B.7. RESIDUE DATA

NB: In some places in this document the active substance **isoflucypram** is sometimes referred to by the company code: **BCS-CN88460**.

Details, including the code numbers, synonyms, structures and chemical names for all the metabolites referred to in this document are included in the Appendix which can be found on page 365.

Please note that the RMS (UK) is aware of ongoing studies on wheat and barley in which positive residues of M01 + conjugates and M06 + conjugates have been found ≥0.01 mg/kg in some matrices (barley grain, barley straw, wheat straw). At the time of writing (December 2018), this data is not available for evaluation and so, at the present time, it is not possible to take account of this new information in the DAR. On the basis of the above, once the ongoing studies have been finalised , the RMS (UK) considers it likely that the residue definition for Risk Assessment in cereals may well need to be updated to: Sum of isoflucypram and its metabolites M01 and M06 and their conjugates, expressed as isoflucypram. The DAR risk assessment will need to be amended accordingly.

B.7.1. STORAGE STABILITY OF RESIDUE

As residue samples in trials with **isoflucypram** on crops were routinely stored frozen prior to their analysis, the effects of frozen storage on the residue levels were investigated.

B.7.1.1. Plant matrices

The longest periods of frozen storage of samples from plant residue studies (field residue, processing, or rotational crop trials) are shown in the Table below:

Table 7.1.1-1: Periods of frozen storage (ca. -18 °C) of plant samples (sampling to analysis)

Sample material		Longest storage duration (days)	Study

A study was conducted to evaluate the stability of **isoflucypram** and its metabolite **M49** during deep frozen storage (≤ -18°C) for a period of 24 months in orange fruit (high acid), tomato fruit (high water), wheat grain (high starch), bean dry seed (high protein) and rape seed (high oil), see below:

Report:	KCA 6.1/01; Uceda, L.; 2018
Title:	Storage stability of residues of BCS-CN88460 and its metabolite BCS-CR60082 in tomato (fruit), bean (dry seed), wheat (grain), rape (seed) and orange (fruit) during deep freeze storage for at least 24 months
Report No.:	MR-17/244
Document No.:	M-605556-02-1
Guidelines:	OECD Test Guideline 506; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA Residue Chemistry Test Guideline OPPTS 860.1380.
Guideline deviations:	Not specified
GLP/GEP:	Yes

Materials and Methods

5 g samples of orange fruit (high acid), tomato fruit (high water), wheat grain (high starch), bean dry seed (high protein) and rape seed (high oil) were spiked separately with either **isoflucypram** or its metabolite **M49** at a level of 0.20 mg/kg. The samples were stored in HDPE containers at an average temperature of ≤ 18 °C. Samples of each matrix were analysed at nominal storage intervals of 0, 3, 8, 13, 18 and 24 months; orange fruit samples were additionally analysed at 6 days, and 1 month. After approximately 25 months of storage at ≤ 18°C, samples of each matrix were transferred to a fridge and analysed after a further 6 days at -1 ± 2°C.

On day 0, 3 samples of each matrix were analysed. At later time points, 2 samples were analysed for all matrices except orange fruit. For orange fruit, the day 0 samples demonstrated higher variability of recovery compared with the other matrices and the method validation data. Consequently, the number of analyses for orange fruit at the later storage intervals was increased to 3. To ensure that sufficient samples would be available to conduct 3 analyses at every time point, additional orange fruit samples were similarly prepared and stored under identical conditions to the original samples. These were analysed at 0, 5 and 10 months only since sufficient samples to conduct 3 analyses at the later time points were found to remain from the initially prepared samples.

One control sample was also analysed for each matrix at each time point, as were procedural recovery samples fortified at 0.01 and 0.20 mg/kg – these were prepared and stored in the same way as the control samples and were spiked on the day of analysis.

Residues of **isoflucypram** and its metabolite **M49** were determined according to analytical method 01475 (Uceda, L.; 2016; M-558986-01-1, see Volume 3, Section B.5 (AS)) which has been validated for this purpose with LOQs of 0.01 mg/kg for both **isoflucypram** and **M49**, expressed as parent.

Findings

Neither **isoflucypram** nor **M49** were detected at levels exceeding 30% of the LOQ in any of the control samples analysed.

For **isoflucypram**, all the procedural recovery means were within the acceptable range of 70-110% with corresponding RSDs (relative standard deviation) below 20%, except the recovery mean of 111% at the storage interval 561 days for bean dry seed. This only slightly exceeds the criteria laid down in SANCO/3029/99 rev. 4, but meets the OECD guidance ENV/JM/MONO(2007)17 criteria. This is not expected to have any impact on the validity of the results.

For **M49**, all the recovery means were within the acceptable range of 70-110% with corresponding RSDs (relative standard deviation) < 20%.

The procedural recovery data are shown in Table 7.1.1-2 for **isoflucypram** and Table 7.1.1-3 for **M49**.

(1) frozen storage interval (-18°C) + refrigerated storage interval (-1 ± 2°C)

* Additional orange fruit samples

** the recovery was performed with a control sample stored for 789 days at -18°C (insufficient control sample stored for the additional 6 days at -1 ± 2°C was available).

On Day 0, average residue recoveries of **isoflucypram** ranged from 96-110% of the nominal spiked concentration in the stored samples and ranged from 92-110% for **M49**.

In the stored samples analysed after approximately 24 months of frozen storage (737-782 days at around -18°C), storage stability recoveries ranged from 84-92% for **isoflucypram** and 78-90% for **M49**. At all sampling points and in all matrices, the recovered residues of **isoflucypram** and **M49** were above 70% (including after correcting for day 0 values and procedural recoveries).

After approximately 25 months of storage (776-785 days) at around -18°C and an additional period of 6 days at -1 ± 2°C, the recovered residues of **isoflucypram** ranged from 83-94% of the nominal spiked concentration in the stored samples and ranged from 79-85% for **M49**.

All storage stability results are summarised below in Table 7.1.1-4 for **isoflucypram** and Table 7.1.1-5 for **M49**.

Table 7.1.1-4: Storage stability data and concurrent recovery data for isoflucypram

* Additional orange fruit samples

** Results confirmed after 782 days with new samples

(1) Frozen storage interval (-18°C) + refrigerated storage interval (-1 ± 2°C)

The time between the beginning of the sample preparation and the sample analysis did not exceed 24 hours for the vast majority of samples with the longest interval being 105 hours for orange fruit. All of the storage periods reported in the study are covered by stability experiments conducted during the validation of method 01475 (Uceda, L.; 2016; M-558986-01-1, see Volume 3, Section B.5 (AS)).

Conclusions

Based on the above results, it can be concluded that residues of **isoflucypram** and its metabolite **M49** are stable for at least 25 months in frozen storage at around -18°C in orange fruit (high acid), tomato fruit (high water), wheat grain (high starch), bean dry seed (high protein) and rape seed (high oil). An additional period of 6 days at -1 ± 2°C also did not result in significant degradation of residues of either compound. Since stability has been demonstrated in one commodity from each of the crop categories as specified in OECD 506, it can be assumed that residues of **isoflucypram** and **M49** are stable for 25 months at ≤ -18 °C in all raw agricultural and processed commodities.

These results validate the storage periods used in the supervised field trials and processing studies with respect to storage stability of samples frozen prior to analysis.

B.7.1.2. **Animal matrices**

The longest storage periods for samples from animal feeding studies are shown in the Table below:

Table 7.1.2-1: Periods of frozen storage (≤ -18 °C) of animal samples (sampling to analysis)

Sample material		Analyte Group*	Longest storage duration (days)	Study	
Animal	**Matrix**			**Report No.**	**Annex point Document No.**
Ruminant	Milk	A	< 30	17-8001	6.4.2/01 M-604191-02-1
	Cream	A			
	Whey	A			
	Fat	A			
	Muscle	A			
	Kidney	A & B			
	Liver	A & B			
Poultry	Eggs	A	< 30	17-8002	6.4.1/01 M-605909-01-1
	Fat	A			
	Muscle	A			
	Liver	A & C			

* Group A: **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**).;
Group B: sum of BCS-CY24813 (**M01**) and its conjugate **M19**; sum of BCS-DC20298 (**M02**) and its conjugate **M20**.
Group C: sum of BCS-DC22055 (**M06**) and its conjugate **M37.**

In the ruminant and poultry feeding studies, the analyses were completed within 30 days of sample collection. Therefore, further storage stability data in animal matrices are not necessary.

Nevertheless, some information on the stability of residues is given in the hen and goat metabolism studies, see Table below:

Table 7.1.2-2: Storage stability data from livestock metabolism studies

Sample	Storage temperature (°C)	Initial analysis after sample collection	Demonstrated storage stability	Document No.	Reference
Hen Liver	≤ -18 °C	< 5 months	20 months	M-601665-01-1	KCA 6.2.2/01
Hen Liver	≤ -18 °C	< 3 months	9 months	M-601667-01-1	KCA 6.2.2/02
Goat Liver	≤ -18 °C	Approx. 3 months	Approx. 13 months	M-604281-01-1	KCA 6.2.3/01
Goat Kidney	≤ -18 °C	Approx. 3 months	Approx. 14 months		
Goat Liver	≤ -18 °C	Approx. 3 months	11 months	M-604286-01-1	KCA 6.2.3/02

During these studies, all samples and extracts were stored in a freezer at ≤ -18 °C or for a short time in a refrigerator. All samples of milk, eggs, excreta, edible organs and tissues were extracted within several months after sample collection. Quantitative analysis by HPLC was performed either on the day of extraction or up to six days after the start of extraction.

A second conventional extraction of liver and kidney was performed within 9-20 months after collection to be used for enzymatic cleavage experiments. Analyses of these second conventional extracts of liver and kidney showed no indication of degradation of parent compound and metabolites in the profiles when compared with the HPLC metabolite profiles obtained after the first extraction. The storage stability of parent compound and metabolites in goat and hen liver as well as in goat kidney illustrate that stability is also expected in other animal matrices.

In most cases, the time between the beginning of sample preparation and sample analysis did not exceed 24 hours in the residue studies. The maximum storage period of extracts was covered by stability experiments conducted in the course of the analytical methods validations (Uceda, L.; 2016; M-558986-01-1; Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1; see Volume 3, Section B.5 (AS)), in residue study 15-2066 (Schulte, G.; 2017; M-584388-02-1) or in residue study 15-2069 (Schulte, G.; 2017; M-584384-02-1). These experiments are summarised in the Table below:

Table 7.1.2-3: Stability of residues in extracts

Hen liver		Extract A	5 °C ± 3 °C	26 days	
Cow kidney (hydrolyse)	BCS-DC20298 (**M02**) + **M20**	Final extract	5 °C ± 3 °C	22 days	
Cow liver (hydrolyse)	BCS-CY24813 (**M01**) + **M19**	Final extract	5 °C ± 3 °C	21 days	
Hen liver (hydrolyse)	BCS-DC22055 (**M06**) + **M37**	Final extract	5 °C ± 3 °C	26 days	

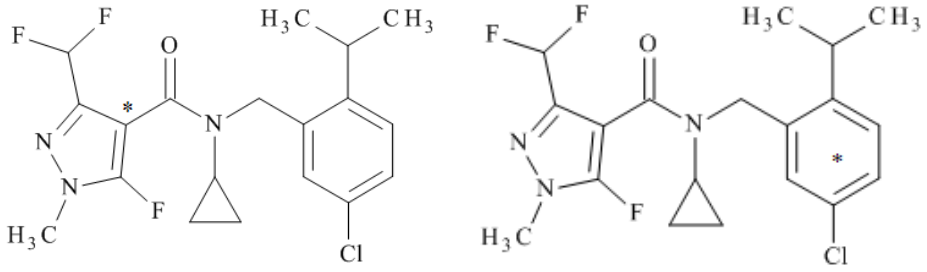
Moreover, the stability of residues in the final and intermediate extracts was demonstrated by the fortification experiments performed during sample analysis. Every analytical batch contains at least one freshly fortified sample for concurrent procedural recovery determination. The extracts of the fortified samples and study samples are handled and stored in parallel. If the recoveries in the fortified samples are within acceptable ranges, the stability of the analytes in the sample extracts is presumed.

B.7.2. METABOLISM, DISTRIBUTION AND EXPRESSION OF RESIDUES

Metabolism studies on primary crops and livestock are presented in this section. See Section B.7.6.1 for the details of metabolism studies in rotational crops.

As **isoflucypram** contains separate ring systems, two different radiolabels were used in all plant and animal metabolism studies; the label positions are shown in the Figure below:

Figure 7.1.2-1: Radiolabelled isoflucypram used in plant and animal metabolism studies



[pyrazole-4-^{14}C] [phenyl-UL-^{14}C]

Numerous metabolites were identified in the metabolism studies. The chemical structures and report names used in the summaries are given at the end of this Section and in the List of Metabolites presented in the List of End Points. All residue values given in mg/kg refer to parent compound equivalents unless indicated otherwise.

B.7.2.1. **Plants**

The metabolism of **isoflucypram** has been investigated after foliar treatment of wheat (Cereal/Grass crops), tomatoes (Fruit), oilseed rape and soybean (Pulses and oilseeds) using either pyrazole- or phenyl- labelled **isoflucypram**. The metabolism has also been investigated in potatoes (Root crops) following seed/tuber treatment using the same radiolabels.

A summary of the available primary crop metabolism studies is summarised in the Table below:

Table 7.2.1-1: Overview of primary crop metabolism studies

Crop Category (OECD 501)	Crop	Mode of Application	Radiolabel	Target Rate	Reference	DAR Section
Cereal/Grass crops	Wheat	Foliar	pyrazole	2 x 65 g a.s./ha	M-604361-02-1	B.7.2.1.1
			phenyl	2 x 65 g a.s./ha	M-604358-02-1	
Fruit	Tomato	Foliar	pyrazole	2 x 75 g a.s./ha	M-597485-01-1	B.7.2.1.2
			phenyl	2 x 75 g a.s./ha	M-597481-01-1

Wheat	Two foliar spray applications, phenyl-labelled **isoflucypram**	2 x 65 g a.s./ha	BBCH 30 and BBCH 69	M-604358-02-1

B.7.2.1.1.1. [pyrazole-4-^{14}C]isoflucypram

Report:	KCA 6.2.1/03; Traub, M.; 2018
Title:	Amendment no.1 to final report - Metabolism of [pyrazole-4-^{14}C] BCS-CN88460 in wheat plants
Report No.:	S14-01087
Document No.:	M-604361-02-1
Guidelines:	OECD Test Guideline 501; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300; JAP FAMIC-ACIS Notification 12 Nousan 8147.
Guideline deviations:	None
GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** was investigated in wheat plants after two spray applications. For each of the two foliar applications the test item [pyrazole-4-^{14}C]BCS-CN88460 was formulated as an aqueous EC 50 using a nominal application rate of 65 g a.s./ha. The applications were performed at growth stage BBCH 30 (beginning of stem elongation) and BBCH 69 (end of flowering). The actual application rates corresponded to 69 and 67 g a.s./ha for the first and second application, respectively resulting in a total application rate of 136 g a.s./ha.

Wheat hay was harvested at BBCH 69, 1 day prior to the second application, wheat straw and grain were harvested at maturity (BBCH 89). The total radioactive residues (TRR) in wheat straw and hay amounted to 15.536 mg eq/kg and 4.032 mg eq/kg, respectively. The TRR in wheat grain was 0.385 mg eq/kg.

Homogenised plant material from the RACs was conventionally extracted with a mixture of acetonitrile/water (8/2; v/v). The extraction rates after conventional extraction of wheat hay, straw and grain were high and amounted to 95.8% (3.864 mg eq/kg) of the TRR for hay, 94.0% (14.604 mg eq/kg) of the TRR for straw and 93.6% (0.360 mg eq/kg) of the TRR for grain. The post extraction solids (PES) of all RACs remaining after conventional extraction amounted to ≤ 6.4% of the TRR.

Solids after conventional extraction of straw were exhaustively extracted using microwave assistance with a mixture of acetonitrile/water/formic acid (50/50/1; v/v/v) releasing a further 4.7% (0.727 mg eq/kg) of the TRR.

Residues in the conventional extracts were analysed and quantified by HPLC. The parent compound and metabolites were either identified by co-chromatography with the reference compound or by spectroscopic analysis in isolated fractions of wheat straw. Additionally, the metabolite pattern and retention times found in this study were compared to that found in the wheat metabolism study conducted with the ^{14}C-phenyl label.

The parent substance **isoflucypram** represented the most prominent residue component in all RACs accounting for 50.0% of TRR (2.016 mg eq/kg) in wheat hay, 64.0% of TRR (9.933 mg eq/kg) in wheat straw and 92.0% of TRR (0.354 mg eq/kg) in wheat grain. Besides parent compound, no other

metabolite was detected in the extract from wheat grain. In wheat straw, 5 metabolites were identified besides the parent compound: BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) accounting for 3.7% (0.561 mg eq/kg), 2.9% (0.448 mg eq/kg), 6.7% (1.042 mg eq/kg), 1.7% (0.267 mg eq/kg) and 1.1% (0.171 mg eq/kg) of the TRR, respectively. BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-propanol (**M01**) were also identified in wheat hay and amounted to 2.4% (0.096 mg eq/kg), 2.5% (0.103 mg eq/kg), 10.3% (0.414 mg eq/kg) and 0.7% (0.029 mg eq/kg) of the TRR, respectively.

Overall, identification rates were sufficient and amounted to 80.0% of TRR for straw, 66.0% of TRR for hay and 92.0% of TRR for grain. Unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤ 3.1% of the TRR.

Comparison of the metabolic profile with that from a parallel study with [phenyl-UL-^{14}C]BCS-CN88460 revealed a high correspondence and no label specific metabolites were observed for either label.

More conjugates may be present among the characterised unknown metabolites in the chromatograms. Therefore, acid hydrolysis (1 M HCl, 100 °C, 1 h) of the conventional extracts of wheat hay and straw were conducted in order to analyse for hydrolysable conjugates. Major hydrolysis products detected in the acidic hydrolysates besides parent compound were the aglycons BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). Identification rates after hydrolytic treatment increased. Based on these results it can be concluded that a significant amount of the residue in the conventional extracts of hay and straw consist of conjugates of BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). Analogous hydrolysis experiments were performed in the parallel study with the phenyl-label and showed good accordance with these results.

As metabolic reactions, hydroxylation of the propyl group followed by conjugation with hexose and malonic acid and the demethylation of the pyrazole moiety were observed.

Based on these results, the metabolic behaviour of [pyrazole-4-^{14}C]BCS-CN88460 in wheat is adequately understood and a metabolic pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[pyrazole-4-^{14}C]
Specific radioactivity	4.22 MBq/mg
Radiochemical purity	100%
Chemical purity	> 99%

Formulation of the test compound

The test compound was formulated as an EC 50 for the experiment. The active substance [pyrazole-4-^{14}C]BCS-CN88460 was dissolved in acetonitrile. For each spray dilution, adequate parts of the stock solution were transferred into special glass vials and evaporated to dryness. Blank formulation was added and the mixtures were homogenised using a magnetic stirrer. The sample was then adjusted with water to a final volume of 100 mL of the spray dilution and homogenised by stirring.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**CEC**
Sandy loam	2.1%	7.23	15.5 meq/100 g

3. Plant: Wheat, variety “KADRILJ”, representative for cereals

B. Study Design

1. Experimental conditions:

The experiment was conducted with wheat plants based on a plant density of 5,000,000 wheat plants per hectare. A planting container with a surface area of 1 m^2 was used corresponding to the rate of 500 grains per m^2. The plants were treated at two different growth stages (BBCH 30 and 69). At both growth stages the target application rate was 65 g a.s./ha. The planting container was filled with sandy loam soil "CUPF_soil". The plants were cultivated in a glass-roofed greenhouse under normal temperature and light conditions, but protected from rainfall. The plants were watered by pouring water onto the soil in the planting containers.

The wheat plants were treated with 100 mL of the aqueous spray dilution using a controlled track sprayer with a flat fan nozzle. At the 1st application 29.1 MBq of the labelled test compound were applied, corresponding to 6.9 mg. At the 2nd application 28.1 MBq of the test compound were applied, corresponding to 6.7 mg. The total actual treatment rate was 69 and 67 g a.s./ha for the 1st and 2nd application, respectively. The seed density was 500 grains/m^2. After spray application onto the wheat plants of the planting container, the spray device and the protective plastic foil around the planting container were rinsed with acetonitrile/water (8/2; v/v). The actual amount applied was calculated by subtracting the losses from the radioactivity in the original application solution.

2. Sampling:

Hay was harvested at growth stage BBCH 69 and straw and grain were harvested at BBCH 89. Plant samples were collected by cutting approximately 1-2 cm above the soil level. Hay samples were dried for 4 days. The total weight of each sample was determined. The samples were homogenised with liquid nitrogen using a high speed blender. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates were extracted conventionally. The final TRR values of the samples were determined by summing up the radioactivity measured in the conventional extracts and in the remaining solids.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

Aliquots of the homogenised samples of wheat hay, straw and grain were conventionally extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and homogenised; aliquots were subjected to combustion.

The extracts were combined and subjected to a clean-up step using a SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The

flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. The less polar, remaining, fractions were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v). The volume and radioactivity of this fraction was determined. Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder. The final conventional extracts were then analysed by HPLC with the general profiling method. All wheat samples and extracts were stored in a freezer (≤ -18 °C).

Exhaustive extraction and corresponding clean-up:

Solids from the conventional extraction of wheat straw were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased temperature (0 to 5 min increase to 120 °C, 5 to 20 min at 120 °C, 800 W). The microwave extracts were cooled to room temperature, combined and concentrated by rotary evaporation. Aliquots of the extracts were centrifuged and separated into supernatant and pellet, which was dissolved in acetonitrile/water. Both extracts were further analysed by HPLC.

Hydrolysis of the conventional extracts from wheat hay and straw:

Hydrolysis experiments in acidic medium were conducted with conventional extract of wheat hay and straw, to further characterise the residues. Aliquots of the conventional concentrated purified extract of wheat hay and straw were incubated with 1 M HCl and 5% acetonitrile at 100 °C for 1 hour and then centrifuged. For wheat straw, the supernatant was removed and the pellet was dissolved in acetonitrile/water (1/1; v/v); no pellet was formed during processing of wheat hay. Aliquots of the extracts were used for further HPLC analysis with the general profiling method. All wheat samples and extracts were stored in a freezer (≤ -18 °C).

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent/ scintillation cocktail mixture and the radioactivity was measured by LSC.

Conventional and microwave extracts were analysed by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

2. Identification and characterisation:

For identification of radioactive ingredients in the conventional extract from wheat straw, selected major radio signals were isolated by HPLC fractionation. Additional fractions were prepared by hydrolysis of isolated fractions using HCl. The structures were identified by spectroscopic methods. The purity of isolated fractions before and after spectroscopic analysis was sufficient and each fraction was used as radiolabelled reference compound.

The metabolic profiles of all RACs were compared with each other and also with the corresponding RACs from the wheat metabolism study conducted using phenyl labelled **isoflucypram**. Parent compound was identified in wheat grain extract by TLC and HPLC co-chromatography with non-radiolabelled and radiolabelled reference compound BCS-CN88460. Metabolic profiles of wheat hay and straw before and after hydrolysis were compared with corresponding profiles of the wheat metabolism study with the phenyl label, as analysed by HPLC.

Major metabolites and hydrolytic cleavage products from conventional extract of wheat straw in isolated fractions were identified by spectroscopic analysis. Metabolites in the conventional extract of wheat straw were confirmed by co-chromatography with the identified compounds. Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-3: Reference compound

Report name / other names/codes	Chemical Name (IUPAC)	Structure
Parent compound : BCS-CN88460 Radiolabeled reference: S_PY_1_1000 Non-radiolabeled reference: BCS-CN88460-01-02	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

All extraction experiments with wheat hay, straw and grain and the first HPLC analyses were performed within one month after harvest of the wheat plant raw material. The stability of the stored extract of wheat hay, straw and grain was demonstrated by re-analysis of the extract by HPLC after 21, 14 and 15 months of storage, respectively.

A second analysis of wheat straw and grain was needed for analytical reasons and performed after 4 and 13 months of storage of the respective plant material after harvest. The storage stability of these samples could be demonstrated.

It was therefore concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The TRR values of the individual RACs were determined by summing up the radioactivity determined in the combined extracts and post extraction solids. The residue levels are shown in mg active substance equivalents per kg sample material (mg eq/kg). The TRR in wheat hay and straw amounted to 4.032 mg eq/kg and 15.536 mg eq/kg, respectively. Wheat grain showed a TRR of 0.385 mg eq/kg.

Table 7.2.1-4: TRR in wheat matrices after foliar application of [pyrazole-4-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Wheat hay	1 spray application at BBCH 30: 69 g a.s./ha	27	4.032
Wheat straw	2 spray applications at BBCH 30 and BBCH 69: 69 and 67 g a.s./ha (136 g a.s./ha total)	17	15.536
Wheat grain		17	0.385

* PHI: Pre-Harvest Interval

Wheat hay was conventionally extracted three times with acetonitrile/water mixtures releasing 95.8% of the TRR (3.864 mg eq/kg). After purification and concentration steps 95.4% of the TRR (3.846 mg eq/kg) were analysed. Losses during sample clean up were 0.4% (0.018 mg eq/kg) of the TRR.

Wheat straw was conventionally extracted three times with acetonitrile/water mixtures releasing 94.0% of the TRR (14.604 mg eq/kg). After purification and concentration steps 93.5% of the TRR (14.521 mg eq/kg) were analysed. For wheat straw samples, a microwave extraction was performed. With this exhaustive method about 4.7% (0.727 mg eq/kg) of the TRR were extracted additionally. Finally, the residue level in the solids of wheat straw was 1.3% of the TRR (0.206 mg eq/kg). Losses during sample clean-up of straw samples were 0.083 mg eq/kg.

Wheat grain was conventionally extracted three times with acetonitrile/water mixtures releasing 93.6%

of the TRR (0.360 mg eq/kg). Based on the low amount of radioactivity (0.002 mg/kg) and high matrix load the third extract was not combined. After purification and concentration steps 92.0% of the TRR (0.354 mg eq/kg) were analysed. Losses during sample clean up were 0.006 mg eq/kg.

-- not performed

In the conventional extract from wheat hay 66.0% of the TRR (2.659 mg eq/kg) was identified in total. The parent compound was the major component representing 50.0% of the TRR (2.016 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-propanol (**M01**) represented 2.4, 2.5, 10.3 and 0.7% of the TRR corresponding to 0.096, 0.103, 0.414 and 0.029 mg eq/kg, respectively.

In the conventional extract from wheat straw 77.1% of the TRR (11.969 mg eq/kg) was identified in total. The parent compound was the major component representing 62.9% of the TRR (9.761 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**) represented 2.5, 2.9, 6.7, 0.7 and 1.4% of the TRR corresponding to 0.383, 0.448, 1.042, 0.116 and 0.219 mg eq/kg, respectively.

In the exhaustive extract of wheat straw 3.0% of the TRR (0.453 mg eq/kg) was further identified, consisting of parent compound and metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**) representing 1.1, 1.2, 0.4 and 0.3% of the TRR corresponding to 0.172, 0.178, 0.055, 0.048 mg eq/kg, respectively. In total, 80.0% (12.422 mg eq/kg) of the TRR were identified in the conventional and exhaustive extracts of wheat straw.

The conventional extract from wheat grain contained only parent compound representing 92.0% of the TRR corresponding to 0.354 mg eq/kg.

The TRR and the distribution of parent and metabolites in wheat matrices are shown in the following table.

More conjugates may be present among the characterised unknown metabolites in the chromatograms. Therefore, acid hydrolysis (1 M HCl, 100 °C, 1 h) of the conventional extracts of wheat hay and straw were conducted in order to analyse for hydrolysable conjugates.

In hydrolysed extract of wheat hay 90.3% of the TRR (3.640 mg eq/kg) were analysed. The parent compound was the major component representing 44.4% of the TRR (1.791 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) represented 0.8, 0.9, 22.3 and 6.9% of the TRR corresponding to 0.031, 0.036, 0.901 and 0.277 mg eq/kg, respectively.

In hydrolysed extract of wheat straw 92.5% of the TRR (14.372 mg eq/kg) were analysed. The parent compound was the major component representing 67.0% of the TRR (10.397 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) represented 0.2, 0.3, 10.5 and 3.6% of the TRR corresponding to 0.024, 0.056, 1.625 and 0.564 mg eq/kg, respectively. In contrast to hydrolysis of the hay extract, a pellet was formed during hydrolysis of the straw extract. Therefore values of analysed residues are given as sum of supernatant and dissolved pellet.

Identification rates after hydrolytic treatment increased for wheat hay from 66.0% of the TRR (2.659 mg eq/kg) before hydrolysis to 75.3% of the TRR (3.035 mg eq/kg) after hydrolysis and for wheat straw from 77.1% of the TRR (11.969 mg eq/kg) before hydrolysis to 81.6% of the TRR (12.666 mg eq/kg) after hydrolysis. Two major metabolites were formed after acidic hydrolysis as a result of de-conjugation of residues: BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). BCS-CN88460-desmethyl-propanol (**M06**) in wheat hay accounted for 6.9% of the TRR (0.277 mg eq/kg) and 3.6% of the TRR (0.564 mg eq/kg) in conventional extract from wheat straw. Metabolite BCS-CN88460-propanol (**M01**) was detected in hydrolysed extract from wheat hay and straw accounting for 22.3% of the TRR (0.901 mg eq/kg) and 10.5% of the TRR (1.625 mg eq/kg), respectively.

Based on these results it can be concluded that a significant amount of residues in the conventional extracts of hay and straw consists of conjugates of BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). A comparison of the distribution of parent compound and metabolites in the conventional wheat hay and straw extracts before and after hydrolysis is given in the table below.

Analogous hydrolysis experiments were performed in the parallel study with the phenyl-label showing good accordance with the current study.

B.7.2.1.1.2. [phenyl-UL-4-^{14}C]isoflucypram

Report:	KCA 6.2.1/04; Traub, M.; 2018
Title:	Amendment no.1 to final report - Metabolism of [phenyl-UL-^{14}C] BCS-CN88460 in wheat plants
Report No.:	S14-01086
Document No.:	M-604358-02-1
Guidelines:	OECD Test Guideline 501; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300; JAP FAMIC-ACIS Notification 12 Nousan 8147.
Guideline deviations:	None
GLP/GEP:	Yes

Summary

The metabolism of the novel fungicide **isoflucypram** was investigated in wheat plants after two spray applications. For each of the two foliar applications the test item [phenyl-UL-^{14}C]BCS-CN88460 was formulated as an aqueous EC 50 using a nominal application rate of 65 g a.s./ha. The applications were performed at growth stage BBCH 30 (beginning of stem elongation) and BBCH 69 (end of flowering). The actual application rates corresponded to 64 and 66 g a.s./ha for the first and second application, respectively resulting in a total application rate of 130 g a.s./ha.

Wheat hay was harvested at BBCH 69, 1 day prior to the second application, wheat straw and grain were harvested at maturity (BBCH 89). The total radioactive residues (TRR) in wheat straw and hay amounted to 16.031 mg eq/kg and 3.040 mg eq/kg, respectively. The TRR in wheat grain was 0.284 mg eq/kg.

Homogenised plant material from the RACs was conventionally extracted with a mixture of acetonitrile/water (8/2, v/v). The extraction rates after conventional extraction of wheat hay, straw and grain were high and amounted to 96.7% (2.940 mg eq/kg) of the TRR for hay, 95.2% (15.264 mg eq/kg) of the TRR for straw and 93.5% (0.266 mg eq/kg) of the TRR for grain. The post extraction solids (PES) of all RACs remaining after conventional extraction amounted to ≤ 6.5% of TRR.

Residues in the conventional extracts were analysed and quantified by HPLC. The parent compound was identified by co-chromatography with the reference compound and metabolites were assigned by comparison of the metabolite pattern and retention times found in this study with that found in the wheat metabolism study conducted with the ^{14}C-pyrazole label.

The parent substance **isoflucypram** represented the most prominent residue component in all RACs accounting for 54.7% of TRR (1.661 mg eq/kg) in wheat hay, 62.1% of TRR (9.954 mg eq/kg) in wheat straw and 92.7% of TRR (0.264 mg eq/kg) in wheat grain. Besides parent compound no other metabolite was detected in the extract of grain. In wheat straw five metabolites were identified besides parent compound: BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) accounting for 2.3% (0.373 mg eq/kg), 1.9% (0.306 mg eq/kg), 5.0 (0.808 mg eq/kg), 0.9 (0.147 mg eq/kg) and 0.3% (0.052 mg eq/kg) of the TRR, respectively. BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-propanol (**M01**) were also identified in wheat hay and amounted to 0.8% (0.023 mg eq/kg), 2.7% (0.081 mg eq/kg), 7.5% (0.229 mg eq/kg) and 0.7% (0.021 mg eq/kg) of the TRR, respectively.

Overall, identification rates were sufficient and amounted to 72.6% of TRR for straw, 66.3% of TRR for hay and 92.7% of TRR for grain. In wheat hay and straw, 23 and 39 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤ 3.1% (0.095 mg eq/kg) and 2.1% (0.345 mg eq/kg) of the TRR, respectively.

Comparison of metabolic profiles with those of a parallel study with [pyrazole-4-^{14}C]BCS-CN88460 revealed a high correspondence and no label specific metabolites were observed for either label.

More conjugates might be present among the characterised unknown metabolites in the chromatograms. Therefore, acid hydrolysis (1 M HCl, 100 °C, 1 h) of the conventional extracts of wheat hay and straw was conducted in order to analyse for hydrolysable conjugates. Major hydrolysis products detected in the acidic hydrolysates besides parent compound were BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). Identification rates after hydrolytic treatment increased. Based on these results it can be concluded that a significant amount of residues in the conventional extracts of hay and straw consists of conjugates of BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). Analogous hydrolysis experiments were performed in the parallel study with the pyrazole-label and showed good accordance with these results.

Storage stability was demonstrated for residues in wheat hay and straw by extraction and comparison of extracts for up to 30 months.

As metabolic reactions, hydroxylation of the propyl group followed by conjugation with hexose and malonic acid and the demethylation of the pyrazole moiety were observed.

Based on these results, the degradation behaviour of [phenyl-UL-^{14}C]BCS-CN88460 in wheat is adequately understood and a pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * Denotes the position of the ^{14}C-label
Radiolabel position	[phenyl-UL-^{14}C]
Specific radioactivity	4.13 MBq/mg
Radiochemical purity	100%
Chemical purity	> 98%

Formulation of the test compound

A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile to give a concentration of about 5 mg/mL. The purity was checked by HPLC with radio detection and was 100%. The test compound was formulated as an EC 50 for the experiment. The active substance [phenyl-UL-^{14}C]BCS-CN88460 was dissolved in acetonitrile. For each spray dilution, adequate parts of the stock solution were transferred into special glass vials and evaporated to dryness. Blank formulation was added and the mixtures were homogenised using a magnetic stirrer. The sample was then adjusted with water to a final volume of 100 mL of the spray dilution and homogenised by stirring.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**CEC**
Sandy loam	2.1%	7.23	15.5 meq/100 g

3. Plant: Wheat, variety “KADRILJ”, representative for cereals

B. Study Design

1. Experimental conditions:

The experiment was conducted with wheat plants based on a plant density of 5,000,000 wheat plants per hectare. A planting container with a surface area of 1 m^2 was used corresponding to the rate of 500 grains per m^2. The plants were treated at two different growth stages (BBCH 30 and 69). The experiment was conducted, representing the intended application type for BCS-CN88460. The formulated test compound was applied to the wheat plants at a target rate of 2 x 65 g a.s./ha. The planting container was filled with sandy loam soil "CUPF_soil". The plants were cultivated in a glass-roofed greenhouse under normal temperature and light conditions, but protected from rainfall. The plants were watered by pouring water onto the soil in the planting containers.

The wheat plants were treated with 100 mL of the aqueous spray dilutions as a spray using a

controlled track sprayer with a flat fan nozzle. At the 1st application 26.3 MBq of the labelled test compound were applied, corresponding to 6.4 mg. At the 2nd application 27.1 MBq were applied, corresponding to 6.6 mg. The total actual treatment rate was 64 and 66 g a.s./ha. The seed density was 500 grains/m^2. After spraying the spray dilution onto the wheat plants of the planting container, the spray device and the protective plastic foil around the planting container were rinsed with acetonitrile/water (8/2; v/v). The actual amount applied was calculated by subtracting the losses from the radioactivity in the original application solution.

2. Sampling:

At growth stage BBCH 69 the RAC hay and at BBCH 89 the RACs straw and grain were harvested. Plant samples were collected by cutting approximately 1-2 cm above the soil level. Plants sampled at hay stage were dried for 4 days. The total weight of each sample was determined. The samples were homogenised with liquid nitrogen using a high speed blender. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates were extracted conventionally. The final TRR values of the samples were determined by summing up the radioactivity measured in the conventional extracts and in the remaining solids.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

Aliquots of the homogenised samples of wheat hay, straw and grain were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and homogenised; aliquots were subjected to combustion.

The extracts were combined and subjected to a clean-up step using a SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. The less polar, remaining fractions were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v). The volume and radioactivity of this fraction was determined. Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder. The final conventional extracts were then analysed by HPLC. All wheat samples and extracts were stored in a freezer (≤ -18 °C).

Hydrolysis of the conventional extracts from wheat hay and straw:

Hydrolysis experiments in acidic medium were conducted with conventional extracts of wheat hay and straw, to further characterise the residues. Aliquots of the conventional concentrated purified extract of wheat hay and straw were incubated with 1 M HCl and 5% acetonitrile at 100 °C for 1 hour and afterwards centrifuged. For wheat straw, the supernatant was removed and the pellet was dissolved in acetonitrile/water (1/1; v/v) whereas no pellet was formed during processing of wheat hay. Aliquots of the extracts were analysed by HPLC.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent/ scintillation cocktail mixture and the radioactivity was measured by LSC.

