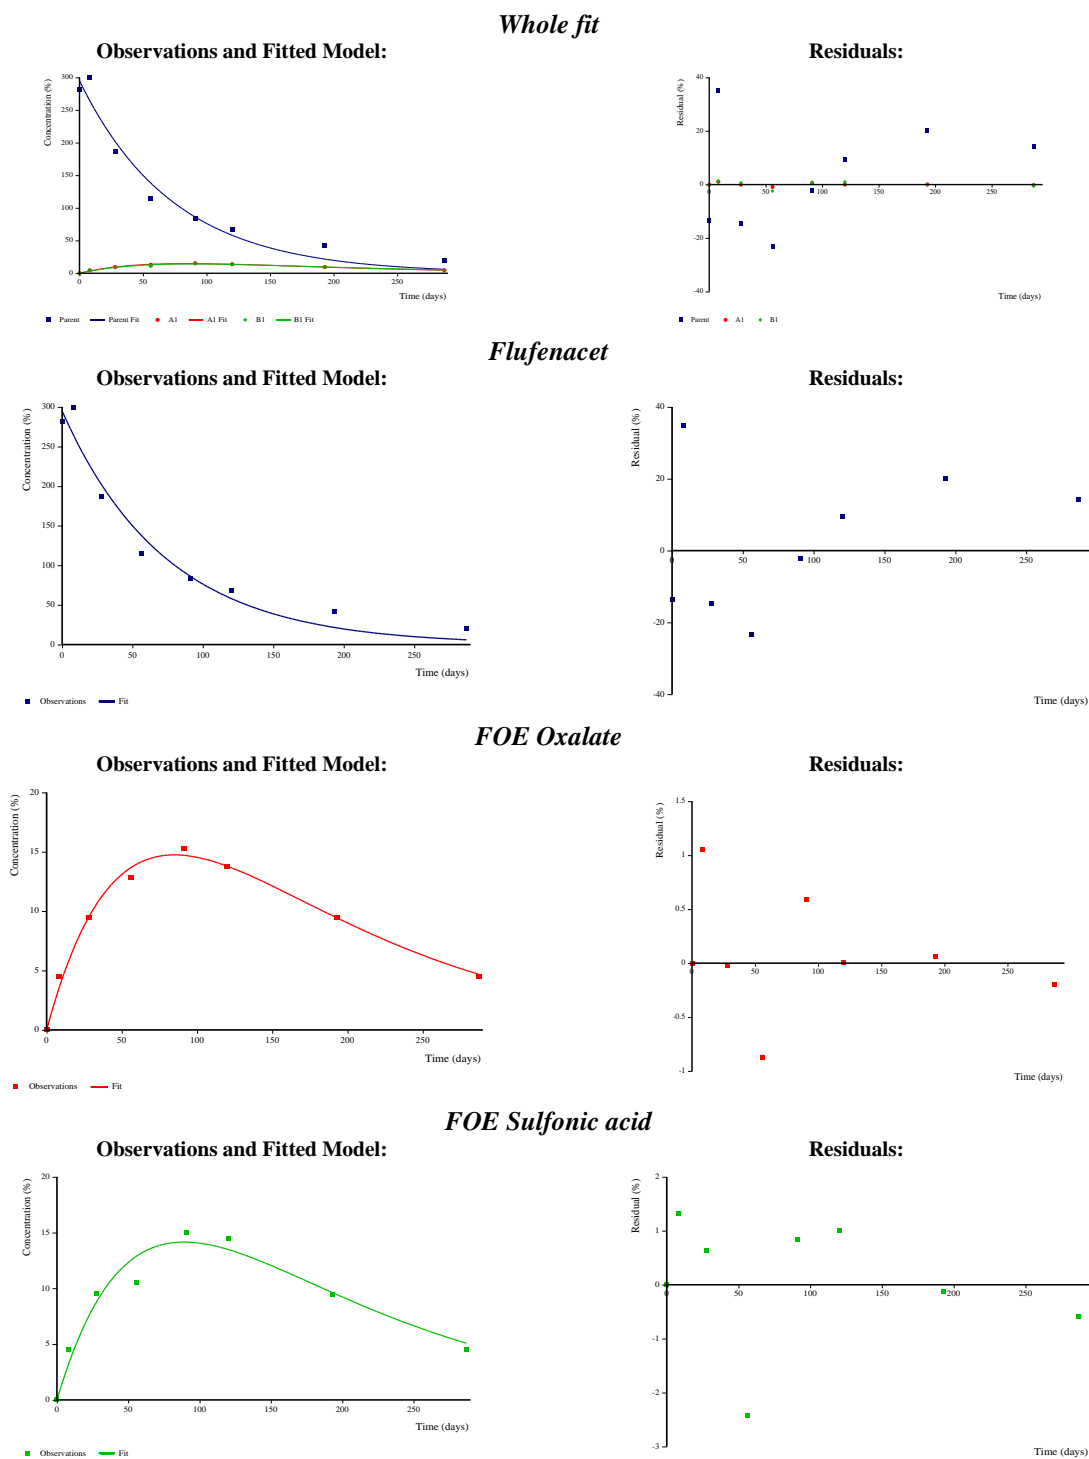

Figure B.8.1.1.2.2.1._CA-65: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Fresne-L'Archeveque 1, 30250/3.

Table B.8.1.1.2.2.1._CA-88: The numerical results of the kinetic examination of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid obtained in the trial Fresne-L'Archeveque 1, 30250/3.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	294.9	17.0	265.2	324.6	-----	11.0	0.9672; Acceptable fit
		k	0.01352	0.001798	0.01038	0.01666	6.14 E-7		
FOE Oxalate	SFO	M ₀	0.0	----	----	----	----	4.53	0.9895; Good fit
		k	0.01091	0.001515	0.007544	0.01284	2.44 E-6		
		ff	0.1188	0.01973	0.08434	0.1532	----		
FOE Sulfonic acid	SFO	M ₀	0.0	----	----	----	----	9.83	0.9477; Good fit
		k	0.00921	0.001872	0.005942	0.01248	7.69 E-5		
		ff	0.1091	0.01994	0.07424	0.1439	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-89.

Table B.8.1.1.2.2.1._CA-89: The kinetic endpoints determined in the experiment.

Determined parameter	Compound		
	Flufenacet	FOE Sulfonic acid	FOE Oxalate
DT ₅₀ [days]	51.3	75.3	68.0
DT ₉₀ [days]	170.0	250.0	226.0
Kinetic formation fraction ff	Not applicable	0.109 ± 0.020	0.119 ± 0.020
Precursor	Not applicable	Flufenacet	Flufenacet
Kinetic model	SFO	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fits obtained for both FOE Oxalate and FOE Sulfonic acid can also be considered acceptable. They display very good conformity of the estimated kinetic curve with the experimental points and low, randomly distributed residuals. They are also statistically reliable – the χ^2 error for them both is well below 15%, not surpassing the level of 10%. Finally, for all three compounds the determined kinetic parameters, and hence kinetic endpoints, are fully reliable.

As a result, it can be stated that in this trial it was possible to obtain reliable fits for Flufenacet, FOE Oxalate and FOE Sulfonic acid using a combination SFO-SFO-SFO.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were similar to those for the parent compound fitted alone and no improvement of the fit was observed for the degradation products – FOE Oxalate and FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Fresne-L'Archeveque 1, 30250/3**, demonstrated that reliable fit, and hence reliable kinetic endpoints representing persistence in soil under realistic – field conditions, was obtained for all compounds for which assessment was carried out – Flufenacet (parent compound), FOE Oxalate (primary degradation product of Flufenacet) and FOE Sulfonic acid (primary degradation product of Flufenacet), when the combination of the kinetic models SFO-SFO-SFO was used. The kinetic endpoints resulting from this kinetic assessment will be presented in the List of End Points as persistence kinetic endpoints for Flufenacet, FOE Oxalate and FOE Sulfonic acid in the trial **Fresne-L'Archeveque 1, 30250/3**.

7) Results of the kinetic examination of the data obtained for the trial *Laudun, 30251/1, South France* (Study No. 107724, [Sommer; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-66 and in numerical form in the table B.8.1.1.2.2.1._CA-90. Additionally the table B.8.1.1.2.2.1._CA-91 provides the kinetic endpoints obtained with each of the kinetic models tested.

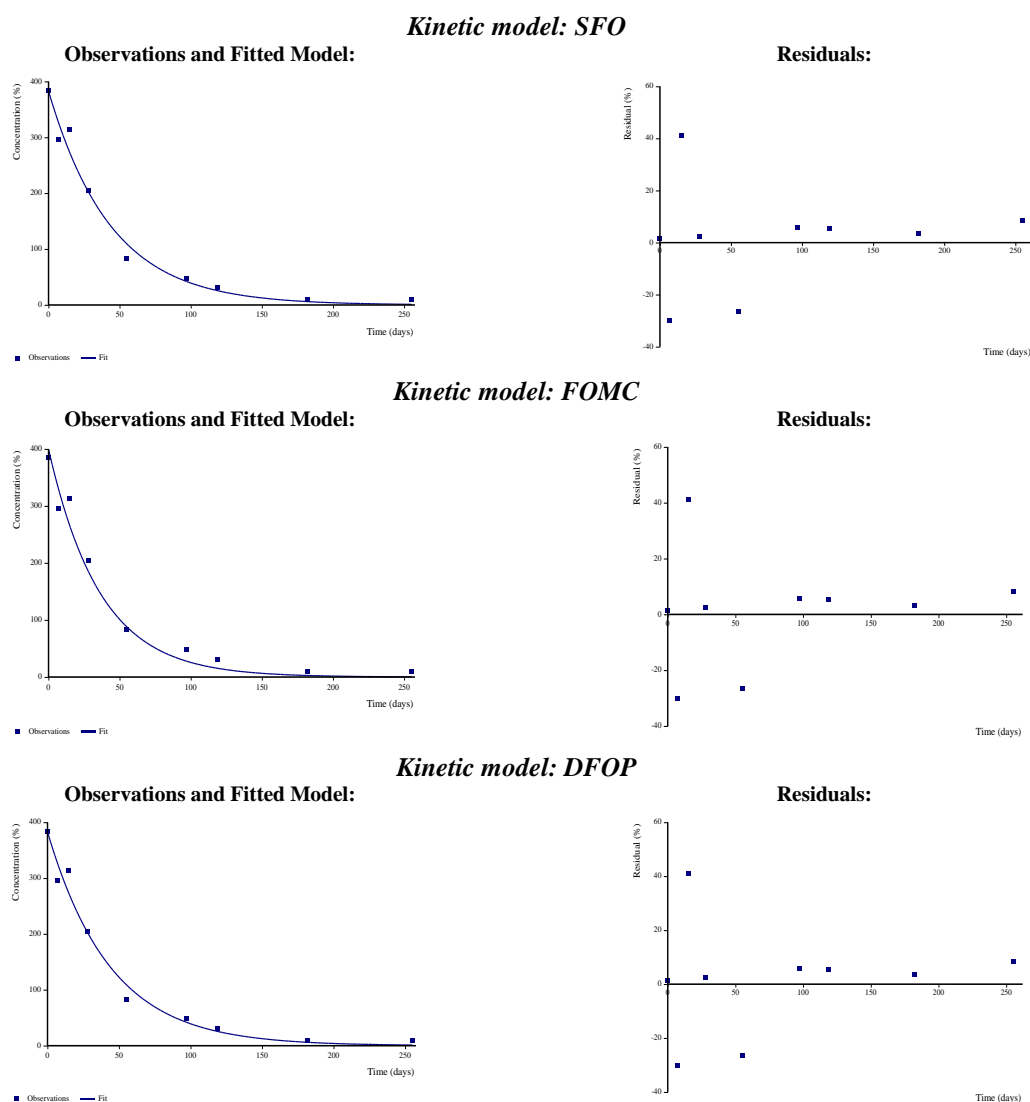

Figure B.8.1.1.2.2.1._CA-66: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-90: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	382.9	16.96	350.8	415.0	-----	10.2	0.9804; Acceptable fit
	k	0.02278	0.00253	0.01799	0.02757	2.13 E-5		
FOMC	M_0	400.0	21.82	357.6	442.4	-----	10.8	0.9804; Acceptable fit
	α	683.7	161.2	370.5	996.8	-----		
	β	24800	6110	12900	36700	-----		
DFOP	M_0	382.9	26.19	330.1	435.7	-----	11.5	0.9804; Acceptable fit
	k_1	0.02278	364.1	-733.6	733.7	0.5000		
	k_2	0.02278	187.8	-378.4	378.4	0.5000		
	g	0.3402	154000	-310000	311000	not given		

Table B.8.1.1.2.2.1._CA-91: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	30.4	25.2	30.4
	DT ₉₀ [days]	101.0	83.7	101.0

The examination of the results showed that all three kinetic models returned visually acceptable and statistically reliable – for all three models the χ^2 error was < 15%. It was stated that of the three SFO returned superior fit, although the differences between the fits were minimal.

DFOP cannot be considered acceptable, because it returned not reliable kinetic parameters. It was noted that for that kinetic model the rate constants k_1 and k_2 were equal and. Moreover, they were equal to the rate constant k determined using SFO model.

FOMC returned fit visually almost identical to that obtained with SFO and statistically slightly worse. The determined kinetic parameters – α and β , were reliable, but very high. RMS noted that the DT₉₀ determined for FOMC model was shorter than that for SFO, what puts a question mark over the problem whether the FOMC model adequately describes the kinetic behaviour of Flufenacet in the evaluated trial.

As a result SFO was identified as kinetic model returning the best fit for this trial and hence adequate to be used at the next stage of the assessment.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-67 and in numerical form in the table B.8.1.1.2.2.1._CA-92. The fitting was performed for combination SFO-SFO-SFO. In the modelling tool A1 was used to denominate FOE Oxalate and B1 – FOE Sulfonic acid.

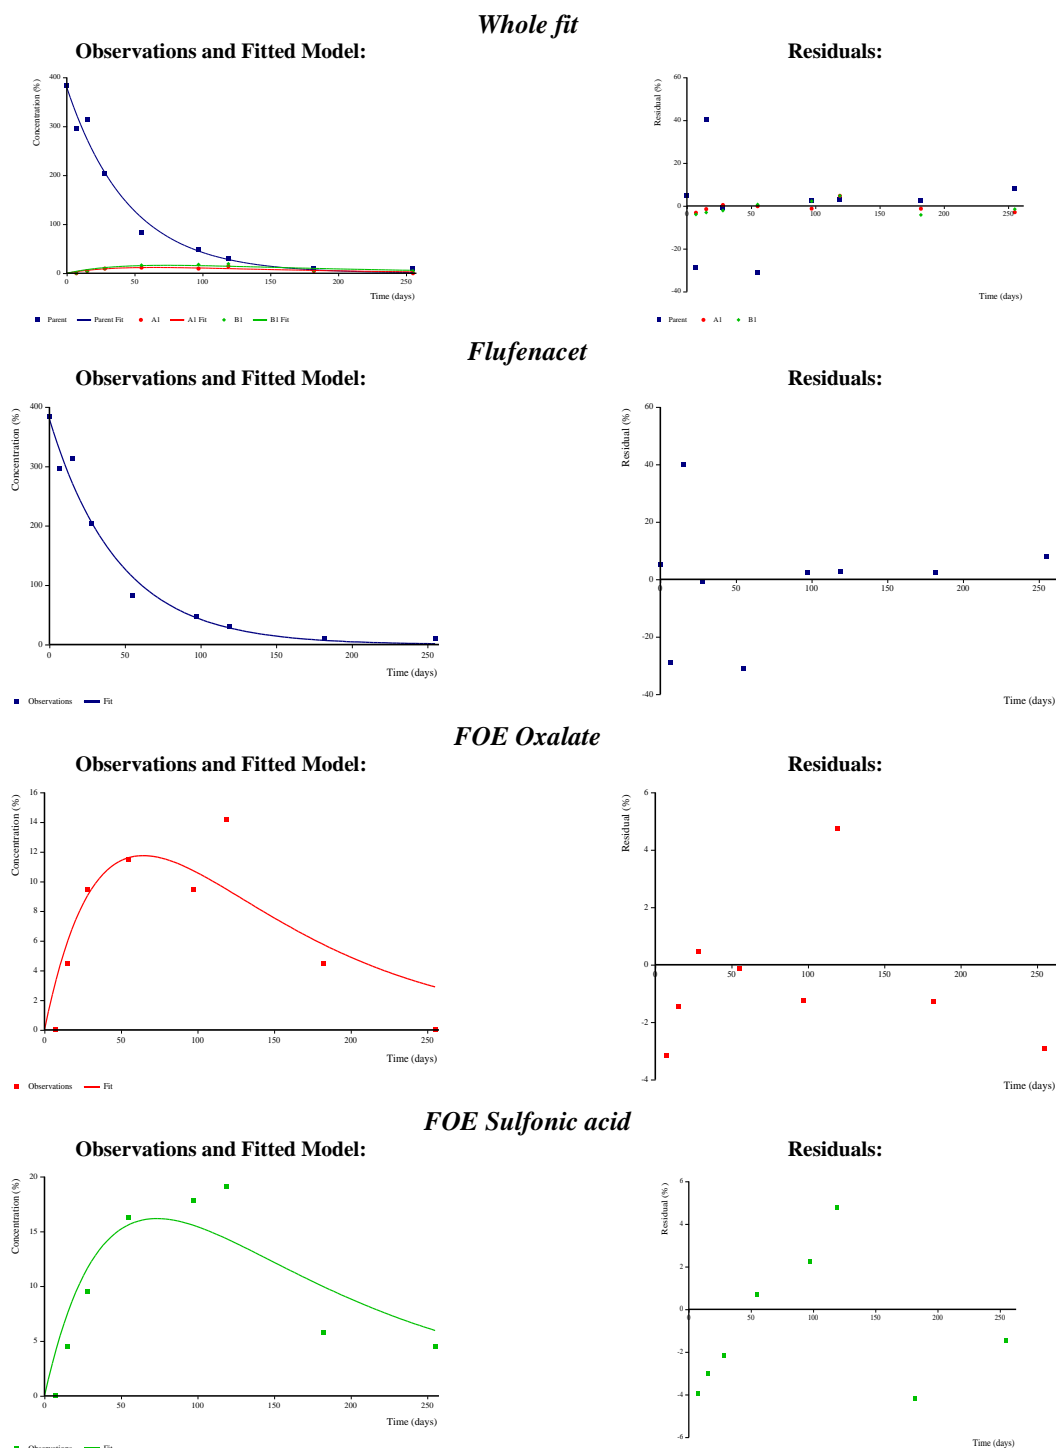

Figure B.8.1.1.2.2.1._CA-67: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Laudun, 30251/1.