Parent compound and metabolites were quantified in the extracts by HPLC with radio detection based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

2. Identification and characterisation:

The metabolic profiles of all RACs were compared with each other and also with the corresponding RACs from the wheat metabolism study conducted using pyrazole labelled **isoflucypram** in which the

major metabolites were identified spectroscopically. Parent compound was identified in wheat grain extract by TLC and HPLC co-chromatography with non-radiolabelled and radiolabelled reference compound BCS-CN88460. Metabolic profiles of wheat hay and straw before and after hydrolysis were compared with corresponding profiles of the wheat metabolism study conducted using the pyrazole label, as analysed by HPLC.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-9: Reference compound

Report name / other names/codes	Chemical Name (IUPAC)	Structure
Parent compound BCS-CN88460 Radiolabeled reference: S_PH_1_1000 Non-radiolabeled reference: BCS-CN88460-01-02	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

All extraction experiments with wheat hay and straw and the first HPLC analyses were performed within one month after harvest of the wheat plant raw material. The stability of the stored extract of wheat hay, straw and grain was demonstrated by re-analysis of the extract by HPLC after 30, 28 and 15 months of storage, respectively.

A second analysis of wheat straw and grain was needed for analytical reasons and performed after 30 months of storage of the respective plant material after harvest. The storage stability of these samples could be demonstrated.

It was therefore concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The TRR values of the individual RACs were determined by summing up the radioactivity determined in the combined extracts and post extraction solids. The residue levels are shown in mg active substance equivalents per kg sample material (mg eq/kg). The TRR in wheat hay and straw amounted to 3.040 mg eq/kg and 16.031 mg eq/kg, respectively. Wheat grain showed a TRR of 0.284 mg eq/kg.

Table 7.2.1-10: TRR in wheat matrices after foliar application of [phenyl-UL-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Wheat hay	1 spray application at BBCH 30: 64 g a.s./ha	32	3.040
Wheat straw	2 spray applications at BBCH 30 and BBCH 69: 64 and 66 g a.s./ha (130 g a.s./ha total)	18	16.031
Wheat grain		18	0.284

* PHI: Pre-Harvest Interval

Wheat hay was conventionally extracted three times with acetonitrile/water mixtures releasing 96.7% of the TRR (2.940 mg eq/kg). After purification and concentration steps 96.2% of the TRR (2.925 mg eq/kg) was analysed. Losses during sample clean up were 0.5% of TRR (0.015 mg eq/kg).

Wheat straw was conventionally extracted three times with acetonitrile/water mixtures releasing 95.2% of the TRR (15.264 mg eq/kg). After purification and concentration steps 93.1% of the TRR (14.922 mg eq/kg) was analysed. Losses during sample clean-up of straw samples were 2.1% of TRR (0.342 mg eq/kg).

Wheat grain was conventionally extracted three times with acetonitrile/water mixtures releasing 93.5% of the TRR (0.266 mg eq/kg). Based on the low amount of radioactivity (0.001 mg/kg) and high matrix load the third extract was not combined. After purification and concentration steps 92.7% of the TRR (0.264 mg eq/kg) was analysed. Losses during sample clean up were 0.8% of TRR (0.002 mg eq/kg).

The distribution of the radioactive residues is shown in the following table.

Table 7.2.1-11: Distribution of radioactivity in the extracts of wheat matrices after two foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

losses during clean up, concentration, centrifugation, etc.

In the conventional extract from wheat hay 66.3% of the TRR (2.015 mg eq/kg) was identified in total. The parent compound was the major component representing 54.7% of the TRR (1.661 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-propanol (**M01**) represented 0.8, 2.7, 7.5 and 0.7% of the TRR corresponding to 0.023, 0.081, 0.229 and 0.021 mg eq/kg, respectively.

In the conventional extract from wheat straw 72.6% of the TRR (11.640 mg eq/kg) were identified in total. The parent compound was the major component representing 62.1% of the TRR (9.954 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**) represented 2.3, 1.9, 5.0, 0.3 and 0.9% of the TRR corresponding to 0.373, 0.306, 0.808, 0.052 and 0.147 mg eq/kg, respectively.

The conventional extract from wheat grain contained only parent compound representing 92.7% of the TRR corresponding to 0.264 mg eq/kg. The compound was identified by co-chromatography using HPLC and TLC.

The TRR and the distribution of parent and metabolites in wheat matrices are shown in the following table.

n.d. not detected

In wheat hay and straw, 23 and 39 unknown metabolites were characterised in the extracts, individually accounting for ≤ 3.1% (0.095 mg eq/kg) and ≤ 2.1% (0.345 mg eq/kg) of the TRR, respectively.

More conjugates might be present among the characterised unknown metabolites in the chromatograms. Therefore, acid hydrolysis (1 M HCl, 100 °C, 1 h) of the conventional extracts of wheat hay and straw were conducted in order to analyse for hydrolysable conjugates

In hydrolysed extract of wheat hay 95.2% of the TRR (2.893 mg eq/kg) were analysed. The parent compound was the major component representing 49.6% of the TRR (1.508 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) represented 0.6, 21.1 and 6.7% of the TRR corresponding to 0.019, 0.642 and 0.204 mg eq/kg, respectively.

In hydrolysed extract of wheat straw 92.5% of the TRR (14.832 mg eq/kg) were analysed. The parent compound was the major component representing 60.8% of the TRR (9.751 mg eq/kg), whereas the metabolites BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) represented 0.3 0.3, 0.1, 12.7 and 4.0% of the TRR corresponding to 0.053, 0.054, 0.022, 2.046 and 0.644 mg eq/kg, respectively. In contrast to hydrolysis of the hay extract, a pellet was formed during hydrolysis of the straw extract. Therefore values of analysed residues are given as sum of supernatant and dissolved pellet.

Identification rates after hydrolytic treatment increased for wheat hay from 66.3% of the TRR (2.015 mg eq/kg) before hydrolysis to 78.0% of the TRR (2.373 mg eq/kg) after hydrolysis and for wheat straw from 72.6% of the TRR (11.640 mg eq/kg) before hydrolysis to 78.2% of the TRR (12.570 mg eq/kg) after hydrolysis. Two major metabolites were formed after acidic hydrolysis as a result of de-conjugation of residues: BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). BCS-CN88460-desmethyl-propanol (**M06**) in wheat hay accounted for 6.7% of the TRR (0.204 mg eq/kg) and 4.0% of the TRR (0.644 mg eq/kg) in the hydrolysed extract from wheat straw. Metabolite BCS-CN88460-propanol (**M01**) was detected in hydrolysed extract from wheat hay and straw accounting for 21.1% of the TRR (0.642 mg eq/kg) and 12.7% of the TRR (2.046 mg eq/kg), respectively.

Based on these results it can be concluded that a significant amount of residues in the conventional extracts of hay and straw consists of conjugates of BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). A comparison of the distribution of parent compound and metabolites in the conventional wheat hay and straw extracts before and after hydrolysis is given in the table below.

Analogous hydrolysis experiments were performed in the parallel study with the pyrazole-label showing good accordance with the current study.

B.7.2.1.1.3. Summary of isoflucypram metabolism in wheat

The metabolism of **isoflucypram** in wheat was investigated after two foliar applications at growth stages BBCH 30 and BBCH 69. The wheat plants were treated with either [pyrazole-4-^{14}C]BCS-CN88460 or [phenyl-4-^{14}C]BCS-CN88460 formulated as an EC 50 at a nominal individual application rate of 65 g a.s./ha (actual: 64-69 g a.s./ha) corresponding to a total nominal application rate of 130 g a.s./ha (actual: 130-136 g a.s./ha). Wheat hay was harvested at BBCH 69, 1 day prior to the second application; wheat straw and grain were harvested at maturity (BBCH 89).

Residues in wheat grain were significantly lower than those in wheat hay and straw. The extraction rates of hay, straw and grain were high. Overall, identification rates in wheat hay, straw and grain were sufficient. In all RACs, parent compound **isoflucypram** was the main residue component and the only component in wheat grain. Besides parent compound, other metabolites were identified in wheat straw and hay: BCS-CN88460-propanol-Glyc (**M18**), BCS-CN88460-desmethyl-propanol-Glyc-MA (**M41**), BCS-CN88460-propanol-Glyc-MA (**M21**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**).

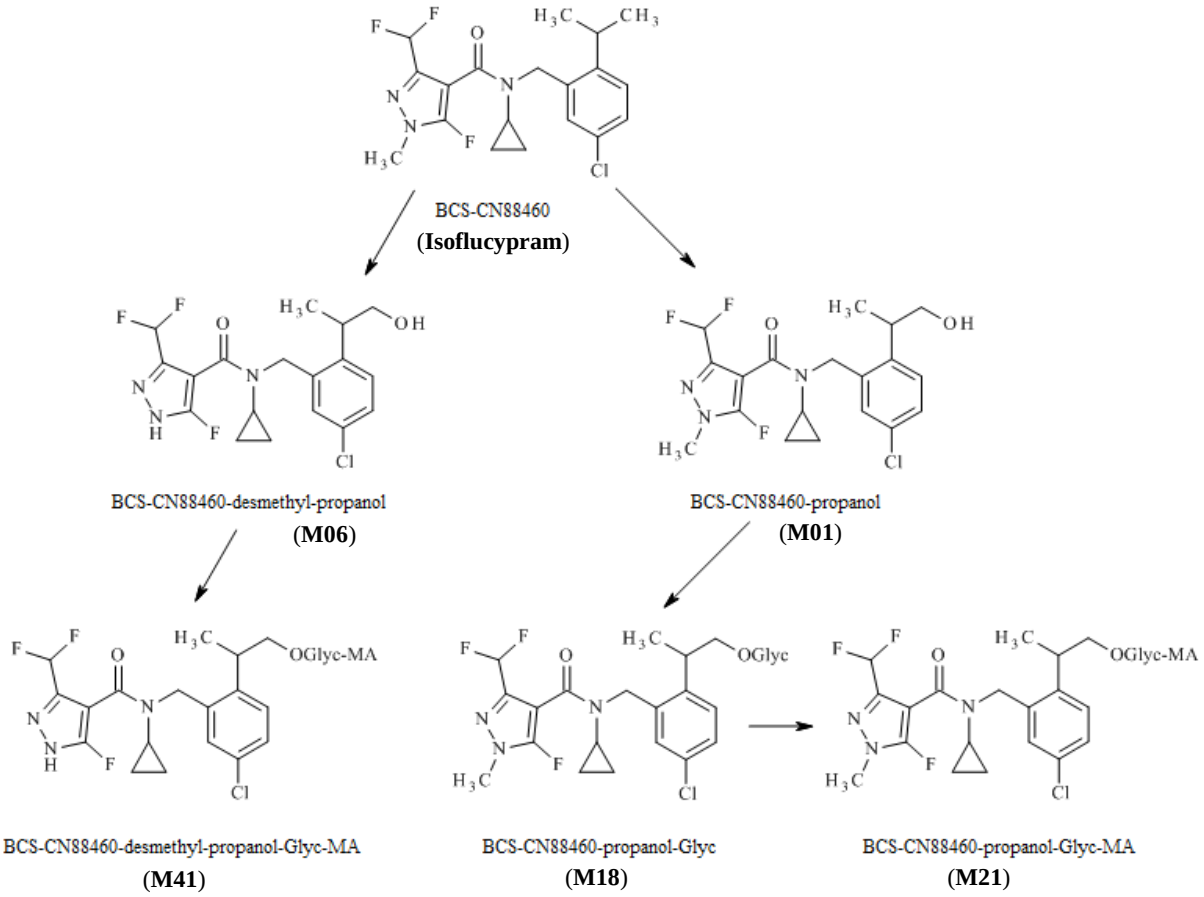
The results from the studies involving the pyrazole- and phenyl-labelled **isoflucypram** are in close agreement. No label specific metabolites were observed using either label. In both studies, acid hydrolysis of the conventional extracts of wheat hay and wheat straw showed cleavage of the identified conjugates to the aglycons BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) and the presence of further conjugates of the aforementioned aglycons.

BCS-CN88460 was found to be moderately metabolised in wheat after two post-emergence applications. The main metabolic reactions are listed below:

- hydroxylation in position 1 of the propyl group followed by conjugation with hexose and malonic acid;
- demethylation of the pyrazole moiety.

Based on these results, the degradation behaviour of **isoflucypram** in wheat is adequately understood and a metabolic pathway is proposed in the figure below:

Figure 7.2.1-1: Proposed metabolic pathway of isoflucypram in wheat



B.7.2.1.2. **Tomatoes (foliar treatment)**

Metabolism studies in tomatoes were conducted with [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C]BCS-CN88460.

Table 7.2.1-14: Overview of tomato metabolism studies

Plant	Application	Target application rate	BBCH Code	Reference
Tomato	Two foliar spray applications, pyrazole-labelled **isoflucypram**	2 x 75 g a.s./ha	BBCH 14-15 and BBCH 85-86	M-597485-01-1
Tomato	Two foliar spray applications, phenyl-labelled **isoflucypram**	2 x 75 g a.s./ha	BBCH 14-15 and BBCH 85-87	M-597481-01-1

GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** in tomato fruits was investigated after two post-emergence spray applications. The test compound, [pyrazole-4-^{14}C]BCS-CN88460, was formulated as an EC 200 and applied to two tomato plants at growth stages BBCH 14 - 15 (four or five leaves unfolded) and BBCH 85 - 86 (50-60% of ripe fruits), i.e. a total of two applications per plant. The total actual application rate was 27.97 mg a.s., corresponding to an application rate of 168 g a.s./ha based on a plant density of 12,000 tomato plants/ha.

Tomato fruits were harvested at the end of the fruit ripening period (BBCH 87 -89). After surface washing with dichloromethane, tomato fruits were homogenised and sufficiently extracted by conventional methods with a mixture of acetonitrile/water.

The TRR in tomato fruits was calculated based on the radioactivity in the surface wash solution and the fruit sample and amounted to 0.170 mg a.s. equivalents/kg in total. The largest portion of the TRR was detected in the surface wash solution (0.125 mg/kg, 73.6% of the TRR). The fruit extract and post-extraction solids (PES) amounted to 0.045 mg/kg (26.1% of the TRR) and < 0.001 mg/kg (0.2% of the TRR), respectively.

Parent compound was the main compound in the tomato fruit sample and amounted to 0.165 mg/kg, 96.7% of the TRR (sum of surface wash solution and extracts). Only four very minor metabolites (total 0.007 mg/kg, single compound ≤0.003 mg/kg) were detected in the surface wash solution and tomato fruit extracts.

Parent compound was identified in an isolated fraction of the surface wash solution by spectroscopic methods and confirmed in extract of fruits by HPLC co-chromatography with the reference compound.

Based on these results, it can be reasonably assumed that no relevant metabolisation of [pyrazole-4-^{14}C]BCS-CN88460 occurs in tomato fruits after foliar treatment.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[pyrazole-4-^{14}C]
Specific radioactivity	4.22 MBq/mg
Radiochemical purity	> 99%
Chemical purity	99%

Formulation of the test compound

Stock solutions were prepared by dissolving of the test compound in acetonitrile. The identity of the test compound in the stock solution was confirmed by spectroscopic methods (LC-MS/MS and

^{1}H-NMR). Adequate parts of the stock solution were transferred into glass vials and evaporated to dryness. The formulation concentrate was prepared by combining the test compound with a corresponding amount of the EC 200 blank formulation. The formulation concentrate was homogenised using a vortex mixer. Afterwards, the formulation was diluted with water by stirring or swirling in order to obtain the ready-to-use application solutions.

2. Soil: "Einheitserde T", pH ($CaCl_2$) = 5.8, 15 vol.% clay.

3. Plant: Tomato, variety "Philona", representative for fruiting crops.

B. Study Design

1. Experimental conditions:

Two tomato plants (*Lycopersicon lycopersicum*, variety: Philona) were cultivated under natural temperature and light conditions in the vegetation area of the test facility. Plants were irrigated as needed to maintain the optimal growth conditions. Each plant was grown in its own planting container (30 L pots). The containers were filled with white moor peat and "Einheitserde T" and marked with the name of the test compound, study number and radioactivity symbol.

The application conditions simulated two spray applications each with an intended application rate of 75 g a.s./ha. The first treatment was performed at growth stage BBCH 14 - 15 (four or five leaves unfolded). The plants were treated with 100 mL of the application solutions. At the first application 55.66 MBq of the labelled test compound were applied to two tomato plants, corresponding to 79.14 g a.s./ha. At the second application (performed at BBCH 85 – 86; 50-60% of ripe fruits) 62.35 MBq of the labelled test compound were applied to two tomato plants, corresponding to 88.65 g a.s./ha.

Taking into the account the amount of radioactivity found in the rinsing solution of the sprayer equipment, a total amount of 118.01 MBq (27.97 mg) was applied onto the two tomato plants. This resulted in a total mean application rate of 168 g a.s./ha based on a plant density of 12,000 tomato plants/ha.

2. Sampling:

Tomato fruits were collected at BBCH 87 – 89, 14 days after the second treatment, weighed and subdivided into two aliquots.

For investigation of the metabolic pathway, a subset of fruits was washed by dipping the fruits into a dichloromethane bath. Afterwards the fruits were diced and homogenised. Aliquots were stored at approximately ≤ -18 °C until extraction.

C. Analytical Procedures

1. Extraction:

After surface washing with dichloromethane, the tomato fruits sample was conventionally extracted three times with mixtures of acetonitrile/water (8/2; v/v) using a high speed blender. The combined extracts were subjected to a clean-up step using an SPE RP 18 cartridge and rinsed with acetonitrile/water (8:2, v/v) and methanol/dichloromethane (1:1, v/v). The surface wash solution and the SPE percolate and rinse were concentrated and analysed by HPLC.

The TRR value of the fruit sample was calculated by summing up the radioactivity in the surface wash, the extract and the post extraction solids (PES) based on the weight of the sample used and the specific radioactivity.

2. Identification and characterisation:

Parent compound and metabolites were quantified in the surface wash solution and in the conventional

extract of tomato fruits by HPLC analysis based on reversed phase chromatography (RP 18) with an acidic water/acetonitrile/THF gradient.

Parent compound was identified by spectroscopic methods in the surface wash and by co-chromatography with reference compound in the extract. The peaks in the individual HPLC profiles of the extracts were numbered in ascending order according to appearance in the chromatogram. Corresponding peaks in the HPLC profiles were designated with the same number. Unidentified metabolites were designated with "unknown" and numbered in ascending order. Corresponding unidentified metabolites in the different HPLC profiles were designated with the same number.

Table 7.2.1-15: Reference compound

Report name	Chemical name (IUPAC)	Chemical Structure
Parent compound (BCS-CN88460)	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

Extraction and quantification of four trace metabolites and parent compound were finished within six month. Hence, no further stability investigations were conducted.

II. Results and Discussion

The metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in tomatoes was investigated after two spray applications.

The TRR value of the tomato fruit sample was calculated by summing up the radioactivity determined in the surface wash solution, the extract and the post extraction solids (PES) based on the weight of the sample used for extraction and the specific radioactivity of the test compound. The TRR for the fruit sample was low considering the application rate and amounted to 0.170 mg/kg.

Table 7.2.1-16: TRR value in tomato fruits after foliar application of [pyrazole-4-^{14}C]BCS-CN88460

Matrix	Timing and Application	Growth stage at harvest	PHI* (days)	TRR (mg a.s. equiv./kg)
Tomato fruits	Two foliar spray applications at BBCH 14-15 and BBCH 85-86 Total application rate: 168 g a.s./ha	BBCH 87 - 89	14	0.170

* PHI: Pre-Harvest Interval

For tomato fruits, the main portion of the radioactivity (0.125 mg/kg, 73.6% of the TRR) was detected in the surface wash solution. Residues in the tomato fruit sample were efficiently extracted with conventional methods using acetonitrile/water (8/2; v/v) and amounted to 26.1% (0.045 mg/kg) of the TRR. The post extraction solids amounted to 0.2% (< 0.001 mg/kg) of the TRR, only. There were no losses during the sample preparation and no radioactivity was observed in the distillate of the concentration procedures.

Table 7.2.1-17: Distribution of radioactivity in the extracts of the tomato fruits after two foliar applications of [pyrazole-4-^{14}C]BCS-CN88460

Sample	Tomato fruits	
	% of TRR	mg/kg
TRR	**100**	**0.170**

GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** in tomato fruits was investigated after two post-emergence spray applications. The test compound, [phenyl-UL-^{14}C]BCS-CN88460, was formulated as an EC 200 and applied to two tomato plants at growth stages BBCH 14 - 15 (four or five leaves unfolded) and BBCH

85 - 87 (50-70% of ripe fruits), i.e. a total of two applications per plant. The total actual application rate was 26.02 mg a.s., corresponding to an application rate of 156 g a.s./ha based on a plant density of 12,000 tomato plants/ha.

Tomato fruits were harvested at the end of the fruit ripening period (BBCH 87 -89). After surface washing with dichloromethane, tomato fruits were homogenised and sufficiently extracted by conventional methods with a mixture of acetonitrile/water.

The TRR in tomato fruits was calculated based on the radioactivity in the surface wash solution and the fruit sample and amounted to 0.095 mg a.s. equivalents/kg in total. The largest portion of the TRR was detected in the surface wash solution (0.071 mg/kg, 74.6% of the TRR). The fruit extract and post-extraction solids (PES) amounted to 0.024 mg/kg (25.1% of the TRR) and < 0.001 mg/kg (0.2% of the TRR), respectively.

Parent compound was the main compound in the tomato fruit sample and amounted to 0.094 mg/kg, 98.2% of the TRR (sum of surface wash solution and extracts). Only two very minor metabolites (total 0.002 mg/kg, single compound ≤0.001 mg/kg) were detected in the surface wash solution and tomato fruit extracts.

Parent compound was identified in extract of fruits by HPLC co-chromatography with reference compound.

Based on these results, it can be reasonably assumed that no relevant metabolisation of [phenyl-UL-^{14}C]BCS-CN88460 occurs in tomato fruits after foliar treatment.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[phenyl-UL-^{14}C]
Specific radioactivity	4.13 MBq/mg
Radiochemical purity	> 99%
Chemical purity	> 99%

Formulation of the test compound

Stock solutions were prepared by dissolving of the test compound in acetonitrile. The identity of the test compound in the stock solution was confirmed by spectroscopic methods (LC-MS/MS and ^{1}H-NMR). Adequate parts of the stock solution were transferred into glass vials and evaporated to dryness. The formulation concentrate was prepared by combining the test compound with a corresponding amount of the EC 200 blank formulation. The formulation concentrate was homogenised using a vortex mixer. Afterwards, the formulation was diluted with water by stirring or swirling in order to obtain the ready-to-use application solutions.

2. Soil: "Einheitserde T", pH (CaCl2) = 5.8, 15 vol.% clay

3. Plant: Tomato, variety "Philona", representative for fruiting crops

B. Study Design

1. Experimental conditions:

Two tomato plants (Lycopersicon lycopersicum, variety: Philona) were cultivated under natural temperature and light conditions in the vegetation area of the test facility. Plants were irrigated as needed to maintain the optimal growth conditions. Each plant was grown in its own planting container (30 L pots). The containers were filled with white moor peat, “Einheitserde T” and marked with the name of the test compound, study number and radioactivity symbol.

The application conditions simulated two spray applications each with an intended application rate of 75 g a.s./ha. The first treatment was performed at growth stage BBCH 14 - 15 (four or five leaves unfolded). The plants were treated with 100 mL of the application solutions. At the first application 53.99 MBq of the labelled test compound were applied to two tomato plants, corresponding to 78.4 g a.s./ha. At the second application (performed at BBCH 85 – 87; 50-70% of ripe fruits) 53.5 MBq of the labelled test compound were applied to two tomato plants, corresponding to 77.7 g a.s./ha.

Taking into the account the amount of radioactivity found in the rinsing solution of the sprayer equipment, a total amount of 107.49 MBq (26.02 mg) was applied onto the two tomato plants. This resulted in a total mean application rate of 156.1 g a.s./ha based on a plant density of 12,000 tomato plants/ha.

2. Sampling:

Tomato fruits were collected at BBCH 87 – 89, 14 days after the second treatment, weighed and subdivided into two aliquots.

For investigation of the metabolic pathway, a subset of fruits was washed by dipping the fruits into a dichloromethane bath. Afterwards the fruits were diced and homogenised. Aliquots were stored at approximately ≤ -18 °C until extraction.

C. Analytical Procedures

1. Extraction:

After surface washing with dichloromethane, the tomato fruit sample was conventionally extracted three times with mixtures of acetonitrile/water (8/2; v/v) using a high speed blender. The combined extracts were subjected to a clean-up step using an SPE RP 18 cartridge and rinsed with acetonitrile/water (8:2, v/v) and THF/methanol (1:1, v/v). The surface wash solution and the SPE percolate and rinse were concentrated and analysed by HPLC.

The TRR value of the fruit sample was calculated by summing up the radioactivity in the surface wash, the extract and the post extraction solids (PES) based on the weight of the sample used and the specific radioactivity.

2. Identification and characterisation:

Parent compound and metabolites were quantified in the surface wash solution and in the conventional extract of tomato fruits by HPLC analysis based on reversed phase chromatography (RP 18) with an acidic water/acetonitrile/THF gradient.

Parent compound was identified by co-chromatography with the reference compound. The peaks in the individual HPLC profiles of the extracts were numbered in ascending order according to appearance in the chromatogram. Corresponding peaks in the HPLC profiles were designated with the same number. Unidentified metabolites were designated with "unknown” and numbered in ascending order. Corresponding unidentified metabolites in the different HPLC profiles were designated with the same number.

Table 7.2.1-19: Reference compound

Report Name	Chemical Name (IUPAC)	Chemical Structure
Parent compound (BCS-CN88460)	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

Extraction and quantification of four trace metabolites and parent compound were finished within six month. Hence, no further stability investigations were conducted.

II. Results and Discussion

The metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in tomatoes was investigated after two spray applications.

The TRR value of the tomato fruit sample was calculated by summing up the radioactivity determined in the surface wash solution, the extract and the post extraction solids (PES) based on the weight of the sample used for extraction and the specific radioactivity of the test compound. The TRR for the fruit sample was low considering the application rate and amounted to 0.095 mg/kg.

Table 7.2.1-20: TRR value in tomato fruits after foliar application of [phenyl-UL-^{14}C]BCS-CN88460

Matrix	Timing and Application	Growth Stage at Harvest	PHI* (days)	TRR (mg a.s. equiv./kg)
Tomato fruit	Two foliar treatments at BBCH 14-15 and BBCH 85-87 Total application rate: 156 g a.s./ha	BBCH 87 - 89	14	0.095

*PHI: Pre-Harvest Interval

For tomato fruits, the main portion of the radioactivity (0.071 mg/kg, 74.6% of the TRR) was detected in the surface wash solution. Residues in the tomato fruit sample were efficiently extracted with conventional methods using acetonitrile/water (8/2; v/v) and amounted to 25.1% (0.024 mg/kg) of the TRR. The post extraction solids amounted to 0.2% (< 0.001 mg/kg) of the TRR, only. There were no losses during the sample preparation and no radioactivity was observed in the distillate of the concentration procedures.

The distribution of the radioactive residues is shown in the following table:

Table 7.2.1-21: Distribution of radioactivity in the extracts of the tomato fruits after two foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

Sample	Tomato fruits	
	% of TRR	mg/kg
TRR	**100**	**0.095**
Surface wash solution	74.6	0.071
Conventional extract	25.1	0.024
Losses (distillate)	---	---
Total extracted	**99.8**	**0.095**
Post extraction solids (PES)	**0.2**	**<0.001**
Accountability	**100.0**	**0.095**

Besides parent compound (0.094 mg/kg, 98.2% of the TRR), only two very minor metabolites (≤0.001 mg/kg) were detected in the surface wash solution and tomato fruit extracts.

The TRR and the distribution of parent and metabolites in tomato fruits are shown in the following table.

Table 7.2.1-22: Distribution of parent compound and metabolites in the extracts of tomato fruits after two foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

Sample	Tomato fruits	
	% TRR	**mg/kg**
TRR	**100**	**0.095**
BCS-CN88460 (parent compound)	98.2	0.094
Total identified	**98.2**	**0.094**
Unknown 1	0.8	0.001
Unknown 2	0.7	<0.001
Total characterised	**1.5**	**0.002**
Analysed extract(s)	99.8	0.095
Extracts not analysed	---	---
Total extracted	**99.8**	**0.095**
Post extraction solids (PES)	0.2	<0.001
Accountability	**100.0**	**0.095**

B.7.2.1.2.3. Summary of isoflucypram metabolism in tomatoes

The metabolism of **isoflucypram** in tomatoes was investigated after two foliar applications at growth stages BBCH 14-15 and BBCH 85-87. The tomato plants were treated with either [pyrazole-4-^{14}C]BCS-CN88460 or [phenyl-4-^{14}C]BCS-CN88460 formulated as an EC 200 at a nominal individual application rate of 75 g a.s./ha (actual: 78-89 g a.s./ha) corresponding to a total nominal application rate of 150 g a.s./ha (actual 156-168 g a.s./ha). Tomato fruits were harvested at the end of the fruit ripening period (BBCH 87-89).

The TRR level in tomatoes was 0.170 mg/kg and 0.095 mg/kg for the pyrazole and phenyl-label, respectively. The radioactive residues were efficiently recovered by surface wash with dichloromethane (73.6%, 0.125 mg/kg of the TRR for the pyrazole label and 74.6%, 0.071 mg/kg for the phenyl label) and conventional extraction with acetonitrile/water mixtures. In total, 99.8% TRR was recovered from the tomatoes in both studies.

Parent compound was the only major component in tomatoes (96.7%, 0.165 mg/kg of the TRR for the pyrazole label and 98.2%, 0.094 mg/kg for the phenyl label).

Therefore, it can be reasonably assumed that no relevant metabolism of **isoflucypram** occurs in tomato fruits after foliar treatment.

B.7.2.1.3. **Oilseed rape (foliar treatment)**

Metabolism studies in oilseed rape were conducted with [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C]BCS-CN88460.

Table 7.2.1-23: Overview of oilseed rape metabolism studies

Plant	Application	Target application rate	BBCH Code	Reference
Oilseed rape	Two foliar spray applications, pyrazole-labelled **isoflucypram**	2 x 60 g a.s./ha	BBCH 14 and BBCH 77	M-609378-01-1
Oilseed rape	Two foliar spray applications, phenyl-labelled **isoflucypram**	2 x 60 g a.s./ha	BBCH 14 and BBCH 77	M-609380-01-1

B.7.2.1.3.1. [pyrazole-4-^{14}C]isoflucypram

Report:	KCA 6.2.1/05; Botterweck, J.; 2017
Title:	Metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in oilseed rape
Report No.:	S16-01038
Document No.:	M-609378-01-1
Guidelines:	OECD Test Guideline 501; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300; JAP FAMIC-ACIS Notification 12 Nousan 8147; PMRA Regulatory Directive DIR 98-02.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** was investigated in oilseed rape plants after two foliar applications. For each of the two foliar applications the test item [pyrazole-4-^{14}C]BCS-CN88460 was formulated as an aqueous EC 50 using a nominal application rate of 60 g a.s./ha each. The applications were performed at the growth stage of BBCH 14 (trifoliolate on the 3rd up to 5th node unfolded) and BBCH 77 (70% of pods have reached final size). The actual application rates corresponded to 64 and 62 g a.s./ha for the first and second application, respectively resulting in a total application rate of 126 g a.s./ha.

Oilseed rape intermediate harvest was harvested at BBCH 30, 2 days after the first application, forage at BBCH 55, 40 days after the first application, and mature plants and seeds were harvested at BBCH 89, 21 days after the second application. The total radioactive residues (TRR) in intermediate harvest and mature plants were high and amounted to 4.751 mg eq/kg and 4.076 mg eq/kg, respectively. The TRR in forage was low due to the increase of plant mass from first application at BBCH 14 until sampling of forage at BBCH 55 and amounted to 0.012 mg eq/kg. The TRR in seeds was low and amounted to 0.099 mg eq/kg.

Homogenised plant material from RACs was conventionally extracted with a mixture of acetonitrile/water (8/2; v/v). The extraction rates after conventional extraction of intermediate harvest, forage, mature plants and seeds were high and amounted to 99.5% (4.730 mg eq/kg) of the TRR for intermediate harvest, 85.4% (0.010 mg eq/kg) of the TRR for forage, 97.4% (3.970 mg eq/kg) of the TRR for mature plants and 71.0% (0.070 mg eq/kg) of the TRR for seeds.

Solids after conventional extraction of seeds were exhaustively extracted using microwave assistance with a mixture of acetonitrile/water/formic acid (50/50/1; v/v/v) releasing further 9.8% (0.010

mg eq/kg) of TRR. The post extraction solids of seeds after microwave extraction were subjected to consecutive enzyme digestion with cellulase and amylase, which released further 1.5% of the TRR (0.002 mg eq/kg). Subsequent extraction under acidic conditions with HCl released 11.0% of the TRR (0.011 mg eq/kg). 8.1% of the TRR (0.008 mg eq/kg) of this extract were further characterised by partitioning with ethyl acetate. In the unpolar ethyl acetate fraction remained 5.4% (0.005 mg eq/kg) of the residues and 2.7% of TRR (0.003 mg eq/kg) remained in the water phase.

The post extraction solids after conventional and exhaustive extractions accounted for 0.5% of the TRR (0.022 mg eq/kg), 14.6% of the TRR (0.002 mg eq/kg), 2.6% of the TRR (0.106 mg eq/kg) and 6.7% of the TRR (0.006 mg eq/kg) for intermediate harvest, forage, mature plants and seeds, respectively.

Residues in the conventional extracts were analysed and quantified by HPLC. The parent compound and metabolites were either identified by co-chromatography with the reference compound or by spectroscopic analysis in isolated fractions of intermediate harvest. Additionally, the metabolite pattern and retention times of the current and the oilseed rape metabolism study with the phenyl label were compared.

The forage extract contained no residue above the limit of detection. Parent compound **isoflucypram** represented the most prominent residue component in all RACs, accounting for 81.9% of TRR (3.890 mg eq/kg) in intermediate harvest, 88.1% of TRR (3.589 mg eq/kg) in mature plants and 71.0% of TRR (0.070 mg eq/kg) in seeds. Parent compound was the only component detected in the extract of seeds.

Besides parent compound four metabolites were identified in intermediate harvest and mature plants.

In intermediate harvest, BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) accounted for 2.3, 2.2, 2.8 and 3.1% of the TRR corresponding to 0.109, 0.106, 0.131 and 0.148 mg eq/kg, respectively.

In mature plants BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) accounted for 0.7, 0.9, 0.6 and 1.0% of the TRR corresponding to 0.027, 0.038, 0.025 and 0.040 mg eq/kg, respectively.

Overall, identification rates were high and amounted to 92.3% of TRR for intermediate harvest, 91.3% of TRR for mature plants and 71.0% of TRR for seeds. In intermediate harvest, 22 unknown metabolites were characterised in the extracts, individually accounting for equal or less than 1.5% of the TRR and 0.072 mg eq/kg and 16 were characterised in mature plants, individually accounting for equal or less than 1.3% of the TRR and 0.054 mg eq/kg.

Comparison of metabolic profiles with those of a parallel study with [phenyl-UL-^{14}C]BCS-CN88460 revealed a high correspondence and no label specific metabolite could be observed for the both labels.

Acid hydrolysis (1 N HCl, 100 °C, 1 h) of the conventional extract of intermediate harvest was performed in order to analyse for hydrolysable conjugates. Comparison of metabolic profiles before and after hydrolysis indicated cleavage of the identified conjugates BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) to less polar compounds. Analogous hydrolysis experiments were performed in a parallel study with the phenyl-label showing good accordance with the current study.

All conventional and exhaustive extraction experiments of the raw agricultural commodities and the first HPLC analyses were performed within three months after harvest of the oilseed rape samples.

As metabolic reactions, hydroxylation in position 1 or 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid and hydroxylation in position 4 of the phenyl moiety followed by conjugation with hexose and malonic acid were observed.

Based on these results, the degradation behaviour of [pyrazole-4-^{14}C]BCS-CN88460 in oilseed rape is adequately understood and a pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[pyrazole-4-^{14}C]
Specific radioactivity	2.11 MBq/mg
Radiochemical purity	> 98% (HPLC); > 99% (TLC)
Chemical purity	> 98%

Formulation of the test compound

The test compound was diluted as a 50:50 mixture of radiolabelled and non-radiolabelled test compound resulting in a calculated final specific activity for the test item of 2.11 MBq/mg. A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile. The purity in the stock solution for both applications and the identity of the test compound in the application dilutions was checked by HPLC with radio detection and was above 98%

The test compound was formulated as an EC 50 for the experiment and therefore [pyrazole-4-^{14}C]BCS-CN88460 was dissolved in acetonitrile. For each of the two spray dilutions, adequate parts of the stock solution were transferred into glass vials and evaporated to dryness. Blank formulation was added and the mixtures were homogenised using a magnetic stirrer. The sample was then adjusted with water to a final volume of 100 mL of the spray dilution and homogenised by stirring.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**CEC**
Sandy loam	2.37%	7.48	20.9 meq/100 g

3. Plant: **Oilseed rape, variety "JERRY", representative for oilseeds.**

B. Study Design

1. Experimental conditions:

The experiment was conducted with oilseed rape plants (variety: JERRY) at the rate of 275 seeds per m^2 in a planting container with a surface area of 1 m^2. The planting container was filled with sandy loam soil. The plants were cultivated in the glass-roofed greenhouse of the test facility and were grown similar to natural temperature and light conditions, but protected from rainfall. They were

watered by pouring onto the soil in the planting containers. The plants were applied at two different growth stages (BBCH 14 and 77). For both applications the target single application rate was 60 g a.s./ha. The target rate corresponds to the anticipated maximum application rate for the use type.

For each application, the plants were treated with 100 mL of the aqueous spray dilutions using a controlled track sprayer with a flat fan nozzle. To avoid contamination of the surrounding area by drift, the plants in the planting container were enclosed with a foil housing. After spraying the spray dilution onto the oilseed rape plants in the planting container, the spray device and the protective plastic foil around the planting container were rinsed with acetonitrile/water (8/2; v/v). The actual amount applied was calculated by subtracting the losses from the radioactivity in the original application solution. At the 1st application 13.5 MBq of the labelled test compound were applied, corresponding to 6.4 mg a.s. At the 2nd application 13.1 MBq of the test compound were applied, corresponding to 6.2 mg a.s. The actual single treatment rates were 64 and 62 g a.s./ha, corresponding to a total actual application rate of 126 g a.s./ha.