Table B.8.1.1.2.2.1._CA-92: The numerical results of the kinetic examination of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid obtained in the trial Laudun, 30251/1.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	379.3	17.08	349.8	408.9	-----	10.3	0.9798; Acceptable fit
		k	0.02189	0.002458	0.01764	0.02614	1.65 E-8		
FOE Oxalate	SFO	M ₀	0.0	----	----	----	----	28.6	0.8631; Acceptable fit
		k	0.01047	0.003737	0.004007	0.01693	0.005696		
		ff	0.0609	0.01469	0.03549	0.08631	----		
FOE Sulfonic acid	SFO	M ₀	0.0	----	----	----	----	25.6	0.9141; Acceptable fit
		k	0.007746	0.002802	0.002901	0.01259	0.006172		
		ff	0.07534	0.01657	0.04669	0.104	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-93.

Table B.8.1.1.2.2.1._CA-93: The kinetic endpoints determined in the experiment.

Determined parameter	Compound		
	Flufenacet	FOE Sulfonic acid	FOE Oxalate
DT ₅₀ [days]	31.7	89.5	66.2
DT ₉₀ [days]	105.0	297.0	220.0
Kinetic formation fraction ff	Not applicable	0.075 ± 0.003	0.061 ± 0.015
Precursor	Not applicable	Flufenacet	Flufenacet
Kinetic model	SFO	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fits obtained for both FOE Oxalate and FOE Sulfonic acid cannot be considered acceptable. They display only intermediate conformity of the estimated kinetic curve with the experimental points and the residuals are not randomly distributed. In addition they are not fully statistically reliable – the χ^2 error for them both is well above 15%, reaching 28.6% for the fit FOE Oxalate and 25.6% for that for FOE Sulfonic acid.

As a result, it can be stated that in this trial it was possible to obtain reliable fit only for Flufenacet.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were similar to those for the parent fitted alone and no improvement of the fit was observed for the degradation products – FOE Oxalate and FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Laudun, 30251/1**, demonstrated that reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field conditions was obtained only for the parent compound – Flufenacet. The kinetic model identified as returning the best fit was SFO.

For the degradation products subjected to the kinetic examination – FOE Oxalate and FOE Sulfonic acid, it was not possible to obtain reliable kinetic fit and hence reliable kinetic endpoints representing the persistence of that compound on the trial site.

As a result, it can be stated that the reliable persistence kinetic endpoints for that trial may be determined for the parent compound – Flufenacet, when fitted alone. These values will be presented in the List of End Points.

8) Results of the kinetic examination of the data obtained for the trial *St. Etienne du Gres, 30253/8, South France* (Study No. 107724, [Sommer; 1995]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1_CA-68 and in numerical form in the table B.8.1.1.2.2.1_CA-94. Additionally the table B.8.1.1.2.2.1_CA-95 provides the kinetic endpoints obtained with each of the kinetic models tested.

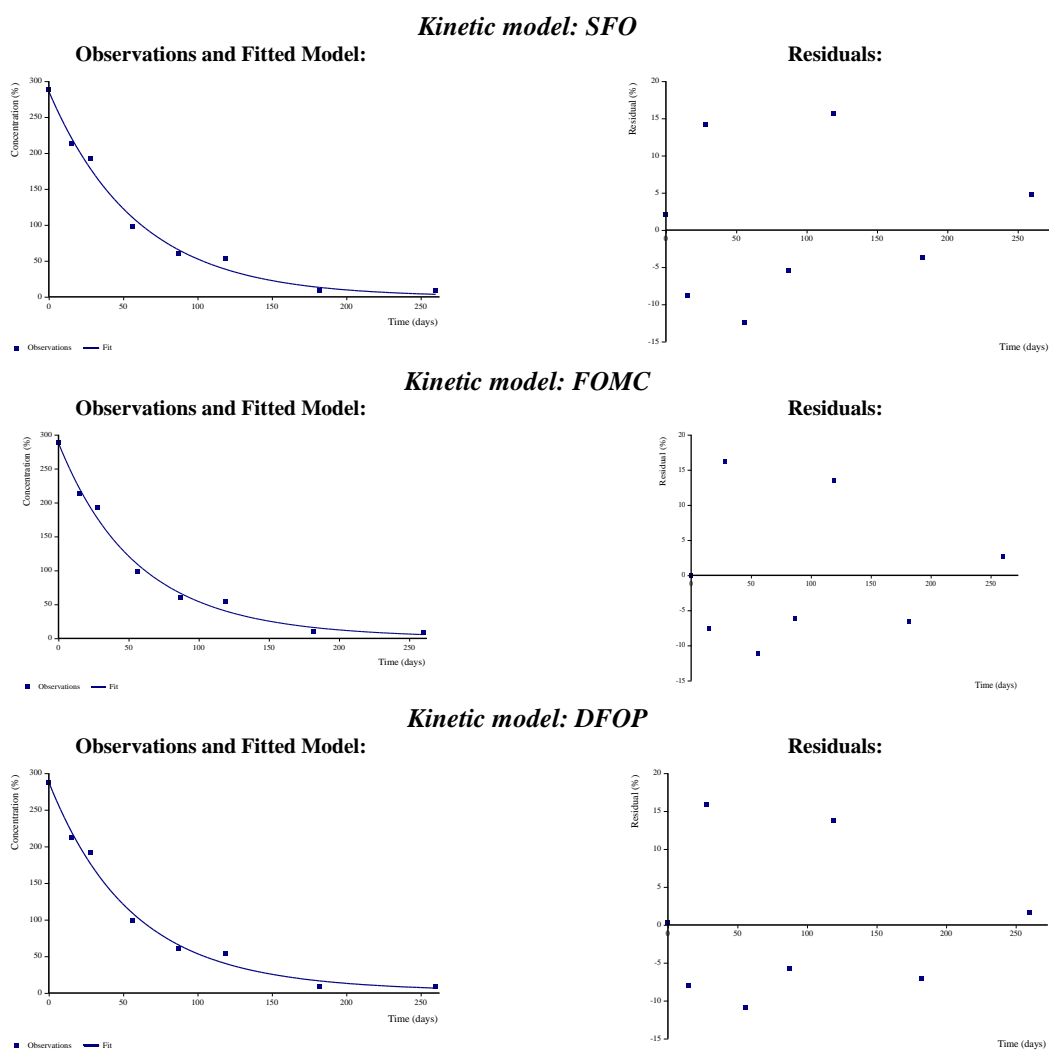

Figure B.8.1.1.2.2.1_CA-68: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-94: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	285.9	9.279	267.9	303.9	-----	6.68	0.9902; Good fit
	k	0.01691	0.001191	0.0146	0.01923	3.81 E-6		
FOMC	M_0	288.0	11.1	265.6	310.3	-----	6.97	0.9904; Good fit
	α	11.85	26.16	-40.86	64.56	-----		
	β	660.	1550.0	-2455.0	3780.0	-----		
DFOP	M_0	287.7	12.59	160.9	314.6	-----	7.51	0.9905; Good fit
	k_1	0.01901	0.01755	-0.0184	0.05642	0.1698		
	k_2	0.007222	0.052887	-0.1055	0.1200	0.4490		
	g	0.8899	1.563	-2.443	4.222	not given		

Table B.8.1.1.2.2.1._CA-95: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	41.0	39.8	39.8
	DT ₉₀ [days]	136.0	142.0	142.0

All three models returned visually and statistically good fits. Of the three SFO fit was superior, although they were all very similar.

However, neither FOMC nor DFOP fits may be considered acceptable because of the lack of reliability of the kinetic parameters they returned. In case of FOMC for both α and β the CI passes through zero. In case of DFOP fit for k_1 and k_2 the $prob > t$ was significantly higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet and as such was used at the next stage of analysis.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-69 and in numerical form in the table B.8.1.1.2.2.1._CA-96. The fitting was performed for combination SFO-SFO.

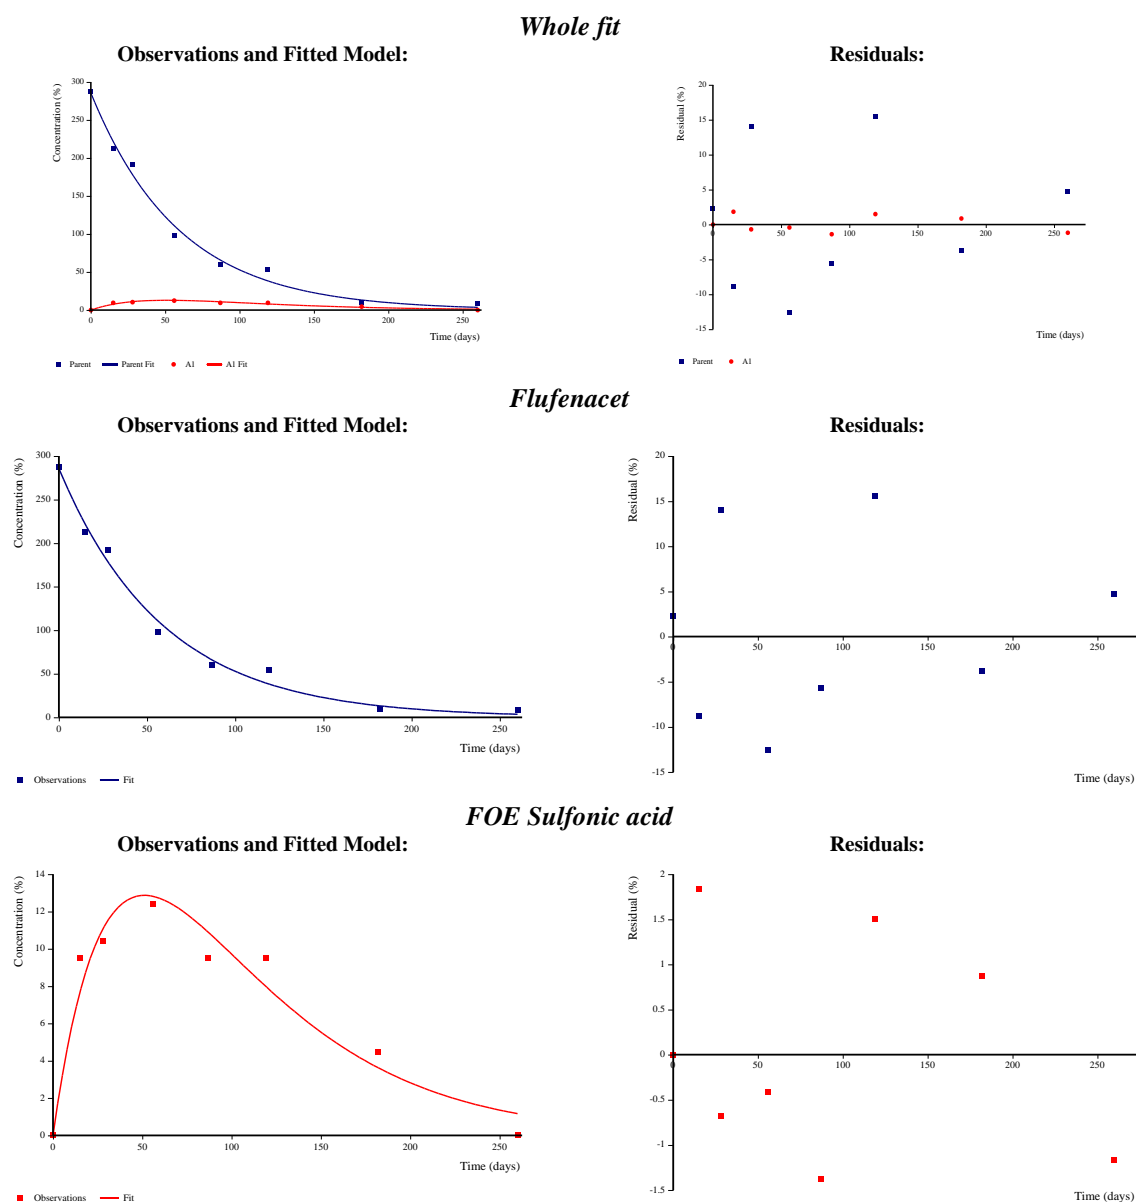

Figure B.8.1.1.2.2.1._CA-69: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial St. Etienne du Gres, 30253/8.

Table B.8.1.1.2.2.1._CA-96: The numerical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial St. Etienne du Gres, 30253/8.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	285.7	9.682	268.3	303.1	-----	6.68	0.9902; Good fit
		k	0.01687	0.001239	0.01465	0.01910	1.58 E-8		
FOE Sulfonic acid	SFO	M ₀	0.0	-----	-----	-----	-----	12.1	0.9379; Good fit
		k	0.02249	0.003981	0.01534	0.02964	7.46 E-5		
		ff	0.1423	0.02255	0.1018	0.1828	-----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-97.

Table B.8.1.1.2.2.1._CA-97: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Sulfonic acid
DT ₅₀ [days]	41.1	30.8
DT ₉₀ [days]	137.0	102.0
Kinetic formation fraction ff	Not applicable – parent compound	0.1423 ± 0.023
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fit obtained for FOE Sulfonic acid can also be considered acceptable. It displays good conformity of the estimated kinetic curve with the experimental points and low, randomly distributed residuals. It is also statistically reliable – the χ^2 error for it is below 15% (12.1%). Finally, for both compounds the determined kinetic parameters, and hence kinetic endpoints, are fully reliable.

As a result, it can be stated that in that trial it was possible to obtain reliable fits for Flufenacet and FOE Sulfonic acid using a combination SFO-SFO.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were very similar to those for the parent fitted alone and no improvement of the fit was observed for the degradation product – FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **St. Etienne du Gres, 30253/8**, demonstrated that reliable fit, and hence reliable kinetic endpoints representing persistence in soil under realistic – field conditions, was obtained for both parent compound – Flufenacet, and its degradation product – FOE Sulfonic acid, when the combination of the kinetic models SFO-SFO was used. The kinetic endpoints resulting from this kinetic assessment will be presented in the List of End Points as persistence kinetic endpoints for Flufenacet and FOE Sulfonic acid in the trial **St. Etienne du Gres, 30253/8**.

9) Results of the kinetic examination of the data obtained for the trial *Burscheid, 30499/9, Germany* (Study No 107722, [Sommer; 1995a]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1_CA-70 and in numerical form in the table B.8.1.1.2.2.1_CA-98. Additionally the table B.8.1.1.2.2.1_CA-99 provides the kinetic endpoints obtained with each of the kinetic models tested.