2. Sampling:

Two days after the first application (at BBCH 30), the RAC intermediate harvest and 40 days after the first application at BBCH 55, the RAC forage was harvested. The RACs seeds and mature plant (= rest of plant including pods without seeds) were harvested at BBCH 89, 21 days after the 2nd application.

Intermediate harvest, forage and mature plants were sampled by cut-off of the plants 1-2 cm above the soil surface. Seeds were isolated from mature plants by hand. The empty pods were combined with the mature plant sample.

The total weight of each sample was determined. The samples were homogenised with liquid nitrogen using a high speed blender. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates were extracted. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

For conventional extraction of oilseed rape intermediate harvest, forage, mature plants and seeds, aliquots of the homogenised samples were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion.

The extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder. The final conventional extracts were analysed by HPLC with the general profiling method.

Exhaustive extraction and corresponding clean-up:

Solids from the conventional extraction of oilseed rape seeds were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased temperature (0 to 5 min increase to 120 °C, 5 to 20 min at 120 °C, 800 W). The microwave extracts were cooled down at room temperature. After each extraction step, extract and solids were filtrated by

suction and centrifuged and finally the extracts were combined.

Aliquots of the combined extract were subjected to a clean-up step using a SPE RP 18 cartridge, which was rinsed with methanol and water beforehand. The flow-through fraction was collected and the cartridge was rinsed with acetonitrile/water (8/2; v/v). Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

The flow-through fraction and the rinse obtained from SPE purification were combined and mixed with emulsifier and evaporated to the aqueous remainder. The final exhaustive extract was analysed by HPLC with the general profiling method. The extract was stored in a freezer (≤ -18 °C).

Release of residues upon enzymatic digestion:

Solids of oilseed rape seeds after exhaustive extraction were further incubated with cellulase in sodium acetate buffer (0.1 M) to release radioactive residues. The solids were autoclaved in buffer (121 °C, 2 bar vapour pressure) for 2 hours. After autoclaving the sample was cooled down at room temperature and the buffer was set to pH 5 by use of acetic acid. The solution was mixed with 100 mg cellulose, incubated for 24 hours in a water bath at 37 °C and centrifuged.

Solids of oilseed rape seeds remaining after cellulase treatment were further incubated with amylase in sodium acetate buffer (0.1 M) to specifically release radioactive residues previously assimilated to carbohydrates. The solids were autoclaved in buffer (121 °C, 2 bar vapour pressure) for 2 hours. After autoclaving the sample was cooled down to 20 °C and the buffer was set to pH 5 by use of acetic acid. The solution was mixed with 50.0 mg amylase (1.9 units/mg), incubated for 24 hours in a water bath at 37 °C and centrifuged.

Release of residues upon acidic extraction with HCl:

Solids of oilseed rape seeds after enzymatic digestion with cellulase and amylase (approximately 5 g) were further extracted with HCl (5 M, 30 mL) to release radioactive residues. After addition of the HCl solution, the mixture was incubated for 60 minutes at 120 °C under microwave assistance.

Residues contained in the combined extracts obtained by acidic extraction were characterised by partitioning. Therefore, the complete extract was neutralized by addition of 10M NaOH and mixed with ethyl acetate (1/1; v/v) in a separatory funnel and shaken by hand. Ethyl acetate and water phase were separated. The water phase was again mixed with ethyl acetate (1/1; v/v) in a separatory funnel and the procedure was repeated.

Hydrolysis of the conventional extracts from oilseed rape intermediate harvest:

Hydrolysis experiments in acidic medium (1 N HCl) were conducted with concentrated conventional extract from intermediate harvest. Therefore, the final purified extract was mixed with 10 N HCl to obtain a concentration of approximately 1 N HCl and incubated 100 °C for 1 hour. Afterwards, the mixture was adjusted to pH 7 with 10 N NaOH and analysed by HPLC.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent/ scintillation cocktail mixture and the radioactivity was measured by LSC.

Conventional and microwave extracts were analysed by HPLC with radio detection based on reversed phase chromatography using an acidic water/acetonitrile/tetrahydrofuran gradient.

2. Identification and characterisation:

For identification of radioactive ingredients in conventional extract from intermediate harvest, selected major radio signals were isolated as fractions of eluent by HPLC fractionation. Isolated fractions were identified by spectroscopic analysis as following metabolites: BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**)

and BCS-CN88460-hydroxyphenyl-Glyc-MA.

Metabolic profiles of all RACs were compared, as analysed by HPLC among themselves. Metabolic profiles of all RACs were compared with metabolic profiles of corresponding RACs in the oilseed rape metabolism study with the phenyl label. Parent compound was identified in oilseed rape seeds extract by TLC and HPLC co-chromatography with the test compound. Metabolic profiles of oilseed rape intermediate harvest extract before and after acid hydrolysis were compared with corresponding profiles of the oilseed rape metabolism study with the phenyl label, as analysed by HPLC.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-24: Reference compound

Report name / other names/codes	**Chemical Name (IUPAC)**	**Structure**
Parent compound BCS-CN88460 Reference: M-00002258 S1000	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

All conventional extraction experiments of the raw agricultural commodities were performed within two months after harvest of the oilseed rape samples. The exhaustive extraction of seeds was performed within three months after harvest. All first quantitative analyses by HPLC were performed within two days after the start of extraction.

It was therefore concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in oilseed rape was investigated after two spray applications.

Oilseed rape plants were treated with [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC 50 at BBCH 14 (trifoliolate on the 3rd up to 5th node unfolded) and BBCH 77 (70% of pods have reached final size). The actual single application rate corresponded to 64 and 62 g a.s./ha which was slightly above the anticipated maximum application rate (2 x 60 g a.s./ha). The total application rate amounted to 126 g a.s./ha.

The TRR values of the individual RACs were determined by summing up the radioactivity determined in the combined extracts and the radioactivity in the solids. The residue levels are shown in mg active substance equivalents per kg sample material (mg a.s.equiv./kg or simplified mg eq/kg).

TRR values in intermediate harvest and mature plants were high and amounted to 4.751 mg eq/kg and 4.076 mg eq/kg, respectively. The TRR in forage and seeds were low and amounted to 0.012 mg eq/kg and 0.099 mg eq/kg.

The high TRRs found for intermediate harvest and mature plants are due to harvest shortly after the

first foliar application (PHI = 2 d) in case of intermediate harvest or due to sampling after two foliar applications in case of mature plants. For forage, the low TRR can be ascribed to the increase of plant mass from the 1st foliar application at BBCH 14 to sampling 40 days after 1st application at BBCH 55.

Table 7.2.1-25: TRR values in oilseed rape matrices after foliar application of [pyrazole-4-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Intermediate Harvest	1 Spray application at BBCH 14: 64 g a.s./ha	2	4.751
Forage		40	0.012
Mature Plants	2 Spray applications at BBCH 14 and BBCH 77: 64 and 62 g a.s./ha (126 g a.s./ha total)	21	4.076
Seeds		21	0.099

* PHI: Pre-Harvest Interval

Intermediate harvest was conventionally extracted three times with acetonitrile/water mixtures releasing 99.5% of the TRR (4.730 mg eq/kg). Losses during sample clean up accounted for 0.4% of the TRR (0.020 mg eq/kg). After concentration and purification steps 99.1% of the TRR (4.710 mg eq/kg) were analysed. The post extraction solids amounted to 0.5% (0.022 mg eq/kg) of the TRR, only.

Forage was conventionally extracted three times with acetonitrile/water mixtures releasing 85.4% of the TRR (0.010 mg eq/kg). No losses of RA occurred during sample clean-up and 85.4% of the TRR (0.010 mg eq/kg) were analysed. The post extraction solids amounted to 14.6% of the TRR (0.002 mg eq/kg), only.

Mature plants were conventionally extracted three times with acetonitrile/water mixtures releasing 97.4% of the TRR (3.970 mg eq/kg). Losses of RA during sample clean up accounted for 0.2% of TRR and 0.006 mg eq/kg). After concentration and purification steps 97.3% of the TRR (3.964 mg eq/kg) were analysed. The post extraction solids contained 2.6% (0.106 mg eq/kg) of the TRR.

Seeds were conventionally extracted three times with acetonitrile/water mixtures releasing 71.0% of the TRR (0.070 mg eq/kg). No losses of RA occurred during sample clean-up and 71.0% of the TRR (0.070 mg eq/kg) were analysed. The post extraction solids after conventional extraction accounted for 29.0% of TRR (0.029 mg eq/kg).

The PES of seeds were subjected to exhaustive extraction under microwave support. This treatment released 9.8% of the TRR (0.010 mg eq/kg). Losses during sample clean up accounted for 2.2% of the TRR (0.002 mg eq/kg) and 7.6% of the TRR (0.008 mg eq/kg) were analysed by HPLC. Additionally, the solids remaining after exhaustive extraction were incubated consecutively with cellulase and amylase to release further residues. This digestion released 1.5% of the TRR (0.002 mg eq/kg).

Subsequent acidic extraction additionally released 11.0% of the TRR (0.011 mg eq/kg). Losses of RA during neutralization of the acidic extract accounted for 2.9% of TRR (0.003 mg eq/kg). The neutralized extract was further characterised by partitioning with ethyl acetate. 5.4% of the TRR (0.005 mg eq/kg) was detected within the ethyl acetate fraction and 2.7% of the TRR (0.003 mg eq/kg) were detected within the water phase.

In total 93.3% of the TRR (0.093 mg eq/kg) was extracted from seeds. Total losses of RA accounted for 5.1% of the TRR (0.005 mg eq/kg). The post extraction solids amounted to 6.7% (0.006 mg eq/kg) of the TRR.

The distribution of the radioactive residues is shown in the following table.

Table 7.2.1-26: Distribution of radioactivity in the extracts of oilseed rape matrices after two foliar applications of [pyrazole-4-^{14}C]BCS-CN88460

n.q. not quantified (< LOQ)

* no individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of seeds

Comparison of chromatograms from conventional extracts of intermediate harvest and mature plants of the current study among themselves indicated a high grade of comparability. Conventional extract of forage contained no individual radio signal above the background noise whereas conventional extract from seeds contained only the test compound.

The comparison of profiles of all RACs to corresponding profiles of the parallel study performed with [phenyl-UL-^{14}C]BCS-CN88460 revealed that no label specific metabolism could be observed.

In conventional extracts from intermediate harvest 92.3% of the TRR (4.384 mg eq/kg) were identified in total. The parent compound was by far the major component representing 81.9% of the TRR (3.890 mg eq/kg), whereas the BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) represented 2.3, 2.2, 2.8 and 3.1% of the TRR corresponding to 0.109, 0.106, 0.131 and 0.148 mg eq/kg, respectively.

Acid hydrolysis (1 N HCl, 100 °C, 1 h) of the conventional extract of intermediate harvest was performed in order to analyse for hydrolysable conjugates. Comparison of metabolic profiles before and after hydrolysis indicated cleavage of the identified conjugates BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) to less polar compounds. Analogous hydrolysis experiments were performed in the parallel study with the phenyl-label showing good accordance with the current study.

In conventional extracts from forage 85.4% of the TRR was analysed in total (0.010 mg eq/kg). No individual radio signal was above the background noise due to low amounts of total radioactive ingredients in the extract.

In conventional extracts from mature plants 91.3% of the TRR (3.719 mg eq/kg) were identified in total. The parent compound was by far the major component representing 88.1% of the TRR (3.589 mg eq/kg), whereas the metabolites BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) represented 0.7, 0.9, 0.6 and 1.0% of the TRR

corresponding to 0.027, 0.038, 0.025 and 0.040 mg eq/kg, respectively.

In conventional extracts from seeds 71.0% of the TRR (0.070 mg eq/kg) were identified. The parent compound was the only component representing 71.0% of the TRR (0.070 mg eq/kg). Parent compound was identified by HPLC and TLC co-chromatography with the test item as radiolabelled reference compound.

Exhaustive extraction of seeds released further 9.8% of the TRR (0.010 mg eq/kg) and 7.6% of the TRR (0.008 mg eq/kg) were analysed by HPLC. No individual radio signal was above the background noise due to low amounts of total radioactive ingredients in the exhaustive extract. Conventional extract of seeds treated under microwave extraction conditions in comparison of the corresponding conventional extract and exhaustive extract, showed that degradation of parent compound by this treatment was negligible.

The TRR and the distribution of parent and metabolites in oilseed rape matrices are shown in the following table.

Table 7.2.1-27: Distribution of parent compound and metabolites in the extracts of oilseed rape matrices after two foliar applications of [pyrazole-4-^{14}C]BCS-CN88460

In conventional extract of intermediate harvest, 22 unknown metabolites were characterised, individually accounting for equal or less than 1.5% of the TRR and 0.072 mg eq/kg and 16 were characterised in mature plants, individually accounting for equal or less than 1.3% of the TRR and 0.054 mg eq/kg.

B.7.2.1.3.2. [phenyl-UL-^{14}C]isoflucypram

Report:	KCA 6.2.1/06; Botterweck, J.; 2017
Title:	Metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in oilseed rape
Report No.:	S16-01044
Document No.:	M-609380-01-1
Guidelines:	OECD Test Guideline 501; Commission Regulation (EU) No 283/2013 of 1 March 2013; EPA OCSPP Harmonized Test Guideline 860.1300; PMRA Regulatory Directive Dir98-02; JMAFF guideline 12 Nousan No 8147 requirement 2-4-1.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** was investigated in oilseed rape plants after two foliar applications. For each of the two foliar applications the test item [phenyl-UL-^{14}C]BCS-CN88460 was formulated as an aqueous EC 50 using a nominal application rate of 60 g a.s./ha each. The applications were performed at the growth stage of BBCH 14 (trifoliolate on the 3rd up to 5th node unfolded) and BBCH 77 (70% of pods have reached final size). The actual application rates corresponded to 63 and 63 g a.s./ha for the first and second application, respectively resulting in a total application rate of 126 g a.s./ha.

Oilseed rape intermediate harvest was harvested at BBCH 30, 2 days after the first application, forage at BBCH 55, 40 days after the first application, and mature plants and seeds were harvested at BBCH 89, 21 days after the second application. The total radioactive residues (TRR) in intermediate harvest and mature plants were high and amounted to 3.295 mg eq/kg and 3.934 mg eq/kg, respectively. The TRR in forage was low due to the increase of plant mass from first application at BBCH 14 until sampling of forage at BBCH 55 and amounted to 0.008 mg eq/kg. The TRR in seeds was low and amounted to 0.126 mg eq/kg.

Homogenised plant material from RACs was conventionally extracted with a mixture of

acetonitrile/water (8/2; v/v). The extraction rates after conventional extraction of intermediate harvest, forage, mature plants and seeds were high and amounted to 99.7% (3.285 mg eq/kg) of the TRR for intermediate harvest, 77.3% (0.006 mg eq/kg) of the TRR for forage, 96.2% (3.786 mg eq/kg) of the TRR for mature plants and 73.6% (0.093 mg eq/kg) of the TRR for seeds.

Solids after conventional extraction of seeds were exhaustively extracted using microwave assistance with a mixture of acetonitrile/water/formic acid (50/50/1; v/v/v) releasing further 10.6% (0.013 mg eq/kg) of TRR. The post extraction solids of seeds after microwave extraction were subjected to consecutive enzyme digestion with cellulase and amylase, which released further 1.3% of the TRR (0.002 mg eq/kg). Subsequent extraction under acidic conditions with HCl released 7.9% of the TRR (0.010 mg eq/kg). 6.5% of the TRR (0.010 mg eq/kg) of this extract were further characterised by partitioning with ethyl acetate. In the unpolar ethyl acetate fraction remained 4.4% (0.007 mg eq/kg) of the residues and 2.1% of TRR (0.003 mg eq/kg) remained in the water phase.

The post extraction solids after conventional and exhaustive extractions accounted for 0.3% of the TRR (0.010 mg eq/kg), 22.7% of the TRR (0.002 mg eq/kg), 3.8% of the TRR (0.148 mg eq/kg) and 6.5% of the TRR (0.008 mg eq/kg) for intermediate harvest, forage, mature plants and seeds, respectively.

Residues in the conventional extracts were analysed and quantified by HPLC. The parent compound was identified by co-chromatography with the reference compound and metabolites were assigned by comparison of the metabolite pattern and retention times of the current and the oilseed rape metabolism study with the pyrazole label.

The forage extract contained no residue above the limit of detection. Parent compound **isoflucypram** represented the most prominent residue component in all RACs, accounting for 84.1% of TRR (2.770 mg eq/kg) in intermediate harvest, 72.0% of TRR (2.831 mg eq/kg) in mature plants and 73.6% of TRR (0.093 mg eq/kg) in seeds. Parent compound was the only component detected in the extract of seeds.

Besides parent compound four metabolites were identified in intermediate harvest and mature plants.

In intermediate harvest, BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) accounted for 2.3, 1.6, 2.2, and 3.8% of the TRR corresponding to 0.077, 0.052, 0.071 and 0.126 mg eq/kg, respectively.

In mature plants BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) accounted for 2.2, 4.6, 2.5, and 3.1% of the TRR corresponding to 0.087, 0.181, 0.097 and 0.122 mg eq/kg, respectively.

Overall, identification rates were high and amounted to 94.0% of TRR for intermediate harvest, 84.4% of TRR for mature plants and 73.6% of TRR for seeds. In intermediate harvest, 23 unknown metabolites were characterised in the extracts, individually accounting for equal or less than 1.2% of the TRR and 0.038 mg eq/kg and 39 were characterised in mature plants, individually accounting for equal or less than 1.3% of the TRR and 0.050 mg eq/kg.

Comparison of metabolic profiles with those of a parallel study with [pyrazole-4-^{14}C]BCS-CN88460 revealed a high correspondence and no label specific metabolite could be observed for the both labels.

Acid hydrolysis (1 N HCl, 100 °C, 1 h) of the conventional extract of intermediate harvest was performed in order to analyse for hydrolysable conjugates. Comparison of metabolic profiles before and after hydrolysis indicated cleavage of the identified conjugates BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) to less polar compounds. Analogous

hydrolysis experiments were performed in the parallel study with the pyrazole-label showing good accordance with the current study.

As metabolic reactions, hydroxylation in position 1 or 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid and the hydroxylation in position 4 of the phenyl moiety followed by conjugation with hexose and malonic acid were observed.

Based on these results, the degradation behaviour of [phenyl-UL-^{14}C]BCS-CN88460 in oilseed rape is adequately understood and is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[phenyl-UL-^{14}C]
Specific radioactivity	2.07 MBq/mg
Radiochemical purity	> 98%
Chemical purity	> 98%

Formulation of the test compound

The test compound was diluted as a 50:50 mixture of radiolabelled and non-radiolabelled test compound resulting in calculated a final specific activity for the test item of 2.07 MBq/mg. A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile. The purity in the stock solution for both applications and the identity of the test compound in the application dilutions was checked by HPLC with radio detection and was above 98%

The test compound was formulated as an EC 50 for the experiment and therefore [phenyl-UL-^{14}C]BCS-CN88460 was dissolved in acetonitrile. For each of the two spray dilutions, adequate parts of the stock solution were transferred into glass vials and evaporated to dryness. Blank formulation was added and the mixtures were homogenised using a magnetic stirrer. The sample was then adjusted with water to a final volume of 100 mL of the spray dilution and homogenised by stirring.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**CEC**
Sandy loam	2.37%	7.48	20.9 meq/100 g

3. Plant: **Oilseed rape, variety "JERRY", representative for oilseeds**

B. Study Design

1. Experimental conditions:

The experiment was conducted with oilseed rape plants (variety: JERRY) at the rate of 275 seeds per

m^2 in a planting container with a surface area of 1 m^2. The planting container was filled with sandy loam soil. The plants were cultivated in the glass-roofed greenhouse of the test facility and were grown similar to natural temperature and light conditions, but protected from rainfall. They were watered by pouring onto the soil in the planting containers. The plants were applied at two different growth stages (BBCH 14 and 77). For both applications the target single application rate was 60 g a.s./ha. The target rate corresponds to the anticipated maximum application rate for the use type.

For each application, the plants were treated with 100 mL of the aqueous spray dilutions using a controlled track sprayer with a flat fan nozzle. To avoid contamination of the surrounding area by drift, the plants in the planting container were enclosed with a foil housing. After spraying the spray dilution onto the oilseed rape plants in the planting container, the spray device and the protective plastic foil around the planting container were rinsed with acetonitrile/water (8/2; v/v). The actual amount applied was calculated by subtracting the losses from the radioactivity in the original application solution. At the 1st application 13.0 MBq of the labelled test compound were applied, corresponding to 6.3 mg a.s.. At the 2nd application 13.1 MBq of the labelled test compound were applied, corresponding to 6.3 mg a.s. The actual single treatment rates were 63 and 63 g a.s./ha, corresponding to a total application rate of 126 g a.s./ha.

2. Sampling:

At growth stage BBCH 30, 2 days after the first application, the RAC intermediate harvest and at BBCH 55, 40 days after the first application, the RAC forage was harvested. The RACs seeds and mature plant (= rest of plant including pods without seeds) were harvested at BBCH 89, 21 days after the 2nd application.

Intermediate harvest, forage and mature plants were sampled by cut-off of the plants 1-2 cm above the soil surface. Seeds were isolated from mature plants by hand. The empty pods were combined with the mature plant sample.

The total weight of each sample was determined. The samples were homogenised with liquid nitrogen using a high speed blender. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates were extracted. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

For conventional extraction of oilseed rape intermediate harvest, forage, mature plants and seeds, aliquots of the homogenised samples were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried, aliquots subjected to combustion.

The extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder. The final conventional extracts were analysed by HPLC with the general profiling method.

Exhaustive extraction and corresponding clean up:

Solids from the conventional extraction of oilseed rape seeds were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased temperature (0 to 5 min increase to 120 °C, 5 to 20 min at 120 °C, 800 W). The microwave extracts were cooled down at room temperature. After each extraction step, extract and solids were filtrated by suction and centrifuged and finally the extracts were combined.

Aliquots of the combined extract were subjected to a clean-up step using a SPE RP 18, which was rinsed with methanol and water beforehand. The flow-through fraction was collected and the cartridge was rinsed with acetonitrile/water (8/2; v/v). Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

The flow-through fraction and the rinse obtained from SPE purification were combined and mixed with emulsifier and evaporated to the aqueous remainder. The final exhaustive extract was analysed by HPLC with the general profiling method. The extracts were stored in a freezer (≤ -18 °C).

Release of residues upon enzymatic digestion:

Solids of oilseed rape seeds after exhaustive extraction were further incubated with cellulase in sodium acetate buffer (0.1 M) to release radioactive residues. The solids were autoclaved in buffer (121 °C, 2 bar vapour pressure) for 2 hours. After autoclaving the sample was cooled down at room temperature and the buffer was set to pH 5 by use of acetic acid. The solution was mixed with 100 mg cellulase and incubated for 24 hours in a water bath at 37 °C and centrifuged.

Solids of oilseed rape seeds remaining after cellulase treatment were further incubated with amylase in sodium acetate buffer (0.1 M) to specifically release radioactive residues previously assimilated to carbohydrates. The solids were autoclaved in buffer (121 °C, 2 bar vapour pressure) for 2 hours. After autoclaving the sample was cooled down to 20 °C and the buffer was set to pH 5 by use of acetic acid. The solution was mixed with 50.0 mg amylase (1.9 units/mg) and incubated for 24 hours in a water bath at 37 °C and centrifuged. Radioactivity in remaining solids was determined by combustion.

Release of residues upon acidic extraction with HCl:

Solids of oilseed rape seeds after enzymatic digestion with cellulase and amylase (approximately 5 g) were further extracted with HCl (5 M, 30 mL) to release radioactive residues. After addition of the HCl solution, the mixture was incubated for 60 minutes at 120 °C under microwave assistance and centrifuged. Radioactivity in remaining solids was determined by combustion.

Residues contained in the combined extracts obtained by acidic extraction were characterised by partitioning. Therefore, the complete extract was neutralized by addition of 10M NaOH and mixed with ethyl acetate (1/1; v/v) in a separatory funnel and shaken by hand. Ethyl acetate and water phase were separated. The water phase was again mixed with ethyl acetate (1/1; v/v) in a separatory funnel and the procedure was repeated.

Hydrolysis of the conventional extracts:

Hydrolysis experiments in acidic medium (1 N HCl) were conducted with concentrated conventional extract from intermediate harvest. Therefore, the final purified extract was mixed with 10 N HCl to obtain a concentration of approximately 1 N HCl and incubated 100 °C for 1 hour. Afterwards, the mixture was adjusted to pH 7 with 10 N NaOH and analysed by HPLC.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent/ scintillation cocktail mixture and the radioactivity was measured by LSC.

Conventional and microwave extracts were analysed by HPLC with radio detection based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

2. Identification and characterisation:

Metabolic profiles of all RACs were compared, as analysed by HPLC among themselves. Metabolic profiles of all RACs were compared with metabolic profiles of corresponding RACs in the oilseed rape metabolism study with the pyrazole label in which the major metabolites were identified spectroscopically. Parent compound was identified in oilseed rape seeds extract by TLC and HPLC co-chromatography with the test compound. Metabolic profiles of oilseed rape intermediate harvest extract before and after hydrolysis were compared with corresponding profiles of the wheat metabolism study with the pyrazole label, as analysed by HPLC.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-29: Reference compound

Report name / other names/codes	Chemical Name (IUPAC)	Structure
Parent compound BCS-CN88460 Radiolabeled reference: M-00002258 S1000	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

All conventional extraction experiments of the raw agricultural commodities were performed within two months after harvest of the oilseed rape samples. The exhaustive extraction of seeds was performed within three months after harvest. All first quantitative analyses by HPLC of the conventional extracts were performed within one day after the start of extraction. For the exhaustive extract of seeds, not showing any radio signal above the background noise, first HPLC analysis was performed within ten days after start of the extraction and degradation due to microwave treatment could be excluded.

It was therefore concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in oilseed rape was investigated after two spray applications. Oilseed rape plants were treated with [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC 50 at BBCH 14 (trifoliolate on the 3rd up to 5th node unfolded) and BBCH 77 (70% of pods have reached final size). The actual single application rate corresponded to 63 and 63 g a.s./ha which was slightly above the anticipated maximum application rate (2 x 60 g a.s./ha). The total application rate amounted to 126 g a.s./ha.

The TRR values of the individual RACs were determined by summing up the radioactivity determined in the combined extracts and the radioactivity in the solids. The residue levels are shown in mg active substance equivalents per kg sample material (mg a.s.equiv./kg or simplified mg eq/kg).

TRR values in intermediate harvest and mature plants were high and amounted to 3.295 mg eq/kg and 3.934 mg eq/kg, respectively. The TRR in forage and seeds were low and amounted to 0.008 mg eq/kg and 0.126 mg eq/kg.

The high TRRs found for intermediate harvest and mature plants are due to harvest shortly after the first foliar application (PHI = 2 d) in case of intermediate harvest or due to sampling after two foliar

applications in case of mature plants. For forage, the low TRR can be ascribed to the increase of plant mass from the 1st foliar application at BBCH 14 to sampling 40 days after 1st application at BBCH 55.

Table 7.2.1-30: TRR values in oilseed rape matrices after foliar application of [phenyl-UL-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Intermediate Harvest	1 Spray application at BBCH 14: 63 g a.s./ha	2	3.295
Forage		40	0.008
Mature Plants	2 Spray applications at BBCH 14 and BBCH 77: 63 and 63 g a.s./ha (126 g a.s./ha total)	21	3.934
Seeds		21	0.126

* PHI: Pre-Harvest Interval

Intermediate harvest was conventionally extracted three times with acetonitrile/water mixtures releasing 99.7% of the TRR (3.285 mg eq/kg). Losses during sample clean up accounted for 0.1% of the TRR (0.004 mg eq/kg). After concentration and purification steps 99.6% of the TRR (3.281 mg eq/kg) were analysed. The post extraction solids amounted to 0.3% (0.010 mg eq/kg) of the TRR, only.

Forage was conventionally extracted three times with acetonitrile/water mixtures releasing 77.3% of the TRR (0.006 mg eq/kg). No losses of RA occurred during sample clean-up and 77.3% of the TRR (0.006 mg eq/kg) were analysed. The post extraction solids amounted to 22.7% of the TRR (0.002 mg eq/kg), only.

Mature plants were conventionally extracted three times with acetonitrile/water mixtures releasing 96.2% of the TRR (3.786 mg eq/kg). Losses during sample clean up accounted for 0.2% of the TRR (0.010 mg eq/kg). After concentration and purification steps 96.0% of the TRR (3.776 mg eq/kg) were analysed. The post extraction solids contained 3.8% (0.148 mg eq/kg) of the TRR.

Seeds were conventionally extracted three times with acetonitrile/water mixtures releasing 73.6% of the TRR (0.093 mg eq/kg). No losses of RA occurred during sample clean-up and 77.3% of the TRR (0.093 mg eq/kg) were analysed. The post extraction solids after conventional extraction accounted for 26.4% of the TRR (0.033 mg eq/kg).

The PES of seeds were subjected to exhaustive extraction under microwave support. This treatment released 10.6% of the TRR (0.013 mg eq/kg). Losses during sample clean up accounted for 1.0% of the TRR (0.001 mg eq/kg) and 9.6% of the TRR (0.012 mg eq/kg) were analysed by HPLC. Additionally, the solids remaining after exhaustive extraction were incubated consecutively with cellulase and amylase to release further residues. These extractions released 1.3% of the TRR (0.002 mg eq/kg).

Subsequent acidic extraction additionally released 7.9% of the TRR (0.010 mg eq/kg). Losses of RA during neutralization of the acidic extract accounted for 1.4% of the TRR (<0.001 mg eq/kg). The neutralized extract was further characterised by partitioning with ethyl acetate. 4.4% of the TRR (0.007 mg eq/kg) was detected within the ethyl acetate fraction and 2.1% of the TRR (0.003 mg eq/kg) was detected in the water phase.

In total 93.5% of the TRR (0.118 mg eq/kg) was extracted from seeds. Total losses of RA accounted for 2.4% of the TRR (0.001 mg eq/kg). The post extraction solids amounted to 6.5% (0.008 mg eq/kg) of the TRR.

The distribution of the radioactive residues is shown in the following table.

Table 7.2.1-31: Distribution of radioactivity in the extracts of oilseed rape matrices after two foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

-- not applicable

n.q. not quantified (< LOQ)

* no individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of seeds

Comparison of chromatograms from conventional extracts of intermediate harvest and mature plants of the current study among themselves indicated a high grade of comparability. Conventional extract of forage contained no individual radio signal above the background noise whereas conventional extract from seeds contained only the test compound.

The comparison of profiles of all RACs to corresponding profiles of the parallel study performed with [pyrazole-4-^{14}C]BCS-CN88460 revealed that no label specific metabolism could be observed.

In conventional extracts from intermediate harvest 94.0% of the TRR (3.096 mg eq/kg) were identified in total. The parent compound was the major component representing 84.1% of the TRR (2.770 mg eq/kg), whereas the metabolites BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) represented 2.3, 1.6, 2.2 and 3.8% of the TRR corresponding to 0.077, 0.052, 0.071 and 0.126 mg eq/kg, respectively.

Acid hydrolysis (1 N HCl, 100 °C, 1 h) of the conventional extract of intermediate harvest was performed in order to analyse for hydrolysable conjugates. Comparison of metabolic profiles before and after hydrolysis indicated cleavage of the identified conjugates BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**) to less polar compounds. Analogous hydrolysis experiments were performed in the parallel study with the pyrazole-label showing good accordance with the current study.

In conventional extracts from forage 77.3% of the TRR was analysed in total (0.006 mg eq/kg). No individual radio signal was above the background noise due to very low amounts of total radioactive ingredients in the extract.

In conventional extracts from mature plants 84.4% of the TRR (3.318 mg eq/kg) were analysed in total. The parent compound was by far the major component representing 72.0% of the TRR (2.831 mg eq/kg), whereas the metabolites BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-

CN88460-hydroxyphenyl-Glyc-MA (**M24**) represented 2.2, 4.6, 2.5 and 3.1% of the TRR corresponding to 0.087, 0.181, 0.097 and 0.122 mg eq/kg, respectively.

In conventional extracts from seeds 73.6% of the TRR (0.093 mg eq/kg) were identified. The parent compound was the only component representing 73.6% of the TRR (0.093 mg eq/kg). Parent compound was identified by HPLC and TLC co-chromatography with the test item as radiolabelled reference compound.

Exhaustive extraction of seeds released further 10.6% of the TRR (0.013 mg eq/kg) and 9.6% of the TRR (0.012 mg eq/kg) were analysed by HPLC. No individual radio signal was above the background noise due to low amounts of total radioactive ingredients in the exhaustive extract. Conventional extract of seeds treated under microwave extraction conditions in comparison of the corresponding conventional extract and exhaustive extract, showed that degradation of parent compound by this treatment was negligible.

The TRR and the distribution of parent and metabolites in oilseed rape matrices are shown in the following table.

Table 7.2.1-32: Distribution of parent compound and metabolites in the extracts of oilseed rape matrices after two foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

B.7.2.1.3.3. Summary of isoflucypram metabolism in oilseed rape

The metabolism of **isoflucypram** in oilseed rape was investigated after two foliar applications at BBCH 14 and BBCH 77. The oilseed rape plants were treated with either [pyrazole-4-^{14}C]BCS-CN88460 or [phenyl-4-^{14}C]BCS-CN88460 formulated as an EC 50 at a nominal individual application rate of 60 g a.s./ha (actual: 62-64 g a.s./ha) corresponding to a total nominal application rate of 120 g a.s./ha (actual 120-126 g a.s./ha). The oilseed rape intermediate harvest was harvested at BBCH 30, 2 days after the first application and forage was harvested at BBCH 55, 40 days after the first application. Mature plants and seeds were harvested at BBCH 89, 21 days after the second application.

Residues in forage and seeds were significantly lower than those in intermediate harvest and mature plants. The extraction rates of intermediate harvest, forage, mature plants and seeds were high.

Overall, identification rates for intermediate harvest, mature plants and seeds were high. Parent compound **isoflucypram** was the main residue component in intermediate harvest and mature plant and the only component in seeds. Conventional extract of forage contained no residues above the limit of detection of the analytical method.

Besides parent compound, four metabolites were identified in intermediate harvest and mature plants: BCS-CN88460-hydroxyphenyl-Gluc-MA (**M23**), BCS-CN88460-2-propanol-Glyc-MA (**M22**), BCS-CN88460-propanol-Glyc-MA (**M21**) and BCS-CN88460-hydroxyphenyl-Glyc-MA (**M24**).

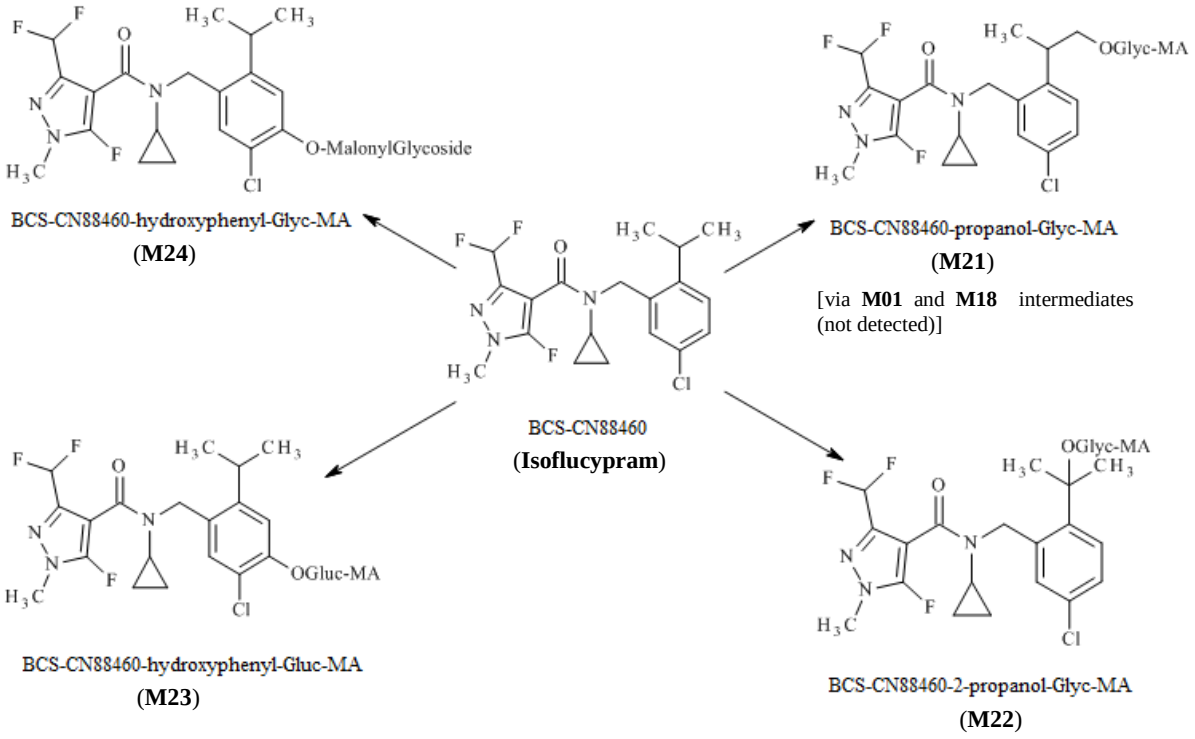
The results from the studies involving the pyrazole- and phenyl-labelled **isoflucypram** are in close agreement. No label specific metabolites were observed using either label.

BCS-CN88460 was moderately metabolised in oilseed rape after two foliar applications. The main metabolic reactions observed were:

- Hydroxylation in position 1 or 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid;
- Hydroxylation in position 4 of the phenyl moiety followed by conjugation with hexose and malonic acid.

Based on these results, the metabolic behaviour of **isoflucypram** in oilseed rape is adequately understood and a metabolic pathway is proposed in the Figure below:

Figure 7.2.1-2: Proposed metabolic pathway of isoflucypram in oilseed rape



B.7.2.1.4. **Soybean (foliar treatment)**

Metabolism studies in soybean after foliar application were conducted with [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C]BCS-CN88460.