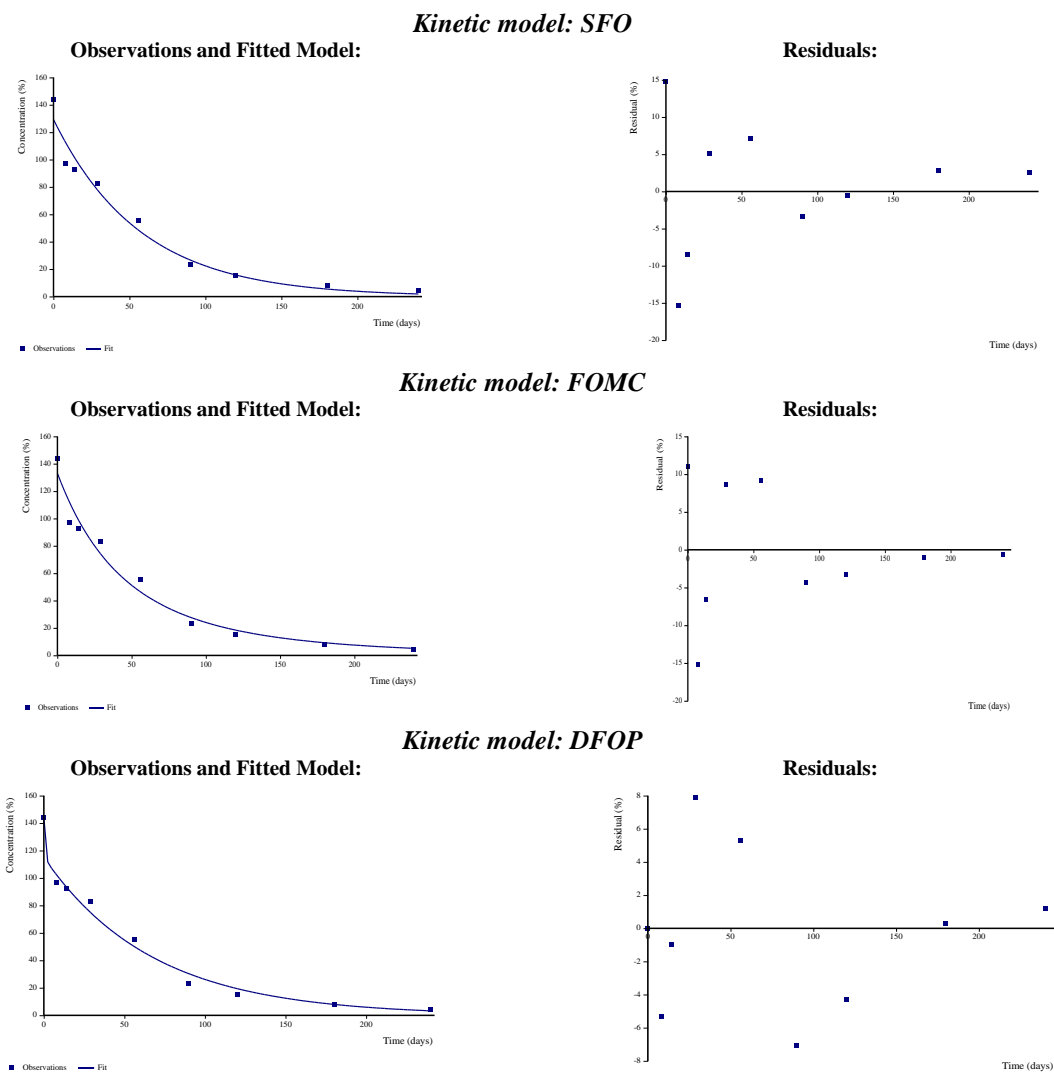

Figure B.8.1.1.2.2.1_CA-70: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-98: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	129.4	6.807	116.5	142.3	-----	11.5	0.9674; Acceptable fit
	k	0.01755	0.002294	0.0132	0.02189	6.06 E-5		
FOMC	M_0	133.1	8.538	116.5	149.7	-----	11.7	0.9695; Acceptable fit
	α	3.64	4.452	-5.011	12.29	-----		
	β	166.7	246.9	-313.1	646.7	-----		
DFOP	M_0	144.2	6.141	131.8	156.6	-----	7.11	0.9902; Good fit
	k_1	1.501	0.5315	0.4301	2.572	0.01846		
	k_2	0.01481	0.001467	0.011861	0.01777	8.15 E-5		
	g	0.2025	0.05184	0.09802	0.3069	not given		

Table B.8.1.1.2.2.1._CA-99: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	39.5	35.0	31.5
	DT ₉₀ [days]	131.0	147.0	140.0

The examination of the results showed that all three kinetic models returned visually and statistically acceptable fits, very similar one to another. Of them the best fit was obtained using DFOP model, which additionally returned fully reliable kinetic parameters. SFO and FOMC were statistically worse, both having χ^2 error slightly above 11%. Also for these two models the residuals were higher than those for DFOP fit, although their distribution was very similar for all three models tested.

Finally it shall be noted that while for SFO and DFOP the determined kinetic parameters were reliable, these were not for FOMC model – for both α and β the CI passes through zero, rendering them not reliable.

As a result it shall be stated that for that trial DFOP kinetic model returned the best kinetic fit for Flufenacet.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Burscheid, 30499/9**, demonstrated that for that trial DFOP shall be considered as the best-fit model for Flufenacet. The results of the fitting – the determined kinetic endpoints, will be presented in the List of End Points.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for this trial due to the lack of the suitable data base for any of them.

10) Results of the kinetic examination of the data obtained for the trial *Monheim, 30500/6, Germany* (Study No. 107722, [Sommer; 1995a]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-71 and in numerical form in the table B.8.1.1.2.2.1._CA-100. Additionally the table B.8.1.1.2.2.1._CA-101 provides the kinetic endpoints obtained with each of the kinetic models tested.

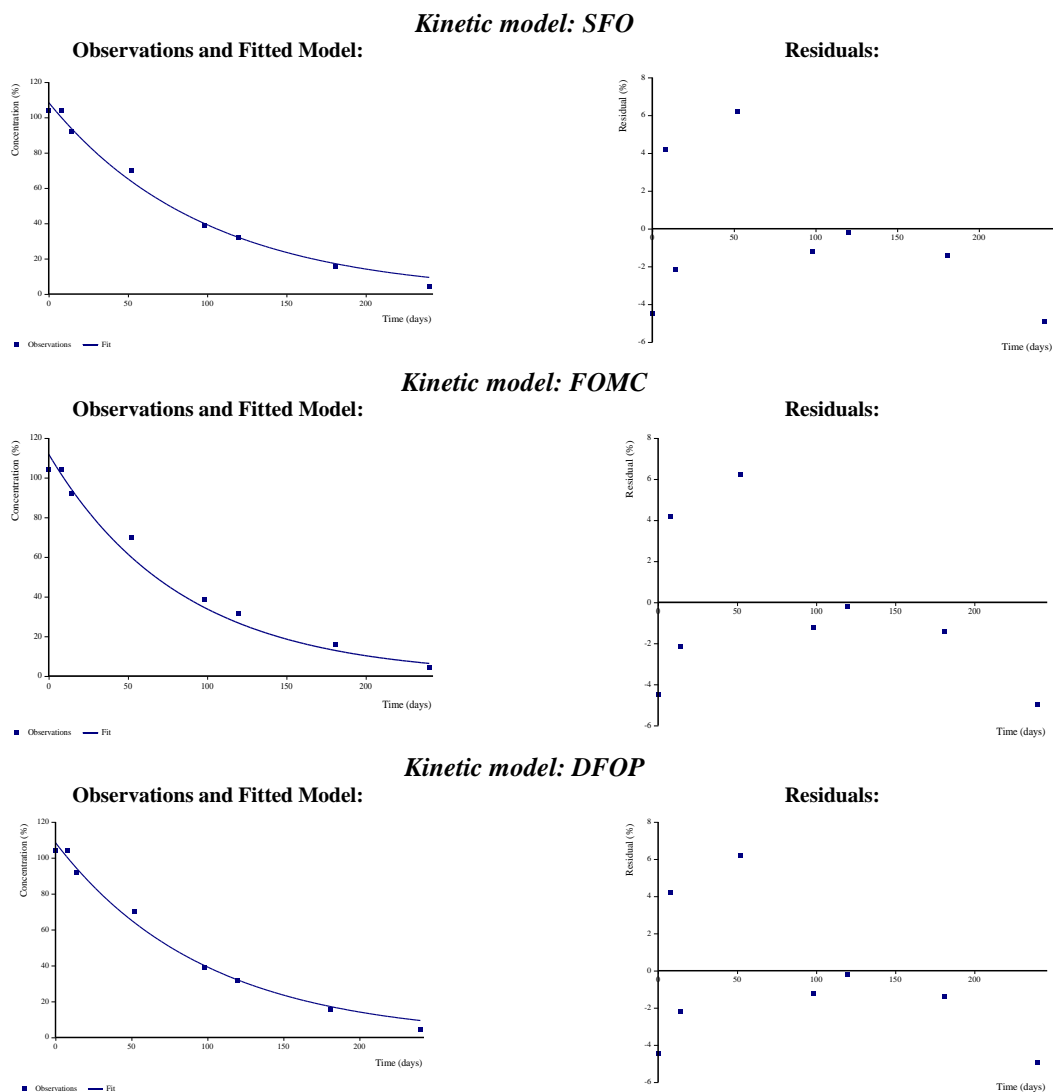

Figure B.8.1.1.2.2.1._CA-71: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-100: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	108.5	2.782	103.1	113.9	-----	5.1	0.991; Good fit
	k	0.01017	6.52 E-4	0.008908	0.01144	2.19 E-6		
FOMC	M_0	111.8	4.501	102.8	120.9	-----	5.46	0.9909; Acceptable fit
	α	310.9	612.6	-923.4	1550	-----		
	β	26000	59300	-93500	146000	-----		
DFOP	M_0	108.5	4.847	98.14	118.8	-----	5.87	0.991; Good fit
	k_1	0.01017	1480	-3144	3140	0.5		
	k_2	0.01017	32.06	-68.33	68.35	0.4999		
	g	0.0332	2.551	-5.107	5.174	not given		

Table B.8.1.1.2.2.1._CA-101: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	68.1	57.9	68.1
	DT ₉₀ [days]	226.0	193.0	226.0

The examination of the results showed that all three kinetic models returned visually acceptable and statistically reliable – for all three models the χ^2 error was well <15%. It was stated that of the three SFO returned superior fit, although the differences between the fits were minimal.

DFOP cannot be considered acceptable, because it returned not reliable kinetic parameters. It was noted that for that kinetic model the rate constants k_1 and k_2 were equal. Moreover, they were equal to the rate constant k determined using SFO model.

Also FOMC did not return reliable kinetic parameters – for both α and β the CI contained zero. RMS noted that the DT₉₀ determined for FOMC model was shorter than that for SFO or DFOP, what additionally puts into doubt the problem of whether the FOMC model adequately describes the kinetic behaviour of Flufenacet in the evaluated trial.

As a result SFO was identified as kinetic model returning the best fit for this trial.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Monheim, 30500/6**, demonstrated that for that trial SFO shall be considered as the best-fit model for Flufenacet. The results of the fitting – the determined kinetic endpoints, will be presented in the List of End Points.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for this trial due to the lack of the suitable data base for any of them.

11) Results of the kinetic examination of the data obtained for the trial *Saussay-la-Campagne, 30254/6, South France* (Study No. 107723, [Sommer; 1995b]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-72 and in numerical form in the table B.8.1.1.2.2.1._CA-102. Additionally the table B.8.1.1.2.2.1._CA-103 provides the kinetic endpoints obtained with each of the kinetic models tested.

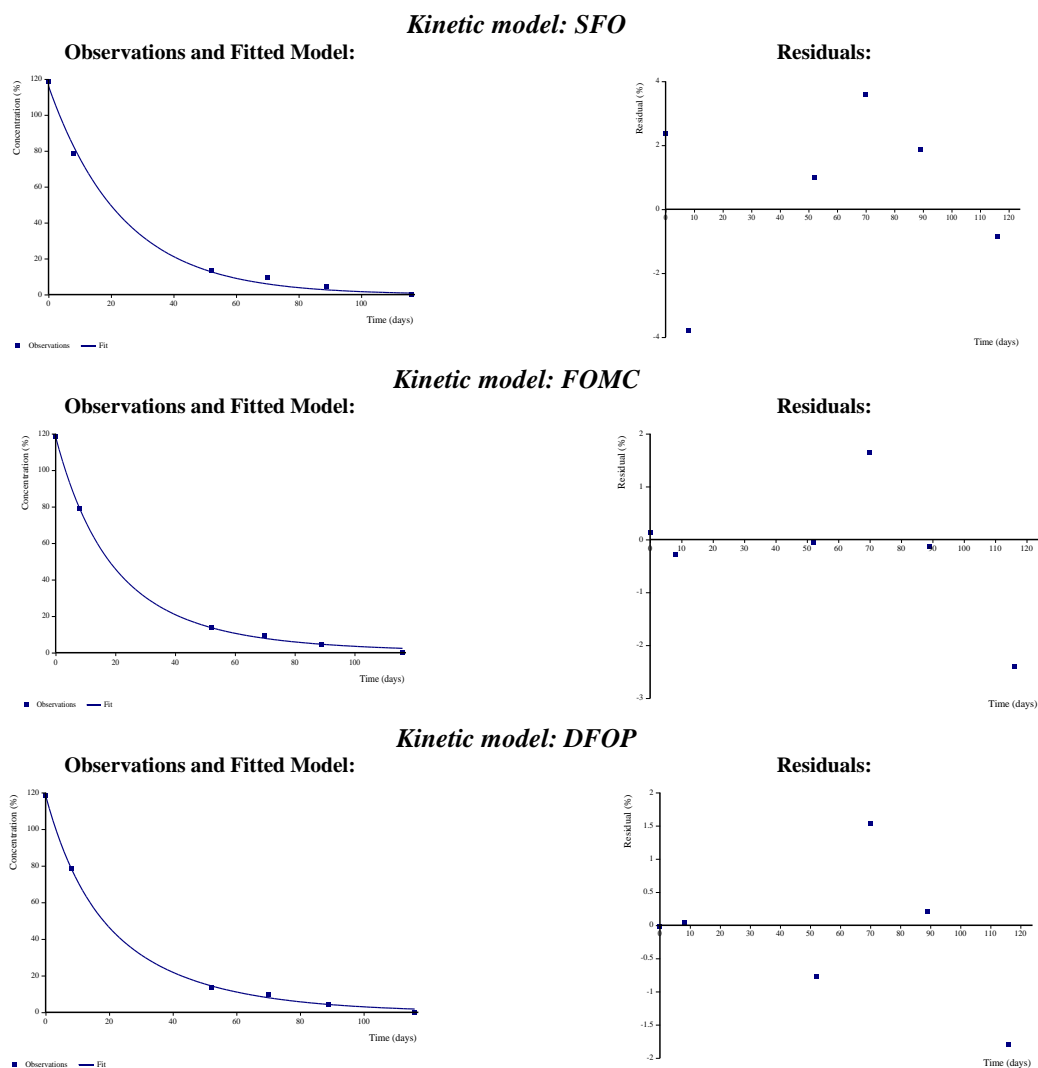

Figure B.8.1.1.2.2.1._CA-72: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-102: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	116.0	2.775	110.1	122.0	-----	5.33	0.9973; Good fit
	k	0.04253	0.00325	0.0356	0.04946	9.85 E-5		
FOMC	M_0	118.3	1.68	114.3	122.2	-----	2.79	0.9648; Good fit
	α	4.673	1.459	1.238	8.108	-----		
	β	88.96	33.43	10.28	167.6	-----		
DFOP	M_0	118.4	1.76	113.3	123.6	-----	2.71	0.9995; Good fit
	k_1	0.0933	0.07921	-0.138	0.3246	0.180		
	k_2	0.03229	0.0112	-0.00042	0.06501	0.05111		
	g	0.3595	0.4998	-1.100	1.819	not given		

Table B.8.1.1.2.2.1._CA-103: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	16.3	14.2	14.2
	DT ₉₀ [days]	54.1	56.7	58.0

The examination of the results showed that all three kinetic models returned visually and statistically good fits, very similar one to another. Of the three kinetic models used the best fit was obtained for FOMC model. In addition, SFO and FOMC returned fully reliable kinetic parameters, while in case of DFOP fit the *prob* > *t* value was above 0.05 for both k_1 and k_2 , in case k_2 , surpassing that level very slightly, but in case of k_1 being higher than 0.1. For that reason the DFOP fit cannot be considered acceptable.

As a result, RMS decided to indicate the FOMC model as returning the best fit for Flufenacet in this trial. At the same time it shall be pointed out that the quality of the SFO fit, comparable to FOMC fit, enables to indicate that fit as providing an accurate estimation of persistence of Flufenacet in the trial **Saussay-la-Campagne, 30254/6**, thus avoiding the would-be overparametrisation in case of the selection of the endpoints from that trial in the exposure assessment.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Saussay-la-Campagne, 30254/6**, demonstrated that reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field, conditions for flufenacet was obtained with FOMC kinetic model. These values will be presented in the List of End Points.

At the same time it shall be indicated that the fit obtained using SFO model was of the comparable quality, therefore it may be also considered as an adequate representation of the persistence of Flufenacet in that trial.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for this trial due to the lack of the suitable data base for any of them.

12) Results of the kinetic examination of the data obtained for the trial *Fresne-L'Archeveque, 30455/7, North France* (Study No. 107723, [Sommer; 1995b]):

The analysis for this data-set was a single step analysis. That was due to the fact that from that data base only the values for Flufenacet could be derived. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-73 and in numerical form in the table B.8.1.1.2.2.1._CA-104. Additionally the table B.8.1.1.2.2.1._CA-105 provides the kinetic endpoints obtained with each of the kinetic models tested.

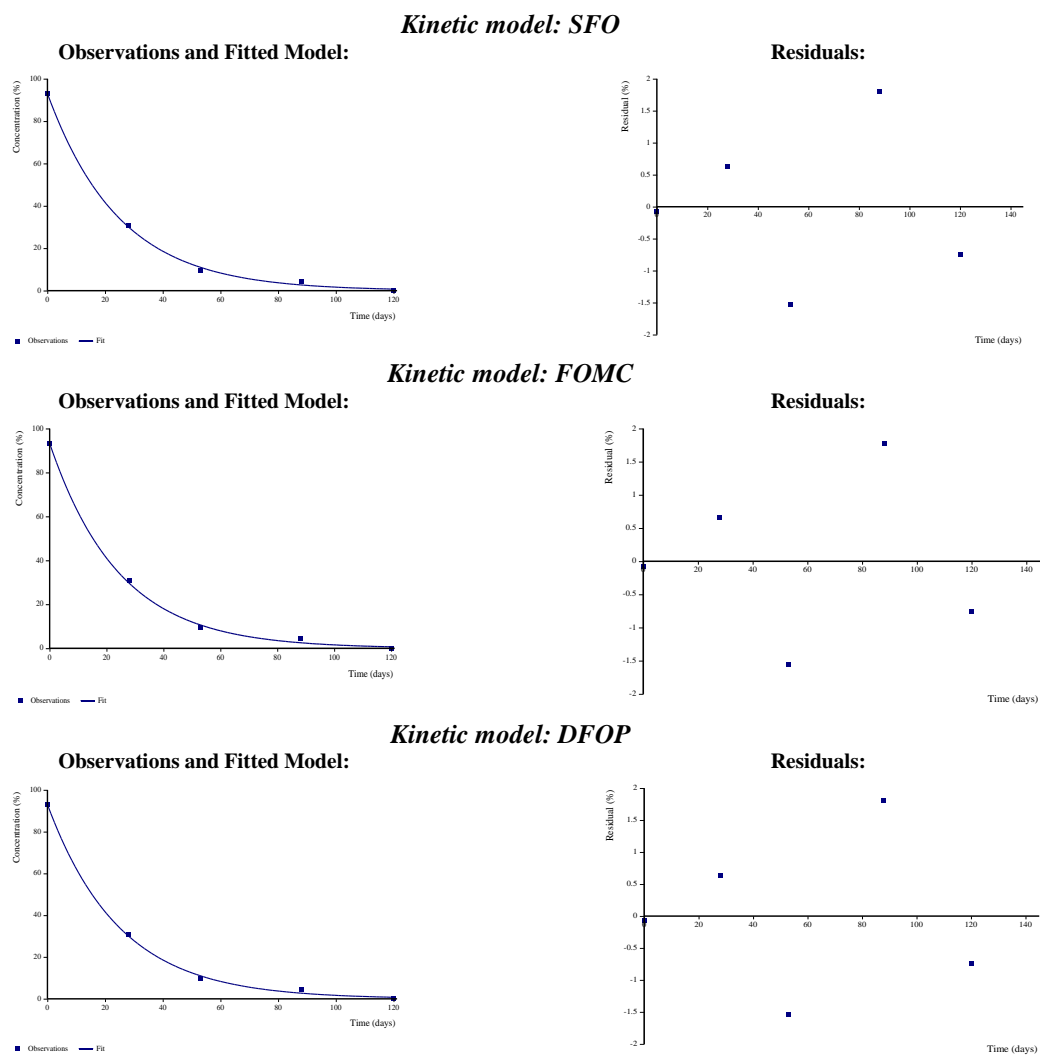

Figure B.8.1.1.2.2.1._CA-73: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-104: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	93.07	1.471	89.61	96.53	-----	3.32	0.9989; Good fit
	k	0.04024	0.001471	0.03677	0.0437	5.36 E-5		
FOMC	M_0	93.32	1.892	87.8	98.84	-----	3.8	0.9989; Good fit
	α	64.32	Not determined	Not determined	Not determined	-----		
	β	3040	Not determined	Not determined	Not determined	-----		
DFOP	M_0	93.07	2.547	76.99	109.2	-----	4.74	0.9989; Good fit
	k_1	0.04024	0.002465	0.02467	0.0558	0.01947		
	k_2	0.04024	0.002619	0.0237	0.05677	0.02069		
	g	0.5086	Not determined	Not determined	Not determined	Not determined		

Table B.8.1.1.2.2.1._CA-105: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	17.2	16.9	17.2
	DT ₉₀ [days]	57.2	56.2	57.2

The examination of the results showed that all three kinetic models returned visually and statistically good fits, all three practically identical. RMS noted that the statistical evaluation of the kinetic parameters was provided for SFO and DFOP fits, while in case of FOMC fit the modelling tool did not return the values. That was due to the fact that, according to the comment provided in the report generated by the tool, it was not possible to create the covariance matrix.

In case of DFOP fit the k_1 and k_2 values were identical and they were the same as the rate constant k determined for SFO model. The $prob > t$ values calculated for them indicated that they were reliable (in both cases they were lower than the threshold value of 0.05). In case of the g value its statistical evaluation was not provided by the model, for the same reason as given above for the kinetic parameters determined in FOMC fit. It shall be also indicated that the value was very close to 0.5, indicating that the would-be amounts of the compound degrading in the compartment at rate k_1 and in that at rate k_2 are almost even.

That in turn indicated that for that trial site the SFO is the only kinetic model adequately describing the persistence of Flufenacet.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Fresne-L'Archeveque, 30455/7**, demonstrated that for that trial SFO shall be considered as the best-fit model for Flufenacet. The results of the fitting – the determined kinetic endpoints, will be presented in the List of End Points.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for this trial due to the lack of the suitable data base for any of them.

13) Results of the kinetic examination of the data obtained for the trial *Laudun, 40163/3, South France* (Study No. 107721, [Sommer; 1995c]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-74 and in numerical form in the table B.8.1.1.2.2.1._CA-106. Additionally the table B.8.1.1.2.2.1._CA-107 provides the kinetic endpoints obtained with each of the kinetic models tested.

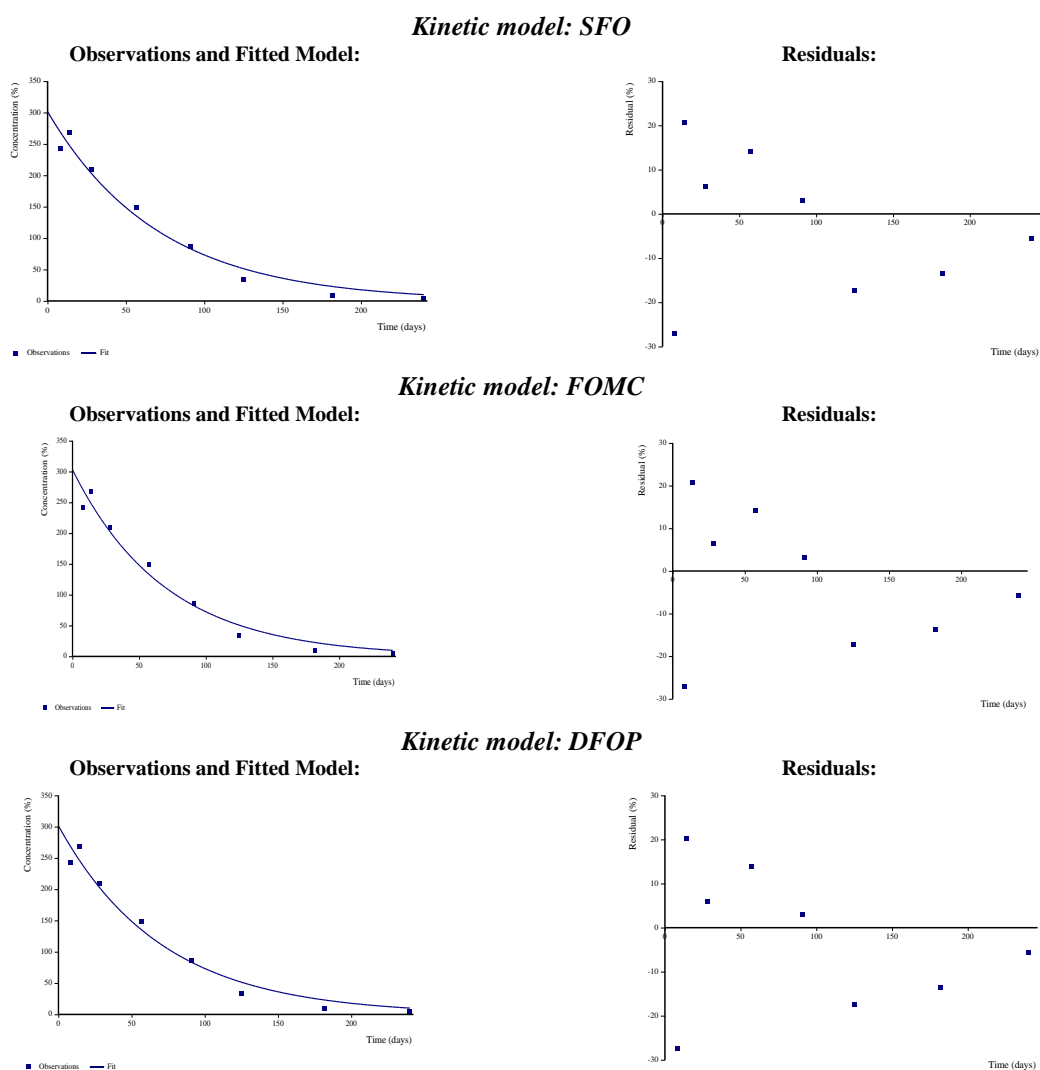

Figure B.8.1.1.2.2.1._CA-74: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-106: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	301.6	16.51	269.5	333.7	-----	9.86	0.9774; Acceptable fit
	k	0.01451	0.001628	0.01099	0.01731	6.40 E-5		
FOMC	M_0	302.9	17.63	267.4	338.4	-----	10.6	0.9773; Acceptable fit
	α	257.4	53.15	150.3	364.5	-----		
	β	17900	3110	11700	24200	-----		
DFOP	M_0	301.6	19.51	260.0	343.2	-----	11.3	0.9774; Acceptable fit
	k_1	0.1081	Not determined	Not determined	Not determined	Not determined		
	k_2	0.01451	0.001834	0.01024	0.01806	7.59 E-4		
	g	4.47 E-9	1.10 E-4	-0.000235	0.000235	not given		

Table B.8.1.1.2.2.1._CA-107: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	49.0	48.4	49.0
	DT ₉₀ [days]	163.0	161.0	163.0

The examination of the results showed that all three kinetic models returned visually acceptable and statistically reliable fits – for all three models the χ^2 error was < 15%. It was stated that of the three SFO returned superior fit, although the differences between the fits were minimal.

DFOP cannot be considered acceptable, because it returned not reliable kinetic parameters. It was noted that for that kinetic model the rate constant k_1 was not statistically evaluated, what was due to the fact that it was not possible to create the covariance matrix. As for k_2 , it was equal to the rate constant k determined by the SFO model. Finally, the extremely low value of g – 4.47 E-9, indicated that the compound degraded in a single compartment. That indicated that SFO is a kinetic model most accurately describing the kinetic behaviour of Flufenacet in the evaluated trial.

FOMC returned fit visually almost identical to that obtained with SFO and statistically slightly worse. The determined kinetic parameters – α and β , were reliable, but very high. RMS noted that the DT₉₀ determined for FOMC model was shorter than that for SFO. That also indicates that FOMC is not appropriate kinetic model to characterise the kinetic behaviour of Flufenacet in the examined trial.

As a result SFO was identified as kinetic model returning the best fit for this trial and hence adequate to be used at the next stage of the assessment.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-75 and in numerical form in the table B.8.1.1.2.2.1._CA-108. The fitting was performed for combination SFO-SFO-SFO. In the modelling tool A1 was used to denominate FOE Oxalate and B1 – FOE Sulfonic acid.

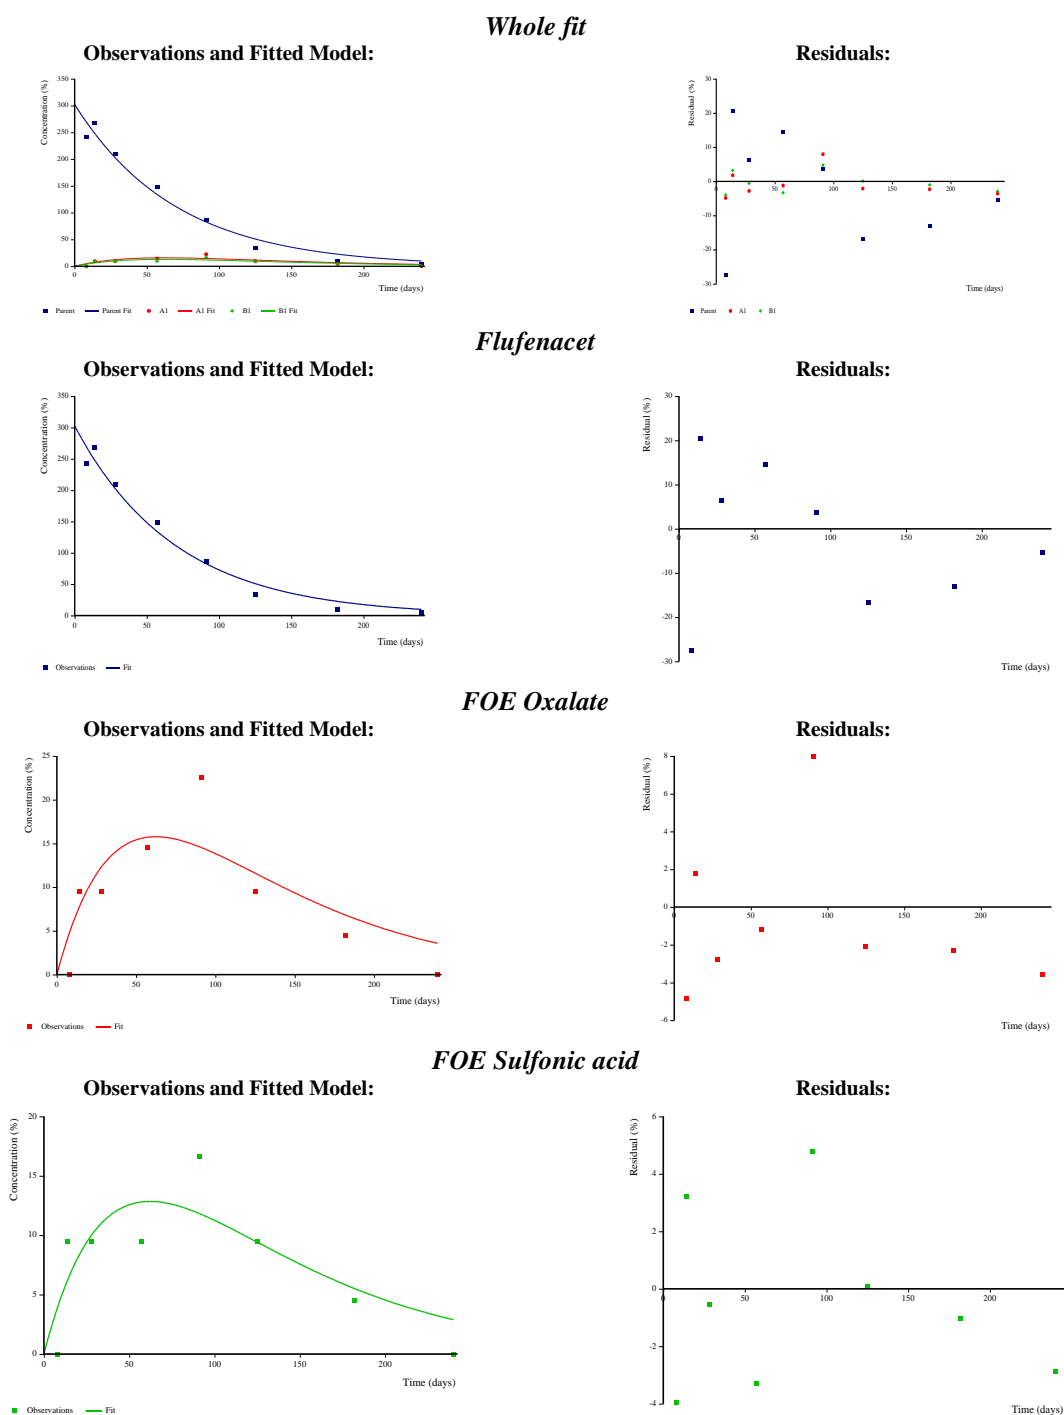

Figure B.8.1.1.2.2.1._CA-75: The graphical results of the kinetic examination of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid obtained in the trial Laudun, 40163/3.

Table B.8.1.1.2.2.1._CA-108: The numerical results of the kinetic examination of the data for Flufenacet, FOE Oxalate and FOE Sulfonic acid obtained in the trial Laudun, 40163/3.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	302.3	16.56	273.5	331.0	-----	9.86	0.9772; Acceptable fit
		k	0.01424	0.001638	0.0114	0.01708	3.67 E-8		
FOE Oxalate	SFO	M ₀	0.0	----	----	----	----	35.6	0.7892; Acceptable fit
		k	0.01799	0.007525	0.004938	0.03104	0.01399		
		ff	0.1601	0.05435	0.06583	0.2543	----		
FOE Sulfonic acid	SFO	M ₀	0.0	----	----	----	----	31.8	0.732; Acceptable fit
		k	0.0181	0.007052	0.005867	0.03033	0.009719		
		ff	0.1309	0.04198	0.05808	0.2037	----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-109.

Table B.8.1.1.2.2.1._CA-109: The kinetic endpoints determined in the experiment.

Determined parameter	Compound		
	Flufenacet	FOE Sulfonic acid	FOE Oxalate
DT ₅₀ [days]	48.7	38.5	38.3
DT ₉₀ [days]	162.0	128.0	127.0
Kinetic formation fraction ff	Not applicable	0.160 ± 0.054	0.131 ± 0.042
Precursor	Not applicable	Flufenacet	Flufenacet
Kinetic model	SFO	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fits obtained for both FOE Oxalate and FOE Sulfonic acid cannot be considered acceptable. They display only intermediate conformity of the estimated kinetic curve with the experimental points and the residuals are not randomly distributed. In addition they are not fully statistically reliable – the χ^2 error for them both is well above 15%, reaching 35.6% for the fit FOE Oxalate and 31.8% for that for FOE Sulfonic acid.