Table 7.2.1-34: Overview of soybean metabolism studies

Plant	Application	Target Application Rate	BBCH Code	Reference
Soybean	Three foliar spray applications, pyrazole-labelled **isoflucypram**	3 x 60 g a.s./ha	BBCH 14, BBCH 51 and BBCH 84	M-609373-01-1
Soybean	Three foliar spray applications, phenyl-labelled **isoflucypram**	3 x 60 g a.s./ha	BBCH 14, BBCH 51 and BBCH 85	M-609376-01-1

B.7.2.1.4.1. [pyrazole-4-^{14}C]isoflucypram

Report:	KCA 6.2.1/07; Traub, M.; 2017
Title:	Metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in soybean plants
Report No.:	S14-01089
Document No.:	M-609373-01-1
Guidelines:	OECD Test Guideline 501; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300; JAP FAMIC-ACIS Notification 12 Nousan 8147.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** was investigated in soybean plants after three post-emergent spray applications. For each of the three foliar applications, the test item [pyrazole-4-^{14}C]BCS-CN88460 was formulated and applied as aqueous EC 50 using a nominal application rate of 60 g a.s./ha each. The actual single application rates corresponded to 59, 57 and 65 g BCS-CN88460/ha resulting in a total actual application rate of 181 g a.s./ha.

Soybean forage was harvested at BBCH stage 49 after the first application (PHI = 5d), hay at BBCH stage 77 after the 2nd application (PHI = 39d) and straw and seeds at BBCH stage 96, 21d after the 3rd application. The radioactive residues of soybean forage, hay, straw and seeds were determined by summing up the extractable and unextractable radioactivity. Soybean seeds contained significantly lower residue amounts than forage, hay and straw. The total radioactive residue (TRR) in soybean straw was highest and amounted to 17.715 mg eq/kg. The TRR in soybean forage and soybean hay were high and amounted to 4.371 mg eq/kg and 4.679 mg eq/kg, respectively. The TRR in seeds was low and amounted to 0.035 mg eq/kg.

Homogenised plant material from RACs was conventionally extracted with acetonitrile/water mixtures. Overall, the extraction rates after conventional extraction of soybean forage, hay, straw and seeds were high and amounted to 92.1, 87.4, 94.1 and 87.7% of the TRR (4.026, 4.091, 16.669 and 0.031 mg eq/kg), respectively. Exhaustive extract of soybean forage, hay and straw increased the extraction rate slightly: 5.1% of the TRR (0.222 mg eq/kg), 6.9% of the TRR (0.321 mg eq/kg) and 2.5% of the TRR (0.441 mg eq/kg) were released by this treatment, respectively.

The post extraction solids after conventional and exhaustive extractions accounted for 2.8% of the TRR (0.123 mg eq/kg), 5.7% of the TRR (0.266 mg eq/kg), 3.4% of the TRR (0.605 mg eq/kg) and 12.3% of the TRR (0.004 mg eq/kg) for soybean forage, hay, straw and seeds, respectively.

Residues in the conventional extracts of all RACs and in the exhaustive extracts of forage and straw were analysed and quantified by HPLC. The parent compound and metabolites were either identified by co-chromatography with the reference compound or by spectroscopic analysis in isolated fractions from the conventional extract of soybean hay. Additionally, the metabolite pattern and retention times of the current and the soybean metabolism study with the phenyl label were compared.

Profiles of forage, hay and straw showed a high grade of comparability among themselves concerning

metabolism of the test item whereas the extract from soybean seeds contained only the parent compound.

The comparison of metabolic profiles of conventional extracts of all RACs with those of a parallel study with [phenyl-UL-^{14}C]BCS-CN88460 revealed a high grade of comparability of the metabolism of the test compound in soybean and no label specific metabolite could be observed for the both labels.

A major component in all RACs was the test compound **isoflucypram** accounting for 18.7% of the TRR (0.819 mg eq/kg) in soybean forage, 10.4% of the TRR (0.487 mg eq/kg) in soybean hay, 64.5% of the TRR (11.424 mg eq/kg) in soybean straw and 76.6% of the TRR (0.027 mg eq/kg) in soybean seeds. Besides parent compound no other metabolite was detected in the extract of soybean seeds.

Besides parent compound five metabolites were identified soybean forage, hay and straw.

BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (**M48**) accounted for 3.4, 15.2 and 3.9% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.147, 0.711 and 0.690 mg eq/kg, respectively. BCS-CN88460-desfluoro-homoGSH (**M44**) accounted for 22.9, 7.8 and 4.8% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.997, 0.366 and 0.857 mg eq/kg, respectively. BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**) accounted for 9.5, 3.2 and 1.9% of the TRR in extracts from soybean forage, hay and straw, corresponding to 0.415, 0.151 and 0.337 mg eq/kg, respectively. BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) accounted for 3.0, 11.1 and 3.0% of the TRR in extracts from soybean forage, hay and straw, corresponding to 0.129, 0.520 and 0.533 mg eq/kg, respectively. BCS-CN88460-desfluoro-Cys-MA (**M45**) accounted for 9.2, 15.4 and 4.6% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.400, 0.723 and 0.828 mg eq/kg, respectively.

Overall, identification rates were sufficient and amounted to 66.6% of TRR for forage, 63.2% of TRR for hay, 82.8% of the TRR for straw and 76.6% of TRR for seeds. In soybean forage, hay and straw, 17, 13 and 20 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for less than 3.9% of the TRR (0.171 mg eq/kg), 4.4% of the TRR (0.208 mg eq/kg) and 1.9% of the TRR (0.329 mg eq/kg) for forage, hay and straw, respectively.

All initial profiles of conventional extracts of the raw agricultural commodities were performed within 6 months after harvest. Furthermore, storage stability of residues in stored sample matrix and extracts could be demonstrated exemplarily for soybean hay and straw for 18 and 27 months, respectively, in the course of a parallel study with the phenyl-label which showed a high grade of comparability of the metabolic profiles of the individual RACs.

As metabolic reactions, de-fluorination at position 5 of the pyrazole ring followed by conjugation with homoglutathione and degradation of the homoglutathione moiety followed by conjugation with malonic acid or degradation and desamination to mercapto lactic acid group and hydroxylation of the benzyl moiety or of the propyl group were observed. Furthermore glycosilation was clearly observed at the mercapto lactic acid group.

Based on these results, the degradation behaviour of [pyrazole-4-^{14}C]BCS-CN88460 in soybean is adequately understood and a pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[pyrazole-4-^{14}C]
Specific radioactivity	4.22 MBq/mg
Radiochemical purity	> 98% (HPLC)
Chemical purity	> 99%

Formulation of the test compound

A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile to give a concentration of about 5 mg/mL. The purity in the stock solution and the identity of the test compound was checked by HPLC with radio detection and was 100%

The test compound was formulated as an EC 50 for the experiment and therefore [pyrazole-4-^{14}C]BCS-CN88460 was dissolved in acetonitrile. For each of the three spray dilutions, adequate parts of the stock solution were transferred into glass vials and evaporated to dryness. Blank formulation was added and the mixtures were homogenised using a magnetic stirrer. The sample was then adjusted with water to a final volume of 50 mL (1st and 2nd application) and 100 mL (3rd application) of the spray dilution and homogenised by stirring.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**CEC**
Sandy loam	2.1%	7.23	15.5 meq/100 g

3. Plant: **Soybean, variety "Amandine", representative for oilseeds**

B. Study Design

1. Experimental conditions:

The experiment was conducted with soybean plants (variety: Amandine) based on a plant density of 800,000 soybean plants per hectare. A planting container with a surface area of 1 m^2 was used corresponding to the rate of 80 seeds per m^2. The plants were cultivated in a glass-roofed greenhouse and grown similar to natural temperature and light conditions, but protected from rainfall. They were watered by pouring onto the soil in the planting containers. The plants were applied at three different growth stages (BBCH 14, 51 and 84). At all these growth stages the target single application rate was 60 g a.s./ha. The target rate corresponds to the anticipated maximum application rates for the use type.

For each application, the soybean plants were treated with 50 mL (1st and 2nd application) and 100 mL (3rd application) of the aqueous spray dilutions using a controlled track sprayer with a flat fan nozzle. To avoid contamination of the surrounding area by drift, the plants in the planting container were enclosed with a foil housing. After spraying the spray dilution onto the oilseed rape plants in the planting container, the spray device and the protective plastic foil around the planting container were rinsed with acetonitrile/water (8/2; v/v). The actual amount applied was calculated by subtracting the losses from the radioactivity in the original application solution. At the 1st application 24.8 MBq of the labelled test compound were applied, corresponding to 5.9 mg a.s.. At the 2nd application 23.9 MBq of the test compound were applied, corresponding to 5.7 mg a.s.. At the 3rd application 27.3 MBq of the test compound were applied, corresponding to 6.5 mg a.s. The actual single application rates were 59,

57 and 65 g a.s./ha resulting in a total actual application rate of 181 g a.s./ha.

2. Sampling:

At growth stage BBCH 49 the RAC forage, at growth stage BBCH 77 the RAC hay and at BBCH 96 the RACs straw and seeds were harvested. Plant samples were collected by cutting approximately 1-2 cm above the soil level. Plants sampled at hay stage were dried in a hood for 4 days.

The total weight of each sample was determined. The samples were homogenised with liquid nitrogen using a high speed blender. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates were extracted. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

Aliquots of the homogenised samples of soybean forage, hay, straw and seeds were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion and LSC.

The extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

Each combined percolate/rinse solution obtained from SPE purification was evaporated to the aqueous remainder. The final conventional extracts were analysed by HPLC with the general profiling method. All soybean samples and extracts were stored in a freezer (≤ -18 °C).

Exhaustive extraction and corresponding clean-up:

Solids from the conventional extraction of soybean forage, hay and straw were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased temperature (0 to 5 min increase to 120 °C, 5 to 20 min at 120 °C, 800 W). The microwave extracts were cooled down at room temperature.

For forage and hay, the individual extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v). Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder.

The exhaustive extracts of straw were directly concentrated by evaporation to the aqueous remainder. The final exhaustive extract of soybean hay was partitioned for characterisation. The final exhaustive extracts of forage and straw were analysed by HPLC with the general profiling method. The extracts were stored in a freezer (≤ -18 °C).

Characterisation of residues by partitioning

Radioactivity released from soybean hay by exhaustive extraction under microwave assistance was characterised by partitioning. Therefore, 2 mL of the concentrate obtained during exhaustive

extraction and after purification were mixed with 8 mL water and 10 mL ethyl acetate in a centrifuge tube. The mixture was incubated 30 min by 150 rpm on a flatbed shaker. Four gram anhydrous magnesium sulphate, one gram sodium chloride, one gram trisodium citrate and 0.5 gram disodium citrate sesquihydrate were added to remove water and adjust the pH value. After addition of the salt mixture, the tube was immediately shaken vigorously by hands for 10 seconds and with a flatbed shaker for at least one minute and afterwards centrifuged. Ethyl acetate and water phase were separated, their volume was determined.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent/ scintillation cocktail mixture and the radioactivity was measured by LSC.

Conventional and microwave extracts were analysed by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

2. Identification and characterisation:

For identification of radioactive ingredients in conventional extract from soybean hay, selected major radio signals were isolated as fractions of eluent by HPLC fractionation. Isolated fractions were identified by spectroscopic analysis as following metabolites: BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (**M48**), BCS-CN88460-desfluoro-homoGSH (**M44**), BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**), BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**).

Metabolic profiles from the conventional and exhaustive extracts of all RACs were compared, as analysed by HPLC among themselves. Metabolic profiles of all RACs were compared with metabolic profiles of corresponding RACs in the soybean metabolism study with the phenyl label. Parent compound was identified in the extract of soybean seeds by TLC co-chromatography with the radiolabelled test compound. Metabolites after structure elucidation in the conventional extract of soybean hay were re-assigned.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-35: Reference compound

Report name / other names/codes	Chemical Name (IUPAC)	Structure
Parent compound BCS-CN88460 Reference: S_PY_1_1000	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

The initial profiles of the conventional extracts of soybean forage, hay, straw and seeds were analysed within 6 months after harvest of the soybean plant raw material. The stability of residues in the stored sample matrices and extracts were demonstrated in the parallel study with the phenyl label. As the profiles of the respective RACs were highly comparable between the parallel studies and no label specific metabolites were observed it was concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in soybean was investigated after three spray applications.

Soybean plants in a 1 m^2 container were treated with [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC 50 at BBCH 14 (beginning of stem elongation), BBCH 51 (first flower buds visible) and BBCH 84 (about 40% of pods are ripe). The actual single application rates corresponded to 59, 57 and 65 g a.s./ha. The total application rate amounted to 181 g a.s./ha, corresponding well to the anticipated maximum application rate.

The TRR values of the individual RACs were determined by summing up the radioactivity determined in the combined extracts and the radioactivity in the solids. The residue levels are shown in mg active substance equivalents per kg sample material (mg a.s.equiv./kg or simplified mg eq/kg).

The TRR in soybean straw was high and amounted to 17.715 mg eq/kg. Soybean forage and hay contained a TRR of 4.371 mg eq/kg and 4.679 mg eq/kg, respectively. The TRR determined for soybean seeds was low and amounted to 0.035 mg eq/kg.

The residue values in the parallel study with the phenyl label were comparable for forage but significantly lower for hay, straw and seeds. This is due to differences in plant growth during cultivation of both studies resulting in vegetation differences during the second and third application.

Table 7.2.1-36: TRR in soybean matrices after foliar application of [pyrazole-4-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Soybean forage	1 spray application at BBCH 14, 59 g a.s./ha	5	4.371
Soybean hay	2 spray applications at BBCH 14 and 51: 59 and 57 g a.s./ha (116 g a.s./ha, total)	39	4.679
Soybean straw	3 spray applications at BBCH 14, 51 and 84: 59, 57 and 65 g a.s./ha (181 g a.s./ha; in total)	21	17.715
Soybean seeds		21	0.035

* PHI: Pre-Harvest Interval

Soybean forage was conventionally extracted three times with acetonitrile/water mixtures releasing 92.1% of the TRR (4.026 mg eq/kg). After concentration and purification steps 91.1% of the TRR (3.981 mg eq/kg) were analysed by HPLC. For soybean forage, a microwave extraction was performed. With this exhaustive method 5.1% (0.222 mg eq/kg) of the TRR were further extracted and 4.4% of the TRR (0.193 mg eq/kg) analysed by HPLC, additionally. The residue level in the solids of soybean forage after conventional and exhaustive extraction amounted to 2.8% of the TRR and 0.123 mg eq/kg. Losses during sample clean-up of forage samples were 1.7% of the TRR (0.074 mg eq/kg).

Soybean hay was conventionally extracted three times with acetonitrile/water mixtures releasing 87.4% of the TRR (4.091 mg eq/kg). After concentration and purification steps 86.5% of the TRR (4.048 mg eq/kg) were analysed by HPLC. Exhaustive extraction of soybean hay, releasing 6.9% of the TRR and 0.321 mg eq/kg, was further characterised by partitioning of the exhaustive extract using ethyl acetate accounting for 6.4% of the TRR (0.299 mg eq/kg) after purification. Complete radioactivity of the exhaustive extract was found in the ethyl acetate phase after partitioning. This is in good accordance to results from the partitioning of experiment performed with soybean hay exhaustive extract in a parallel study with [phenyl-UL-^{14}C]BCS-CN88460. Since the complete radioactivity of the exhaustive extracts of soybean hay in both studies was found in the ethyl acetate phase, it can be assumed that the residues were highly unpolar and likely ascribable to radioactivity derived from parent compound. The residue level in the solids of soybean hay after conventional and exhaustive extraction amounted to 5.7% of the TRR and 0.266 mg eq/kg. Losses during sample clean up were 1.4% of the TRR (0.065 mg eq/kg).

Soybean straw was conventionally extracted three times with acetonitrile/water mixtures releasing 94.1% of the TRR (16.669 mg eq/kg). After concentration and purification steps, 93.2% of the TRR (16.516 mg eq/kg) were analysed by HPLC. For soybean straw samples, a microwave extraction was performed. With this method 2.5% (0.441 mg eq/kg) were extracted and 2.4% of the TRR (0.432 mg eq/kg) analysed by HPLC, additionally. The residue level in the solids of soybean straw after conventional and exhaustive extraction amounted to 3.4% of the TRR and 0.605 mg eq/kg. Losses during sample clean up were 0.9% of the TRR (0.163 mg eq/kg).

Soybean seeds were conventionally extracted three times with acetonitrile/water mixtures releasing 87.7% of the TRR (0.031 mg eq/kg). After concentration and purification steps 76.6% of the TRR (0.027 mg eq/kg) were analysed by HPLC. Losses during sample clean up were 11.0% of the TRR (0.004 mg eq/kg). The residue level in the solids of soybean seeds after conventional extraction amounted to 12.3% of the TRR and 0.004 mg eq/kg.

The distribution of the radioactive residues is shown in the following table.

Table 7.2.1-37: Distribution of radioactivity in the extracts of soybean matrices after three foliar applications of [pyrazole-4-^{14}C]BCS-CN88460

-- not performed

n.q.: not quantified

Comparison of profiles of all RACs to corresponding profiles of the parallel study performed with [phenyl-UL-^{14}C]BCS-CN88460 showed good correspondence to each other and revealed that no label specific metabolism could be observed for the pyrazole label.

In the parallel study with the phenyl-labelled test compound, chromatograms obtained after exhaustive extraction were compared to the profile of conventional extract of soybean straw treated under microwave conditions. This experiment demonstrated that the parent compound and the major metabolites were not degraded by this form of extraction.

In conventional extract from soybean forage 64.5% of the TRR (2.817 mg eq/kg) were identified in total. The parent compound and BCS-CN88460-desfluoro-homoGSH (**M44**) were major component representing 17.6% of the TRR (0.770 mg eq/kg) and 21.9% of the TRR (0.955 mg eq/kg), respectively. The metabolites BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**), BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 3.4, 9.5, 3.0 and 9.2% of the TRR corresponding to 0.147, 0.415, 0.129 and 0.400 mg eq/kg, respectively. In exhaustive extract 2.1% of the TRR (0.091 mg eq/kg) were further identified. The parent compound and the metabolite BCS-CN88460-desfluoro-homoGSH (**M44**) represented 1.1 and 1.0% of the TRR corresponding to 0.049 and 0.042 mg eq/kg, respectively.

In conventional extract from soybean hay 63.2% of the TRR (2.958 mg eq/kg) were identified in total. The parent compound and the metabolites BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (**M48**), BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**) were major components representing 10.4, 15.2, 11.1 and 15.4% of the TRR corresponding to 0.487, 0.711, 0.520 and 0.723 mg eq/kg, respectively. The metabolites BCS-CN88460-desfluoro-homoGSH (**M44**) and BCS-CN88460-desfluoro-mercapto-lactic acid-OH represented 7.8 and 3.2% of the TRR corresponding to 0.366 and 0.151 mg eq/kg, respectively. Residues in the exhaustive extract of soybean hay were characterised by partitioning using ethyl acetate. Complete radioactivity of the exhaustive extract was found in the ethyl acetate phase after partitioning. This is in good accordance to results from the partitioning experiment performed with soybean hay exhaustive extract in a parallel study with [phenyl-UL-^{14}C]BCS-CN88460. Since the complete radioactivity of the exhaustive extracts of soybean hay in both studies was found in the ethyl acetate phase, it can be assumed that the residues were highly unpolar and likely ascribable to radioactivity derived from parent compound.

In conventional extract from soybean straw 81.2% of the TRR (14.380 mg eq/kg) were identified in total. The parent compound was by far the major component representing 63.6% of the TRR (11.262 mg eq/kg), whereas the metabolites BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, BCS-CN88460-desfluoro-homoGSH (**M44**), BCS-CN88460-desfluoro-mercapto-lactic acid-OH, BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 3.8, 4.8, 1.5, 3.0 and 4.4% of the TRR corresponding to 0.667, 0.857, 0.272, 0.533 and 0.788 mg eq/kg, respectively. In the exhaustive extract of straw further 1.6% of the TRR (0.288 mg eq/kg) were identified. The parent compound and the metabolites BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**) and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 0.9, 0.1, 0.4 and 0.2% of the TRR corresponding to 0.162, 0.023, 0.065 and 0.040 mg eq/kg, respectively.

Conventional extract from soybean seeds contained only parent compound representing 76.6% of the TRR corresponding to 0.027 mg eq/kg. The compound was identified by TLC co-chromatography of the parent compound fraction isolated from conventional extract of soybean seeds with the non-radiolabelled reference compound BCS-CN88460.

The TRR and the distribution of parent and metabolites in soybean matrices are shown in the following table.

Table 7.2.1-38: Distribution of parent compound and metabolites the extracts of soybean matrices after three foliar applications of [pyrazole-4-^{14}C]BCS-CN88460

Overall, identification rates were sufficient and amounted to 66.6% of TRR for forage, 63.2% of TRR for hay, 82.8% of the TRR for straw and 76.6% of TRR for seeds. In soybean forage, hay and straw, 17, 13 and 20 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for less than 3.9% of the TRR (0.171 mg eq/kg), 4.4% of the TRR (0.208 mg eq/kg) and 1.9% of the TRR (0.329 mg eq/kg).

B.7.2.1.4.2. [phenyl-UL-4-^{14}C]isoflucypram

Report:	KCA 6.2.1/08; Traub, M.; 2017
Title:	Metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in soybean plants
Report No.:	S14-01090
Document No.:	M-609376-01-1
Guidelines:	OECD Test Guideline 501; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300; JAP FAMIC-ACIS Notification 12 Nousan 8147.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** was investigated in soybean plants after three post-emergent spray applications. For each of the three foliar applications, the test item [phenyl-UL-^{14}C]BCS-CN88460 was formulated and applied as aqueous EC 50 using a nominal application rate of 60 g a.s./ha each. The actual single application rates corresponded to 54, 56 and 66 g a.s./ha resulting in a total actual application rate of 176 g a.s./ha.

Soybean forage was harvested at BBCH 49 after the first application (PHI = 6d), hay at BBCH 77

after the 2nd application (PHI = 38d) and straw and seeds at BBCH 96, 21d after the 3rd application. The radioactive residues of soybean forage, hay, straw and seeds were determined by summing up the extractable and unextractable radioactivity. Soybean seeds contained significantly lower residue amounts than forage, hay and straw. The total radioactive residue (TRR) in soybean straw was highest and amounted to 8.527 mg eq/kg. The TRR in soybean forage and soybean hay were high and amounted to 3.936 mg eq/kg and 1.397 mg eq/kg, respectively. The TRR in seeds was low and amounted to 0.015 mg eq/kg.

Homogenised plant material from RACs was conventionally extracted with acetonitrile/water mixtures. Overall, the extraction rates after conventional extraction of soybean forage, hay, straw and seeds were high and amounted to 91.4, 88.6, 92.8 and 69.8% of the TRR (3.597, 1.238, 7.914 and 0.011 mg eq/kg), respectively. Exhaustive extract of soybean forage, hay and straw increased the extraction rate slightly: 5.2% of the TRR (0.205 mg eq/kg), 6.3% of the TRR (0.088 mg eq/kg) and 3.1% of the TRR (0.264 mg eq/kg) were released by this treatment, respectively.

The post extraction solids after conventional and exhaustive extractions accounted for 3.4% of the TRR (0.134 mg eq/kg), 5.1% of the TRR (0.071 mg eq/kg), 4.1% of the TRR (0.349 mg eq/kg) and 30.2% of the TRR (0.005 mg eq/kg) for soybean forage, hay, straw and seeds, respectively.

Residues in the conventional extracts of all RACs and in the exhaustive extracts of forage and straw were analysed and quantified by HPLC. The parent compound was identified by co-chromatography with the reference compound and metabolites were assigned by comparison of the metabolite pattern and retention times of the current and the soybean metabolism study with the pyrazole label.

Profiles of forage, hay and straw showed a high grade of comparability among themselves concerning metabolism of the test item whereas the extract from soybean seeds contained only the parent compound.

The comparison of metabolic profiles of conventional extracts of all RACs with those of a parallel study with [pyrazole-4-^{14}C]BCS-CN88460 revealed a high grade of comparability of the metabolism of the test compound in soybean and no label specific metabolite could be observed for the both labels.

A major component in all RACs was the test compound **isoflucypram** accounting for 19.2% of the TRR (0.756 mg eq/kg) in soybean forage, 10.3% of the TRR (0.144 mg eq/kg) in soybean hay, 70.2% of the TRR (5.983 mg eq/kg) in soybean straw and 69.8% of the TRR (0.011 mg eq/kg) in soybean seeds. Besides parent compound no other metabolite was detected in the extract of soybean seeds.

Besides parent compound five metabolites were identified soybean forage, hay and straw.

BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (**M48**) accounted for 4.8, 17.6 and 2.1% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.187, 0.246 and 0.177 mg eq/kg, respectively. BCS-CN88460-desfluoro-homoGSH (**M44**) accounted for 20.2, 7.8 and 2.8% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.793, 0.109 and 0.235 mg eq/kg, respectively. BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**) accounted for 17.0, 2.8 and 2.5% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.672, 0.040 and 0.215 mg eq/kg, respectively. BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) accounted for 2.7, 10.7 and 2.8% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.107, 0.150 and 0.235 mg eq/kg, respectively. BCS-CN88460-desfluoro-Cys-MA (**M45**) accounted for 8.2, 20.5 and 4.3% of the TRR in extracts from soybean forage hay and straw, corresponding to 0.323, 0.286 and 0.370 mg eq/kg, respectively.

Overall, identification rates were sufficient and amounted to 72.2% of TRR for forage, 69.8% of TRR for hay, 84.6% of the TRR for straw and 69.8% of TRR for seeds. In soybean forage, hay and straw 14, 5 and 20 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for less than 3.0% of the TRR (0.116 mg eq/kg), 6.1% of the TRR (0.086 mg eq/kg) and 2.8% of the TRR (0.230 mg eq/kg) for forage, hay and straw, respectively.

All initial profiles of conventional extracts of the raw agricultural commodities were performed within 6 months after harvest. Storage stability of matrix and extract samples was demonstrated exemplarily for soybean hay and straw for 18 and 27 months, respectively.

As metabolic reactions, de-fluorination at position 5 of the pyrazole ring followed by conjugation with homoglutathione and degradation of the homoglutathione moiety followed by conjugation with malonic acid or degradation and desamination to mercapto lactic acid group and hydroxylation of the benzyl moiety or of the propyl group were observed. Furthermore glycosilation was clearly observed at the mercapto lactic acid group.

Based on these results, the degradation behaviour of [phenyl-UL-^{14}C]BCS-CN88460 in soybean is adequately understood and a pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[phenyl-UL-^{14}C]
Specific radioactivity	4.13 MBq/mg
Radiochemical purity	> 98%
Chemical purity	> 98%

Formulation of the test compound

A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile to give a concentration of about 5 mg/mL. The purity in the stock solution was checked by HPLC with radio detection and was 100%

The test compound was formulated as an EC 50 for the experiment and therefore [phenyl-UL-^{14}C]BCS-CN88460 was dissolved in acetonitrile. For each of the three spray dilutions, adequate parts of the stock solution were transferred into glass vials and evaporated to dryness. Blank formulation was added and the mixtures were homogenised using a magnetic stirrer. The sample was then adjusted with water to a final volume of 50 mL (1st and 2nd application) and 100 mL (3rd application) of the spray dilution and homogenised by stirring.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**CEC**
Sandy loam	2.1%	7.23	15.5 meq/100 g

3. Plant: Soybean, variety “Amandine”, representative for oilseeds

B. Study Design

1. Experimental conditions:

The experiment was conducted with soybean plants (variety: Amandine) based on a plant density of 800,000 soybean plants per hectare. A planting container with a surface area of 1 m^2 was used corresponding to the rate of 80 seeds per m^2. The plants were cultivated in the glass-roofed greenhouse (Göbrichen) of the test facility and were grown similar to natural temperature and light conditions, but protected from rainfall. They were watered by pouring onto the soil in the planting containers. The plants were applied at three different growth stages (BBCH 14, 51 and 85). At all these growth stages the target single application rate was 60 g a.s./ha. The target rate corresponds to the anticipated maximum application rates for the use type.

For each application, the soybean plants were treated with 50 mL (1st and 2nd application) and 100 mL (3rd application) of the aqueous spray dilutions using a controlled track sprayer with a flat fan nozzle. To avoid contamination of the surrounding area by drift, the plants in the planting container were enclosed with a foil housing. After spraying the spray dilution onto the oilseed rape plants in the planting container, the spray device and the protective plastic foil around the planting container were rinsed with acetonitrile/water (8/2; v/v). The actual amount applied was calculated by subtracting the losses from the radioactivity in the original application solution. At the 1st application 22.2 MBq of the labelled test compound were applied, corresponding to 5.4 mg a.s.. At the 2nd application 23.1 MBq of the test compound were applied, corresponding to 5.6 mg a.s.. At the 3rd application 27.3 MBq of the test compound were applied, corresponding to 6.6 mg a.s.. The actual single application rates were 54, 56 and 66 g a.s./ha, resulting in a total actual application rate of 176 g a.s./ha.

2. Sampling:

At growth stage BBCH 49 the RAC forage, at growth stage BBCH 77 the RAC hay and at BBCH 96 the RACs straw and seeds were harvested. Plant samples were collected by cutting approximately 1-2 cm above the soil level. Plants sampled at hay stage were dried in a hood for 4 days.

The total weight of each sample was determined. The samples were homogenised with liquid nitrogen using a high speed blender. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates were extracted. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

Aliquots of the homogenised samples of soybean forage, hay, straw and seeds were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion and LSC.

The extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

Each combined percolate/rinse solution obtained from SPE purification was evaporated to the aqueous remainder. The final conventional extracts were analysed by HPLC with the general profiling method. All soybean samples and extracts were stored in a freezer (≤ -18 °C).

Exhaustive extraction and corresponding clean-up:

Solids from the conventional extraction of soybean forage, hay and straw were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased

temperature (0 to 5 min increase to 120 °C, 5 to 20 min at 120 °C, 800 W). The microwave extracts were cooled down at room temperature.

For forage and hay, the individual extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge, which was rinsed with methanol and water and conditioned with acetonitrile/water (8/2; v/v) beforehand. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v). Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder.

The exhaustive extracts of straw were directly concentrated by evaporation to the aqueous remainder. The final exhaustive extract of soybean hay was partitioned for characterisation. The final exhaustive extracts of forage and straw were analysed by HPLC with the general profiling method. The extracts were stored in a freezer (≤ -18 °C).

Characterisation of residues by partitioning

Radioactivity released from soybean hay by exhaustive extraction under microwave assistance was characterised by partitioning. Therefore, 2 mL of the concentrate obtained during exhaustive extraction and after purification were mixed with 8 mL water and 10 mL ethyl acetate in a centrifuge tube. The mixture was incubated 30 min by 150 rpm on a flatbed shaker. Four gram anhydrous magnesium sulphate, one gram sodium chloride, one gram trisodium citrate and 0.5 gram disodium citrate sesquihydrate were added to remove water and adjust the pH value. After addition of the salt mixture, the tube was immediately shaken vigorously by hands for 10 seconds and with a flatbed shaker for at least one minute and afterwards centrifuged. Ethyl acetate and water phase were separated, their volume was determined. An aliquot of the concentrated ethyl acetate phase was analysed by HPLC.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent/ scintillation cocktail mixture and the radioactivity was measured by LSC.

Conventional and microwave extracts were analysed by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

2. Identification and characterisation:

Metabolic profiles from the conventional and exhaustive extracts of all RACs were compared, as analysed by HPLC among themselves. Metabolic profiles of all RACs were compared with metabolic profiles of corresponding RACs in the soybean metabolism study with the pyrazole label in which the major metabolites were identified spectroscopically. Parent compound was identified in soybean seeds extract by TLC co-chromatography with the test compound.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-40: Reference compound

Report name / other names/codes	**Chemical Name (IUPAC)**	**Structure**
Parent compound BCS-CN88460 Radiolabelled reference: S_PH_1_1000 Non-radiolabelled reference: BCS-CN88460-01-02	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

The initial profiles of the conventional extracts of soybean forage, hay, straw and seeds were analysed within 6 months after harvest of the soybean plant raw material. The stability of the residues in the stored sample matrices and extracts were exemplarily demonstrated in of soybean hay and straw by re-extraction followed by HPLC after 18 and 27 months of storage, respectively.

The comparison of the respective HPLC chromatograms revealed that the profiles of the extracts did not significantly change after storage of the material. Therefore, the residues were sufficiently stable during the experimental period of the study and the chromatograms represent the metabolic pattern in the samples at harvest.

II. Results and Discussion

The metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in soybean was investigated after three spray applications.

Soybean plants in a 1 m^2 container were treated with [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC 50 at BBCH 14 (beginning of stem elongation), BBCH 51 (first flower buds visible) and BBCH 85 (about 50% of pods are ripe). The actual single application rate corresponded to 54, 56 and 66 g a.s./ha. The total application rate amounted to 176 g a.s./ha, which was slightly below the anticipated maximum application rate of 180 g a.s./ha.

The TRR values of the individual RACs were determined by summing up the radioactivity determined in the combined extracts and the radioactivity in the solids. The residue levels are shown in mg active substance equivalents per kg sample material (mg a.s.equiv./kg or simplified mg eq/kg).

The TRR in soybean straw was high and amounted to 8.527 mg eq/kg. Soybean forage and hay contained a TRR of 3.936 mg eq/kg and 1.397 mg eq/kg, respectively. The TRR determined for soybean seeds was low and amounted to 0.015 mg eq/kg.

The residue values in the parallel study with the pyrazole label were comparable for forage but significantly higher for hay, straw and seeds. This is due to differences in plant growth during cultivation of both studies resulting in vegetation differences during the second and third application.

Table 7.2.1-41: TRR values in soybean matrices after foliar application of [phenyl-UL-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Soybean forage	1 spray application at BBCH 14, 54 g a.s./ha	6	3.936
Soybean hay	2 spray applications at BBCH 14 and 51: 54 and 56 g a.s./ha (110 g a.s./ha, total)	38	1.397
Soybean straw	3 spray applications at BBCH 14, 51 and 85: 54, 56 and 66 g a.s./ha (176 g a.s./ha; in total)	21	8.527
Soybean seeds		21	0.015

* PHI: Pre-Harvest Interval (corresponds to days after last treatment (DAT) at harvest/sampling)

Soybean forage was conventionally extracted three times with acetonitrile/water mixtures releasing 91.4% of the TRR (3.597 mg eq/kg). After concentration and purification steps 90.4% of the TRR (3.557 mg eq/kg) were analysed by HPLC. For soybean forage, a microwave extraction was performed. With this exhaustive method 5.2% (0.205 mg eq/kg) of the TRR were further extracted and 4.5% of the TRR (0.176 mg eq/kg) analysed by HPLC, additionally. The residue level in the solids of soybean forage after conventional and exhaustive extraction amounted to 3.4% of the TRR and 0.134 mg eq/kg. Losses during sample clean-up of forage samples were 1.7% of the TRR (0.069 mg eq/kg).

Soybean hay was conventionally extracted three times with acetonitrile/water mixtures releasing 88.6% of the TRR (1.238 mg eq/kg). After concentration and purification steps 87.5% of the TRR (1.222 mg eq/kg) were analysed by HPLC. Exhaustive extraction of soybean hay, releasing 6.3% of the TRR and 0.088 mg eq/kg, was further characterized by partitioning of the exhaustive extract using ethyl acetate accounting for 5.9% of the TRR (0.082 mg eq/kg) after purification. Complete radioactivity of the exhaustive extract was found in the ethyl acetate phase after partitioning. This is in good accordance to results from the partitioning of experiment performed with soybean hay exhaustive extract in a parallel study with [pyrazole-4-^{14}C]BCS-CN88460. Since the complete radioactivity of the exhaustive extracts of soybean hay in both studies was found in the ethyl acetate phase, it can be assumed that the residues were highly unpolar and likely ascribable to radioactivity derived from parent compound. An aliquot of the concentrated ethyl acetate phase was further analysed by HPLC but not peak above detection limit was detected due to low radioactivity concentrations and high matrix content of the sample. The residue level in the solids of soybean hay after conventional and exhaustive extraction amounted to 5.1% of the TRR and 0.071 mg eq/kg. Losses during sample clean-up were 1.5% of the TRR (0.022 mg eq/kg).

Soybean straw was conventionally extracted three times with acetonitrile/water mixtures releasing 92.8% of the TRR (7.914 mg eq/kg). After concentration and purification steps 91.8% of the TRR (7.830 mg eq/kg) were analysed by HPLC. For soybean straw samples, a microwave extraction was performed. With this method 3.1% (0.264 mg eq/kg) were extracted and 3.1% of the TRR (0.264 mg eq/kg) analysed by HPLC, additionally. The residue level in the solids of soybean straw after conventional and exhaustive extraction amounted to 4.1% of the TRR and 0.349 mg eq/kg. Losses during sample clean-up were 1.0% of the TRR (0.084 mg eq/kg).

Soybean seeds were conventionally extracted three times with acetonitrile/water mixtures releasing 69.8% of the TRR (0.011 mg eq/kg). No losses during concentration and purification steps occurred and all of the residues in the extract (69.8% of the TRR, 0.011 mg eq/kg) were quantitatively analysed by HPLC. The residue level in the solids of soybean seeds after conventional extraction amounted to 30.2% of the TRR and 0.005 mg eq/kg.

The distribution of the radioactive residues is shown in the following table.

Table 7.2.1-42: Distribution of radioactivity in the extracts of soybean matrices after three foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

-- not performed

n.q.: not quantified

Comparison of profiles of all RACs to corresponding profiles of the parallel study performed with [pyrazole-4-^{14}C]BCS-CN88460 showed good correspondence to each other and revealed that no label specific metabolism could be observed for the pyrazole label.

Chromatograms of conventional extracts of soybean straw were compared to the profile of conventional extract of soybean straw treated under microwave conditions. This demonstrated that the parent compound and major metabolites were not degraded by this form of extraction.

In conventional extract from soybean forage 69.4% of the TRR (2.729 mg eq/kg) were identified in total. The parent compound, BCS-CN88460-desfluoro-homoGSH (**M44**) and BCS-CN88460-desfluoro-mercapto-lactic acid-OH were major components representing 17.9, 19.6 and 16.7% of the TRR corresponding to 0.703, 0.770 and 0.658 mg eq/kg, respectively. The metabolites BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 4.8, 2.7 and 7.7% of the TRR corresponding to 0.187, 0.107 and 0.304 mg eq/kg, respectively. In the exhaustive extract of forage 2.8% of the TRR (0.108 mg eq/kg) were further identified. The parent compound and the metabolites BCS-CN88460-desfluoro-homoGSH (**M44**), BCS-CN88460-desfluoro-mercapto-lactic acid-OH and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 1.3, 0.6, 0.3 and 0.5% of the TRR corresponding to 0.053, 0.023, 0.014 and 0.019 mg eq/kg, respectively.

In conventional extract from soybean hay 69.8% of the TRR (0.974 mg eq/kg) were identified in total. The parent compound, BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc and BCS-CN88460-desfluoro-Cys-MA (**M45**) were major components representing 10.3, 17.6, 10.7 and 20.5% of the TRR corresponding to 0.144, 0.246, 0.150 and 0.286 mg eq/kg, respectively. The metabolites BCS-CN88460-desfluoro-homoGSH (**M44**) and BCS-CN88460-desfluoro-mercapto-lactic acid-OH represented 7.8 and 2.8% of the TRR corresponding to 0.109 and 0.040 mg eq/kg, respectively. Residues in the exhaustive extract of soybean hay were characterized by partitioning using ethyl acetate. Complete radioactivity of the exhaustive extract was found in the ethyl acetate phase after partitioning. This indicates the residues contained and previously extracted under microwave assistance were highly unpolar residues and likely ascribable to radioactivity derived from parent compound. Exhaustive extract of soybean hay was partitioned using ethyl acetate. Radioactivity in the concentrated ethyl acetate phase was analysed by HPLC but no single ingredient in the extract was detected above the limit of detection due to low radioactivity concentration and high matrix content of the sample.

In conventional extract from soybean straw 83.3% of the TRR (7.107 mg eq/kg) were identified in total. The parent compound was by far the major component representing 69.6% of the TRR (5.934 mg eq/kg), whereas the metabolites BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, BCS-CN88460-desfluoro-homoGSH (**M44**), BCS-CN88460-desfluoro-mercapto-lactic acid-OH, BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 2.1, 2.5, 2.4, 2.7 and 4.1% of the TRR corresponding to 0.177, 0.211, 0.206, 0.228 and 0.350 mg eq/kg, respectively. In the exhaustive extract of straw further 3.1% of the TRR (0.264 mg eq/kg) were identified. The parent compound and the metabolites BCS-CN88460-desfluoro-homoGSH (**M44**), BCS-CN88460-desfluoro-mercapto-lactic acid-OH, BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**) represented 0.6, 0.3, 0.1, 0.1 and 0.2% of the TRR corresponding to 0.049, 0.024, 0.009, 0.007 and 0.020 mg eq/kg, respectively.

Conventional extract from soybean seeds contained only parent compound representing 69.8% of the TRR corresponding to 0.011 mg eq/kg. The compound was identified by TLC co-chromatography of the parent compound fraction isolated from conventional extract of soybean seeds with the non-radiolabelled reference compound BCS-CN88460.

The TRR and the distribution of parent and metabolites in soybean matrices are shown in the following table.

Table 7.2.1-43: Distribution of parent compound and metabolites the extracts of soybean matrices after three foliar applications of [phenyl-UL-^{14}C]BCS-CN88460

Overall, identification rates were sufficient and amounted to 72.2% of TRR for forage, 69.8% of TRR

for hay, 84.6% of the TRR for straw and 69.8% of TRR for seeds. In soybean forage, hay and straw, 14, 5 and 20 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for less than 3.0% of the TRR (0.116 mg eq/kg), 6.1% of the TRR (0.086 mg eq/kg) and 2.8% of the TRR (0.230 mg eq/kg).

B.7.2.1.4.3. Summary of isoflucypram metabolism in soybean

The metabolism of **isoflucypram** in soybean plants was investigated after three foliar applications at growth stages BBCH 14, BBCH 51 and BBCH 84-85. The soybean plants were treated with either [pyrazole-4-^{14}C]BCS-CN88460 or [phenyl-4-^{14}C]BCS-CN88460 formulated as an EC 50 at a nominal application rate of 60 g a.s./ha (actual: 54-66 g a.s./ha) corresponding to a total nominal application rate of 180 g a.s./ha (actual 176-181 g a.s./ha). Soybean forage was harvested at BBCH 49, soybean hay at BBCH 77, soybean straw and seeds were harvested at BBCH 96.

Residues in soybean forage, hay and straw were high compared to very low residues in seeds. The main portion of residues of forage, hay, straw and seeds were released by conventional extraction. Minor amounts were additionally released for forage, hay and straw by exhaustive extraction. Overall, identification rates in soybean forage hay, straw and seeds were sufficient. Parent compound **isoflucypram** was the only component in soybean seeds.

In soybean forage, hay and straw parent compound was a major component besides the identified major metabolites: BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (**M48**), BCS-CN88460-desfluoro-homoGSH (**M44**), BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**), BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc (**M47**) and BCS-CN88460-desfluoro-Cys-MA (**M45**). No label specific metabolites were observed. Storage stability of matrices and extracts was demonstrated for a period of 18 and 27 months.

The main metabolic reactions observed were:

- de-fluorination at position 5 of the pyrazole ring followed by conjugation with homoglutathione. Degradation of the homoglutathione moiety followed by conjugation with malonic acid leading to BCS-CN88460-desfluoro-Cys-MA (**M45**);

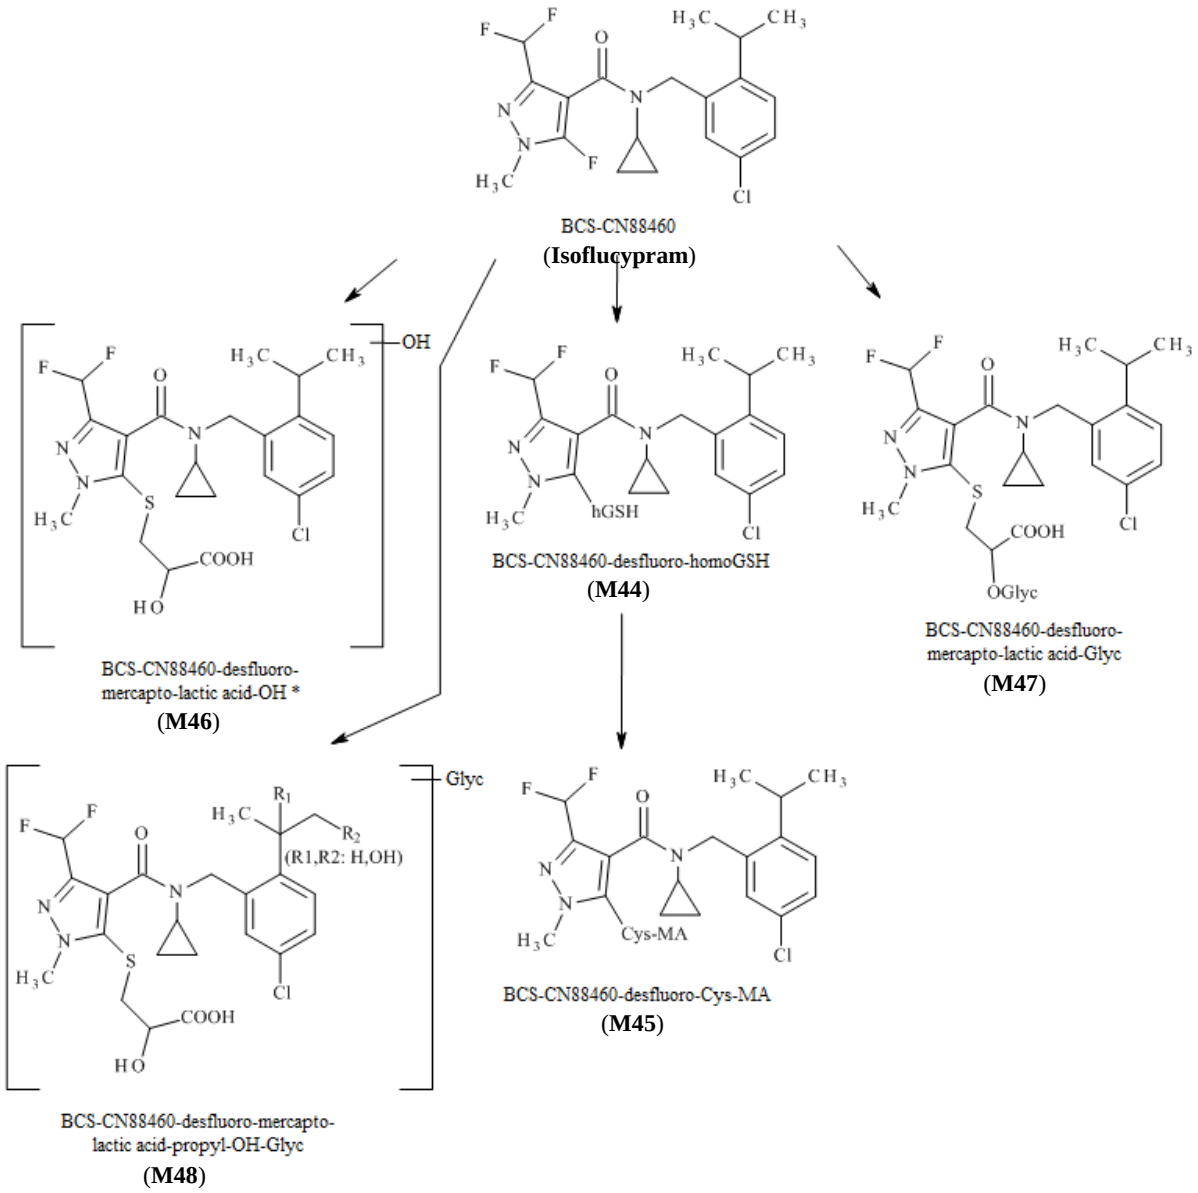
- de-fluorination at position 5 of the pyrazole ring followed by conjugation with homoglutathione, degradation and desamination to mercapto lactic acid group and hydroxylation of the benzyl moiety or of the propyl group;

- glycosilation was clearly observed at the mercapto lactic acid group and could not be located for metabolite BCS-CN88460-desfluoro-mercapto lactic acid-propyl-OH-Glyc.

The results from the studies involving the pyrazole- and phenyl-labelled **isoflucypram** are in close agreement. No label specific metabolites were observed using either label.

Based on these results, the degradation behaviour of **isoflucypram** in soybean is adequately understood and a metabolic pathway is proposed in the figure below:

Figure 7.2.1-3: Proposed metabolic pathway of isoflucypram in soybean



* BCS-CN88460-desfluoro-mercapto-lactic acid-OH (**M46**): OH position based on mass spectrometry: benzyl moiety.

B.7.2.1.5. **Potato (tuber/seed treatment)**

Metabolism studies in potatoes after tuber/seed treatment with [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C]BCS-CN88460 were conducted.

Table 7.2.1-45: Overview of potato metabolism studies

Plant	Application	Target application rate	BBCH Code	Reference
Potato	Tuber /seed treatment, pyrazole-labelled **isoflucypram**	1 x 25 g a.s./ha	BBCH 03	M-634586-01-1
Potato	Tuber/seed treatment, phenyl-labelled **isoflucypram**	1 x 25 g a.s./ha	BBCH 03	M-634587-01-1

Summary of metabolism in potato (tuber/seed treatment)

In both potato studies metabolism of **isoflucypram** following seed/tuber treatment was investigated at

the envisaged use rate (1x) and in addition at a 10x overdosed application rate. The TRRs in samples of the phenyl labelled study were lower than the TRRs found in the study with the pyrazole label. The TRRs in tubers of the normal dose experiments (1x) were very low and therefore no identification and quantitation of parent compound and metabolites in tubers was performed. Parent compound was the main component of the residue in tubers from the overdosed (10x) experiments. Potato leaves were also investigated in order to support metabolite identification and investigation of the metabolic pathway. The main metabolic reactions deduced from analysis of leaves were hydroxylation in position 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid and hydroxylation of the phenyl moiety followed by conjugation with hexose and malonic acid. One metabolite specific to the pyrazole label resulting from cleavage of **isoflucypram** followed by demethylation was identified in leaves as well as in low amounts in tubers of the overdosed experiment. **Isoflucypram** and/or metabolites were taken up and translocated into leaves and tubers only to a very small extent.

B.7.2.1.5.1. [pyrazole-4-^{14}C]isoflucypram

Report:	KCA 6.2.1/09; Botterweck, J.; 2018
Title:	Metabolism of [pyrazole-4-^{14}C] BCS-CN88460 in potato after seed treatment
Report No.:	S17-01394
Document No.:	M-634586-01-1
Guideline(s):	OECD Test Guideline 501; US EPA OCSPP Test Guideline No. 860.1300; JMAFF guideline 12 Nousan No 8147 requirement 2-4-1; Regulation (EC) No. 1107/2009.
Guideline deviation(s):	None
GLP/GEP:	Yes

Summary

The metabolism of [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC200 was investigated in potato following seed treatment. The application rate was approx. 28 g a.s./ha corresponding to approximately 1 g a.s./100 kg tubers. Additionally, a 10x overdosed experiment was conducted.

Potato tubers and leaves were harvested at BBCH growth stage 97 in each experiment. The leaves were harvested for analyses to support metabolite identification and investigation of the metabolic pathway. The total radioactive residue (TRR) in tubers of the normal dose experiment was very low and amounted to 0.009 mg eq/kg. In the 10x overdosed experiment the TRR in tubers was 0.064 mg eq/kg. In leaves, the TRR was 0.374 mg eq/kg for the normal dose experiment and 1.071 mg eq/kg for the 10x experiment. Parent compound and/or metabolites were taken up and translocated into leaves and tubers only to a very small extent (calculated rate of uptake into tubers and leaves based on the applied radioactivity amounts to ≤0.3% and ≤1.0% of the applied radioactivity for tubers and leaves, respectively).

Potato tubers of the normal dose experiment were not extracted due to the very low TRR and therefore no identification and quantitation of parent compound and metabolites in tubers of the normal dose experiment was performed. Homogenised tuber sample of the overdosed experiment was conventionally extracted with acetonitrile/water. The extraction rate for tubers was high, amounting to 97.7% of TRR. Supportively, leaves of both experiments were extracted with acetonitrile/water. Extraction rates for leaves were also high, amounting to 96.1 and 93.2% of the TRR for the normal dose and overdosed experiment, respectively.

Residues in the extracts were analysed and quantified by HPLC. The parent compound and metabolites were either identified by co-chromatography with the reference compound or by spectroscopic analysis in isolated fractions of leaves of the overdosed experiment. In addition, the metabolite pattern and retention times of the current and the potato metabolism study with the phenyl label were compared.

Parent substance **isoflucypram** represented the most prominent residue component in tubers of the overdosed experiment accounting for 86.4% of TRR (0.056 mg eq/kg). Only one further component was detected in low amounts (0.007 mg eq/kg) in tubers of the 10x experiment: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**).

In extracts of leaves of the normal and overdosed experiment, parent compound was a minor component and represented 2.0% of TRR (0.007 mg eq/kg) and 2.5% of TRR (0.027 mg eq/kg), respectively. Besides parent compound, three major metabolites were identified in leaves: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**).

Identification rates were excellent for tubers of the overdosed experiment (97.5% of TRR) and moderate for leaves samples due to extensive metabolism observed in leaves indicated by few major components and a large number of minor or trace metabolites detected for leaves (up to 34 unknown metabolites, individually accounting for equal or less than 6.3% of TRR or 0.064 mg eq/kg).

Overall, comparison of metabolic profiles with those of a parallel study with [phenyl-UL-^{14}C]BCS-CN88460 revealed a high correspondence and one metabolite specific for the pyrazole label was identified: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**)

All extraction experiments of the potato samples and the first HPLC analyses were performed within 6 months after harvest.

Investigation of leaves lead to the identification of metabolic reactions and pathway in potato which could not be derived from potato tubers solely. [pyrazole-4-^{14}C]BCS-CN88460 was extensively metabolised in potato after seed treatment. The main metabolic reactions were hydroxylation in position 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid and hydroxylation of the phenyl moiety followed by conjugation with hexose and malonic acid. Cleavage of **Isoflucypram** followed by demethylation lead to a label specific metabolite identified for the pyrazole label.

Based on these results, the degradation behaviour of [pyrazole-4-^{14}C]BCS-CN88460 in potato is adequately understood and a pathway is proposed.

Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[pyrazole-4-^{14}C]
Specific radioactivity	4.22 MBq/mg
Radiochemical purity	> 98% (HPLC)
Chemical purity	> 98% (HPLC)

Formulation of the test compound

A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile. The test compound was formulated as an EC 200 for both normal dose and overdosed experiment.

Therefore, an adequate amount of the stock solution was transferred into a glass vial and evaporated to dryness. Blank formulation was added, the mixture was homogenised and adjusted to a final volume of 10 mL of the application dilution.

2. Soil:

Soil characteristics			
Type	**TOC**	**pH ($CaCl_2$)**	**Total nitrogen**
Sandy loam	2.77%	7.38	0.282%

3. Plant: Potato, variety "Annabelle", representative for root crops

B. Study Design

1. Experimental conditions:

Two individual experiments were conducted.

Normal dose experiment (1x): This experiment simulated the envisaged seed/tuber treatment use pattern and was based on a maximum proposed application rate of 1 g a.s./100 kg tubers. This rate corresponds to 25 g a.s./ha or 0.5 mg a.s./seed potato assuming a rate of 50,000 seed potatoes/ha and a mean weight of 50 g per seed potato. Each seed potato was treated with 0.55 mg [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC 200. This resulted in an actual application rate of 28 g a.s./ha deviating by +10% from the maximum proposed application rate. A total of 5 seed potatoes were planted in a planting container with a surface area of 1 m^2.

Overdosed experiment (10x): This experiment was performed as additional overdosed experiment in order to facilitate the identification of formed metabolites. In this experiment [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC 200 was applied at a rate of approx. 5.5 mg a.s./tuber. This resulted in an actual application rate of 274 g a.s./h deviating by +10% from the envisaged 10x rate. A total of 5 seed potatoes were planted in a planting container with a surface area of 1 m^2.

For both experiments the plants were cultivated in the glass-roofed greenhouse of the test facility and were grown similar to natural temperature and light conditions with an average temperature of 27.1°C and a relative humidity of 49.1%. They were watered by pouring onto the soil in the planting containers.

2. Sampling

At maturity (BBCH growth stage 97, 119 days after the application) the RAC tubers and leaves as supportive matrix of both experiments were harvested. Tubers were dug out of the soil and leaves were cut off and combined with fallen leaves. The total weight of each sample was determined. The samples were homogenised under dry ice using a robot coupe stirrer. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates of tubers (10x) and leaves (1x and 10x) were extracted. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids. The TRR value for tubers of the 1x experiment was determined by combustion analysis.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

Due to the very low TRR of tubers of the normal dose experiment no extraction was performed. For conventional extraction of tubers (overdosed experiment) and leaves (normal dose and overdosed experiment), aliquots of the homogenised samples were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were

filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion analysis.

The extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

Each combined percolate/rinse solution obtained from SPE purification was evaporated to the aqueous remainder and mixed with emulsifier beforehand. The final conventional extracts were analysed by HPLC with the general profiling method.

Exhaustive extraction and corresponding clean-up:

Solids from the conventional extraction of potato leaves of the normal dose experiment were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased temperature. The microwave extracts were combined and concentrated by rotary evaporation. Aliquots of the final exhaustive extract were subjected to a clean-up step using a SPE RP 18 cartridge analogously to the conventional extraction. The combined fractions from SPE purification were evaporated to the aqueous remainder.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent / scintillation cocktail mixture and the radioactivity was measured by LSC. The TRR of extracted samples was determined by summation of the radioactivity of the combined extract(s) and of the remaining solids. The TRR of tubers of the low dose experiment was determined by combustion analysis. The TRR was expressed in mg a.s. equivalents per kg sample weight. Amounts of radioactive residues in the extracts were expressed as percentage of the TRR and also as mg a.s. equivalents per kg sample weight.

2. Identification and characterisation:

For elucidation of metabolism, extracts were analysed by HPLC and/or TLC. Parent compound and metabolites were either identified by LC-MS(/MS) of isolated peaks from leaves of the overdosed experiment or by co-chromatography with an authentic reference compound using two independent chromatographic methods with different selectivity (e.g. HPLC and TLC).

In addition, metabolic profiles of all potato sample extracts were compared, as analysed by HPLC among themselves. Metabolic profiles of all sample extracts were compared with metabolic profiles of corresponding sample extracts in the potato metabolism study with the phenyl label.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 7.2.1-46: Reference compound

Report name / other names/codes	**Chemical Name (IUPAC)**	**Structure**
Parent compound BCS-CN88460 Reference: M-00002258	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

All extraction experiments of tubers and leaves and the first HPLC analyses were performed within six months after harvest of the samples, storage stability data are not required. Complementary storage stability investigations proved that the metabolic profile of potato leaves did not significantly change during 8 months of storage of the plant material at ≤-18 °C.

It was therefore concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The metabolism of [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC 200 was investigated in potatoes after seed treatment.

The application rate was approx. 28 g a.s./ha corresponding to approx. 1 g a.s./100 kg tubers. Additionally, a 10x overdosed experiment was conducted.

The total radioactive residue (TRR) in tubers of the normal dose experiment was very low and amounted to 0.009 mg eq/kg. In the 10x overdosed experiment the TRR in tubers was 0.064 mg eq/kg. Potato leaves were analysed as additional matrix to support metabolite identification and investigation of the metabolic pathway. In leaves, the TRR was 0.374 mg eq/kg for the normal dose experiment and 1.071 mg eq/kg for the 10x experiment.

TRRs of tubers and leaves of the 10x overdosed experiment were significantly higher compared to tubers and leaves of the 1x experiment. Residues in tubers were generally low and significantly lower compared to leaves indicating that uptake and transfer of residues derived from seed treatment with **isoflucypram** into the plant as well as transfer of residues from leaves to tubers is limited. Based on the applied radioactivity (RA) and the amount of total radioactivity determined in the harvested samples it can be roughly estimated (by recalculation from data given in the report), that only ≤0.3% and ≤1.0% of the applied RA were taken up and translocated into tubers and leaves, respectively (e.g. the maximum theoretical residue in tubers 1x would be 2.8 mg applied a.s./0.877 kg tubers harvested = 3.2 mg eq/kg. Actually, 0.009 mg eq/kg (=0.3% of the applied radioactivity) were found).

Table 7.2.1-47: TRR in potato matrices after seed treatment with [pyrazole-4-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)*	TRR (mg eq/kg)
Potato tubers	Normal dose experiment: seed/tuber treatment at a nominal rate of 1 g a.s./100 kg tubers corresponding to 25 g a.s./ha	119	0.009
Potato leaves		119	0.374
Potato tubers	Overdosed experiment (10x): seed/tuber treatment at approx. 10x of the rate in the normal dose experiment	119	0.064
Potato leaves		119	1.071

* PHI: Pre-Harvest Interval

The results of the normal dose experiment are as follows:

Due to the very low TRR of tubers of the 1x experiment no extraction and therefore no identification and quantification of parent compound and metabolites was performed.

Leaves were conventionally extracted with acetonitrile/water releasing 88.6% of the TRR (0.331 mg eq/kg). Losses during sample clean up accounted for 1.7% of TRR (0.007 mg eq/kg). After concentration and purification steps 86.9% of TRR (0.324 mg eq/kg) were analysed. Solids after conventional extraction of leaves were further subjected to exhaustive extraction under microwave support releasing 7.5% of the TRR (0.028 mg eq/kg). After purification of this extract 6.9% of the TRR (0.026 mg eq/kg) were analysed. In total, 96.1% of the TRR (0.359 mg eq/kg) was extracted

from leaves of the normal dose experiment. The post extraction solids (PES) amounted to 3.9% of the TRR (0.015 mg eq/kg).

The results of the overdosed experiment (10x) are as follows:

Potato tubers of the overdosed experiment were conventionally extracted with acetonitrile/water releasing 97.7% of the TRR (0.063 mg eq/kg). Losses during sample clean up accounted for 0.3% of TRR (<0.001 mg eq/kg).After concentration and purification steps 97.5% of the TRR (0.063 mg eq/kg) were analysed. Only 2.3% of TRR (0.001 mg eq/kg) remained in the solids.

Leaves were conventionally extracted with acetonitrile/water releasing 93.2% of the TRR (0.998 mg eq/kg). Losses during sample clean up accounted for 0.6% of TRR (0.007 mg eq/kg). After concentration and purification steps 92.6% of TRR (0.991 mg eq/kg) were analysed. The PES amounted to 6.8% of the TRR (0.073 mg eq/kg).

* no individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of leaves

For elucidation of metabolism, extracts were analysed by HPLC and/or TLC. Metabolites were either identified by LC-MS(/MS) of isolated peaks from leaves of the overdosed experiment or by co-chromatography with an authentic reference compound using two independent chromatographic methods with different selectivity (e.g. HPLC and TLC).

A total of 97.5% of the TRR was identified in extract of tubers of the overdosed experiment. The parent compound **isoflucypram** represented by far the main residue component in tubers of the overdosed experiment accounting for 86.4% of TRR (0.056 mg eq/kg). Only one further component was detected in low amounts in tubers of the overdosed experiment accounting for 0.007 mg eq/kg (11.1% of the TRR): BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**).

The leaves were analysed as additional matrix to support metabolite identification and investigation of the metabolic pathway. In extracts of leaves of the normal dose and overdosed experiment, parent compound was a minor component and represented 2.0% of TRR (0.007 mg eq/kg) and 2.5% of TRR (0.027 mg eq/kg), respectively. Besides parent compound, three major metabolites were identified in leaves: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**). BCS-CN88460-OH-phenyl-Glyc-MA(**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**) represent conjugates of the test compound with hexose and malonic acid and were only detected in leaves. BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**) is a metabolite specific for the pyrazole label resulting from cleavage of the parent compound followed by demethylation. In leaves, up to 34 unknown minor or trace metabolites were characterised, individually accounting for equal or less than 6.3% of TRR or 0.064 mg eq/kg.

The TRR and the distribution of parent and metabolites in potato matrices are shown in the following tables.

Table 7.2.1-49: Distribution of parent and metabolites in the extracts of potato matrices after seed/tuber treatment with [pyrazole-4-^{14}C]BCS-CN88460 (normal dose)

n.d. not detected

The metabolic profiles of conventional extracts from leaves of the 1x and 10x experiment were qualitatively comparable, indicating a similar pattern of degradation in both experiments.

Overall, comparison of metabolic profiles with those of a parallel study with [phenyl-UL-^{14}C]BCS-CN88460 revealed a high correspondence and one metabolite specific for the pyrazole label was identified: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**).

III. Conclusions

The metabolism of [pyrazole-4-^{14}C]BCS-CN88460 formulated as an EC200 was investigated in potato following seed treatment. The application rate was approx. 28 g a.s./ha corresponding to approx. 1 g a.s./100 kg tubers. Additionally, a 10x overdosed experiment was conducted.

The residue in tubers at the envisaged use rate was very low (<0.01 mg eq/kg). The TRR of tubers of the overdosed experiment was significantly higher compared to tubers of the normal dose experiment, similarly for residues in leaves compared to tubers. **isoflucypram** and/or possible metabolites were taken up and translocated into the tubers only to a very small extent.

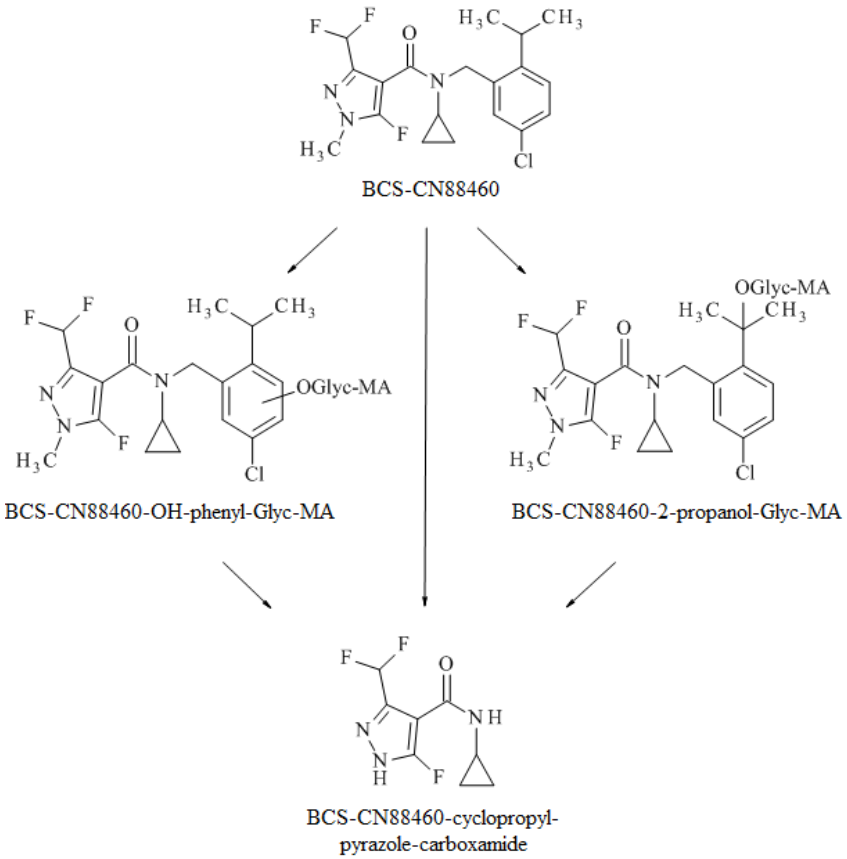
Leaves were analysed to support metabolite identification and investigation of the metabolic pathway. The extraction rates for tuber and leaves samples were very high (>93% of the TRR). The identification rate in tubers was very high (>97% of the TRR) and moderate for leaves samples due to extensive metabolism observed in leaves indicated by few major components and a large number of minor or trace metabolites detected in leaves. Parent compound was the main component in tubers of the overdosed experiment and a minor component in leaves. Besides parent compound three major metabolites were identified in potato leaves: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**). Metabolite BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**) is specific for the pyrazole label and was further detected in low amounts in tubers of the overdosed experiment.

The results in the present study are in good agreement with the results with the phenyl-label. One label specific metabolite was identified for the pyrazole label: BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**). Based on the identified metabolites the following metabolic routes were deduced:

- Hydroxylation in position 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid;
- Hydroxylation of the phenyl moiety followed by conjugation with hexose and malonic acid;
- Cleavage of the molecule followed by demethylation leading to BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**).

Based on these results, the degradation behaviour of [pyrazole-4-^{14}C]BCS-CN88460 in potato is adequately understood and a metabolic pathway is proposed in the figure below.

Figure 7.2.1-4: Proposed metabolic pathway of [pyrazole-4-^{14}C]BCS-CN88460 in potato



B.7.2.1.5.2. [phenyl-UL-^{14}C]isoflucypram

Report:	KCA 6.2.1/10; Botterweck, J.; 2018; M-634587-01-1
Title:	Metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in potato after seed treatment
Report No.:	M-634587-01-1
Document No.:	M-634587-01-1
Guideline(s):	OECD Test Guideline No. 501 EPA guideline OPPTS 860.1300 JMAFF guideline 12 Nousan No 8147 requirement 2-4-1 Regulation (EC) No. 1107/2009 of the European Parliament and of the Council of 21 October 2009 concerning the placing of plant protection products on the market and repealing Council Directives 79/117/EEC and 91/414/EEC
Guideline deviation(s):	None
GLP/GEP:	Yes

Summary

The metabolism of [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC200 was investigated in potato following seed treatment. The application rate was approx. 28 g a.s./ha corresponding to approx. 1 g a.s./100 kg tubers. Additionally, a 10x overdosed experiment was conducted.

Potato tubers and leaves were harvested at BBCH growth stage 97 in each experiment. The leaves were harvested for analyses to support metabolite identification and investigation of the metabolic pathway. The total radioactive residue (TRR) in tubers of the normal dose experiment was very low and amounted to 0.002 mg eq/kg. In the 10x overdosed experiment the TRR in tubers was 0.042 mg eq/kg. In leaves, the TRR was 0.050 mg eq/kg for the normal dose experiment and 0.688 mg eq/kg for the 10x experiment. Parent compound and/or metabolites were taken up and translocated into leaves

and tubers only to a very small extent (calculated rate of uptake into tubers and leaves based on the applied radioactivity (RA) amounts to ≤0.2% and 0.6% of the applied RA for tubers and leaves, respectively).

Potato tubers of the normal dose experiment were not extracted due to the very low TRR and therefore no identification and quantitation of parent compound and metabolites in tubers of the normal dose experiment was performed. From tubers of the overdosed experiment, most of the radioactivity (82.2% of TRR) was conventionally extracted with acetonitrile/water. Subsequent exhaustive microwave extraction of solids released additional 12.9% of TRR leading to very high overall extraction rates of 95.1% of TRR for tubers of the overdosed experiment. Supportively, leaves of both experiments were extracted with acetonitrile/water. Extraction rates for leaves were very high and amounted to 92.6 and 93.8% of the TRR for the normal dose and overdosed experiment, respectively.

Residues in the extracts were analysed and quantified by HPLC. The parent compound and metabolites were identified by co-chromatography with authentic reference compounds using two independent chromatographic methods with different selectivity (e.g. HPLC and TLC) or by co-chromatography with compounds identified by spectroscopic analysis in isolated fractions of potato leaves within the potato metabolism study with the pyrazole label. In addition, the metabolite pattern and retention times of the current and the potato metabolism study with the pyrazole label were compared.

Parent substance **isoflucypram** represented the most prominent residue component in tubers of the overdosed experiment accounting for 69.2% of TRR (0.029 mg eq/kg). One minor metabolite in tubers of the overdosed experiment remained unknown, accounting to 0.005 mg eq/kg (13.0% of TRR).

In extracts of leaves of the normal and overdosed experiment, parent compound was a minor component and represented 7.3% of TRR (0.004 mg eq/kg) and 4.0% of TRR (0.027 mg eq/kg), respectively. Besides parent compound, two major metabolites were identified in leaves: BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**).

In tubers of the overdosed experiment, a total of 69.2% of TRR was identified. For leaves, identification rates were moderate due to extensive metabolism observed in leaves indicated by few major components and a large number of minor or trace metabolites detected for leaves (up to 21 unknown metabolites in leaves of the overdosed experiment, individually accounting for equal or less than 8.6% of TRR and 0.059 mg eq/kg).

Overall, comparison of metabolic profiles with those of a parallel study with [pyrazole-4-^{14}C]BCS-CN88460 revealed a high correspondence. Within the parallel study one label specific metabolite for the pyrazole label was identified whereas no metabolite specific for the phenyl study was detected.

All extraction experiments of the potato samples and the first HPLC analyses were performed within 6 months after harvest.

Investigation of leaves lead to the identification of metabolic reactions and pathway in potato which could not be derived from potato tubers solely. [phenyl-UL-^{14}C]BCS-CN88460 was extensively metabolised in potato after seed treatment. The main metabolic reactions were hydroxylation in position 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid and hydroxylation of the phenyl moiety followed by conjugation with hexose and malonic acid.

Based on these results, the degradation behaviour of [phenyl-UL-^{14}C]BCS-CN88460 in potato is adequately understood and a pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure	 * denotes the position of the ^{14}C-label
Radiolabel position	[phenyl-UL-^{14}C]
Specific radioactivity	4.13 MBq/mg
Radiochemical purity	> 98% (HPLC)
Chemical purity	> 99% (HPLC)

Formulation of the test compound

A stock solution of the test compound was prepared by dissolving the test compound in acetonitrile. The test compound was formulated as an EC 200 for both normal dose and overdosed experiment. Therefore, an adequate amount of the stock solution was transferred into a glass vial and evaporated to dryness. Blank formulation was added, the mixture was homogenised and adjusted to a final volume of 10 mL of the application dilution.

2. Soil:

Soil characteristics			
Type	TOC	pH ($CaCl_2$)	Total nitrogen
Sandy loam	2.77%	7.38	0.282%

3. Plant: potato, variety “Annabelle”, representative for root crops

B. Study Design

1. Experimental conditions:

Two individual experiments were conducted.

Normal dose experiment (1x): This experiment simulated the envisaged seed/tuber treatment use pattern and was based on a maximum proposed application rate of 1 g a.s./100 kg tubers. This rate corresponds to 25 g a.s./ha or 0.5 mg a.s./seed potato assuming a rate of 50000 seed potatoes/ha and a mean weight of 50 g per seed potato. Each seed potato was treated with 0.55 mg [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC 200. This resulted in an actual application rate of 28 g a.s./ha deviating by +10% from the maximum proposed application rate. A total of 5 seed potatoes were planted in a planting container with a surface area of 1 m^2.

Overdosed experiment (10x): This experiment was performed as additional overdosed experiment in order to facilitate the identification of formed metabolites. In this experiment [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC 200 was applied at a rate of approx. 5.5 mg a.s./tuber. This resulted in an actual application rate of 280 g a.s./h deviating by +10% from the envisaged 10x rate. A total of 5 seed potatoes were planted in a planting container with a surface area of 1 m^2.

For both experiments the plants were cultivated in the glass-roofed greenhouse of the test facility and were grown similar to natural temperature and light conditions with an average temperature of 26.2°C and a relative humidity of 47.5%. They were watered by pouring onto the soil in the planting containers.

2. Sampling

At maturity (BBCH growth stage 97, 119 days after the application) the RAC tubers and leaves as supportive matrix of both experiments were harvested. Tubers were dug out of the soil and leaves were cut off and combined with fallen leaves. The total weight of each sample was determined. The samples were homogenised under dry ice using a robot coupe stirrer. The sample materials were stored in a freezer (≤ -18 °C). Aliquots of the homogenates of tubers (10x) and leaves (1x and 10x) were extracted. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids. The TRR value for tubers of the 1x experiment was determined by combustion analysis.