As a result, it can be stated that in this trial it was possible to obtain reliable fits only for Flufenacet.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were similar to those for the parent fitted alone and no improvement of the fit was observed for the degradation products – FOE Oxalate and FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Laudun, 40163/3**, demonstrated that reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field conditions was obtained only for the parent compound – Flufenacet. The kinetic model identified as returning the best fit was SFO.

For the degradation products subjected to the kinetic examination – FOE Oxalate and FOE Sulfonic acid, it was not possible to obtain reliable kinetic fit and hence reliable kinetic endpoints representing the persistence of that compound on the trial site.

As a result, it can be stated that the reliable persistence kinetic endpoints for that trial may be determined for the parent compound – Flufenacet, when fitted alone. These values will be presented in the List of End Points.

14) Results of the kinetic examination of the data obtained for the trial *St. Etienne du Gres, 40164/1, South France* (Study No. 107721, [Sommer; 1995c]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The preliminary analysis of the data set used in the kinetic analysis resulted in the identification of the two possible outliers – DAT 14 and DAT 28. Due to the distribution of the preceding and following data points it was not possible to identify, on the basis of the simple assessment, which data point is an outlier. Therefore RMS decided to carry out the fitting exercise firstly using the whole data set, then repeating it for the data set with either DAT 14 or DAT 28 time point removed, compare the results and on that basis decide which of the data points is an outlier. The results are presented below. The fitting in each case was performed using all three models, in order not to bias the results by eliminating the models not providing the acceptable fit at the initial stage – when the kinetic examination was performed for the whole data set.

Results for the whole data set

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-76 and in numerical form in the table B.8.1.1.2.2.1._CA-110. Additionally the table B.8.1.1.2.2.1._CA-111 provides the kinetic endpoints obtained with each of the kinetic models tested.

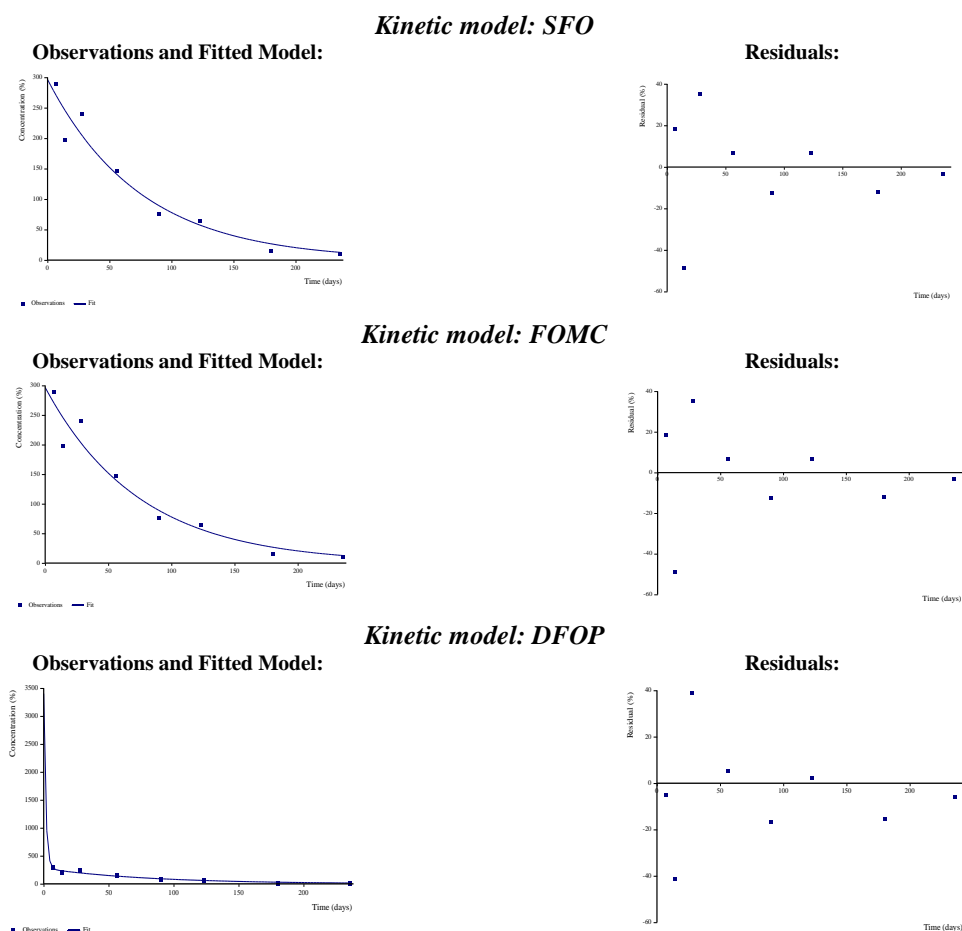

Figure B.8.1.1.2.2.1._CA-76: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-110: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
SFO	M_0	296.6	23.82	250.3	342.9	-----	14.4	0.9437; Acceptable fit
	k	0.01336	0.002282	0.008922	0.01779	5.49 E-4		
FOMC	M_0	296.8	25.73	245.0	348.7	-----	15.3	0.9436; Acceptable fit
	α	350.4	Not determined	Not determined	Not determined	-----		
	β	26100	Not determined	Not determined	Not determined	-----		
DFOP	M_0	3400	1510	191.2	6620	-----	15.5	0.9524; Poor fit
	k_1	0.6458	0.1827	0.2562	1.035	0.01207		
	k_2	0.01236	0.002589	0.006842	0.01788	0.004406		
	g	0.9188	0.03745	0.8389	0.9986	not given		

Table B.8.1.1.2.2.1._CA-111: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	51.9	51.8	1.21
	DT ₉₀ [days]	172.0	172.0	5.63

Only SFO model returned fit that can be classified as visually and statistically acceptable. In case of FOMC fit the shape of kinetic curve, its conformity to the experimental data and the distribution of the residuals are similar to the corresponding features of the SFO fit. However the fit cannot be considered acceptable due to the lack of any statistical evaluation of the kinetic parameters α and β . Additionally the χ^2 error is, slightly, higher than the threshold value – 15%. Finally, RMS noticed that the kinetic endpoints – DT₅₀ and DT₉₀ values, returned by the SFO and FOMC fits are the same.

In case of DFOP fit it was stated that it cannot be considered acceptable, because the visual fit is poor, despite the fact that the correlation coefficient $r = 0.9524$. The main reason for classifying it as such is abnormally high M_0 calculated by the modelling tool – 3400 [µg/kg soil], several times higher than the theoretical application rate. That not only significantly altered the shape of the kinetic curve in its initial stage, but also artificially caused its better conformity with the experimental data after the break point. The problems with fitting were reflected also in the calculated kinetic endpoints, which were very short and not represented the kinetic behaviour of the test compound.

As a result it can be stated that:

- the fitting showed already at that stage that neither FOMC nor DFOP are the kinetic models adequately describing the persistence of Flufenacet in this trial;
- the distribution of the data points in relation to the determined kinetic curve for SFO model, in combination with the residuals, seem to indicate that the DAT-14 point should be considered an outlier and removed from the data base.

Both hypotheses will be verified further down the report.

Results for the data set without DAT 14 time point

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-77 and in numerical form in the table B.8.1.1.2.2.1._CA-112. Additionally the table B.8.1.1.2.2.1._CA-113 provides the kinetic endpoints obtained with each of the kinetic models tested.

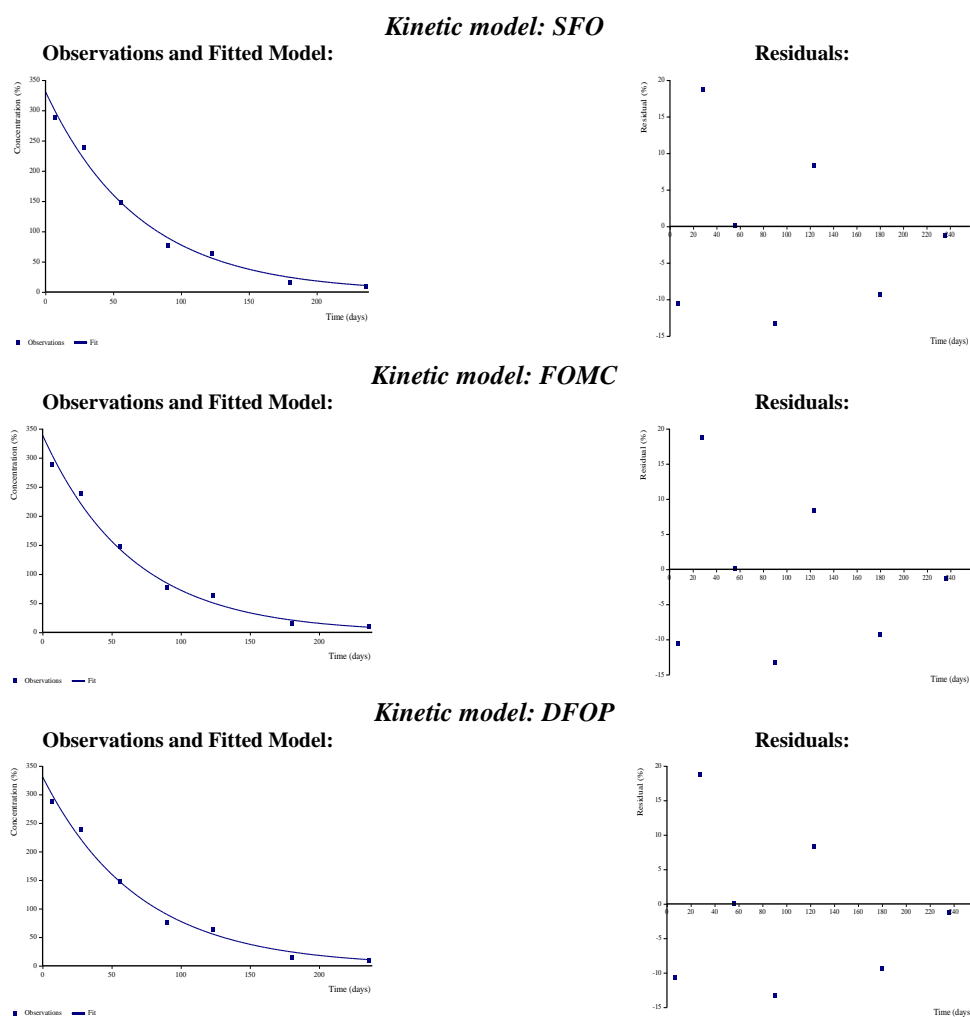

Figure B.8.1.1.2.2.1._CA-77: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-112: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
SFO	M_0	331.1	13.77	303.3	358.8	-----	7.08	0.9891; Good fit
	k	0.0145	0.001094	0.0123	0.01671	2.91 E-5		
FOMC	M_0	339.0	12.1	313.2	364.8	-----	7.64	0.9891; Good fit
	α	413.5	Not determined	Not determined	Not determined	-----		
	β	26700	Not determined	Not determined	Not determined	-----		
DFOP	M_0	331.1	23.27	276.3	385.8	-----	8.42	0.9905; Good fit
	k_1	0.0145	1900	-4468.0	4470.0	0.5000		
	k_2	0.0145	472.5	-1112.0	1110.0	0.5000		
	g	0.1992	31500	-74090	74100	not given		

Table B.8.1.1.2.2.1._CA-113: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	47.8	44.9	47.8
	DT ₉₀ [days]	159.0	149.0	159.0

The removal of DAT-14 time point resulted in general improvement of all three fits, which became visually good and statistically reliable.

However, as it was in case of the whole data set, neither FOMC nor DFOP fits may be considered acceptable because of the lack of reliability of the kinetic parameters they returned. In case of FOMC the statistical evaluation of α and β was not provided, while for DFOP fit for k_1 and k_2 the $prob > t$ was significantly higher than 0.1. It was also noted that the values k_1 and k_2 were the same and that they were identical to the rate constant k determined using SFO kinetic model.

As a result it was stated that:

- the removal of DAT-14 time point substantially improved the fitting results for all three models, what may conform that this data point is an outlier not to be take into consideration in the kinetic analysis;
- both FOMC and DFOP fits cannot be considered acceptable because of the lack of reliability of the kinetic parameters determined for them, so SFO shall be, as previously considered a sole kinetic model adequately characterising the persistence of Flufenacet in soil of the trial site.

Results for the data set without DAT 28 time point:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-78 and in numerical form in the table B.8.1.1.2.2.1._CA-114. Additionally the table B.8.1.1.2.2.1._CA-115 provides the kinetic endpoints obtained with each of the kinetic models tested.

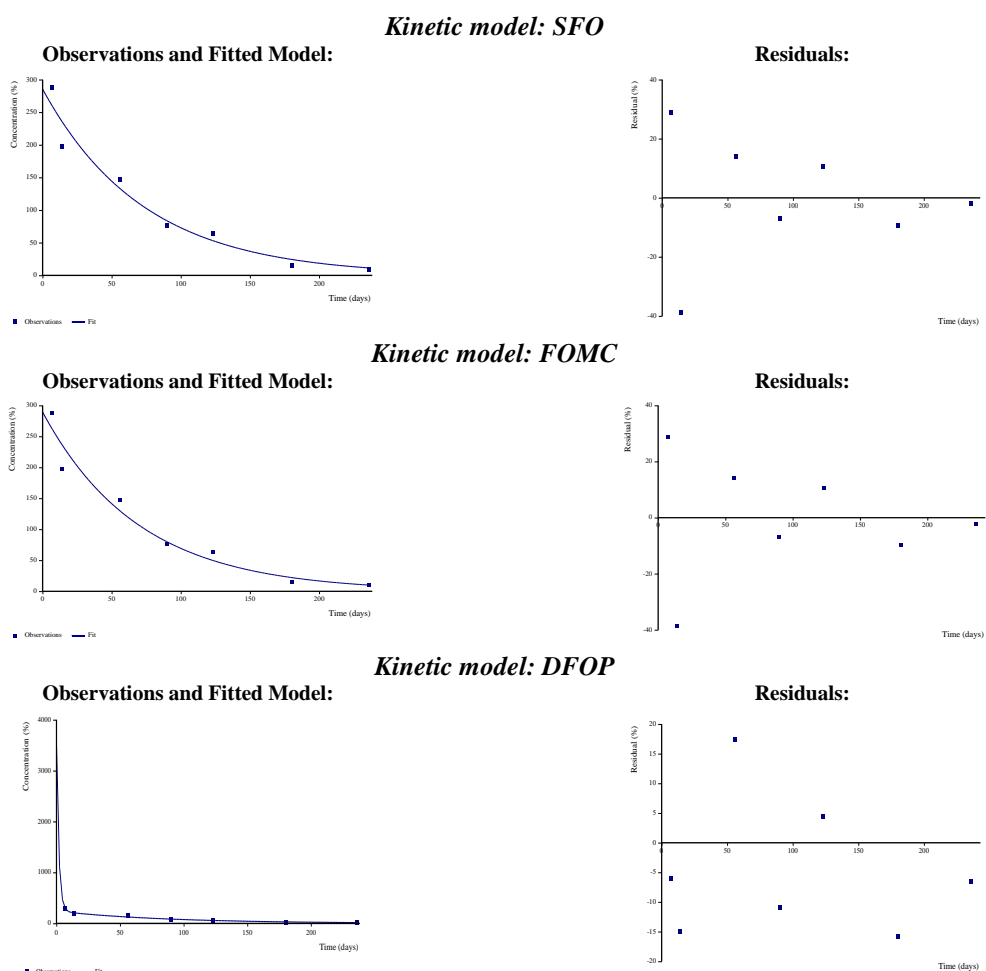

Figure B.8.1.1.2.2.1._CA-78: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-114: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	285.5	22.05	241.1	330.0	-----	13.9	0.9558; Acceptable fit
	k	0.01365	0.002146	0.009323	0.01797	7.10 E-4		
FOMC	M_0	289.4	24.87	236.4	342.4	-----	15.1	0.9558; Acceptable fit
	α	192.5	Not determined	Not determined	Not determined	-----		
	β	13400	Not determined	Not determined	Not determined	-----		
DFOP	M_0	3540	Not determined	Not determined	Not determined	-----	9.92	0.9866; Poor fit
	k_1	0.5588	Not determined	Not determined	Not determined	Not determined		
	k_2	0.01159	0.00161	0.007797	0.01538	0.002765		
	g	0.8899	Not determined	Not determined	Not determined	not given		

Table B.8.1.1.2.2.1._CA-115: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	50.8	48.4	1.37
	DT ₉₀ [days]	169.0	161.0	5.81

The elimination of the DAT-28 data point only slightly improved the results of the fitting in comparison to what was achieved for the whole data base. They were however worse than the results obtained when the DAT-14 time point was removed from the set. Additionally, the kinetic curve for DFOP fit took a shape very similar to that obtained for the whole data base with that kinetic model used. All that conforms the hypothesis about the DAT-14 data point being an outlier, which had to be removed from the data base.

Additionally it was determined that neither FOMC nor DFOP returned fully acceptable and reliable kinetic fits, the fact consistently stated for all three fitting exercises.

As a result, it can be stated that solely SFO shall be considered as a kinetic model adequately characterising the kinetic behaviour and persistence of Flufenacet in soil on St. Etienne du Gres, 40164/1 trial site.

Evaluation of the fitting:

The presented above results of the kinetic examination of the data obtained in the trial **St. Etienne du Gres, 40164/1**, demonstrated that reliable fit, and hence reliable kinetic endpoints representing persistence in soil under realistic – field conditions, was obtained for Flufenacet using SFO when the DAT-14 time point was removed from the set. Therefore such combination will be further used to examine the kinetic behaviour of Flufenacet and its degradation product – FOE Sulfonic acid in this trial.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1_CA-79 and in numerical form in the table B.8.1.1.2.2.1_CA-116. The fitting was performed for combination SFO-SFO.