C. Analytical Procedures

1. Extraction:

Conventional extraction procedure and sample clean up:

Due to the very low TRR of tubers of the normal dose experiment no extraction was performed. For conventional extraction of tubers (overdosed experiment) and leaves (normal dose and overdosed experiment), aliquots of the homogenised samples were extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a high speed blender. After each extraction step, the extracts were filtered by suction and the solids were rinsed with a small amount of the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion analysis.

The extracts were combined and subjected to a clean-up step using an SPE RP 18 cartridge. The flow-through fraction (percolate) was collected and the cartridge was rinsed with a small volume of acetonitrile/water (8/2; v/v). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/tetrahydrofuran (1/1; v/v).

Each combined percolate/rinse solution obtained from SPE purification was evaporated to the aqueous remainder and mixed with emulsifier beforehand. The final conventional extracts were analysed by HPLC with the general profiling method.

Exhaustive extraction and corresponding clean-up:

Solids from the conventional extraction of potato tubers of the overdosed experiment were exhaustively extracted two times with acetonitrile/water/formic acid (50/50/1; v/v/v) under microwave assistance at increased temperature. The microwave extracts were combined and concentrated by rotary evaporation. Aliquots of the final exhaustive extract were subjected to a clean-up step using a SPE RP 18 cartridge analogously to the conventional extraction. The combined fractions from SPE purification were evaporated to the aqueous remainder.

The radioactivity in liquid samples was determined by liquid scintillation counting (LSC). Solid samples were combusted. The CO_2 produced by combustion was absorbed in a CO_2 absorbent / scintillation cocktail mixture and the radioactivity was measured by LSC. The TRR of extracted samples was determined by summation of the radioactivity of the combined extract(s) and of the remaining solids. The TRR of tubers of the low dose experiment was determined by combustion analysis. The TRR was expressed in mg a.s. equivalents per kg sample weight. Amounts of radioactive residues in the extracts were expressed as percentage of the TRR and also as mg a.s. equivalents per kg sample weight.

2. Identification and characterisation:

For elucidation of metabolism, extracts were analysed by HPLC and/or TLC. The parent compound and metabolites were identified by co-chromatography with authentic reference compounds using two independent chromatographic methods with different selectivity (e.g. HPLC and TLC) or by co-chromatography with compounds identified by spectroscopic analysis in isolated fractions of potato leaves within the potato metabolism study with the pyrazole label.

In addition, metabolic profiles of all potato sample extracts were compared, as analysed by HPLC among themselves. Metabolic profiles of all sample extracts were compared with metabolic profiles of corresponding sample extracts in the potato metabolism study with the phenyl label.
Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Table 6.2.1- 1: List of reference compound

Report name / other names/codes	**Chemical Name (IUPAC)**	**Structure and formula**
Isoflucypram **Parent compound** **BCS-CN88460** Reference: M-00002258	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
3. Storage stability:

All extraction experiments of tubers and leaves and the first HPLC analyses were performed within six months after harvest of the samples, storage stability data are not required. Complementary stability investigations of stored extract of leaves proved that the metabolic profile of potato leaves did not significantly change during 6 months of storage of the plant extract at ≤-18 °C.

It was therefore concluded, that the residues in the samples were sufficiently stable during the experimental period of the study and that the chromatograms represented the metabolic pattern in the samples at harvest.

II. Results and Discussion

The metabolism of [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC 200 was investigated in potatoes after seed treatment.

The application rate was approx. 28 g a.s./ha corresponding to approx. 1 g a.s./100 kg tubers. Additionally, a 10x overdosed experiment was conducted.

The total radioactive residue (TRR) in tubers of the normal dose experiment was very low and amounted to 0.002 mg eq/kg. In the 10x overdosed experiment the TRR in tubers was 0.042 mg eq/kg. Potato leaves were analysed as additional matrix to support metabolite identification and investigation of the metabolic pathway. In leaves, the TRR was 0.050 mg eq/kg for the normal dose experiment and 0.688 mg eq/kg for the 10x experiment.

TRRs of tubers and leaves of the 10x overdosed experiment were significantly higher compared to tubers and leaves of the 1x experiment. TRRs of tubers were generally low and significantly lower compared to leaves indicating limited transfer of residues from leaves to tubers. Based on the applied radioactivity (RA) and the amount of total radioactivity determined in the harvested samples it can be roughly estimated (by recalculation from data given in the report), that only ≤ 0.2% and 0.6% of the applied RA were taken up and translocated into tubers and leaves, respectively (e.g. the maximum theoretical residue in tubers 1x would be 2.8 mg applied a.s./1.415 kg tubers harvested = 2.0 mg eq/kg. Actually, 0.002 mg eq/kg (=0.1% of the applied radioactivity) were found).

Table 6.2.1- 2: TRR values in potato matrices after seed/tuber treatment with [phenyl-UL-^{14}C]BCS-CN88460

Matrix	Timing and Application	PHI (days)	TRR (mg eq/kg)
Tubers	Normal dose experiment: seed/tuber treatment at a nominal rate of 1 g a.s./100 kg tubers corresponding to 25 g a.s./ha	119	0.002
Leaves		119	0.050
Tubers	Overdosed experiment (10x): seed/tuber treatment at approx. 10x of the rate in the normal dose experiment	119	0.042
Leaves		119	0.688

The results of the normal dose experiment are as follows:

Due to the very low TRR of tubers of the 1x experiment no extraction and therefore no identification and quantification of parent compound and metabolites was performed.

Leaves were conventionally extracted with acetonitrile/water releasing 92.6% of the TRR (0.046 mg eq/kg). Losses during sample clean up accounted for 0.4% of TRR (<0.001 mg eq/kg). After concentration and purification steps 92.2% of TRR (0.046 mg eq/kg) were analysed. The post extraction solids (PES) amounted to 7.4% of the TRR (0.004 mg eq/kg).

The results of the overdosed experiment (10x) are as follows:

Potato tubers of the overdosed experiment were conventionally extracted with acetonitrile/water releasing 82.2% of the TRR (0.034 mg eq/kg). After concentration and purification steps 82.2% of the TRR (0.034 mg eq/kg) were analysed. Solids after conventional extraction of tubers were further subjected to exhaustive extraction under microwave support releasing 12.9% of the TRR (0.005 mg eq/kg). After purification of this extract 8.7% of the TRR (0.004 mg eq/kg) were analysed. In total, 95.1% of the TRR (0.039 mg eq/kg) was extracted from tubers of the overdosed experiment. Only 4.9% of the TRR (0.003 mg eq/kg) remained in the solids.

Leaves were conventionally extracted with acetonitrile/water releasing 93.8% of the TRR (0.645 mg eq/kg). Losses during sample clean up accounted for 0.5% of TRR (0.003 mg eq/kg). After concentration and purification steps 93.3% of TRR (0.641 mg eq/kg) were analysed. The PES amounted to 6.2% of the TRR (0.043 mg eq/kg).

* no individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of tubers of the overdosed experiment

For elucidation of metabolism, extracts were analysed by HPLC and/or TLC. Parent compound and metabolites were identified by co-chromatography with authentic reference compounds using two independent chromatographic methods with different selectivity (e.g. HPLC and TLC) or by co-chromatography with compounds identified by spectroscopic analysis in isolated fractions of potato leaves within the potato metabolism study with the pyrazole label.

A total of 69.2% of the TRR was identified in extract of tubers of the overdosed experiment. The parent compound **isoflucypram** represented by far the main residue component in tubers of the overdosed experiment accounting for 69.2% of TRR (0.029 mg eq/kg). One minor metabolite in tubers of the overdosed experiment remained unknown, accounting to 0.005 mg eq/kg (13.0% of TRR).

The leaves were analysed as additional matrix to support metabolite identification and investigation of the metabolic pathway. In extracts of leaves of the normal dose and overdosed experiment, parent compound was a minor component and represented 7.3% of TRR (0.004 mg eq/kg) and 4.0% of TRR (0.027 mg eq/kg), respectively. Besides parent compound, two major metabolites were identified in leaves: BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**). BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**) represent conjugates of the test compound with hexose and malonic acid and were only detected in leaves. In leaves, up to 21 unknown minor or trace metabolites were characterised, individually accounting for equal or less than 19.9% of TRR and 0.010 mg eq/kg for the normal dose experiment and equal or less than 8.6% of TRR and 0.059 mg eq/kg for the overdosed experiment.

The TRR and the distribution of parent and metabolites in potato matrices are shown in the following tables.

n.d. not detected

The metabolic profiles of conventional extracts from leaves of the 1x and 10x experiment were qualitatively well comparable, indicating a similar pattern of degradation in both experiments.

Overall, comparison of metabolic profiles with those of a parallel study with [pyrazole-4-^{14}C]BCS-CN88460 revealed a high correspondence. Within the parallel study one label specific metabolite for the pyrazole label was identified whereas no metabolite specific for the phenyl study was detected in the present study.

III. Conclusions

The metabolism of [phenyl-UL-^{14}C]BCS-CN88460 formulated as an EC200 was investigated in potato

following seed treatment. The application rate was approx. 28 g a.s./ha corresponding to approx. 1 g a.s./100 kg tubers. Additionally, a 10x overdosed experiment was conducted.

The residue in tubers at the envisaged use rate was very low (<0.01 mg eq/kg). The TRR of tubers of the overdosed experiment was significantly higher compared to tubers of the normal dose experiment, similarly for residues in leaves compared to tubers. **isoflucypram** and/or possible metabolites were translocated into the tubers only to a limited extent.

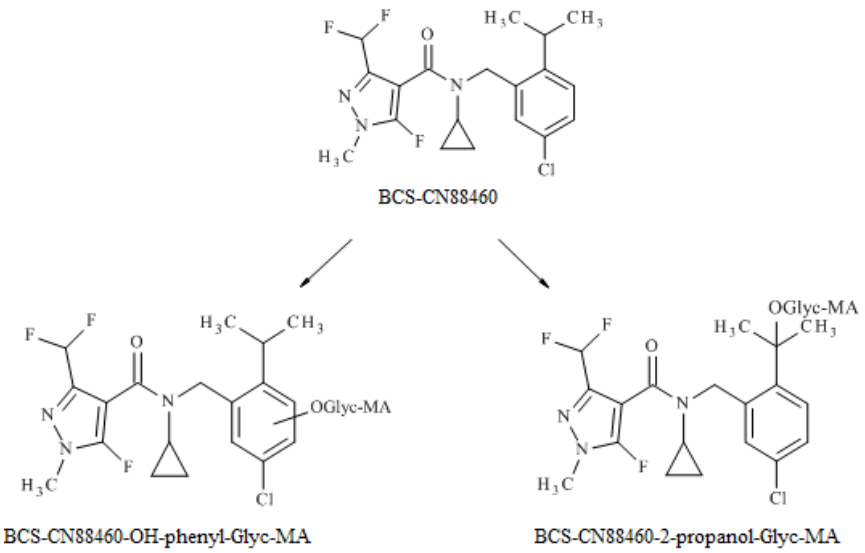
Leaves were analysed to support metabolite identification and investigation of the metabolic pathway. The extraction rates for tuber and leaves samples were very high (>92% of the TRR). The identification rate in tubers was sufficient (>69% of the TRR) and moderate for leaves samples due to extensive metabolism observed in leaves indicated by few major components and a large number of minor or trace metabolites detected in leaves. Parent compound was the main component in tubers of the overdosed experiment and a minor component in leaves. Besides parent compound two major metabolites were identified in potato leaves: BCS-CN88460-OH-phenyl-Glyc-MA (**M23a**) and BCS-CN88460-2-propanol-Glyc-MA (**M22**).

The results in the present study are in good agreement with the results with the phenyl-label. No metabolite specific for the phenyl label was observed in the present study whereas one label specific metabolite was identified in the study performed with [pyrazole-4-^{14}C] BCS-CN88460. Based on the identified metabolites the following metabolic routes were deduced:

- Hydroxylation in position 2 of the propyl group of the phenyl ring followed by conjugation with hexose and malonic acid;
- Hydroxylation of the phenyl moiety followed by conjugation with hexose and malonic acid.

Based on these results, the degradation behaviour of [phenyl-UL-^{14}C]BCS-CN88460 in potato is adequately understood and a metabolic pathway is proposed in the figure below.

Figure 7.2.1-5: Proposed metabolic pathway of [phenyl-UL-14C]BCS-CN88460 in potato



B.7.2.2. **Poultry**

The metabolism of the fungicide **isoflucypram** in laying hens was investigated after administration with **isoflucypram** either labelled in the phenyl or in the pyrazole moiety. Parent compound and metabolites were isolated from the eggs (6 - 13 days) and the extract of excreta and identified in the isolated fractions by spectroscopic methods in the study with the pyrazole-label and assigned to the metabolites in the laying hen study with phenyl-UL-^{14}C label by comparison of metabolite profiles and

retention times.

Table 7.2.2-1: Overview of poultry metabolism studies

Poultry	Application	Dose	Reference
Laying hen	14 daily administrations of pyrazole-labelled **isoflucypram** in aqueous 0.5% Tragacanth suspension via gavage	1.0 mg/kg bw/day	M-601665-01-1
Laying hen	14 daily administrations of phenyl-labelled **isoflucypram** in aqueous 0.5% Tragacanth suspension via gavage	1.0 mg/kg bw/day	M-601667-01-1

Summary of metabolism in poultry

The metabolite pattern corresponds well when comparing the two metabolism studies in laying hens. **Isoflucypram** was metabolised extensively in liver of hens. With the exception of fat, only low amounts of the parent compound were detected in the edible tissues and eggs. The major metabolites detected were BCS-CN88460-desmethyl-1,2-propandiol (**M07**), BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**). The main metabolic reactions were hydroxylations with further oxidation or demethylation of the pyrazole moiety.

B.7.2.2.1.1. [pyrazole-4-^{14}C]isoflucypram

Report:	KCA 6.2.2/01; [redacted] 2017
Title:	[Pyrazole-4-^{14}C]BCS-CN88460: Metabolism in the laying hen
Report No.:	EnSa-17-0307
Document No.:	M-601665-01-1
Guideline(s:	OECD Test Guideline 503; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism and excretion of [pyrazole-4-^{14}C]BCS-CN88460 was investigated in laying hens as a model for poultry. The test compound was orally administered to six hens as aqueous 0.5% Tragacanth suspension at an intended dose rate of 1 mg per kg body weight (actual dose: 1.04 mg/kg bw/day). Based on the daily feed consumption, the dose level corresponded up to 16.6 mg a.s./kg dry feed/day. The hens received 14 doses in the morning at 24-hour intervals and were sacrificed approximately 6 hours after the last dosing. Throughout the experiment, the hens were housed in metabolism cages, which permitted separate collection of eggs and excreta. The eggs were collected once daily and before sacrifice. Total radioactive residues (TRR) were determined in each egg (mixed sample from egg white and yolk) and in dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/ oviduct) at sacrifice. The total radioactivity (% of total dose administered) was additionally determined in each excreta sample.

Recovery and Elimination of Radioactivity

The overall recovery amounted to 96% of the total dose and up to the time of sacrifice the excretion accounted for up to 95.8% of the total dose. After the third administration the daily excretion rate was on a more or less constant level of about 6.3 to 7.7% within 24 hours. The remaining amount of radioactivity (approximately 4%) was expected to still be present in the gastrointestinal tract at sacrifice, because of the short period of time between last administration and sacrifice (approximately 6 hours).

An average amount of approximately 0.12% of the total dose was measured in the eggs. At sacrifice, radioactive residues in the organs and tissues dissected from the bodies were calculated or estimated to be about 0.22% of the total dose.

Total Radioactive Residues in Eggs, Organs and Tissues

The TRR-values and transfer factors for eggs and organs and tissues were very low compared to the dose level of 16.6 mg a.s. /kg feed/day and a dosing period of 14 days. The TRR-values in eggs ranged from 0.029 mg/kg at day two to 0.057 mg/kg at sacrifice. Following a linear increase a residue plateau-level of 0.050 mg/kg was reached at day six after the first administration.

Regarding organs and tissues, the TRR-values amounted to 0.370 mg/kg in liver, 0.390 mg/kg in kidney, 0.042 mg/kg in subcutaneous fat, 0.075 mg/kg in skin, 0.029 mg/kg in leg muscle and 0.018 mg/kg in thorax muscle.

Metabolism

The majority of the residues in the eggs as well as organs and tissues were efficiently extracted (83.9% to 93.4%) using acetonitrile/water mixtures. In case of liver, the solids after conventional extraction were exhaustively extracted with microwave treatment. Only up to 8.2% of the TRR or 0.003 mg/kg of the residues remained in the post extraction solids (PES).

For sample preparation the extracts were partitioned against n-heptane except the extract from fat. Very low amounts of radioactivity were recovered in the n-heptane phases and amounted to ≤1.3% (0.001 mg/kg) of the TRR.

Metabolites were isolated from extracts of eggs and excreta and identified by spectroscopic investigations. Parent compound and metabolites were further identified based on co-chromatography with the isolated metabolites and by comparison of the metabolite pattern and retention times. In addition, the assignment of parent compound and metabolites in the current study was performed based on a comparison of the extracts from excreta of this study with those from the hen metabolism study conducted with the phenyl label.

The identification rates amounted to 69.6% of the TRR for eggs, 73.5% for leg muscle, 67.6% for thorax muscle, 55.5% for fat and 54.3% for liver.

Parent compound was only detected in eggs, leg muscle and fat and amounted to 0.002 mg/kg (3.7% of the TRR) for eggs, 0.001 mg/kg (2.3% of the TRR) for leg muscle and up to 0.010 mg/kg (23.6% of the TRR) for fat.

Metabolites BCS-CN88460-desmethyl-1,2-propandiol (**M07**), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**) were detected in all edible materials and eggs.

The amount of BCS-CN88460-desmethyl-1,2-propandiol (**M07**) ranged from 5.1% to 17.9% of the TRR and it represented a major residue (>10% of the TRR) in leg and thorax muscle. The amount of BCS-CN88460-desmethyl-propanol (**M06**) (representing a major compound in eggs, both muscles and fat) ranged from 5.3% to 29.7% of the TRR and the amount of BCS-CN88460-carboxylic acid (**M12**) (representing a major compound in thorax muscle and liver) ranged from 3.4% to 11.9% of the TRR. The amount of BCS-CN88460-propanol (**M01**) (representing a major residue in eggs and fat) ranged from 1.7% to 35.5% of the TRR.

BCS-CN88460-desmethyl-carboxylic acid (**M11**) was only detected in leg and thorax muscle and liver accounting for between 12.0% and 14.4% of the TRR.

BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**), BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**) and BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**) were only detected in liver,

accounting for 5.4%, 6.1% and 2.5% of the TRR, respectively.

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the chromatograms. All unknown metabolites in the extracts were characterised by their extraction and chromatographic behaviour and amounted to each ≤19.5% of the TRR or 0.004 mg/kg.

The metabolic profile of excreta from day 1 was similar to the profiles of edible materials, especially liver, with the difference that metabolites BCS-CN88460-desmethyl-1,2-propandiol-SA (**M42**), BCS-CN88460-1,2-propandiol-SA (**M27**), BCS-CN88460-1,2-propandiol (**M03**) and BCS-CN88460-propanol-SA (**M26**) were only detected in excreta.

A summary of the distribution of parent compound and metabolites for edible materials can be found in Table 7.2.2-5.

The main metabolic reactions were the hydroxylation in the propyl group of the phenyl ring and demethylation of the pyrazole moiety. Hydroxylation in the propyl group was leading to mono- or dihydroxy compounds. Conjugation with glucuronic acid was observed after demethylation of the pyrazole moiety and conjugation with sulphuric acid after hydroxylation in position 1 of the propyl group. Another metabolic reaction was further oxidation of BCS-CN88460-propanol (**M01**) to BCS-CN88460-carboxylic acid.

Based on the results the metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in the laying hen is considered as adequately understood and a metabolic pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Materials

Chemical structure	 * denotes the ^{14}C-label position
Radiolabelled test material	[pyrazole-4-^{14}C]BCS-CN88460
Specific radioactivity	4.22 MBq/mg = 2.53 x 10^8 dpm/mg
Radiochemical purity	>98% (HPLC); >99% (TLC)
Chemical purity	>98% (HPLC)
Dose level	14 oral doses of 16.57 mg a.s./kg feed/day (1.04 mg a.s./kg bw/day)
Vehicle	0.5% aqueous Tragacanth® suspension

2. Test Animals

Species	Laying hen (Gallus gallus domesticus)
Strain	"LB Lohmann White"
Breeder	[redacted]
Animal numbers	8 animals in total, from which 6 (no's 403 - 408) were chosen for the test. The hens were selected by maximum egg production.

Mean body weights	1.54 kg at delivery (2015-01-15) 1.63 kg at the first administration (2015-01-28) 1.68 kg at sacrifice (2015-02-10)
Identification	During the acclimation period, the animals were identified by individual cage cards (1 – 8). During the testing period an individual animal number (see above) was allocated on the cage cards and additionally by foot ring.
Acclimation period	13 days
Husbandry	Conventional hygienic conditions in air-conditioned rooms
Housing	During the acclimation period and the whole testing period, the hens were kept individually in electro-polished stainless steel metabolism cages for laying hens, supplied by ZOONLAB GmbH, Hermannstr. 6, 44579 Castrop-Rauxel, Germany. These cages allow almost separate and quantitative collection of excreta and eggs.
Dietary regimen	During the whole residence time, the hens were fed with "RWZ-LegeGold Mehl", a pulverised chicken feed. This feed was not a certified diet, i.e. it was not checked for contamination according to current standards. The feed was supplemented by eggshells during the acclimation period. The feed consumption during the testing period was recorded by back-weighing. Tap water from the local mains supply was given ad libitum during the whole residence time.
Environmental conditions	Temperature: 19 – 21 °C Relative humidity: 20 – 38% Photoperiod: alternating 16- to 8-hours light / dark cycles Air change: 10 – 15 times per hour

B. Study Design

Preparation of the Test Item for Administration

The radiolabelled test compound was delivered in solid form and dissolved in 50 mL acetonitrile for preparation of the stock solution. The radiochemical purity amounted to >98% as assured by HPLC. The identity of the test compound was confirmed by LC/MS/MS.

Four administration suspensions were prepared and each suspension was applied for three to four administrations. Definite volumes of the stock solution were concentrated to near dryness by a gentle stream of nitrogen gas. Afterwards, the residue was suspended in a 0.5% aqueous Tragacanth® suspension. Aliquots were taken for determination of the total radioactivity by LSC. The suspensions were kept permanently under stirring at + 5 °C in a cooling cabinet until the administrations at which they were stirred at room temperature and were proved to be stable until the last dose.

Dosing

All oral administrations were performed by gavage using a syringe attached to an animal-feeding knob cannula once daily for 14 consecutive days in the morning in relation to the individual body weights. The laying hens received on each day an average amount of 1.69 mg ^{14}C- **isoflucypram** which corresponded to 7.13 MBq (mean per animal and day). The total administered average amount and radioactivity accounted for 23.70 mg and 100.01 MBq, respectively. The administration volume was 1.0 mL/kg body weight.

The total amount of radioactivity administered to each animal served as reference value (A_0 = 100%) for the percentage calculation of the total radioactivity in the biological samples.

Based upon the experimentally determined daily feed consumption during the testing period of 102 g dry feed per day (= 6.12% of the body weight), the dose of 1.04 mg a.s./kg bw corresponded to a concentration of 16.57 mg a.s. /kg dry feed per day in the diet. This dose was tolerated without any observable toxicological effects.

Collection of eggs

The egg production of the laying hens was checked during the acclimation period (beginning of the laying phase) and during the testing period. Assuming an average laying rate of 314 eggs per hen and year the mean egg production during the acclimation period was 109% and 123% during the testing period. Therefore, the egg production exceeded the target value for laying hens being in good egg production.

During the test, the cages were inspected for egg production once daily (in the morning before administration) and the number of eggs was recorded for all hens. After removal of the shells, the contents of each egg were weighed and thoroughly mixed afterwards. Aliquots of each homogenate were mixed with scintillator for determination of the radioactivity by LSC. The remaining samples were stored in a freezer until start of metabolite analysis.

Collection of excreta

The excreta of each hen were collected from the collecting tins as far as possible quantitatively in daily intervals until sacrifice. Individual samples were weighed after water was added. Afterwards, the individual samples were homogenised. Aliquots of each sample were processed for radioactivity measurement by combustion / LSC. The remaining samples were stored in a freezer until start of metabolite analysis.

Sacrifice

The animals were sacrificed approximately 6 hours after the last administration, a time distance that is consistent with normal slaughtering practices. Each laying hen was transferred into a special cage, weighed and anaesthetized using carbon dioxide gas. Under general anaesthesia the animals were sacrificed by decapitation followed by exsanguination.

Preparation of organs and tissues

After exsanguination, the following edible organs and tissues were dissected: muscle (leg and thorax), fat (subcutaneous), liver (without gall bladder), skin (without subcutaneous fat), kidneys and eggs from the ovary and oviduct.

The organs or tissue samples were transferred into tared weight plastic vessels. After determination and recording of the individual weights, muscle, fat, liver, skin, kidney samples and eggs dissected from the ovary and oviduct were passed several times through a mincing machine in half-frozen state or blended with an Ultra Turrax in thawed state. Aliquots of the individual organ and tissue samples were combusted and the radioactivity measured by LSC.

The organ and tissue samples of the six hens were pooled separately for each sample type, divided in suitable portions that were stored frozen at ≤ -18 °C until the start of metabolite analysis. For skin, the remaining homogenates of kidneys and eggs from the ovary/oviduct, metabolite analysis was optional.

All individual samples were identified with a specific sample number. The individual excreta, egg, as well as organ and tissue samples were kept frozen at ≤ -18 °C at all times except during aliquotation for analysis. During the analytical work the samples and extracts of samples were stored either in a freezer at ≤ -18 °C or for a short period in a refrigerator at +4 °C.

Radioactivity measurement

The radioactivity measurement in liquid samples was carried out by liquid scintillation counting (LSC). The solid samples were either dissolved in BIOLUTE S and radioactivity determined by LSC or combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

C. Analytical Procedures

Sample Extraction and Analysis of Extracts

Aliquot samples from eggs, muscle, fat, liver and excreta were conventionally extracted three times with a mixture of acetonitrile/ water (8/2; v/v) using a Polytron homogeniser. For sample preparation the combined conventional extracts from eggs, muscle, liver and excreta were partitioned against n-heptane. The purified conventional extracts were concentrated by rotary evaporation and subjected to HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

Solids of liver from the first conventional extraction were exhaustively extracted twice with acetonitrile/water (8/2; v/v) using microwave assistance followed by microwave treatment with 0.1 M hydrochloric acid. The exhaustive extracts were characterised using TLC analysis.

Aliquots of the conventional liver extracts were incubated for 96 hours at 37 °C with a defined amount of ß-glucuronidase/arylsulfatase. After incubation, the enzymatic suspensions were purified and analysed by HPLC.

Metabolite analysis

Parent compound and metabolites were quantified in the extracts by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

The following strategy was used for identification of the parent compound and metabolites:

All metabolites were assigned based on a comparison of the metabolite profiles and retention times. Metabolites were isolated from extracts of egg pool and excreta and used as reference compounds after structure elucidation. Parent compound and metabolites were identified by HPLC co-chromatography with radiolabelled reference compounds in selected samples. The conventional extract of liver was enzymatically digested. The glucuronic acid and sulphate conjugates of **isoflucypram** were thereby digested and converted into the corresponding BCS-CN88460-aglycons. The HPLC profile of excreta was compared to the profile of excreta from the phenyl labelled hen metabolism study conducted in parallel to demonstrate the comparability.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

II. Results and Discussion

A. Recovery and Elimination of Radioactivity

The overall recovery accounted for 96.14% of the total dose and up to the time of sacrifice, 95.8% of the total dose was excreted. After the third administration the daily excretion rate was on a more or less constant level of about 6.3 to 7.7% within 24 hours. The remaining amount of radioactivity (approximately 4%) was expected to still be present in the gastrointestinal tract at sacrifice, due to the short period of time between last administration and sacrifice (approximately six hours). An average amount of 0.12% of the total dose was measured in the eggs. At sacrifice, the radioactive residues in the organs and tissues dissected from the bodies were calculated or estimated to be about 0.22% of the total dose.

All TRRs for eggs and dissected organs and tissues were calculated as radioactivity originating from the radiolabelled test compound. Therefore, all concentration data in this report represent active substance equivalents (mg a.s. equiv./kg_{sample}).

Table 7.2.2-2: Distribution of residues in matrices of laying hens following oral administration of 14 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 (1.04 mg/kg bw/day)

Sample	Collection time	TRR (mg/kg)*	Transfer factor **	Percent of total dose administered
Liver	approx. 6 h after last admin.	0.370	0.022	0.07
Kidney		0.390	0.024	0.02
Eggs from ovary/oviduct		0.076	0.005	0.01
Total skeletal muscle #		0.023	0.001	0.07
Total body skin #		0.075	0.005	0.02
Total body fat #		0.042	0.003	0.04
Total of organs/tissues		-----	-----	0.22
Eggs, total	day 1 –13.25	0.044	0.003	0.12
Eggs, plateau-level	day 6 – 13	0.050	0.003	-----
Excreta, total	day 1 – 13.25	-----	-----	95.79
			Total Recovery	**96.14**
Feeding level	16.57	mg a.s. /kg dry feed/day		

Percentage values were calculated from the body weights at sacrifice, assuming 40%, 12% and 4% of the body weight for total skeletal muscle, fat, or skin (without subcutaneous fat), respectively.

* Weighted mean TRR-values of the individual animals.

** The transfer factor was calculated by dividing the TRR-value of the respective sample by the feeding level (mg a.s./kg dry feed on each day).

B. Levels and Time Course of Total Radioactive Residues in Eggs

The TRR-values in eggs ranged from 0.029 mg/kg at day two to 0.057 mg/kg at sacrifice. Following a linear increase a residue plateau-level of 0.050 mg/kg was reached at day six after the first administration.

Table 7.2.2-3: Time course of total radioactivity in eggs following oral administration of 14 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 (1.04 mg/kg bw/day)

Animal no's.	Time after first admin. (days)	Admin. no.	Cumulative secretion (% of total dose admin.) (mean)	Mean TRR (mg/kg)

	13	14	0.10	0.049
	13.25	---	0.12	0.057
Weighted mean				0.044

---- # no egg collected

n.c. not calculated

TRR, plateau-level (day 4 – 13): approximately 0.050 mg/kg

C. Total Radioactive Residues in Dissected Organs and Tissues

The highest TRR-value was determined in kidney (0.390 mg/kg; 0.02% of total administered dose) followed by liver (0.370 mg/kg; 0.07% of total administered dose) indicating the significance of these organs for metabolism and excretion. The TRR-value of the eggs collected from the ovary and oviduct at sacrifice (0.076 mg/kg) was by a factor of 1.3 higher than the levels of the laid eggs collected at sacrifice (0.057 mg/kg). This showed that the egg yolk was a preferential site for secretion of test compound related radioactivity. Lower TRR-values were detected for subcutaneous fat (0.042 mg/kg), skin (0.075 mg/kg) and total skeletal muscle (0.029 mg/kg). The TRR-values of the total subcutaneous fat, skin and muscle corresponded to about 0.04%, 0.02% and 0.07% of the total dose assuming values of 12%, 4% and 40% of the body weight for these tissues, respectively.

D. Extraction Efficiency of Residues

The majority of the residues in the eggs as well as organs and tissues were efficiently extracted (83.9% to 93.4%) using acetonitrile/water mixtures. In case of liver, the solids after conventional extraction were further extracted using microwave treatment. Only up to 8.2% of the TRR or 0.003 mg/kg of the residues remained in the post extraction solids (PES).

For sample preparation, the extracts were partitioned against n-heptane except the extract from fat. Very low amounts of radioactivity were recovered in the n-heptane phases amounting to ≤1.3% (0.001 mg/kg) of the TRR. Concentration procedures of the aqueous phases caused no losses, so all of the residues in the aqueous phases were quantitatively analysed by HPLC.

A summary of the extraction efficiency is shown in the table below.

Table 7.2.2-4: Extraction efficiency of poultry samples following oral administration of 14 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 (1.04 mg/kg bw/day)

Sample	**Eggs (day 4 – 13)**		**Muscle Leg**		**Muscle Thorax**		**Fat**		**Liver**	
	% of TRR	mg/kg	% of TRR	mg/kg	% of TRR	mg/kg	% of TRR	mg/kg	% of TRR	mg/kg

E. Quantification, Identification and Characterisation of Residues

Parent compound and metabolites were quantified in the conventional extracts by HPLC chromatography based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Metabolites in the extracts were assigned to each other by comparison of the metabolite profiles and their retention times. Corresponding metabolites were named with the same peak ID.

The identification of metabolites was performed in isolated fractions from the extract of eggs and excreta by spectroscopic methods and by enzymatic cleavage of selected conjugates. The identified metabolites and aglycons in the isolated fractions were used as reference compounds. **Isoflucypram** metabolites were identified by co-chromatography with radiolabelled reference compounds. Metabolites in edible organs and tissues were assigned by comparison of the metabolic profiles and retention times. In addition, the assignment of parent compound and metabolites in the current study was performed based on a comparison of the extracts from excreta of the current study and the hen

metabolism study with the phenyl label.

F. Distribution of Parent Compound and Metabolites in Eggs, Organs and Tissues

The identification rates amounted to 69.6% of the TRR for eggs, 73.5% for leg muscle, 67.6% for thorax muscle, 55.5% for fat, 54.3% for liver and 60.1% for excreta.

Parent compound was only detected in eggs, leg muscle and fat and amounted to 0.002 mg/kg (3.7% of the TRR) for eggs, 0.001 mg/kg (2.3% of the TRR) for leg muscle and to 0.010 mg/kg (23.6% of the TRR) for fat.

Metabolites in eggs

Metabolites BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) were the main residues in eggs and accounted for 35.0% (0.018 mg/kg) of the TRR and 22.3% (0.011 mg/kg) of the TRR, respectively. Other prominent metabolites in eggs were BCS-CN88460-desmethyl-1,2-propandiol (**M07**), BCS-CN88460-carboxylic acid (**M12**) and parent compound, each ≤5.2% of TRR.

Metabolites in leg and thorax muscle

The main residues in leg muscle were BCS-CN88460-desmethyl-propanol (29.7% (0.009 mg/kg) of the TRR), BCS-CN88460-desmethyl-1.2-propandiol (15.0% (0.004 mg/kg) of the TRR) and BCS-CN88460-desmethyl-carboxylic acid (12.1% (0.004 mg/kg) of the TRR). These three main metabolites were also detected in the thorax muscle and amounted between 20.9% and 12.0% of the TRR. BCS-CN88460-carboxylic acid (**M12**) was also a main residue in thorax muscle with 11.0% of the TRR (0.002 mg/kg) which was a prominent metabolite in leg muscle amounting to 9.1% of the TRR. Another prominent metabolite in muscle was BCS-CN88460-propanol (**M01**), amounting to 5.3% and 5.9% of the TRR in leg and thorax muscle, respectively.

Metabolites in fat

Besides parent compound as the main residue in fat, two main metabolites were identified, namely BCS-CN88460-propanol (**M01**) with 11.9% of the TRR (0.005 mg/kg) and BCS-CN88460-desmethyl-propanol (**M06**) with 10.1% of the TRR (0.004 mg/kg). Other prominent metabolites were identified and named as BCS-CN88460-desmethyl-1,2-propandiol (**M07**) and BCS-CN88460-carboxylic acid (**M12**). These two metabolites amounted to between 4.8% and 5.1% of the TRR.

Metabolites in liver

The main residue in liver were identified as BCS-CN88460-desmethyl-carboxylic acid (**M11**) (14.4% (0.053 mg/kg) of the TRR) and BCS-CN88460-carboxylic acid (**M12**) (11.9% (0.044 mg/kg) of the TRR). Prominent metabolites in the liver were BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**), BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**), BCS-CN88460-desmethyl-1.2-propandiol (**M07**) and BCS-CN88460-desmethyl-propanol (**M06**) and amounted to between 5.3% and 6.9% of the TRR. Two minor metabolites named as BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**) and BCS-CN88460-propanol (**M01**) were detected (both ≤ 2.5 of TRR).

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the chromatograms. All unknown metabolites in the extracts were characterised by their extraction and chromatographic behaviour and amounted to each ≤19.5% of the TRR or 0.004 mg/kg.

The distribution of the parent compound and metabolites in milk, organs and tissues is summarised in the table overleaf.

Conjugates in the liver like BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**), BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**) and BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**) could be enzymatically cleaved to their aglycons. The cleavage of some unknown conjugates in non-resolved zones resulted in higher amounts of the aglycons. None of the unknown compounds after cleavage accounted for more than 0.010 mg/kg (2.6% of the TRR) after enzymatic cleavage. The following main aglycons could be clearly identified after enzymatic cleavage: BCS-CN88460-desmethyl-1,2-propandiol (**M07**) and BCS-CN88460-desmethyl-propanol (**M06**).

Metabolites in Excreta

The excreta extract of day 1 was analysed by HPLC. Parent compound accounted for 2.6% of the dose. BCS-CN88460-desmethyl-carboxylic acid (**M11**) and BCS-CN88460-carboxylic acid (**M12**) were the most prominent compound, accounting for 17.7% and 15.4% of the dose, respectively. Further eight identified metabolites ranged from 1.4% to 8.6% of the dose.

Generally, metabolites in the extract from excreta were the same as in eggs, organs and tissues, except for metabolites BCS-CN88460-desmethyl-1,2-propandiol-SA (**M42**), BCS-CN88460-1,2-propandiol-SA (**M27**) and BCS-CN88460-1,2-propandiol (**M03**) which accounted for equal or less than 8.6% of the dose, respectively.

G. Storage Stability of Residues

All samples of eggs, excreta, edible organs and tissues were extracted within five months after sample collection. Quantitative analysis by HPLC was performed either on the day of extraction or up to four days after the start of extraction.

A second conventional extraction of liver was performed approximately 20 months after sampling. The extract was used for enzymatic cleavage experiments. The storage stability was demonstrated for

these liver samples. It was therefore concluded, that the metabolic profiles represent the residues in the matrices and analysed samples at sacrifice.

B.7.2.2.1.2. [phenyl-UL-^{14}C]isoflucypram

Report:	KCA 6.2.2/02; [redacted] 2017
Title:	[Phenyl-UL-^{14}C]BCS-CN88460: Metabolism in the laying hen
Report No.:	EnSa-17-0306
Document No.:	M-601667-01-1
Guidelines:	OECD Test Guideline 503; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism and excretion of [phenyl-UL-^{14}C]BCS-CN88460 was investigated in laying hens as a model for poultry. The test compound was orally administered to six hens as aqueous 0.5% Tragacanth suspension at an intended dose rate of 1 mg per kg body weight (actual dose: 1.01 mg/kg bw/day). Based on the daily feed consumption, the dose level corresponded up to 18.12 mg a.s./kg dry feed/day. The hens received 14 doses at 24-hour intervals in the morning and were sacrificed approximately 6 hours after the last dosing. Throughout the experiment, the hens were housed in metabolism cages, which permitted separate collection of eggs and excreta. The eggs were collected once daily and before sacrifice. Total radioactive residues (TRR) were determined in each egg (mixed sample from egg white and yolk) and in dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/ oviduct) at sacrifice. The total radioactivity (% of total dose administered) was additionally determined in each excreta sample.

Recovery and Elimination of Radioactivity

The overall recovery amounted to 103.36% of the total dose and up to the time of sacrifice the excretion accounted for up to 102.97% of the total dose. After the third administration the daily excretion rate was on a more or less constant level of about 7.1 to 8.8% within 24 hours.

An average amount of approximately 0.14% of the total dose was measured in the eggs. At sacrifice, radioactive residues in the organs and tissues dissected from the bodies were calculated to be about 0.24% of the total dose.

Total Radioactive Residues in Eggs, Organs and Tissues

The TRR-values and transfer factors for eggs and organs and tissues were very low compared to the dose level of 18.12 mg a.s. /kg feed/day and a dosing period of 14 days.

The TRR-values in eggs ranged from 0.032 mg/kg at day three to 0.066 mg/kg at sacrifice. Following a linear increase a residue plateau-level of 0.050 mg/kg was reached at day four after the first administration.

Regarding organs and tissues, the TRR-values amounted to 0.373 mg/kg in liver, 0.360 mg/kg in kidney, 0.047 mg/kg in subcutaneous fat, 0.109 mg/kg in skin, 0.029 mg/kg in leg muscle and 0.017 mg/kg in thorax muscle.

Metabolism

The majority of the residues in the eggs as well as organs and tissues were efficiently extracted (85.4% to 93.3%) using acetonitrile/water (8/2; v/v) mixtures. In case of liver, the solids after conventional extraction were exhaustively extracted using acetonitrile/water (1/1; v/v) mixtures and 0.1 M hydrochloric acid with microwave treatment. Only up to 8.2% of the TRR (0.004 mg/kg) of the residues remained in the post extraction solids (PES).

For sample preparation the extracts were partitioned against n-heptane except the extract from fat. Very low amounts of radioactivity were recovered in the n-heptane phases and amounted to ≤1.2% (0.001 mg/kg) of the TRR.

Parent compound and metabolites were identified based on co-chromatography with reference compounds or by comparison of the metabolite pattern and retention times. Reference compounds were taken from the hen metabolism study with the pyrazole label or the goat metabolism study with the phenyl label.

The identification rates amounted to 79.2% of the TRR for eggs, 79.8% for leg muscle, 76.3% for thorax muscle, 51.5% for fat and 62.0% for liver.

Parent compound was only detected in eggs, leg muscle and fat and amounted to 0.003 mg/kg (6.4% of the TRR) for eggs, 0.001 mg/kg (2.9% of the TRR) for leg muscle and to 0.009 mg/kg (20.1% of the TRR) for fat.

Metabolites BCS-CN88460-desmethyl-1,2-propandiol (**M07**), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**) were detected in all edible materials and eggs.

The amount of BCS-CN88460-desmethyl-1,2-propandiol (**M07**) ranged from 5.6% to 22.3% of the TRR and it represented a major residue (>10% of the TRR) in leg and thorax muscle. The amount of BCS-CN88460-desmethyl-propanol (**M06**) (representing a major compound in eggs and both muscles) ranged from 2.7% to 25.8% of the TRR and the amount of BCS-CN88460-propanol (representing a major compound in eggs) ranged from 1.7% to 33.9% of the TRR, while the amount of BCS-CN88460-carboxylic acid (**M12**) ranged from 3.0% to 8.6% of the TRR. BCS-CN88460-desmethyl-carboxylic acid (**M11**) was detected as major residue in muscle and liver, while it was detected in minor amounts in fat. Its amount ranged thereby from 7.9% to 21.9% of the TRR.

BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**) was detected in leg muscle and liver, accounting for 4.1% to 9.2% of the TRR, respectively. BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**) was detected in eggs, leg muscle and liver, ranging from 3.0% to 10.8% of the TRR.

Metabolites BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**) and BCS-CN88460-propanol-SA (**M26**) were only detected in liver (both equal or less than 3.0% of the TRR).

The metabolic profile of excreta from day 1 was similar to the profiles of edible materials, especially liver, with the difference that metabolites BCS-CN88460-desmethyl-1,2-propandiol-SA (**M42**), BCS-CN88460-1,2-propandiol-SA (**M27**) and BCS-CN88460-1,2-propandiol (**M03**) were only detected in excreta.

A summary of the distribution of parent compound and metabolites for edible materials is provided in the table overleaf.

Table 7.2.2-7: Overview Radioactive residues of parent compound and metabolites in eggs and edible organs and tissues of laying hens following oral administration of 14 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.01 mg/kg

The main metabolic reactions were the demethylation of the pyrazole moiety and hydroxylation in the propyl group of the phenyl ring. Hydroxylation in the propyl group was leading to mono- or dihydroxy compounds. Conjugation with glucuronic acid was observed after demethylation of the pyrazole moiety and conjugation with sulphuric acid after hydroxylation in position 1 of the propyl group. Another metabolic reaction was further oxidation of BCS-CN88460-propanol (**M01**) to BCS-CN88460-carboxylic acid (**M12**).

Based on the results the metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in the laying hen is considered as adequately understood and a metabolic pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material

Chemical structure	 * denotes the ^{14}C-label position
Radiolabelled test material	[phenyl-UL-^{14}C]BCS-CN88460
Specific radioactivity	4.13 MBq/mg = 2.48 x 10^8 dpm/mg
Radiochemical purity	>98% (HPLC)
Chemical purity	>98% (HPLC)
Dose level	14 oral doses of 18.12 mg a.s./kg feed/day (1 mg a.s./kg bw/day)
Vehicle	0.5% aqueous Tragacanth® suspension

2. Test Animals

Species	Laying hen (Gallus gallus domesticus)
Strain	"LB Lohmann Brown"
Breeder	[redacted]
Animal numbers	8 animals in total, from which 6 (no's 493 – 498) were chosen for the test. The hens were selected by maximum egg production.
Mean body weights	1.83 kg at delivery (2015-10-06) 1.82 kg at the first administration (2015-10-21) 1.80 kg at sacrifice (2015-11-03)
Identification	During the acclimation period, the animals were identified by individual cage cards (1 – 8). During the testing period an individual animal number (see above) was allocated on the cage cards and additionally by foot ring.
Acclimation period	15 days
Husbandry	Conventional hygienic conditions in air-conditioned rooms
Housing	During the acclimation period and the whole testing period, the hens were kept individually in electro-polished stainless steel metabolism cages for laying hens, supplied by ZOONLAB GmbH, Hermannstr. 6, 44579 Castrop-Rauxel, Germany. These cages allow almost separate and quantitative collection of excreta and eggs.
Dietary regimen	During the whole residence time, the hens were fed with "RWZ-LegeGold Mehl", a pulverised chicken feed. This feed was not a certified diet, i.e. it was not checked for contamination according to current standards. The feed was supplemented by eggshells during the acclimation period. The feed consumption during the testing period was recorded by back-weighing. Tap water from the local mains supply was given ad libitum during the whole residence time.
Environmental conditions	Temperature: 19 – 23 °C Relative humidity: 23 – 78% Photoperiod: alternating 16- to 8-hours light / dark cycles Air change: 10 – 15 times per hour

B. Study Design

Preparation of the Test Item for Administration

The radiolabelled test compound was delivered in solid form and dissolved in 25 mL acetonitrile for preparation of the stock solution. The radiochemical purity amounted to >98% as assured by HPLC. The identity of the test compound was confirmed by LC/MS/MS.

Four administration suspensions were prepared and each suspension was applied for three to four administrations. Definite volumes of the stock solution were concentrated to near dryness by a gentle stream of nitrogen gas. Afterwards, the residue was suspended in a 0.5% aqueous Tragacanth® suspension. Aliquots were taken for determination of the total radioactivity by LSC. The suspensions were kept permanently under stirring at + 5 °C in a cooling cabinet until the administrations at which they were stirred at room temperature and were proved to be stable until the last dose.

Dosing

All oral administrations were performed by gavage using a syringe attached to an animal-feeding knob cannula once daily for 14 consecutive days in the morning in relation to the individual body weights. The laying hens received on each day an average amount of 1.83 mg ^{14}C- **isoflucypram** which corresponded to 7.56 MBq (mean per animal and day). The total administered average amount and radioactivity accounted for 25.56 mg and 105.56 MBq, respectively. The administration volume was 1.0 mL/kg body weight.

The total amount of radioactivity administered to each animal served as reference value (A0 = 100%) for the percentage calculation of the total radioactivity in the biological samples.

Based upon the experimentally determined daily feed consumption during the testing period of 101 g dry feed per day (= 5.61% of the body weight), the dose of 1.01 mg a.s. /kg bw corresponded to a concentration of 18.12 mg a.s. /kg dry feed per day in the diet. This dose was tolerated without any observable toxicological effects.

Collection of eggs

The egg production of the laying hens was checked during the acclimation period (beginning of the laying phase) and during the testing period. Assuming an average laying rate of 314 eggs per hen and year the mean egg production during the acclimation period was 113% and 121% during the testing period. Therefore, the egg production exceeded the target value for laying hens being in good egg production.

During the test, the grates of the cages were inspected for egg production once daily and the number of eggs was recorded for all hens. After removal of the shells, the contents of each egg were weighed and thoroughly mixed afterwards. Aliquots of each homogenate were mixed with scintillator for determination of the radioactivity by LSC. The remaining samples were stored in a freezer until start of metabolite analysis.

Collection of excreta

The excreta of each hen were collected from the collecting tins as far as possible quantitatively in daily intervals until sacrifice. Individual samples were weighed after water was added. Afterwards, the individual samples were homogenised. Aliquots of each sample were processed for radioactivity measurement by combustion / LSC. The remaining samples were stored in a freezer until start of metabolite analysis.

Sacrifice

The animals were sacrificed approximately 6 hours after the last administration, a time distance that is consistent with normal slaughtering practices. Each laying hen was transferred into a special cage, weighed and anaesthetized using carbon dioxide gas. Under general anaesthesia the animals were sacrificed by decapitation followed by exsanguination.

Preparation of organs and tissues

After exsanguination, the following edible organs and tissues were dissected: muscle (leg and thorax), fat (subcutaneous), liver (without gall bladder), skin (without subcutaneous fat), kidneys and eggs from the ovary and oviduct.

The organs or tissue samples were transferred into tared weight plastic vessels. After determination and recording of the individual weights, muscle, fat, liver, skin, kidney samples and eggs dissected from the ovary and oviduct were passed several times through a mincing machine in half-frozen state or blended with an Ultra Turrax in thawed state. Aliquots of the individual organ and tissue samples were combusted and the radioactivity measured by LSC.

The organ and tissue samples of the six hens were pooled separately for each sample type, divided in suitable portions that were stored frozen at ≤ -18 °C until the start of metabolite analysis. For skin, the remaining homogenates of kidneys and eggs from the ovary/oviduct, metabolite analysis was optional.

All individual samples were identified with a specific sample number. The individual excreta, egg, as well as organ and tissue samples were kept frozen at ≤ -18 °C at all times except during aliquotation for analysis. During the analytical work the samples and extracts of samples were stored either in a freezer at ≤ -18 °C or for a short period in a refrigerator at +4 °C.

Radioactivity measurement

The radioactivity measurement in liquid samples was carried out by liquid scintillation counting (LSC). The solid samples were either dissolved in BIOLUTE S and radioactivity determined by LSC or combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

C. Analytical Procedures

Sample Extraction and Analysis of Extracts

Aliquot samples from eggs, muscle, fat, liver and excreta were conventionally extracted three times with a mixture of acetonitrile/ water (8/2; v/v) using a Polytron homogeniser. For sample preparation the combined conventional extracts from eggs, muscle, liver and excreta were partitioned against n-heptane. The purified conventional extracts were concentrated by rotary evaporation and subjected to HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

Solids of liver from the first conventional extraction were exhaustively extracted twice with acetonitrile/water (8/2; v/v) using microwave assistance followed by further treatment with microwave and 0.1 M hydrochloric acid. All exhaustive extracts were characterised using TLC analysis.

Aliquots of the conventional liver extracts were incubated for 96 hours at 37 °C with a defined amount of ß-glucuronidase/arylsulfatase. After incubation, the enzymatic suspensions were purified and analysed by HPLC.

Metabolite analysis

Parent compound and metabolites were quantified in the extracts by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

The following strategy was used for identification of the parent compound and metabolites:

All metabolites were assigned based on a comparison of the metabolite profiles and retention times analysed in the hen metabolism study after administration of pyrazole labelled BCS-CN88460. Parent compound and metabolites were identified in selected samples by HPLC or TLC co-chromatography with radiolabelled reference compounds taken from the hen metabolism with the pyrazole label or from the goat metabolism study with the phenyl label. The assignment of parent compound and metabolites in all samples was then achieved by comparison of HPLC metabolite profiles of the analysed samples among each other. The conventional extract of liver was enzymatically digested. The glucuronic acid and sulphate conjugates were thereby digested and converted into their corresponding aglycons.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

II. Results and Discussion

A. Recovery and Elimination of Radioactivity

The overall recovery accounted for 103.36% of the total dose and up to the time of sacrifice, 102.97% of the total dose was excreted. After the third administration the daily excretion rate was on a more or less constant level of about 7.1 to 8.8% within 24 hours. An average amount of 0.14% of the total dose was measured in the eggs. At sacrifice, the radioactive residues in the organs and tissues dissected from the bodies were calculated or estimated to be about 0.24% of the total dose.

All TRRs for eggs and dissected organs and tissues were calculated as radioactivity originating from the radiolabelled test compound. Therefore, all concentration data in this report represent active substance equivalents (mg a.s. equiv. /kg_{sample}).

Table 7.2.2-8: Distribution of residues in matrices of laying hens following oral administration of 14 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 (1.01 mg/kg bw/day)

Sample	Collection time	TRR (mg/kg)*	Transfer factor**	Percent of total dose administered

Eggs, total	day 1 –13.25	0.047	0.003	0.14
Eggs, plateau-level	day 4 – 13	0.050	0.003	-----
Excreta, total	day 1 – 13.25	-----	-----	102.97
Total Recovery				**103.36**
Feeding level	18.12	mg a.s. /kg dry feed/day		

Percentage values were calculated from the body weights at sacrifice, assuming 40%, 12% and 4% of the body weight for total skeletal muscle, fat, or skin (without subcutaneous fat), respectively.

* weighted mean TRR-values of the individual animals

** The transfer factor was calculated by dividing the TRR-value of the respective sample by the feeding level (milligrams of a.s. per kilograms dry feed on each day).

B. Levels and Time Course of Total Radioactive Residues in Eggs

The TRR-values in eggs ranged from 0.032 mg/kg at day three to 0.066 mg/kg at sacrifice. Following a linear increase a residue plateau-level of 0.050 mg/kg was reached at day four after the first administration.

Table 7.2.2-9: Time course of total radioactivity in eggs following oral administration of 14 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.01 mg/kg

TRR, plateau-level (day 4 – 13): 0.050 mg/kg

C. Total Radioactive Residues in Dissected Organs and Tissues

The highest TRR-value was determined in liver (0.373 mg/kg; 0.07% of total administered dose) followed by kidney (0.360 mg/kg; 0.01% of total administered dose) indicating the significance of these organs for metabolism and excretion. The TRR-value of the eggs collected from the ovary and oviduct at sacrifice (0.096 mg/kg) was by a factor of 1.5 higher than the levels of the laid eggs collected at sacrifice (0.066 mg/kg). This showed that the egg yolk was a preferential site for secretion of test compound related radioactivity. Lower TRR-values were detected for subcutaneous fat (0.047 mg/kg), skin (0.109 mg/kg) and total skeletal muscle (0.024 mg/kg). The TRR-values of the total subcutaneous fat, skin and muscle corresponded to about 0.04%, 0.03% and 0.07% of the total dose assuming values of 12%, 4% and 40% of the body weight for these tissues, respectively.

D. Extraction Efficiency of Residues

The majority of the residues in the eggs as well as organs and tissues were efficiently extracted (85.4% to 93.3%) using acetonitrile/water mixtures. In case of liver, the solids after conventional extraction were further extracted using microwave treatment releasing 14.5% of the TRR (0.054 mg/kg). Only up to 8.2% of the TRR (0.004 mg/kg) of the residues remained in the post extraction solids (PES).

For sample preparation, the extracts were partitioned against n-heptane except the extract from fat. Very low amounts of radioactivity were recovered in the n-heptane phases amounting to ≤1.2% (0.001 mg/kg) of the TRR. Concentration procedures of the aqueous phases caused no losses, so all of the residues in the aqueous phases were quantitatively analysed by HPLC.

A summary of the extraction efficiency is shown in the table below.

Table 7.2.2-10: Extraction efficiency of poultry samples following oral administration of 14 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 (1.01 mg/kg bw/day)

Sample	Eggs (day 4 – 13)		Muscle Leg		Muscle Thorax		Fat		Liver

E. Quantification, Identification and Characterisation of Residues

Parent compound and metabolites were quantified in the conventional extracts by HPLC chromatography based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Metabolites in the extracts were assigned to each other by comparison of the metabolite profiles and their retention times. Corresponding metabolites were named with the same peak ID.

Isoflucypram metabolites were identified by co-chromatography with radiolabelled reference compounds taken from the hen metabolism study after administration of pyrazole labelled **isoflucypram** or from the goat metabolism study after administration of phenyl labelled **isoflucypram**. Metabolites in other organs and tissues were assigned by comparison of the metabolic profiles and retention times. In addition, the assignment of parent compound and metabolites in the current study was performed based on a comparison of the retention times and metabolic profile of the current study and the hen metabolism study with the pyrazole label.

F. Distribution of Parent Compound and Metabolites in Eggs, Organs and Tissues

The identification rates amounted to 79.2% of the TRR for eggs, 79.8% for leg muscle, 76.3% for thorax muscle, 51.5% for fat and 62.0% for liver.

Parent compound was only detected in eggs, leg muscle and fat and amounted to 0.003 mg/kg (6.4% of the TRR) for eggs, 0.001 mg/kg (2.9% of the TRR) for leg muscle and to 0.009 mg/kg (20.1% of the TRR) for fat.

Metabolites in eggs (day 4 – 13)

Metabolites BCS-CN88460-propanol (**M01**) and BCS-CN88460-desmethyl-propanol (**M06**) were the main residues in eggs and accounted for 0.017 mg/kg (33.9% of the TRR) and 0.011 mg/kg (22.6% of the TRR), respectively. Other prominent metabolites in eggs were BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**), BCS-CN88460-desmethyl-1,2-propandiol (**M07**) and BCS-CN88460-carboxylic acid (**M12**), each ≤7.2% of TRR.

Metabolites in leg and thorax muscle

The main residues in leg muscle were BCS-CN88460-desmethyl-propanol (25.8% (0.007 mg/kg) of the TRR), BCS-CN88460-desmethyl-carboxylic acid (19.9% (0.006 mg/kg) of the TRR) and BCS-CN88460-desmethyl-1.2-propandiol (14.2% (0.004 mg/kg) of the TRR). These three main metabolites were also detected in the thorax muscle and amounted between 20.2% and 22.3% of the TRR. BCS-CN88460-carboxylic acid (**M12**) was a prominent metabolite in leg and thorax muscle and amounted to 6.6% and 8.6% of the TRR, respectively. Minor metabolites in muscle were BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA, BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**) (both only detected in leg muscle) and BCS-CN88460-propanol (**M01**) (all ≤4.3% of TRR).

Metabolites in fat

Besides parent compound as the main residue in fat, five abundant metabolites were identified and named as BCS-CN88460-desmethyl-1,2-propandiol (**M07**), BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-desmethyl-propanol, BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**). These five metabolites amounted between 3.0% and 8.0% of the TRR.

Metabolites in liver

The main residue in liver was identified as BCS-CN88460-desmethyl-carboxylic acid (21.9% (0.082 mg/kg) of the TRR). Prominent metabolites in the liver were BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**), BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**), BCS-CN88460-desmethyl-1,2-propandiol (**M07**) and BCS-CN88460-carboxylic acid (**M12**) and amounted between 5.5% and 10.8% of the TRR. Four minor metabolites named as BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**), BCS-CN88460-propanol-SA (**M26**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**) were detected (all ≤3.0 of TRR).

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the chromatograms. All unknown metabolites in the extracts were characterised by their extraction and chromatographic behaviour and amounted to each ≤10.0% of the TRR.

The distribution of the parent compound and metabolites in milk, organs and tissues is summarised in the table below.

Table 7.2.2-11: Radioactive residues of parent compound and metabolites in eggs and edible organs and tissues of laying hens following oral administration of 14 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.01 mg/kg

Conjugates in the liver like BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**), BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**), BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**) and BCS-CN88460-propanol-SA (**M26**) could be enzymatically cleaved to their aglycons. The cleavage of some unknown conjugates in non-resolved zones resulted in higher amounts of the aglycons. None of the unknown compounds after cleavage accounted for more than 5.4% (0.020 mg/kg) of the TRR. The following main aglycons could be clearly identified after enzymatic cleavage: BCS-CN88460-desmethyl-1,2-propandiol (**M07**) and BCS-CN88460-desmethyl-propanol (**M06**).

Table 7.2.2-12: Radioactive residues of parent compound and metabolites in liver samples of first and second conventional extraction and after enzymatic cleavage for 96 h

Metabolites in Excreta

The excreta extract of day 1 was analysed by HPLC. Parent compound accounted for 1.2% of the dose. BCS-CN88460-desmethyl-carboxylic acid (**M11**) was the most prominent compound and amounted to 20.0% of the dose. Further nine identified metabolites ranged from 0.8% to 9.6% of the dose.

Generally, metabolites in the extract from excreta were the same as in eggs, organs and tissues, except for metabolites BCS-CN88460-desmethyl-1,2-propandiol-SA (**M42**), BCS-CN88460-1,2-propandiol-SA (**M27**) and BCS-CN88460-1,2-propandiol (**M03**) which accounted for equal or less than 7.2% of the dose, respectively.

G. Storage Stability of Residues

All samples of eggs, excreta, edible organs and tissues were extracted within three months after sample collection. Quantitative analysis by HPLC was performed either on the day of extraction or up to one day after the start of extraction.

A second conventional extraction of liver was performed approximately 9 months after sampling. The extract was used for enzymatic cleavage experiments. The storage stability was exemplarily demonstrated for these liver samples.

It was therefore concluded, that the metabolic profiles represent the residues in the matrices and analysed samples at sacrifice.

B.7.2.2.1.3. Summary of isoflucypram metabolism in poultry

The TRR-values and transfer factors in eggs and edible tissues were low with respect to the dose level and the dosing period of 14 days. This indicates that test compound-related radioactivity does not accumulate during the time of feeding. The evaluations of the TRR-values should however consider the fact that exaggerated dose levels (16.57 mg a.s./kg feed/day for the pyrazole label and 18.12 mg a.s./kg feed/day for the phenyl label) were administered. Furthermore, the fact that the entire radioactivity was detected in the excreta and the relatively high TRR in kidney and liver at sacrifice approximately 6 hours after the last administration revealed that the test compound related residues are further metabolised and finally eliminated from the hen's bodies. A residue plateau level in eggs was reached 6 days after first administration of the pyrazole labelled material and 4 days after first administration of the phenyl labelled material.

The radioactive residues were extracted with conventional methods from eggs and tissues; extraction rates ranged from 83.9% to 93.4%. Extraction with conventional and exhaustive methods from edible organs accounted for 99.9% for the liver.

The identification rates in eggs, edible organs and tissues ranged between 51.5% and 79.8% of the TRR.

Parent compound was detected as the major compound in fat and minor in eggs and leg muscle.

Overall nine metabolites were identified in eggs, edible organs and tissues. Metabolites BCS-CN88460-propanol (**M01**), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-desmethyl-1,2-propandiol (**M07**) and BCS-CN88460-carboxylic acid (**M12**) were major residues in eggs, leg muscle, thorax muscle, fat and liver. In liver, metabolites BCS-CN88460-desmethyl-propanol-N-GlucA (**M37**) and BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA (**M36**) were further prominent metabolites for both labels, but found only in liver for the pyrazole label. Minor metabolites were BCS-CN88460-propanol (**M01**), BCS-CN88460-desmethyl-2-propanol-N-GlucA (**M38**) and BCS-CN88460-propanol-SA (**M26**).

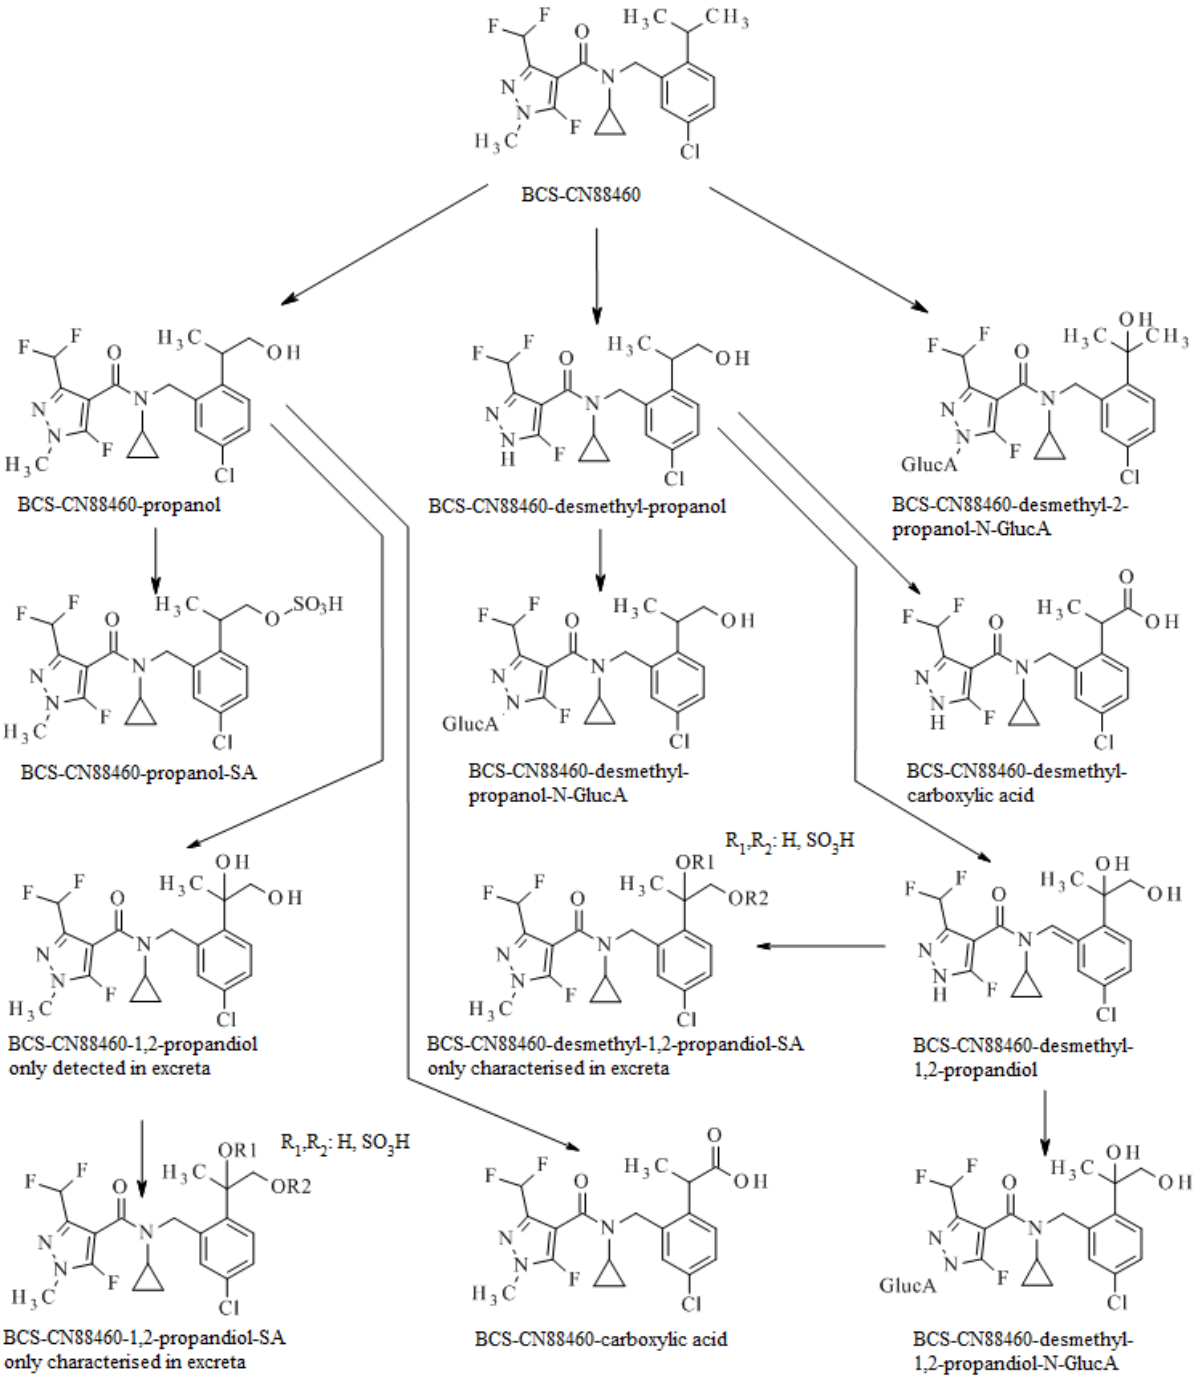
The metabolic profile of excreta from day 1 was similar to the profiles of edible materials, especially liver, with the following differences: metabolites BCS-CN88460-desmethyl-1,2-propandiol-SA (**M42**), BCS-CN88460-1,2-propandiol-SA (**M27**) and BCS-CN88460-1,2-propandiol (**M03**) were present in the liver of animals tested from both studies whilst BCS-CN88460-propanol-SA (**M26**) was present in the liver of animals dosed with the phenyl label only.

The principal metabolic reactions of **isoflucypram** in the laying hen are listed below:

- demethylation of the pyrazole moiety;
- conjugation with glucuronic acid after demethylation of the pyrazole moiety;
- hydroxylation in position 1 and position 2 of the propyl group in the phenyl ring;
- further oxidation of the 1-propanol group was leading to a carboxylic acid group ;
- conjugation with sulphuric acid after hydroxylation in position 1 or position 2 of the propyl group.

Based on these results, the metabolism of **isoflucypram** in the laying hen is considered as sufficiently understood and a metabolic pathway is proposed in the figure below:

Figure 7.2.2-1: Proposed metabolic pathway of isoflucypram in laying hens



B.7.2.3. **Lactating ruminants**

The metabolism of the fungicide **isoflucypram (**BCS-CN88460) in lactating goats was investigated after administration with **isoflucypram** either labelled in the pyrazole or in the phenyl moiety.

Table 7.2.3-1: Overview of lactating goat metabolism studies

Poultry	Application	Dose	Reference
Lactating goat	5 daily doses over 5 days of pyrazole-labelled **isoflucypram** via gelatine capsules	1.0 mg/kg bw	M-604281-01-1
Lactating goat	5 daily doses over 5 days of phenyl-labelled **isoflucypram** via gelatine capsules	1.0 mg/kg bw	M-604286-01-1

Summary of metabolism in ruminants

The metabolite pattern corresponds well when comparing the two metabolism studies in lactating goats. Parent compound was detected in milk, muscle, fat, liver and kidney. It was a major compound in milk, muscle and fat and a minor compound in liver and kidney. BCS-CN88460-2-propanol (**M02**), BCS-CN88460-propanol (**M01**), BCS-CN88460-2-propanol-GlucA (**M20**), BCS-CN88460-propanol-GlucA (isomer 1, **M19** - isomer 1) and BCS-CN88460-carboxylic acid (**M12**) were major metabolites. The metabolic reactions were hydroxylation in position 1 and/or position 2 of the propyl group following conjugation with glucuronic acid.

B.7.2.3.1.1. [pyrazole-4-^{14}C]isoflucypram

Report:	KCA 6.2.3/01; [redacted] 2017
Title:	[Pyrazole-4-^{14}C]BCS-CN88460 - Metabolism in the lactating goat
Report No.:	EnSa-17-0309
Document No.:	M-604281-01-1
Guidelines:	OECD Test Guideline 503; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism and excretion of [pyrazole-4-^{14}C]BCS-CN88460 was investigated in the lactating goat as a model for ruminants. The test compound was orally administered to a lactating goat in gelatine capsules at a dose of approximately 1 mg per kg body weight. Based on the daily feed consumption, the dose level corresponded to 45.19 mg a.s./kg dry feed/day. The goat received five doses at 24-hour intervals in the morning after milking and was sacrificed approximately 6 hours after the last dosing.

Throughout the experiment, the goat was housed in a metabolism cage, which permitted separate collection of urine and faeces. The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and approximately 1 hour before sacrifice. The total radioactive residues (TRRs) were determined in each milk sample and in dissected organs and tissues (muscle, fat, liver and kidney) at sacrifice. The total radioactivity (% of total dose administered) was additionally determined in each urine and faeces sample.

Recovery and Elimination of Radioactivity

The overall recovery accounted for approximately 64% of the total dose. The remaining amount of radioactivity (approximately 36%) was expected to still be present in the non-edible part of the animal body and especially in the gastrointestinal tract at sacrifice due to the short time period between last administration and sacrifice (approximately six hours).

An amount of approximately 0.03% of the total dose was secreted with the milk, only. At sacrifice, radioactive residues in the edible organs and tissues dissected from the body were calculated to be approximately 0.72% of the total dose and were very low.

Up to the time of sacrifice, approximately 6.9% of the total dose was excreted with the urine and approximately 56.1% with faeces. The daily renal excretion of the radioactivity started shortly after the first dosing before the daily renal excretion rate reached a more or less constant level with round

about 1.1% to 1.9%. The daily faecal excretion of the radioactivity started after the first dosing. The daily faecal excretion rate exhibited a more or less constant gradient and amounted to 19.4% after the fifth dosing. The cumulative renal and faecal excretion was characterised by a linear increase from 24 h until sacrifice.

Total Radioactive Residues in Milk, Organs and Tissues

The TRR-values and transfer factors for milk, organs and tissues were very low compared to the dose level of 45.19 mg a.s./kg feed/day and a dosing period of five days.

The TRR-values in milk samples ranged from 0.009 mg/kg to 0.021 mg/kg after the first and third administration, respectively. The time course of TRR-values of the evening and morning milk samples indicated a diurnal pattern for the testing period. The radioactive residues increased significantly during the eight-hour period after each administration.

Regarding organs and tissues, the TRR-values amounted to 0.038 mg/kg for muscle (composite of round and loin muscle), 0.102 mg/kg for fat (composite of perirenal and omental fat), 0.717 mg/kg for liver and 0.189 mg/kg for kidney.

Metabolism

The majority of the residues in the milk as well as organs and tissues were efficiently extracted (extraction rates between 89.2% and 98.7%) using acetonitrile/water (8/2; v/v) mixtures. In case of muscle and liver, the solids after conventional extraction were exhaustively extracted using acetonitrile/water mixtures with microwave treatment. Up to 7.8% of the TRR or 0.036 mg/kg of the residues remained in the post extraction solids (PES). After partitioning of the conventional extracts against n-heptane very low amounts of radioactivity were detected in the organic phases amounting to ≤1.4% of the TRR, only.

Parent compound and metabolites were identified based on co-chromatography with isolated metabolites and reference compounds or by comparison of the metabolite pattern and retention times. Metabolites were isolated from urine and identified by spectroscopic investigations.

The identification rates amounted to 53.7% of the TRR for milk, 67.7% for muscle, 81.5% for fat, 58.3% for liver, and 65.4% for kidney.

Parent compound was detected in milk, muscle, fat, liver and kidney. It was the major compound in milk, muscle and fat and a minor compound in liver and kidney. Overall up to eleven metabolites were identified.

Metabolite BCS-CN88460-2-propanol (**M02**) was detected in all matrices, amounting from 2.6% to 20.3% of the TRR and represented a major residue (>10% of the TRR) in milk, muscle and fat. Metabolites BCS-CN88460-carboxylic acid (**M12**, representing a major metabolite in kidney) and BCS-CN88460-propanol (**M01**, representing a major metabolite in muscle) were detected in muscle, fat, liver and kidney. The amount of BCS-CN88460-carboxylic acid (**M12**) amounted between 3.3% and 18.0% of the TRR, while the amount of BCS-CN88460-propanol (**M01**) amounted between 2.7% and 10.2% of the TRR. BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propanol-GlucA (isomer 1, **M19** – isomer 1) (both representing a major metabolite in liver) were detected in liver and kidney and ranged between 2.6% and 13.8% of the TRR. Metabolites BCS-CN88460-propanol-GlucA (**M19**) (isomer 2, **M19** – isomer 2) and BCS-CN88460-desmethyl-propanol (**M06**) were detected in muscle, liver and kidney and their amount ranged between 0.5% and 7.7% of the TRR. BCS-CN88460-lactic acid (**M10**) and BCS-CN88460-desmethyl-carboxylic acid (**M11**) were identified in liver and kidney, BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) and BCS-CN88460-propenol-GlucA (**M25**) were detected in kidney, only. All metabolites were minor abundant and accounted for equal or less than 6.1% of the TRR.