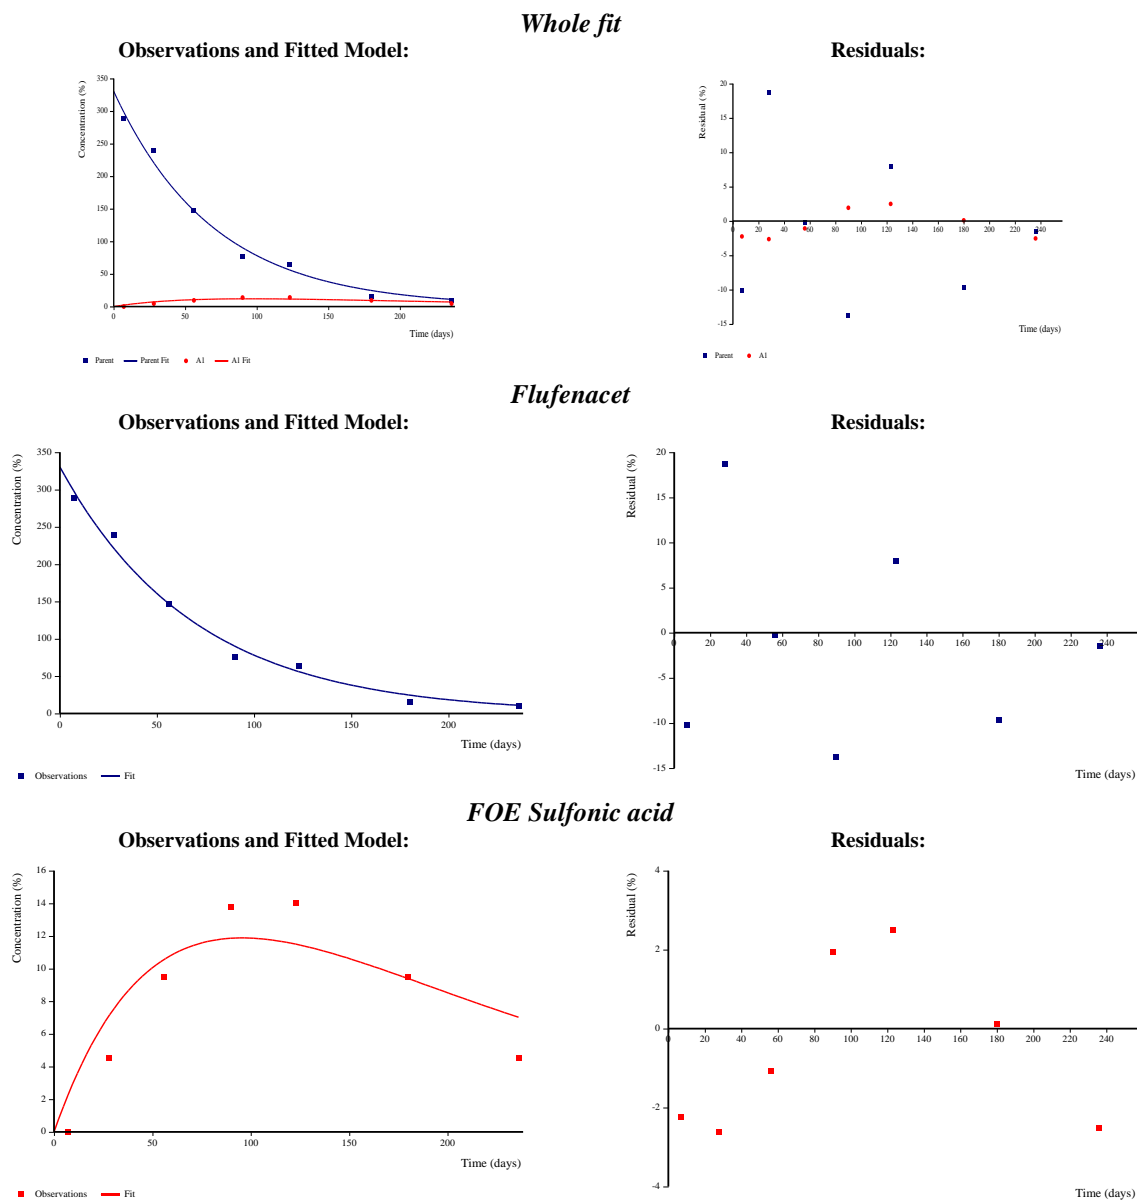

Figure B.8.1.1.2.2.1_CA-79: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial St. Etienne du Gres, 40164/1.

Table B.8.1.1.2.2.1. CA-116: The numerical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial St. Etienne du Gres, 40164/1.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	330.4	13.75	305.5	355.3	-----	7.08	0.9892; Acceptable fit
		k	0.01442	0.001089	0.01245	0.0164	5.75 E-8		
FOE Sulfonic acid	SFO	M ₀	0.0	-----	-----	-----	-----	20.5	0.9319; Acceptable fit
		k	0.007303	0.002706	0.002399	0.01221	0.01117		
		ff	0.0723	0.01594	0.0434	0.1021	-----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-117.

Table B.8.1.1.2.2.1. CA-117: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Sulfonic acid
DT ₅₀ [days]	48.1	94.9
DT ₉₀ [days]	160.0	315.0
Kinetic formation fraction ff	Not applicable – parent compound	0.0723 ± 0.003
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fit obtained for FOE Sulfonic acid can also be considered acceptable, although it displays only intermediate conformity of the estimated kinetic curve with the experimental points and the χ^2 error > 15% (20.5%). However, the residuals are low and randomly distributed. Finally, for both compounds the determined kinetic parameters, and hence kinetic endpoints, are fully reliable.

As a result, it can be stated that in that trial it was possible to obtain reliable fits for Flufenacet and FOE Sulfonic acid using a combination SFO-SFO.

RMS performed also the fitting for other combinations – for this data set (without DAT-14 data point) using the two remaining kinetic models for the parent – FOMC and DFOP, as well as the whole data set and for the data set without DAT-28 time point using all three kinetic models for the parent compound – SFO, FOMC and DFOP. The kinetic fits for the parent compound were very similar to those for the parent fitted alone and no improvement of the fit, if not its worsening, was observed for the degradation product – FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Final evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **St. Etienne du Gres, 40164/1**, demonstrated that reliable fit, and hence reliable kinetic endpoints representing persistence in soil under realistic – field conditions, was obtained for both parent compound – Flufenacet and its degradation product – FOE Sulfonic acid when the combination of the kinetic models SFO-SFO was used and when the DAT-14 time point was removed from the data set as an outlier. The kinetic endpoints resulting from this kinetic assessment will be presented in the List of End Points as persistence kinetic endpoints for Flufenacet and FOE Sulfonic acid in the trial **St. Etienne du Gres, 40164/1**.

15) Results of the kinetic examination of the data obtained for the trial *Ravenna, 40494/2, Italy* (Study No. 107721, [Sommer; 1995c]):

The analysis for this data-set was a two-step analysis. Its results are presented below, individually for each step.

a) Results obtained at **Step 1** – fitting of the data for the parent compound (Flufenacet) alone:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-80 and in numerical form in the table B.8.1.1.2.2.1._CA-118. Additionally the table B.8.1.1.2.2.1._CA-119 provides the kinetic endpoints obtained with each of the kinetic models tested.

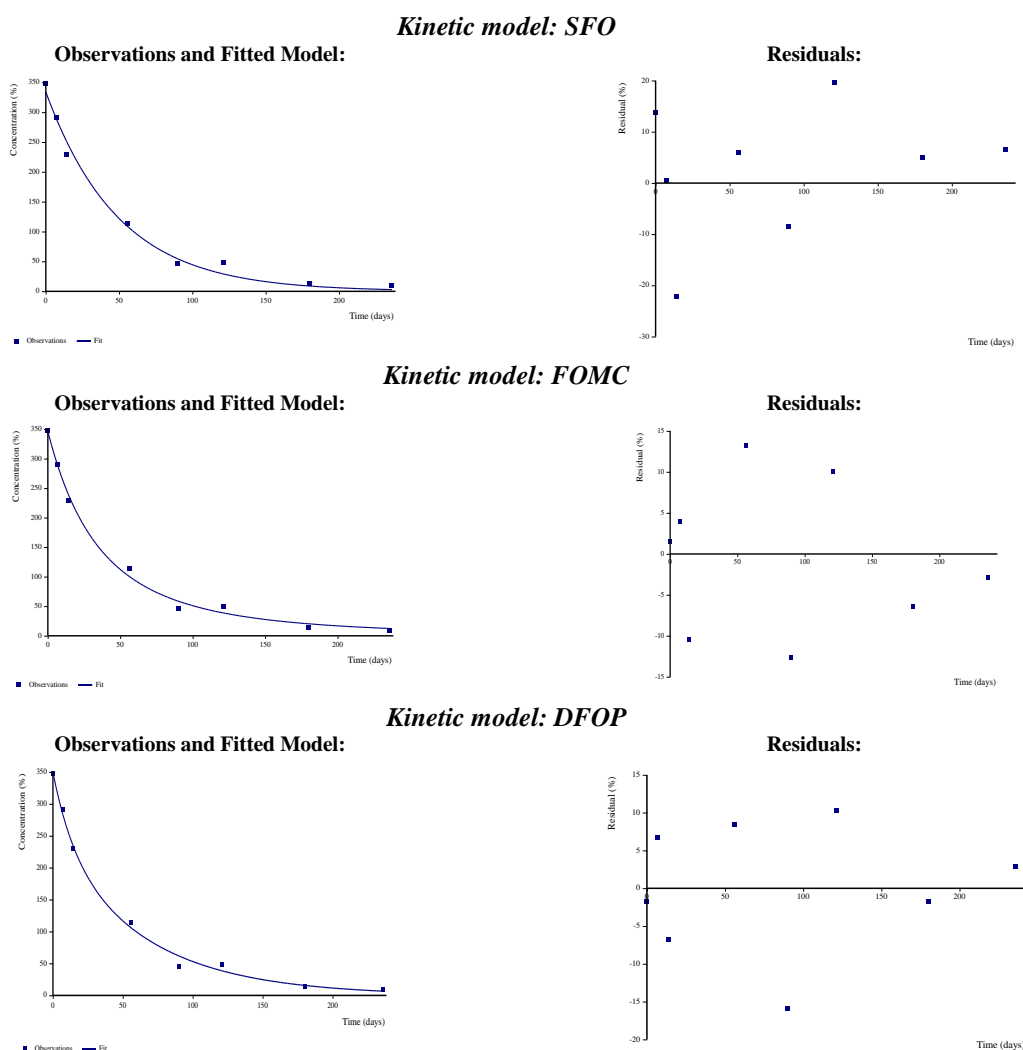

Figure B.8.1.1.2.2.1._CA-80: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-118: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	334.1	10.59	313.6	354.7	-----	7.23	0.991; Good fit
	k	0.02016	0.001727	0.0168	0.02352	1.19 E-5		
FOMC	M_0	346.3	10.08	326.0	366.6	-----	5.42	0.9951; Good fit
	α	2.684	1.129	0.4048	4.960	-----		
	β	95.94	53.62	-12.12	204.0	-----		
DFOP	M_0	349.6	11.3	325.5	373.7	-----	5.46	0.9957; Good fit
	k_1	0.06935	0.05467	-0.0472	0.1859	0.1367		
	k_2	0.01523	0.004248	0.006175	0.02429	0.01153		
	g	0.3055	0.2639	-0.2571	0.8681	not given		

Table B.8.1.1.2.2.1._CA-119: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	34.4	28.3	27.7
	DT ₉₀ [days]	114.0	130.0	127.0

All three models returned visually and statistically good fits. Of the three FOMC was superior and DFOP was the second best, although they were all very similar.

However, neither FOMC nor DFOP fits may be considered acceptable because of the lack of reliability of the kinetic parameters they returned. In case of FOMC for β the CI passes through zero. In case of DFOP fit for k_1 the $prob > t$ was higher than 0.1.

Only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet and as such was used at the next stage of analysis.

- b) Results obtained at **Step 2** – fitting of the data for the parent compound (Flufenacet) and its degradation products:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1_CA-81 and in numerical form in the table B.8.1.1.2.2.1_CA-120. The fitting was performed for combination SFO-SFO.

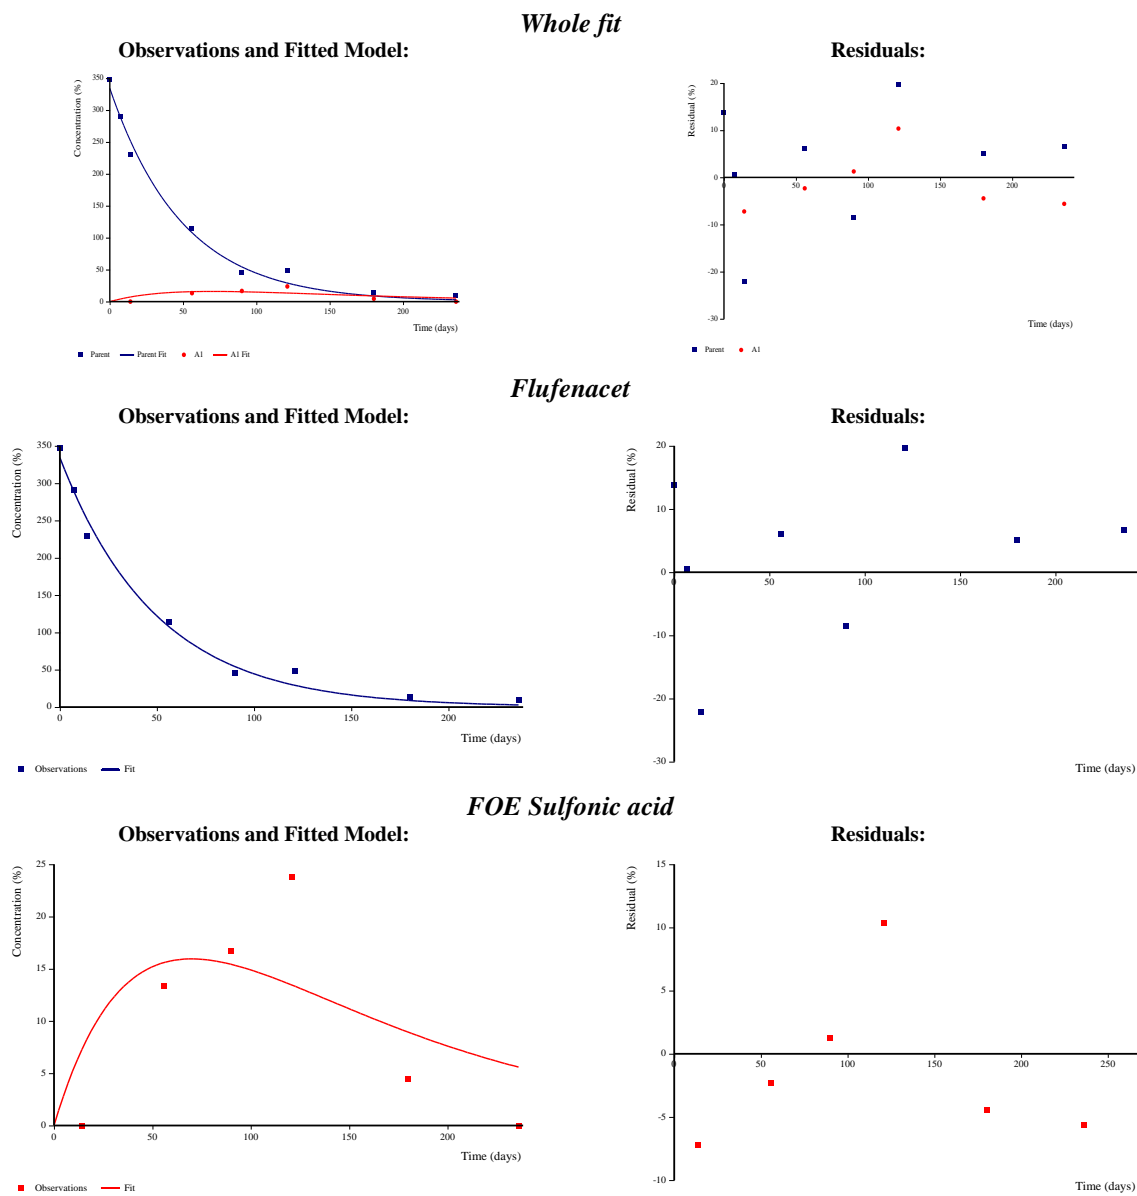

Figure B.8.1.1.2.2.1_CA-81: The graphical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Ravenna, 40494/1.

Table B.8.1.1.2.2.1._CA-120: The numerical results of the kinetic examination of the data for Flufenacet and FOE Sulfonic acid obtained in the trial Ravenna, 40494/1.

Compound	Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
			Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
					Lower	Upper			
Flufenacet	SFO	M ₀	333.9	10.84	314.2	353.5	-----	7.23	0.9909; Acceptable fit
		k	0.02007	0.001759	0.01688	0.02325	2.35 E-7		
FOE Sulfonic acid	SFO	M ₀	0.0	-----	-----	-----	-----	49.2	0.7348; Poor fit
		k	0.009774	0.007263	-0.00339	0.02294	0.1041		
		ff	0.0946	0.04661	0.01012	0.1791	-----		

The kinetic endpoints derived from the study are presented below in the table B.8.1.1.2.2.1._CA-121.

Table B.8.1.1.2.2.1._CA-121: The kinetic endpoints determined in the experiment.

Determined parameter	Compound	
	Flufenacet	FOE Sulfonic acid
DT ₅₀ [days]	34.5	70.9
DT ₉₀ [days]	115.0	236.0
Kinetic formation fraction ff	Not applicable – parent compound	0.0946 ± 0.047
Precursor	Not applicable – parent compound	Flufenacet
Kinetic model	SFO	SFO

The kinetic fit obtained for Flufenacet may be classified as statistically and visually acceptable. Also the calculated kinetic parameters and derived from them kinetic endpoints are reliable.

The kinetic fits obtained for FOE Sulfonic acid cannot be considered acceptable. It displays no conformity of the estimated kinetic curve with the experimental points and the residuals are high and not randomly distributed. In addition the fit is not fully statistically reliable – the χ^2 error for it is well above 15%, reaching 49.2%. Finally, it shall be noted that also the determined kinetic parameter – the rate constant *k* is not statistically reliable.

As a result, it can be stated that in this trial it was possible to obtain reliable fits only for Flufenacet.

RMS performed also the fitting using the two other kinetic models for the parent compound (Flufenacet) – FOMC and DFOP. The kinetic fits for the parent compound were very similar to those for the parent fitted alone and no improvement of the fit was observed for the degradation product – FOE Sulfonic acid. Therefore it may be stated that the change of the kinetic model for parent compound will not result in better fitting. RMS decided to not present the results of those kinetic examinations in order to not overburden the Assessment Report.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **Ravenna, 40494/1** demonstrated that reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field conditions was obtained only for the parent compound – Flufenacet. The kinetic model identified as returning the best fit was SFO.

For its degradation product, subjected to the kinetic examination, – FOE Sulfonic acid, it was not possible to obtain reliable kinetic fit and hence reliable kinetic endpoints representing the persistence of that compound on the trial site.

As a result, it can be stated that the reliable persistence kinetic endpoints for that trial may be determined for the parent compound – Flufenacet, when fitted alone. These values will be presented in the List of End Points.

16) Results of the kinetic examination of the data obtained for the trial *S. Romualdo, 40495/0, Italy* (Study No. 107721, [Sommer; 1995c]):

The analysis for this data-set was a single step analysis. That was due to the fact that for that data base only the values for Flufenacet could be derived. The initial inspection of the data set showed that it contained two possible outliers – the DAT-14 and DAT-28 time points. As it was not possible to state which of them is a real outlier using simple method, the RMS decided to perform the fitting for three options – the whole data base, data base without DAT-14 time point and the data base without DAT-28 time point. The method of the identification of outlier data point was identical to that used earlier for the data set obtained in *St. Etienne du Gres, 40164/1* trial. The results are presented below, individually for each option.

The results of the fitting for the whole data set:

The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-82 and in numerical form in the table B.8.1.1.2.2.1._CA-122. Additionally the table B.8.1.1.2.2.1._CA-123 provides the kinetic endpoints obtained with each of the kinetic models tested.

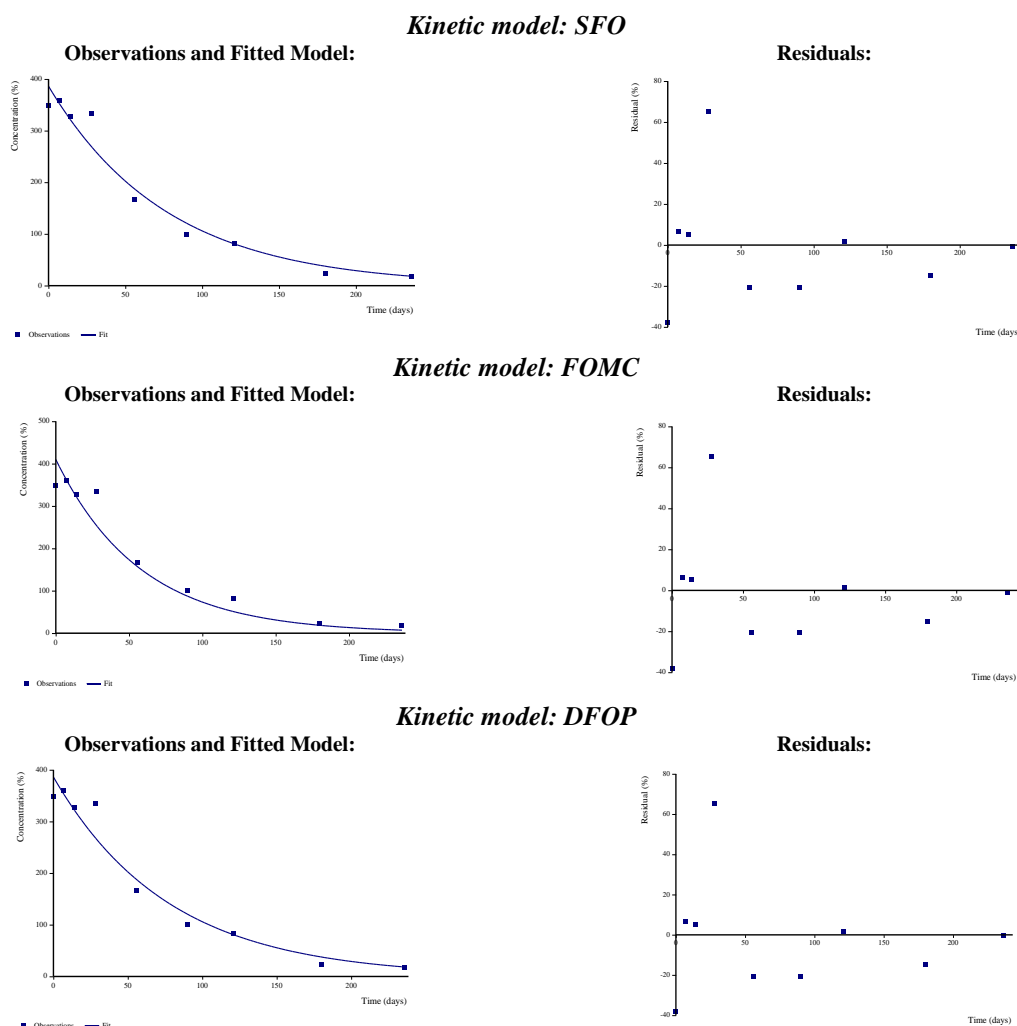

Figure B.8.1.1.2.2.1._CA-82: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-122: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	386.2	20.55	347.3	425.1	-----	11.3	0.9605; Acceptable fit
	k	0.01293	0.001747	0.009624	0.01625	7.46 E-5		
FOMC	M_0	410.0	28.71	354.2	465.8	-----	12.0	0.9604; Acceptable fit
	α	64.32	Not determined	Not determined	Not determined	-----		
	β	3040	Not determined	Not determined	Not determined	-----		
DFOP	M_0	386.2	35.54	314.6	457.8	-----	12.7	0.9605; Acceptable fit
	k_1	0.01293	1940.0	-3917.0	3920.0	0.5000		
	k_2	0.01293	542.4	-1093.0	1090.0	0.5000		
	g	0.2182	52200.0	-105200	105000	not given		

Table B.8.1.1.2.2.1._CA-123: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	53.6	40.2	53.6
	DT ₉₀ [days]	178.0	134.0	178.0

The examination of the results showed that all three kinetic models returned visually and statistically acceptable fits, very similar one to another. However, neither the FOMC fit nor that obtained using DFOP model may be considered acceptable because of the lack of reliability of the kinetic parameters. In case of FOMC fit the results of the statistical analysis – error and CI values, for both α and β , was not provided by the modelling tool. The reason for that was that the model was not able to create the covariance matrix.

In case of DFOP fit for both k_1 and k_2 the $prob > t$ was significantly higher than 0.1, reaching the level of 0.5. RMS also noticed that the k_1 and k_2 values were identical, and also the same as the rate constant k determined for SFO model, what in turn indicates that the partition of the compound between the “fast-degrading” and “slow degrading” compartments is artificial.

On that basis it was stated that only SFO returned visually and statistically acceptable fit with fully reliable kinetic parameters, hence it should be considered as the best-fit model for the parent compound – Flufenacet in this trial.

Finally, RMS analysed the conformity of the estimated kinetic curve with experimental data points. The results indicate that the DAT-28 time point may be considered an outlier. In order to conform that an additional fitting using all three kinetic models was carried out.

The results of the fitting for the data set without DAT-14 data point:

As a next step DAT-14 time point was removed from the data set and kinetic fitting repeated. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-83 and in numerical form in the table B.8.1.1.2.2.1._CA-124. Additionally the table B.8.1.1.2.2.1._CA-125 provides the kinetic endpoints obtained with each of the kinetic models tested.

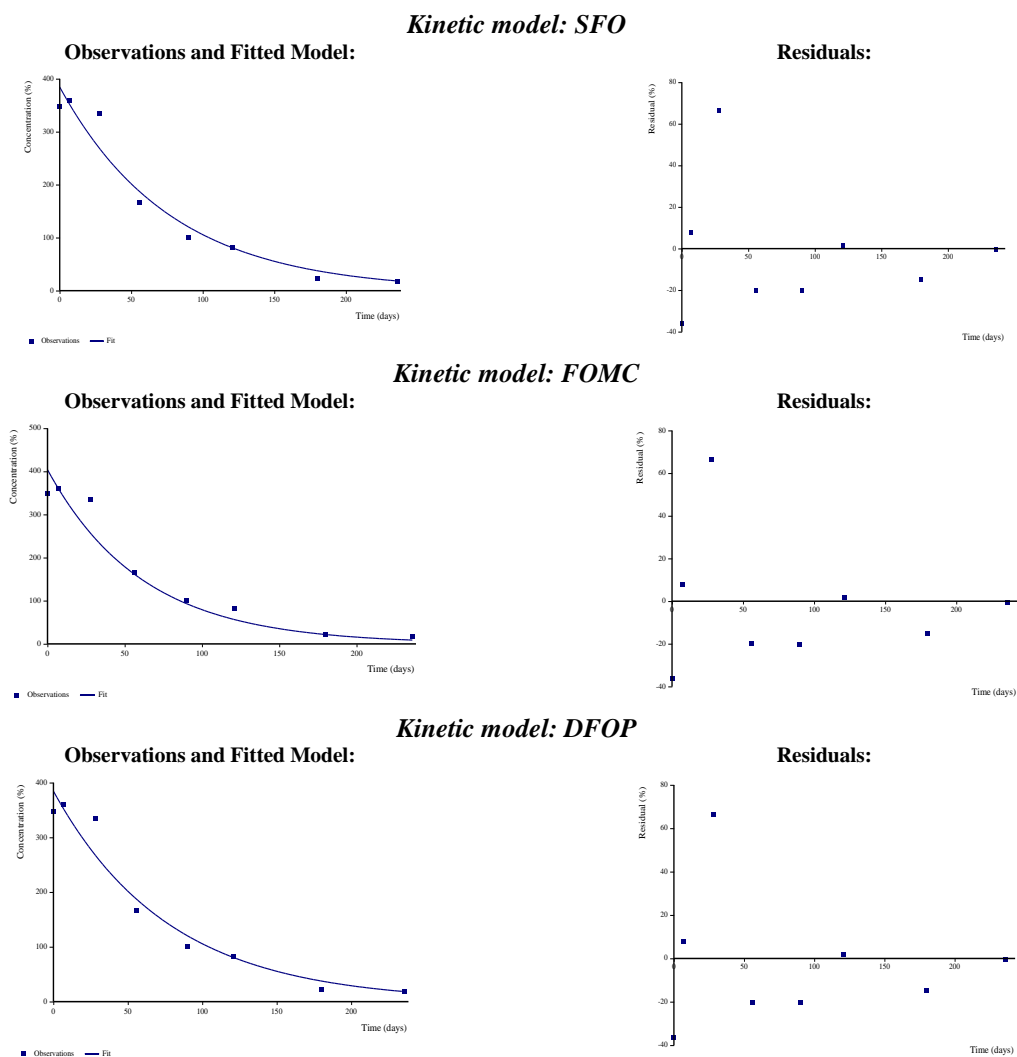

Figure B.8.1.1.2.2.1._CA-83: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-124: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper			
SFO	M_0	384.5	24.33	337.2	431.8	-----	13.0	0.9556; Acceptable fit
	k	0.01292	0.001892	0.009239	0.01659	2.43 E-4		
FOMC	M_0	404.0	31.93	339.7	468.3	-----	13.9	0.9555; Acceptable fit
	α	274.7	Not determined	Not determined	Not determined	-----		
	β	16800.0	Not determined	Not determined	Not determined	-----		
DFOP	M_0	384.5	28.46	323.9	445.2	-----	15.0	0.9556; Acceptable fit
	k_1	0.01292	0.01639	-0.02202	0.04786	0.2374		
	k_2	0.01292	0.001158	0.01045	0.01538	1.84 E-4		
	g	0.05023	Not determined	Not determined	Not determined	not given		

Table B.8.1.1.2.2.1._CA-125: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	53.7	42.5	53.7
	DT ₉₀ [days]	178.0	142.0	178.0

The examination of the results showed that all three kinetic models returned visually and statistically acceptable fits, very similar one to another. It was also noticed that statistically it worsened – the level of the χ^2 error increased, but was still below or equal to (for DFOP fit) 15%.

Nothing changed with regard to the acceptability of the fit – only SFO fit can be considered fully reliable and acceptable. In case of FOMC the modelling tool did not return, for the same reason as given for the fitting using the whole data set, statistical parameters of the determined kinetic parameters – error and CIs. In case of DFOP fit the removal of DAT-14 time point resulted only in that that the k_2 value became reliable, but k_1 lacked reliability. It was also noticed that, as previously, k_1 and k_2 were identical, and also the same as the rate constant k determined for SFO model. On that basis it may be stated that DFOP fit is artificial, as in fact there is no “fast degradation” and “slow degradation” compartments.

Therefore the conclusions from that fitting are following:

- SFO, also identified as such at previous stage of the analysis, is a model returning the best fit;
- the removal of DAT-14 time point from the data set did not let to the improvement of the fits, so that time point is conformed **not to be an outlier**.

The results of the fitting for the data set without DAT-28 data point:

The final stage was the verification whether DAT-28 data point was an outlier. To do that the data base was modified by removing that point and the fitting repeated. The results of the kinetic analysis are presented below, in graphical form on figure B.8.1.1.2.2.1._CA-84 and in numerical form in the table B.8.1.1.2.2.1._CA-126. Additionally the table B.8.1.1.2.2.1._CA-127 provides the kinetic endpoints obtained with each of the kinetic models tested.

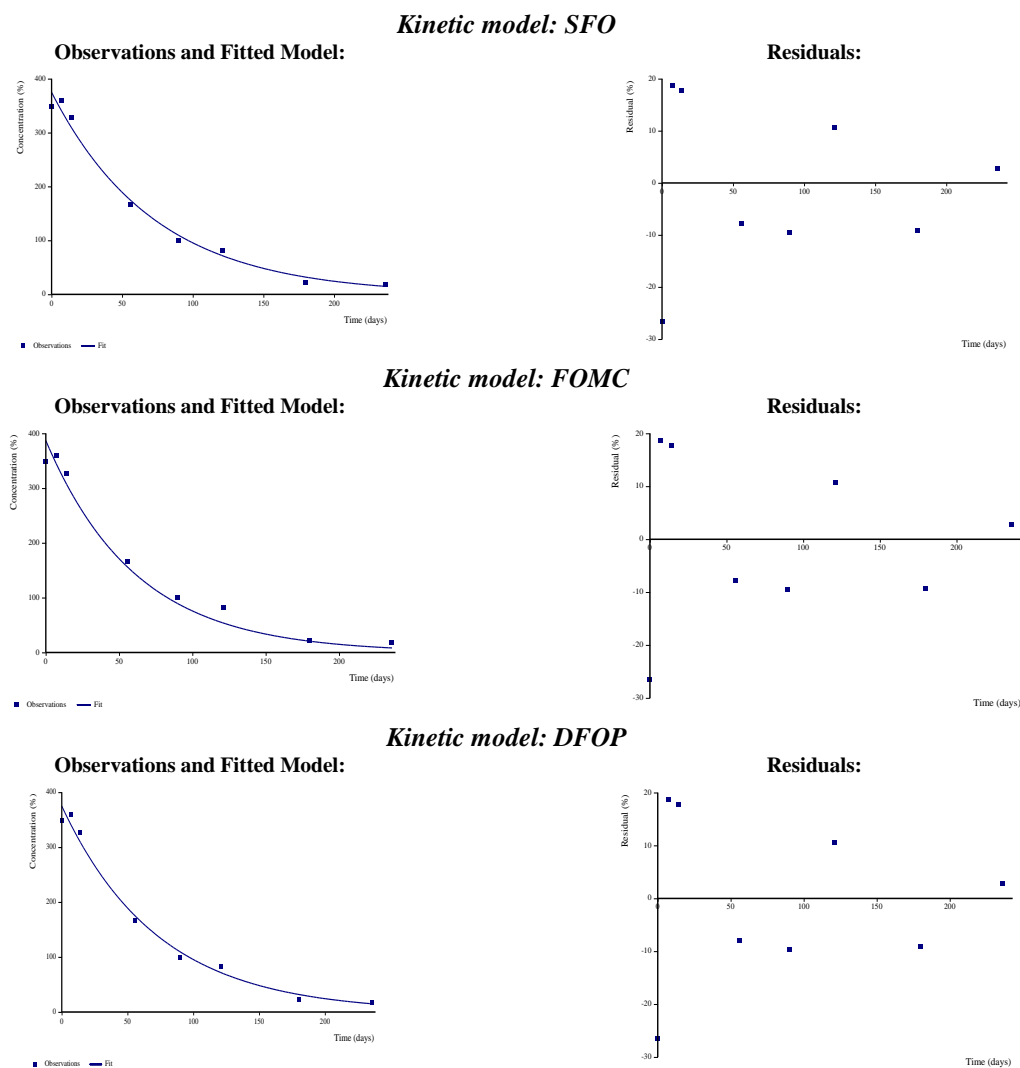

Figure B.8.1.1.2.2.1._CA-84: The graphical results of the kinetic analysis.

Table B.8.1.1.2.2.1._CA-126: The numerical results of the kinetic analysis.

Kinetic model	Model parameters	Statistical evaluation of the parameter					Evaluation of the fit	
		Value	Error	Confidence intervals		Prob. > t	χ^2 % error	R^2 and visual assessment
				Lower	Upper

Table B.8.1.1.2.2.1._CA-127: The kinetic endpoints obtained as a result of the fitting.

Compound	Kinetic endpoint	Kinetic model tested		
		SFO	FOMC	DFOP
Flufenacet	DT ₅₀ [days]	50.7	42.5	50.7
	DT ₉₀ [days]	168.0	141.0	168.0

The removal of DAT-28 time point from the data set led to significant improvement of the fits for all three models. The curves displayed good conformity with the experimental results, the levels of residuals were lower, although their distribution was not altered. That enabled to change the classification of the visual fits from “acceptable” to “good”. It was stated that all three kinetic models returned visually and statistically acceptable fits, very similar one to another.

In addition SFO and FOMC returned reliable kinetic parameters. That cannot be stated for DFOP fit, in case of which for both k_1 and k_2 the $prob > t$ was significantly higher than 0.1, reaching the level of 0.5. Additionally it was noticed that k_1 and k_2 were identical and moreover the same as the rate constant k determined for SFO fit. The results obtained for SFO and FOMC kinetic models did not differ significantly, although it was noticed that for SFO the χ^2 error was lower. Additionally SFO returned longer DT₉₀ than FOMC, what may indicate that for Flufenacet in that trial bi-phasic kinetic model does not provide an adequate description of its kinetic behaviour in soil.

The conclusions drawn from this fitting are following:

- the results indicate that DAT-28 time point should be considered as an outlier and removed from the data base subjected to the kinetic analysis;
- the best-fit model is SFO.

Evaluation of the fitting exercise:

The presented above results of the kinetic examination of the data obtained in the trial **S. Romualdo, 40495/0**, demonstrated that reliable fit and reliable kinetic endpoints representing persistence in soil under realistic – field conditions was obtained only for the parent compound – Flufenacet. The kinetic model identified as returning the best fit was SFO. The data base needs to be modified by the removal of DAT-28 time point identified as an outlier. The results of the fitting – the determined kinetic endpoints, will be presented in the List of End Points.

The kinetic analysis for the degradation products – FOE Alcohol, FOE Oxalate and FOE Sulfonic acid, was not performed for this trial due to the lack of the suitable data base for any of them.

Summary:

The kinetic examination of the data on the field dissipation of Flufenacet and its degradation products was performed for sixteen field trials. For eight of them the available data set enabled to carry out the fitting for Flufenacet only. In case of eight remaining trials it was possible to include also two of the three examined degradation products: FOE Oxalate in case of three trials and FOE Sulfonic acid for all eight trials. The final outcome of the fitting exercise – reliable key results for each evaluated compound, are presented below in tables B.8.1.1.2.2.1_CA-128 – B.8.1.1.2.2.1.CA-130.

Table B.8.1.2.2.1_CA-128: The results of the best-fit kinetic examination of the data for Flufenacet obtained in field dissipation trials.

The results presented above will also be given in format recommended for their reporting in the List of Endpoints.

The Applicant performed the kinetic examination of the data obtained in the four soil dissipation studies summarized above as **Studies 1-4**. The aim of this evaluation was to obtain the kinetic endpoints for Flufenacet and FOE Sulfonic acid suitable for modelling. The Applicant performed the kinetic assessment of the data using the inverse modeling approach. Doing that the Applicant did not take into account the results of all studies for Flufenacet and FOE Sulfonic acid examining the persistence, sorption and mobility of these two compounds submitted for the current evaluation, as the assessment pre-dated several of them.

RMS evaluated the study taking into consideration, among the other factors, the findings of the kinetic examination of the data aimed on the identification of the best-fit kinetic model and determination of the persistence endpoints.

The study's summary together with the RMS's evaluation is presented below as **Study 7**.

Study 7:

Report: Hammel K., (2008): “Kinetic Evaluation of the Dissipation of Flufenacet and its Metabolite Flufenacet-sulfonic acid in soil based on Field Studies.”; Bayer CropScience AG, Institute for Metabolism and Environmental Fate, Alfred-Nobel-Strasse 50, 40789 Monheim, Germany; study Report No. MEF-08/266; 2008. 08. 25; study reference number: M-306683-01-1;

Guidelines: The study was declared to be performed following the guidance of the FOCUS Kinetics Work Group given in:

- FOCUS, 2005: “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.”; Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0;

GLP: No, not required – this is a modelling study;

RMS comments: This is a newly submitted study, evaluated for the purpose of the current assessment. The Applicant stated that it was carried out to comply with the recommendations of the earliest version of the FOCUS Kinetics Guidance Document – version 1.0 issued in 2005. It shall be indicated that already at the date of issuing the report the updated version of that Guidance document – version 2.0 issued in June 2006, was available. Therefore RMS decided to evaluate that study using the updated version of FOCUS Kinetics Guidance document, and in particular:

- FOCUS, 2006: “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.”; Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 2.0, 434 pp.;
- FOCUS, 2011: “Generic Guidance for Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration.” Version 1.0, Nov. 23, 2011.

Additionally, to evaluate the study report in the area of the inverse modelling the following documents were consulted:

- European Commission (2014): “Assessing Potential for Movement of Active Substances and their Metabolites to Ground water in the EU.”; Report of FOCUS Ground Water Work Group, EC Document Reference Sanco/13144/2010 version 3, 613 pp. (Chapter 7 and Appendices 10 and 11);
- “The Application of Inverse Modelling Techniques to Pesticide Leaching Models.”; SSLRC support for PSD data evaluation and risk Assessment activities; MAFF project code PL0528, pp. 12- 23, available on-line on DEFRA webpage in the folder “Science and Research Projects”;
- Dubus I., Beulke S., Brown C. D., (2002): “Review: Calibration of pesticide leaching models: critical review and guidance for reporting.” *Pest Management Science* 2002, **58**, 745 – 758;

The summary of the study and its evaluation performed by the RMS is presented below.

Summary:

The aim of the study was to evaluate the degradation of Flufenacet and its major soil degradation product – FOE Sulfonic acid, and to determine the kinetic parameters suitable for modelling. Because of relatively high mobility of FOE Sulfonic acid in soil an inverse modelling approach was included into assessment to take account of the leaching of that compound.

The kinetic fitting of the data was performed using the PEST optimisation algorithm, while the losses due to leaching and other processes, such as plant uptake, were estimated using PEARL modelling tool in order to distinguish between degradation and dissipation.

Finally, the conservatism of the kinetic evaluation was assessed by comparison with independent data from two lysimeter studies.

The Applicant performed the kinetic analysis of the data obtained for Flufenacet and FOE sulfonic acid obtained in 16 field trials – 6 run in Germany, 8 in France and 2 in Italy, presented above in **Studies 1-4**.

The brief characterisation of these trials, as presented by the Applicant in the study report, is provided below in the table B.8.1.1.2.2.1._CA-131. Where necessary the data reported by the Applicant were corrected.

Table B.8.1.1.2.2.1._CA-131: The brief characteristic of field trials.

Study	Information on the trial site			Data on application		Data on crop cover

	40494/2	Ravenna	Italy	600	27. 04. 1994	Soybean	25. 04. 1994	2
	40495/0	S. Romualdo	Italy	600	27. 04. 1994	Soybean	26. 04. 1994	1

Characterising the trials the Applicant stated that seven of them were performed on bare soil while the remaining nine on soil cropped with maize, sunflower, winter wheat or soybean. It shall be indicated however that the trial 30248/1 – Fresne-L'Archeveque was incorrectly characterised as performed on the bare soil, while in fact it was performed on the cropped soil, on which maize was grown. The Applicant however subsequently corrected that mistake in the modelling assessment of the data set for that trial.

Next the residue data obtained for Flufenacet and its degradation product – FOE Sulfonic acid were pre-processed in order to obtain the data sets suitable for the kinetic evaluation.

Doing that the Applicant stated that the samples were taken as soil cores, in ten trials down to 30-cm – in the studies [Sommer; 1995] and [Sommer; 1995a], and in six remaining trials – in the studies by [Sommer; 1995b] and [Sommer; 1995c], down to 50 cm. These cores were next divided into 10-cm sections and analysed. It was stated that for the purpose of the evaluation only 0-30 cm layers were considered for two reasons:

- 1) no residues of either Flufenacet or FOE Sulfonic acid were detected below 30 cm in trials in which 50-cm soil cores were sampled;
- 2) potential leaching below the depth of 30 cm was accounted for by the inverse modelling procedure.

The trials lasted for 231 – 303 days after application of the test compound – Flufenacet. During that period samples were taken eight or nine times. Typically four replicates were analysed for 0-10 cm layer, two for 10-20 cm layer and one for 20-30 cm layer. The mean values for each layer were used in the evaluation. It was stated that in course of the trials the quantifiable (> LOQ) residues of Flufenacet and FOE Sulfonic acid were found almost uniquely in the topmost layer 0-10 cm.

The residue data were processed using the following analytical parameters: LOD = 3 µg/kg and LOQ = 10 µg/kg. These values were used in the data processing, following the recommendations given by FOCUS [2005]. That procedure was already presented in the paragraph summarising the kinetic evaluation of the data aimed on the identification of the best-fit model and determination of persistence endpoints and, for completeness, is outlined here:

- the residues < LOQ were set to 0.5 (LOD + LOQ) = 6.5 µg/kg – the mean of the interval between LOD and LOQ;
- values < LOD were set to 0.5 LOD = 1.5 µg/kg for their first appearance before or after the values > LOD, also in deeper layers, for samples between the values > LOQ.
- The kinetic curve was cut-off after the first non-detect (< LOD) unless later value > LOQ followed;
- On DAT 0 values < LOD in deeper layers were set to zero;
- To increase the conservatism of the assessment for FOE Sulfonic acid all depth were considered during the whole experimental period – starting from the second sampling for the layer 10-20 cm and from the third sampling for the layer 20-30 cm all values < LOD were set to 0.5 LOD irrespective of the values obtained in deeper layers.
- After averaging the residue concentrations in each layer were summed up to represent the concentration in the topmost 10-cm layer;
- Finally, the so determined concentrations were transformed, using the soil density determined for 0-30 cm soil layer of each trial site, to obtain the value expressed in g/ha, subsequently used in the kinetic evaluation of the data; in the study report it was explained that that was done because the amount expressed in units [mass/area down to a given soil depth] is a direct output of PEARL, what simplifies the inverse modelling.

The last step was not used by the RMS in the kinetic analysis of the data aimed on the identification of the best-fit model and determination of the persistence kinetic endpoints in each trial.

The resulting pre-processed data sets for each trial, with concentrations expressed in [µg/kg], are presented below in tables B.8.1.1.2.2.1._CA-132 and B.8.1.1.2.2.1._CA-132a.

Footnotes to the table:

- 1) the time point not used in the evaluation as no measurable residues were found in soil sample;
 2) not available – the values were below the LOD.

According to the Applicant for three of sixteen data sets it was not possible to perform the kinetic analysis for FOE Sulfonic acid, because there were no values above the LOD. Such situation was observed in the trials 30254/6 Saussay-la-Campagne, 30455/7 Fresne-L'Archeveque and 30500/6 Monheim. RMS for these trials also did not performed the kinetic assessment aimed on the determination of the persistence.

Further comparative analysis of the data sets showed that in case of four other trials – 30163/9 Monheim, 30164/7 Burscheid, 30499/9 Burscheid and 40495/0 S. Romualdo, the residues of FOE Sulfonic acid, when detected, were all lower than the LOQ. In another trial – 30162/0 Kirchlauter practically all values for FOE Sulfonic acid, when that compound was detected in soil, were <LOQ (the exception concerned one replicate in 0-10 cm layer of DAT 90, in which the residue level was 10.20 µg/kg; however when the average was calculated the resulting value was very close to the average for values < LOQ – 7.4 µg/kg) . In the reference document “The Application of Inverse Modelling Techniques to Pesticide Leaching Models” (ref.: MAF project PL 0528), in paragraph 4.7 – *Influence of the quality of the experimental dataset*, it is stated that the handling of the values <LOQ is problematic. They use to be set either to zero or some fraction of LOQ, but there is no information about the influence of such setting on the results. RMS, being aware of the significant level of uncertainty related to the numerical values attributed to the residues <LOQ, and hence to the data sets comprising only these values as “measurables”, decided not to perform the kinetic evaluation of the data sets containing no values > LOQ. For that reason for the trials 30162/0 Kirchlauter, 30163/9 Monheim, 30164/7 Burscheid, 30499/9 Burscheid and 40495/0 S. Romualdo the kinetic examination of the data aimed on the determination of persistence kinetic endpoints for FOE Sulfonic acid was not performed because the results would bear to high level of uncertainty. For the same reason RMS is of the opinion that the results obtained in this experiment for FOE Sulfonic acid in the trials listed above should not be taken into account in the further assessment.

As a result, the analysis of the pre-processed data presented by the Applicant led to the conclusion that in case of the following eight trials it was not possible to perform the reliable kinetic analysis for FOE Sulfonic acid: 30162/0 Kirchlauter, 30163/9 Monheim, 30164/7 Burscheid, 30254/6 Saussay-la-Campagne, 30455/7 Fresne-L'Archeveque, 30499/9 Burscheid, 30500/6 Monheim and 40495/0 S. Romualdo.

The remaining data base, for which RMS performed the evaluation of the results of the kinetic analysis obtained by the Applicant for Flufenacet and FOE Sulfonic acid, comprised the following trials:

- 30159/0 Breitenfelde;
- 30248/1 Fresne-L'Archeveque;
- 30250/3 Fresne-L'Archeveque;
- 30251/1 Laudun;
- 30253/8 St. Etienne du Gres;
- 40163/3 Laudun;
- 40164/1 St. Etienne du Gres;
- 40494/2 Ravenna.

It shall be noted that of all trials listed above only one – 30159/0 Breitenfelde, was performed on bare soil, and the remaining seven on cropped soil with the test compound applied to the soil surface shortly before or after the emergence of the crop.

In case of the remaining eight trials the results of the kinetic examination obtained for Flufenacet were evaluated by the RMS.

As a next element the Applicant presented the method of the normalisation of the degradation parameters for the temperature and soil moisture, used in the study. It was stated that neither on-field daily soil temperature nor soil moisture data, necessary to normalise these parameters were available, the suitable simulation method was used to generate them.

In the study report from the field trials the data on temperature and rainfall were reported as weekly, then 10-days and finally monthly sums and averages. The utility of such weather data is limited, because the normalisation procedures in the current Guidelines recommend to use the continuous weather data, measured day-by-day. For that reason the MARS weather data base was used to provide the daily variations of these parameters. For each trial site the data taken from the data base covered the period in which it was carried out and the selected MARS grid cell was closest to the specific location of the trial. The Applicant stated that because of the dimension of the grid cells within the MARS database – 50/50 km, the weather data collected on the test site or by the weather station closest were used to calibrate the MARS data. For that purpose the mean temperature and cumulative rainfall values measured on/at the site and resulting from MARS data were calculated. Next the ratio between the cumulative rainfall and the difference between mean temperature values were determined and applied to the original MARS daily data. Finally, these corrections were implemented in PEARL via *FacPrc* and *DifTem* factors. The obtained estimated values for precipitation and temperature were used as climatic conditions on the trial sites.

The results of that estimation of the weather data, as presented in the study report, are provided below in the table B.8.1.1.2.2.1_CA-133.

According to the current Guidelines that approach is admissible, but not recommended as a first-choice solution. It may be used only when the weather data measured in daily intervals are not available, and not unconditionally – the approach is recommended only where the averaging period is short (in case of the discussed trials the duration is on average 248 days, with range 231 – 303 days) and the climatic conditions within that period are stable (in this particular case the trials cover the period from spring to winter of the same year, but for two trials they start in late autumn and last until summer of the next year, so the variability of the climatic conditions within the experimental period may be, in RMS's opinion, significant). Additionally it is recommended that the calculated weather data should be checked against the measured ones whenever that is possible.

Table B.8.1.1.2.2.1_CA-133: The climatic conditions and weather data on each trial site used in the kinetic evaluation of the data obtained in field dissipation studies for Flufenacet.

Information on the trial:			Duration of the trial after application of the test compound [days]	Weather data			
Trial number	Trial site - name	Location - country		Source of the weather data	Mars grid cell	Experimental weather data collected at trial site