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the

chromatograms. All unknown metabolites in the extracts were characterised by their extraction and chromatographic behaviour and amounted to ≤14.3% of the TRR.

The metabolic profiles of urine and faeces were similar to the profiles of edible materials, especially liver and kidney, except that parent compound was not present in the sample of urine.

A summary of the distribution of parent compound and metabolites for edible materials is provided in the following table:

Table 7.2.3-2: Radioactive residues of parent compound and metabolites in milk and edible organs of lactating goats following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

* BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propenol-GlucA (**M25**) were co-eluting in the kidney and were subquantified by TLC.

The main metabolic reaction was the hydroxylation in the propyl group of the phenyl ring. Conjugation with glucuronic acid was observed after hydroxylation in position 1 or 2 of the propyl group. Another important metabolic reaction was the carboxylation of the 1-propanol group, leading to a carboxylic acid or with a hydroxyl group in position 2 of the propyl group to a lactic acid. Minor metabolic reactions were the demethylation of the pyrazole moiety, the cleavage of the phenyl moiety in combination with cleavage of the cyclopropyl ring and the dehydration after hydroxylation in position 1 and 2 of the propyl group followed by conjugation with glucuronic acid.

Based on the results the metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in the lactating goat is considered as adequately understood and a metabolic pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material

Chemical structure	 * denotes the ^{14}C-label position	
Radiolabelled test material	[Pyrazole-4-^{14}C]BCS-CN88460	
Specific radioactivity used for administration	4.22 MBq/mg = 2.53 x 10^8 dpm/mg (delivered sample before radiodilution)	2.11 MBq/mg =1.27 x 10^8 dpm/mg (sample after radiodilution)
Radiochemical purity	>98% (HPLC)	
Non-labelled test material	BCS-CN88460 (**isoflucypram**)	
Chemical purity	98.4%	
Dose level	5 daily oral doses of 1 mg/kg bw	
Vehicle	Gelatine capsule	

2. Test Animals

Species	Lactating goat (*Capra hircus*)
Strain	"Weiße Deutsche Edelziege"
Breeding facility	[redacted]
Body weight	99 kg at delivery (2015-06-08) 89 kg at first administration (2015-06-15) 90 kg at sacrifice (2015-06-19)
Acclimatization	7 days
Identification	On arrival, the goat was arbitrarily allocated a stock number, or supplier's number. During the acclimation and testing period an individual animal number was allocated.
Husbandry	Conventional hygienic conditions in air-conditioned rooms
Housing	During the acclimation period, the goat was kept in a raised stall with a metal grid as base and straw and hay as bedding. During the whole testing period, the goat was kept in an electro-polished stainless steel metabolism cage for farm animals (goat, sheep, and pig), supplied by E. Becker & Co. GmbH "EBECO", Hermannstr. 2 – 8, 44579 Castrop-Rauxel, Germany. With this cage, an almost separate and quantitative collection

	of urine and faeces was possible. The cage was equipped with a variable-restraining device.
Dietary regimen	During the whole residence time, the goat was fed *ad libitum* with ruminant feed ("Raiffeisen Lamm-Gold" supplied by Raiffeisen Markt Monheim, Heerweg 10 – 14, 40789 Monheim am Rhein, Germany). It was supplemented by hay (during the acclimation period only), hay pellets and carrots. The feed was not a certified diet, i.e. it was not checked for contamination according to current standards. The feed consumption was recorded by back-weighing during the experiment. Tap water from the local mains supply was given *ad libitum* during the whole residence time.

B. Study Design

Preparation of the Test Compound for Administration

The radiolabelled test compound was delivered in solid form. It was diluted in a ratio of 1:1 with the non-radiolabelled test compound. In total, five gelatine capsules containing the solid test compound were prepared and stored in a freezer at ≤ -18 °C. The identity confirmation of the test compound was proven by LC-MS/MS. In order to demonstrate the stability of the solid test compound in the capsules, a small portion of the test compound was stored together with the capsules until the last administration. Aliquots of the small portion were analysed for stability and purity of the test compound after the first and the last administration by HPLC. In both cases, the purity amounted to >98%.

Dosing

All oral administrations were performed using a capsule applicator once daily for five consecutive days in the morning after milking. Each gelatine capsule contained an average amount of 89.17 mg, which corresponded to 188 MBq. The total administered amount and radioactivity accounted for 445.87 mg and 941 MBq, respectively.

The total amount of radioactivity administered to the animal served as reference-value (A_0 = 100%) for the percentage calculation of the total radioactivity in the biological samples.

Based upon the experimentally determined daily feed consumption during the testing period of 1,974 g dry feed per day (= 2.22% of the body weight), the dose of 1.0 mg a.s./kg bw corresponded to a concentration of 45.19 mg a.s./kg dry feed per day in the diet. This dose was tolerated without any observable toxicological effects.

Sampling of milk, urine and faeces during the in-life phase

The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and directly before the scheduled termination. After weighing, aliquots were taken from each sample for radioactivity measurement by LSC.

Urine and faeces samples were collected in plastic vessels or collecting grids as quantitatively as possible under dry ice cooling in intervals of 24 hours after the administrations 1 to 4 and 6 hours after the last administration. The vessels were exchanged immediately before the next administration. The collection funnel was rinsed with deionised water into the urine vessel of the respective collection period. After determination of the total volumes, aliquots of each urine sample were used for radioactivity measurement by LSC. For collection of faeces, the collecting grid was cleaned prior to each administration. After determination and recording of the individual weights each faeces fraction was passed several times through a mincing machine in half-frozen state. Aliquots of each faeces fraction were combusted and the radioactivity measured by LSC.

Sacrifice and dissection of organs and tissues

The animal was sacrificed approximately 6 hours after the last administration, a time interval that is

consistent with normal slaughtering practices. The animal was at first sedated by an intramuscular mixed injection of Xylazin/Rompun (2%; 0.2 mg/kg bw) and Ketamin (10%; 5 mg/kg bw) and afterwards anaesthetised by an intravenous dose of about 40 mg/kg bw Pentobarbital-Na (Narcoren®). Under deep anaesthesia, the animal was then exsanguinated by transection the jugular vein and finally terminated by intracardiac injection with approximately 10 mL of the veterinary drug "T 61®". Following exsanguination, the following edible organs and tissues were dissected: muscle (round and loin), fat (omental and perirenal), liver (without gall bladder) and kidneys.

Preparation of Organs and Tissues

The organs or tissue samples were transferred into tared plastic vessels. After determination and recording of the individual weights, muscle, fat, liver and kidney samples were passed several times through a mincing machine in half-frozen state. Aliquots of the individual organ and tissue samples were combusted and the radioactivity measured by LSC. All samples were stored at ≤ -18 °C until the start of metabolite analysis.

For metabolism investigations, pooled samples of milk (collected from 32 h until 101 h), muscle (loin and round muscle) and fat (perirenal and omental) were prepared. Liver, kidney and faeces (0 - 24 h) were homogenised and aliquots were stored frozen until start of extraction. The radioactivity and TRR-values of the samples were calculated from the in-life data

C. Analytical Procedures

Sample Extraction and Analysis of Extracts

Aliquots from milk, muscle, fat, liver, kidney and faeces were conventionally extracted three times with a mixture of acetonitrile/water (8/2; v/v) using a Polytron homogeniser. Additionally milk was extracted once with THF and once with acetonitrile/water (3/7; v/v). Minor radioactivity could be released by these additional extractions, only. The combined conventional extracts were partitioned against n-heptane.

The aqueous phases were concentrated by rotary evaporation and subjected to HPLC analysis based on reversed phase chromatography with an acidic water/acetonitrile/THF gradient.

Solids of muscle from the conventional extraction were exhaustively extracted with acetonitrile/water (1/1; v/v) using microwave assistance. Solids of liver from the first conventional extraction were exhaustively extracted twice with acetonitrile/water (8/2; v/v) followed by acetonitrile/water (1/1; v/v) and by 0.1 M HCl using microwave assistance. The metabolites in the exhaustive extract were further characterised using TLC analysis.

Aliquots of the conventional liver extracts and kidney extracts were incubated for 20 hours at 37 °C with a defined amount of ß-glucuronidase/arylsulfatase. After incubation, the enzymatic suspensions were purified and analysed by HPLC.

Determination of the Radioactivity in the Cream Fraction of Milk

To evaluate the radioactivity in the cream fraction of milk, an aliquot of the milk sample was partitioned against n-heptane.

Radioactivity measurement

The radioactivity measurement in liquid samples was carried out by liquid scintillation counting (LSC). The solid samples were either dissolved in BIOLUTE S or combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

Metabolite analysis

Parent compound and metabolites were quantified in the extracts by HPLC based on reversed phase

chromatography using an acidic water/acetonitrile/THF gradient.

The peaks in the individual HPLC profiles were numbered increasingly in the order of elution in the HPLC-profiling methods. Corresponding metabolites were named with the same peak-ID.

The assignment of parent compound and metabolites was achieved by comparison of HPLC metabolite profiles of the analysed samples among each other and compared to the goat metabolism study with the phenyl label. Furthermore, metabolites were isolated from urine by HPLC. They were identified in the isolated fractions by spectroscopic methods. Other metabolites were identified by chromatographic comparison of the metabolic profile or by co-chromatography with radiolabelled test and reference compounds in selected samples. The conventional extracts of liver and kidney were enzymatically digested. The glucuronic acid conjugates were thereby digested and converted into their corresponding aglycons.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

II. Results and Discussion

A. Recovery and Elimination of Radioactivity

The overall recovery in the lactating goat after administration of a mean daily dose of 1.0 mg [pyrazole-4-^{14}C]BCS-CN88460 per kg body weight (according to 45.19 mg a.s./kg feed/day) on five consecutive days accounted for 63.78% of the total dose. The remaining amount of radioactivity (approximately 36%) was expected to still be present in the gastrointestinal tract at sacrifice, due to the short period between last administration and sacrifice (approximately 6 hours).

Table 7.2.3-3: Recovery of radioactivity in dissected organs and tissues, milk, and excreta of lactating goats following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Biological matrix	Percent of total dose administered
Liver	0.23
Kidney	0.01
Total body muscle	0.23
Total body fat	0.25
Total of organs/tissues	0.72
Milk, 0 – 101 h	0.03
Urine, 0 – 102 h (plus funnel rinsing)	6.94
Faeces, 0 – 102 h	56.09
Total excreted	63.03
Total Recovery	63.78

An amount of approximately 0.03% of the total dose was secreted with the milk, only. At sacrifice, radioactive residues in the organs and tissues dissected from the body were calculated or estimated to be 0.72% of the total dose.

Up to the time of sacrifice, 6.94% of the total dose was excreted with the urine and 56.09% with faeces (see table above). The daily renal excretion of the radioactivity started shortly after the first dosing before the daily renal excretion rate reached a more or less constant level with round about 1.1% to 1.9%. The daily faecal excretion of the radioactivity started after the first dosing. The daily

faecal excretion rate exhibited a more or less constant gradient and the faecal excretion reached its maximum after the fifth dosing with 19.4%. The cumulative renal and faecal excretion was characterised by a linear increase from 24 h until sacrifice

Table 7.2.3-4: Distribution of residues in liver, kidney, muscle, fat and milk of lactating goats following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Organ/Tissue	Collection Time	Fresh weight (g)	TRR (mg/kg)	Transfer factor (TF)***	Percent of total dose administered

Milk, plateau-level	day 3-4	4,584.45	0.015	≤0.001	0.02
Feeding level		45.19	mg a.s./kg dry feed/day		

* Percentage values and fresh weights were calculated from the body weight at sacrifice, assuming 30% and 12% of the body weight for total body muscle and total body fat, respectively.

** weighted mean TRR-values from the two types of muscle and fat

*** The transfer factor was calculated by dividing the TRR-value of the respective sample by the feeding level (milligrams of a.s. per kilograms dry feed for each day).

B. Levels and Time Course of Total Radioactive Residues in Milk

The radioactivity levels measured in milk samples and the calculated amounts are shown in the table below. The TRR-values in milk samples ranged from 0.009 mg/kg at 24 hours after the first administration to 0.021 mg/kg approximately 8 hours after the third administration and approximately 1 h before sacrifice. The time course of TRR-values of the evening and morning milk indicated a diurnal pattern for the testing period. The radioactive residues increased significantly during the eight-hour period after each administration. A residue plateau-level of 0.015 mg/kg was reached at about day 3-4 after the first administration. This value was calculated from the evening sample of day 3, both samples of day 4 and the morning sample of day 5.

Table 7.2.3-5: Time course of total radioactivity in the milk of lactating goats following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Time after the first admin. (h)	Admin. no.	Cumulative secretion [% of total dose admin.]	Secretion per day [% of total dose admin.]	TRR (mg/kg)
0	1	-----	-----	-----
8		0.0019		0.009
24		0.0048	0.005	0.009
24	2	-----	-----	-----
32		0.0089		0.020
48		0.0126	0.008	0.011
48	3	-----	-----	-----
56		0.0171		0.021
72		0.0202	0.008	0.011
72	4	-----	-----	-----
80		0.0238		0.018
96		0.0277	0.008	0.012
96	5	-----	-----	-----
101		0.0305	0.003	0.021

C. Total Radioactive Residues in the Dissected Organs and Tissues

The highest TRR-value was determined in liver (0.717 mg/kg; 0.23% of total administered dose) indicating the significance of this organ for metabolism. The TRR-value for kidney accounted for 0.189 mg/kg (0.01% of total administered dose) and demonstrated that test compound related radioactivity partly was eliminated from the animal via urinary excretion. For body fat, the TRR-value amounted to 0.102 mg/kg (0.25% of total administered dose assuming 12% of the body weight for this tissue). The lowest TRR-value was determined in muscle (0.038 mg/kg; 0.23% of total administered dose assuming a value of 30% of the body weight for this tissue).

D. Extraction Efficiency of Residues

The majority of the residues in the milk as well as organs and tissues were efficiently extracted (89.2% to 98.7%) using acetonitrile/water (8/2; v/v) mixtures. In case of muscle and liver, the solids after conventional extraction were exhaustively extracted using acetonitrile/water mixtures with microwave treatment. Only up to 7.8% of the TRR or 0.036 mg/kg of the residues remained in the post extraction solids (PES) of liver and kidney. For sample preparation the extracts were partitioned against n-heptane. Very low amounts of radioactivity were recovered in the organic phase of the extracts amounting to ≤1.4% or ≤0.001 mg/kg of the TRR. Concentration procedures of the aqueous phases caused no losses so all of the residues in the aqueous phases were quantitatively analysed by HPLC.

A summary of the extraction efficiency is shown in the table below.

Table 7.2.3-6: Extraction efficiency of milk, muscle, fat, liver and kidney samples of lactating goats following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Sample	Milk (32 – 101 h)		Muscle		Fat		Liver		Kidney

E. Quantification, Identification and Characterisation of Residues

Quantification of Parent Compound and Metabolites

Parent compound and metabolites were quantified in the extracts as well as in the sample of urine (0-24 h) by HPLC-chromatography based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Metabolites in the exhaustive extracts from muscle and liver as well as co-eluting metabolites in a fraction of kidney were quantified by TLC.

Metabolites in the extracts as well as in the sample of urine (0-24 h) were assigned to each other by comparison of the metabolite profiles and their retention times. Corresponding metabolites were named with the same peak ID. Detailed information can be found in the report.

Isolation and Identification of Parent Compound and Metabolites

The assignment of parent compound and metabolites was achieved by comparison of HPLC metabolite profiles of the analysed samples among each other and by comparison of the metabolite profiles of the current study with the profiles of the goat metabolism study of the phenyl label.

Metabolites were isolated from urine (24 - 48 h) by HPLC. They were identified in the isolated fractions by spectroscopic methods. In addition parent compound and metabolites were identified in urine (0 - 24 h), in the conventional extracts of milk, muscle and fat as well as in isolated fractions from milk, muscle, fat, liver and kidney by HPLC co-chromatography with radiolabelled reference compounds taken from the hen metabolism study with the pyrazole label or from the goat metabolism study with the phenyl label. Conjugates were subjected to enzymatic cleavage with an aqueous solution of ß-glucuronidase/sulfatase before HPLC-analysis.

F. Distribution of Parent Compound and Metabolites in Milk, Organs and Tissues

The identification rates amounted to 53.7% of the TRR for milk, 67.7% for muscle, 81.5% for fat, 58.3% for liver, and 65.4% for kidney.

Parent compound was detected in milk, muscle, fat, liver and kidney and amounted to 0.005 mg/kg (33.4% of the TRR) for milk, 0.008 mg/kg (22.3% of the TRR) for muscle, 0.061 mg/kg (58.7% of the TRR) for fat, 0.025 mg/kg (3.5% of the TRR) for liver and 0.005 mg/kg (2.7% of the TRR) for kidney.

Metabolites in milk

Besides parent compound as the main residue in milk, BCS-CN88460-2-propanol (**M02**) was the major metabolite (20.3% (0.003 mg/kg) of the TRR).

Metabolites in muscle

Besides parent compound as the main residue, BCS-CN88460-2-propanol (**M02**) was the major metabolite and accounted for 17.9% (0.006 mg/kg) of the TRR. Other prominent metabolites were BCS-CN88460-propanol (10.2% (0.004 mg/kg) of the TRR) and BCS-CN88460-carboxylic acid (**M12**) (8.1% (0.003 mg/kg) of the TRR). BCS-CN88460-desmethyl-propanol (**M06**) (4.4% (0.002

mg/kg) of the TRR) and BCS-CN88460-propanol-GlucA (**M19**) (isomer 2) (4.8% (0.002 mg/kg) of the TRR) were minor compounds.

Metabolites in fat

Besides parent compound, the major metabolite was BCS-CN88460-2-propanol (**M02**) accounting for 16.8% (0.017 mg/kg) of the TRR. BCS-CN88460-carboxylic acid (**M12**) (3.3% (0.003 mg/kg) of the TRR) and BCS-CN88460-propanol (**M01**) (2.7% (0.003 mg/kg) of the TRR) were minor compounds in fat.

Metabolites in liver

BCS-CN88460-2-propanol-GlucA (**M20**) was the main residue in liver and accounted for 0.099 mg/kg (13.8% of the TRR). Other prominent metabolites were BCS-CN88460-propanol-GlucA (**M19**) (isomer 1 and 2) accounting for 0.094 mg/kg (13.1% of the TRR) and 0.055 mg/kg (7.7% of the TRR), respectively, BCS-CN88460-carboxylic acid (**M12**) accounting for 8.9% (0.064 mg/kg) of the TRR, as well as BCS-CN88460-propanol accounting for 0.042 mg/kg (5.8% of the TRR). The four metabolites BCS-CN88460-lactic acid, BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-2-propanol (**M02**) were minor metabolites and ranged between 0.003 mg/kg (0.5% of the TRR) and 0.019 mg/kg (2.6% of the TRR).

Metabolites in kidney

BCS-CN88460-carboxylic acid (**M12**) was the main metabolite in kidney, accounting for 0.034 mg/kg (18.0% of the TRR). Other prominent metabolites in kidney were BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) (5.8% (0.011 mg/kg) of the TRR), BCS-CN88460-lactic acid (**M10**) (6.1% (0.012 mg/kg) of the TRR), BCS-CN88460-propanol-GlucA (**M19**) (isomer 2) (7.0% (0.013 mg/kg) of the TRR) and BCS-CN88460-propanol (5.6% (0.011 mg/kg) of the TRR). The two minor co-eluting metabolites BCS-CN88460-2-propanol-GlucA (2.6% (0.005 mg/kg) of the TRR) and BCS-CN88460-propenol-GlucA (**M25**) (3.6% (0.007 mg/kg) of the TRR) were subquantified by TLC. Four metabolites BCS-CN88460-propanol-GluA (isomer 1), BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-desmethyl-propanol and BCS-CN88460-2-propanol (**M02**) were detected in minor amounts (≤4.2% of the TRR).

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the chromatograms. All unknown metabolites in the extracts were characterised by their extraction and chromatographic behaviour and amounted to each ≤14.3% of the TRR.

The distribution of the parent compound and metabolites in milk, organs and tissues is summarised in the table below.

Table 7.2.3-7: Radioactive residues of parent compound and metabolites in milk and edible organs of lactating goats following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

* BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propenol-GlucA (**M25**) were co-eluting in the kidney and were subquantified by TLC.

The distribution of radioactivity in milk between the cream fraction and the remaining skimmed milk showed that the major portion of the radioactivity was found in the fraction of skimmed milk (see below).

Table 7.2.3-8: Distribution of radioactivity in milk between cream and skimmed milk fractions

Sample description	% of TRR	mg/kg
n-heptane phase (cream)	13.3	0.002
aqueous phase (skimmed milk)	86.7	0.013
Total	100.0	0.015

Conjugates in the liver and kidney like BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propanol-GlucA (**M19**) (both isomer 1 and 2) could be enzymatically cleaved to their aglycons (see tables below). The cleavage of some unknown conjugates in non-resolved zones resulted in higher amounts of the aglycons. None of the unknown compounds after cleavage of the liver and kidney extracts accounted for more than 9.6% (0.069 mg/kg) of the TRR (mean of all three replicates) or 9.3% (0.018 mg/kg) of the TRR, respectively. The following main aglycons could be clearly identified after enzymatic cleavage: BCS-CN88460-2-propanol (**M02**) and BCS-CN88460-propanol (**M01**).

Distribution of Metabolites in Urine and Faeces

The metabolic profile of urine (0 - 24 h) and faeces (0 - 24 h) were similar to the profiles of edible materials, especially liver and kidney, except that parent compound was not present in the sample of urine. In faeces, parent compound was the main residue (8.4% of the first dose). All identified metabolites in urine and faeces accounted for ≤1.3% of the first dose.

The distribution of the parent compound and metabolites in urine and faeces is summarised in the table below.

Table 7.2.3-11: Radioactive residues of parent compound and metabolites in non-edible samples of lactating goat following oral administration of 5 daily doses of [pyrazole-4-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

* BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propenol-GlucA (**M25**) co-eluted in HPLC-analysis with the profiling method BCS460_1. Subquantification in the fraction of the sample of urine resulted in a ratio of 60.6% of BCS-CN88460-2-propanol-GlucA (**M20**) to 39.4% of BCS-CN88460-propenol-GluA.

G. Storage Stability of Residues

During the study, all samples and extracts were stored in a freezer at ≤ -18 °C or for a short time in a refrigerator. All samples of milk, and edible organs and tissues were extracted within three months after sample collection. The first metabolite profile was recorded not later than six days after the start of the extraction and sample preparation.

A second conventional extraction of milk was performed approximately 15 months after sampling, a second conventional extraction of liver was performed approximately 13 months after sampling and a second conventional extraction of kidney was performed approximately 14 months after sampling. From the stored milk sample, the distribution of radioactivity in the fractions of skimmed milk and cream was determined. The extracts of liver and kidney were used for enzymatic cleavage experiments. The storage stability was exemplarily demonstrated for these samples. It was therefore concluded, that the metabolic profiles represent the residues in the matrices and analysed samples at sacrifice.

III. Conclusion

The metabolic behaviour of [pyrazole-4-^{14}C]BCS-CN88460 in the lactating goat can be characterised by the following observations:

The TRR-values and the transfer factors in milk, organs and tissues were very low compared to the dose level of 45.19 mg a.s./kg feed/day and a dosing period of five days. The highest TRR-value was detected for liver and was caused by the short time period of 6 hours between last dosing and sacrifice. It indicates the significance of this organ for metabolism. The significantly lower TRR-value for kidney shows that no residues were retained in this tissue and reflects the low amount of radioactivity, which was excreted by the urine. The TRR-values in the respective evening and morning milk samples showed a diurnal pattern as they declined slightly prior to the delivery of the next dose for most days. A continuous increase was observed before a residue plateau-level was reached at day three after the first administration.

The elimination of radioactivity was mainly faecal (56.1% of the dose) and only 6.9% were eliminated via urine. This excretion behaviour was similar to the findings in the ADME studies with rats.

The radioactive residues were efficiently extracted from milk as well as from edible organs and tissues; extraction rates ranged from 92.2% to 98.7%.

The identification rates ranged between 53.7% and 81.5% for the TRR in milk, and edible organs and tissues.

Parent compound was detected in milk, muscle, fat, liver and kidney. Parent compound was a major compound in milk, muscle and fat and a minor compound in liver and kidney. Overall up to eleven metabolites were identified.

BCS-CN88460-2-propanol (**M02**) was detected as a major metabolite in milk (32 - 101 h), muscle and fat, BCS-CN88460-propanol (**M01**) was detected as a major metabolite in muscle, BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propanol-GlucA (isomer 1, **M19** – isomer 1) as major metabolites in liver and BCS-CN88460-carboxylic acid (**M12**) as a major metabolite in kidney. Further abundant metabolites were BCS-CN88460-propanol-GlucA (isomer 2, **M19** – isomer 2) in liver and kidney, BCS-CN88460-lactic acid (**M10**) in kidney, BCS-CN88460-N-methyl-pyrazole-carboxylic acid in kidney (**M50**), BCS-CN88460-carboxylic acid (**M12**) in muscle and liver and BCS-CN88460-propanol (**M01**) in liver and kidney. BCS-CN88460-desmethyl-carboxylic (**M11**) was a minor compound in liver and kidney, BCS-CN88460-desmethyl propanol (**M06**) was a minor metabolite in muscle, liver and kidney. BCS-CN88460-propenol-GlucA (**M25**) was only detected as a minor metabolite in kidney and in urine.

The metabolic profiles of urine and faeces were similar to the profiles of edible materials, especially liver and kidney, except that parent compound was not present in the sample of urine.

The principal metabolic reactions of [pyrazole-4-^{14}C]BCS-CN88460 in the lactating goat are listed below:

- hydroxylation in position 1 or position 2 of the propyl group in the phenyl ring;
- conjugation with glucuronic acid;
- oxidation of the 1-propanol group was leading to carboxylic acid or with a hydroxyl group in position 2 to lactic acid;
- demethylation of the pyrazole moiety;
- cleavage of the phenyl moiety in combination with cleavage of the cyclopropyl ring leading to BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**);
- dehydration after hydroxylation in position 1 and 2 of the propyl group followed by conjugation with glucuronic acid.

Based on these results, the metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in the lactating goat is considered as sufficiently understood and a metabolic pathway is proposed.

B.7.2.3.1.2. [phenyl-UL-^{14}C]isoflucypram

Report:	KCA 6.2.3/02; [redacted] 2017
Title:	[Phenyl-UL-^{14}C]BCS-CN88460 - Metabolism in the lactating goat
Report No.:	EnSa-17-0308
Document No.:	M-604286-01-1
Guidelines:	OECD Test Guideline 503; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Test Guideline No. 860.1300.
Guideline deviation:	None
GLP/GEP:	Yes

Summary

The metabolism and excretion of [phenyl-UL-^{14}C]BCS-CN88460 was investigated in the lactating goat as a model for ruminants. The test compound was orally administered to a lactating goat in gelatine capsules at a dose of approximately 1 mg per kg body weight. Based on the daily feed consumption, the dose level corresponded to 20.57 mg a.s./kg dry feed/day. The goat received five doses at 24-hour intervals in the morning after milking and was sacrificed approximately 6 hours after the last dosing.

Throughout the experiment, the goat was housed in a metabolism cage, which permitted separate collection of urine and faeces. The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and approximately 1 hour before sacrifice. The total radioactive residues (TRRs) were determined in each milk sample and in dissected organs and tissues (muscle, liver and kidney) at sacrifice. Omental fat and perirenal fat could not be found. The goat was relatively young and fatless. The total radioactivity (% of total dose administered) were additionally determined in each urine and faeces sample.

Recovery and Elimination of Radioactivity

The overall recovery accounted for approximately 51% of the total dose. The remaining amount of radioactivity was expected to still be present in the non-edible part of the animal body and especially in the gastrointestinal tract.

An amount of approximately 0.06% of the total dose was secreted with the milk, only. At sacrifice, radioactive residues in the edible organs and tissues dissected from the body were calculated to be approximately 0.27% of the total dose and were very low.

Up to the time of sacrifice, approximately 9.8% of the total dose was excreted with the urine and approximately 40.8% with faeces. The daily renal excretion of the radioactivity started shortly after the first dosing before the daily renal excretion rate reached a more or less constant level with 1.2% to 3.6%. The daily faecal excretion of the radioactivity started after the first dosing. After the third dosing, the excretion rate amounted to approximately 17.5% and the daily faecal excretion rate exhibited a more or less constant gradient. The cumulative renal and faecal excretion was characterised by a linear increase from day 3 until sacrifice.

Total Radioactive Residues in Milk, Organs and Tissues

The TRR-values and transfer factors for milk, organs and tissues were very low compared to the dose level of 20.57 mg a.s./kg feed/day and a dosing period of five days. The TRR-values in milk samples were very low and ranged from 0.008 mg/kg after the first administration to 0.016 mg/kg after the fourth administration. The time course of TRR-values of the evening and morning milk samples indicated a diurnal pattern for the testing period as a whole. The radioactive residues increased significantly during the eight-hour period after each administration followed by a small decrease measured prior to the delivery of the next dose.

Regarding organs and tissues, the TRR-values amounted to 0.011 mg/kg for muscle (composite of round and loin muscle), 0.348 mg/kg for liver and 0.183 mg/kg for kidney.

Metabolism

The majority of the residues in the milk as well as organs and tissues were efficiently extracted (extraction rates between 88.3% and 100.0%) using acetonitrile/water mixtures. In case of liver, the solids after conventional extraction were exhaustively extracted using acetonitrile/water (1/1; v/v) mixtures with microwave treatment. Up to 8.2% of the TRR (0.029 mg/kg) of the residues remained in the post extraction solids (PES).

For sample preparation the extracts of liver and kidney were partitioned against n-heptane. The extracts of milk and muscle were purified with SPE cartridges and a subsequent phase separation with NaCl. Very low amounts of radioactivity were recovered in the organic phases amounting to ≤0.8% of the TRR. Concentration procedures of the aqueous phases caused minor losses of radioactivity amounting to ≤6.3% of the TRR.

Parent compound and metabolites were identified based on co-chromatography with isolated metabolites and reference compounds or by comparison of the metabolite pattern and retention times. Metabolites were isolated from urine and identified by spectroscopic investigations.

The identification rates amounted to 50.4% of the TRR for milk, 64.0% for muscle, 47.2% for liver, and 42.4% for kidney.

Parent compound was detected in milk, muscle, liver and kidney. It was a major compound in milk and muscle and a prominent compound in liver. Overall up to ten metabolites were identified.

Metabolites BCS-CN88460-2-propanol (**M02**) and BCS-CN88460-propanol-GlucA (**M19**) (isomer 2, **M19** – isomer 2) were detected in all matrices. BCS-CN88460-2-propanol (**M02**) represented a major residue in muscle and amounted between 1.4% and 14.2% of the TRR for all matrices, while BCS-CN88460-propanol-GlucA (**M19**) (isomer 2) amounted between 2.5% and 8.6% of the TRR. Metabolites BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**) were identified in muscle, liver and kidney and ranged between 2.5% and 9.0% of the TRR. BCS-CN88460-2-propanol-GlucA (**M20**), BCS-CN88460-lactic acid (**M10**) and BCS-CN88460-desmethyl-carboxylic acid (**M11**) were detected in liver and kidney and accounted for between 0.5% and 13.0% of the TRR. BCS-CN88460-propanol-GlucA (**M19**) (isomer 1, **M19** – isomer 1) was identified in milk, liver and kidney and its amount ranged from 2.3% to 8.8% of the TRR. BCS-CN88460-desmethyl-propanol (**M06**) was detected in milk, muscle and liver and amounted between 0.6% and 6.7% of the TRR. BCS-CN88460-propenol-GlucA (**M25**) was detected in kidney and accounted for 6.2% of the TRR.

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the chromatograms. All unknown metabolites in the extracts were characterised by their chromatographic behaviour and amounted to ≤38.6% of the TRR but to very low mg/kg values (0.005 mg/kg).

The metabolic profiles of urine (0 - 24 h) and faeces (0 - 24 h) were similar to the profiles of edible materials, especially liver and kidney, except that parent compound was not present in the sample of urine.

A summary of the distribution of parent compound and metabolites for edible materials is provided in the following Table:

Table 7.2.3-12: Radioactive residues of parent compound and metabolites in milk and edible organs of lactating goats following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

* BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propenol-GlucA (**M25**) were co-eluting in the chromatography of the extract of kidney and were subquantified by TLC.

The main metabolic reaction was the hydroxylation in the propyl group of the phenyl ring. Conjugation with glucuronic acid was observed after hydroxylation in position 1 or 2 of the propyl group. Another important metabolic reaction was the carboxylation of the 1-propanol group, leading to a carboxylic acid or with a hydroxyl group in position 2 of the propyl group to a lactic acid group. Minor metabolic reactions were the demethylation of the pyrazole moiety, hydroxylation in position 4 of the phenyl moiety and the dehydration after hydroxylation in position 1 and 2 of the propyl group followed by conjugation with glucuronic acid.

Based on the results the metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in the lactating goat is considered as adequately understood and a metabolic pathway is proposed.

I. Materials and Methods

A. Materials

1. Test Material

Chemical structure	 * denotes the ^{14}C-label position	
Radiolabelled test material	[Phenyl-UL-^{14}C]BCS-CN88460	
Specific radioactivity used for administration	4.13 MBq/mg = 2.48 x 10^8 dpm/mg (delivered sample before radiodilution)	2.065 MBq/mg =1.24 x 10^8 dpm/mg (sample after radiodilution)
Radiochemical purity	>98% (HPLC)	
Non-labelled test material	BCS-CN88460 (**isoflucypram)**	
Chemical purity	99.4%	
Dose level	5 daily oral doses of 1 mg/kg bw	
Vehicle	Capsule	

2. Test Animals

Species	Lactating goat (*Capra hircus*)
Strain	"Weiße Deutsche Edelziege"
Breeding facility	[redacted]
Body weight	54.8 kg at delivery (2015-08-10) 47.3 kg at first administration (2015-08-17) 45.5 kg at sacrifice (2015-08-21)
Acclimatization	7 days
Identification	On arrival, the goat was arbitrarily allocated a stock number, or supplier's number. During the acclimation and testing period an individual animal number was allocated.
Husbandry	Conventional hygienic conditions in air-conditioned rooms
Housing	During the acclimation period, the goat was kept in a raised stall with a metal grid as base and straw and hay as bedding. During the whole testing period, the goat was kept in an electro-polished stainless steel metabolism cage for farm animals (goat, sheep, and pig), supplied by E. Becker & Co. GmbH "EBECO", Hermannstr. 2 – 8, 44579 Castrop-Rauxel, Germany. With this cage, an almost separate and quantitative collection of urine and faeces was possible. The cage was equipped with a variable-restraining device.
Dietary regimen	During the whole residence time, the goat was fed *ad libitum* with ruminant feed ("Raiffeisen Lamm-Gold" supplied by Raiffeisen Markt Monheim, Heerweg 10 – 14, 40789 Monheim am Rhein, Germany). It was supplemented by hay (during the acclimation period only), hay pellets and carrots. The feed was not a certified diet, i.e. it was not checked for contamination according to current standards. The feed consumption was recorded by back-weighing during the experiment. Tap water from the local mains supply was given *ad libitum* during the whole residence time.

B. Study Design

Preparation of the Test Compound for Administration

The radiolabelled test compound was delivered in solid form. It was diluted in a ratio of 1:1 with the non-radiolabelled test compound. An amount of approximately 47.3 mg of this diluted test compound was taken for preparation of each administration capsule. In total, five gelatine capsules containing the solid test compound were prepared and stored in a freezer at ≤ -18 °C. A small portion of the test

compound was dissolved in acetonitrile from which an aliquot was taken for identity confirmation of the test compound by LC-MS/MS.

In order to demonstrate the stability of the solid test compound in the capsules, a small portion of the test compound was stored together with the capsules until the last administration. Aliquots of the small portion were analysed for stability and purity of the test compound after the first and the last administration by HPLC. In both cases, the purity amounted to >98%.

Dosing

All oral administrations were performed using a capsule applicator once daily for five consecutive days in the morning after milking. Each gelatine capsule contained an average amount of 47.31 mg, which corresponded to 97.7MBq. The total administered amount and radioactivity accounted for 236.56 mg and 488 MBq, respectively.

The total amount of radioactivity administered to the animal served as reference-value (A_0 = 100%) for the percentage calculation of the total radioactivity in the biological samples.

Based upon the experimentally determined daily feed consumption during the testing period of 2,300 g dry feed per day (= 4.86% of the body weight), the dose of 1.0 mg a.s./kg bw corresponded to a concentration of 20.57 mg a.s./kg dry feed per day in the diet. This dose was tolerated without any observable toxicological effects.

Sampling of milk, urine and faeces during the in-life phase

The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and directly before the scheduled termination. After weighing, aliquots were taken from each sample for radioactivity measurement by LSC.

Urine and faeces samples were collected in plastic vessels or collecting grids as quantitatively as possible under dry ice cooling in intervals of 24 hours after the administrations 1 to 4 and 6 hours after the last administration. The vessels were exchanged immediately before the next administration. The collection funnel was rinsed with deionised water into the urine vessel of the respective collection period. After determination of the total volumes, aliquots of each urine sample were used for radioactivity measurement by LSC. For collection of faeces, the collecting grid was cleaned prior to each administration. After determination and recording of the individual weights each faeces fraction was passed several times through a mincing machine in half-frozen state. Aliquots of each faeces fraction were combusted and the radioactivity measured by LSC.

Sacrifice and dissection of organs and tissues

The animal was sacrificed approximately 6 hours after the last administration, a time interval that is consistent with normal slaughtering practices. The animal was at first sedated by an intramuscular mixed injection of Xylazin/Rompun (2%; 0.2 mg/kg bw) and Ketamin (10%; 5 mg/kg bw) and afterwards anaesthetised by an intravenous dose of about 40 mg/kg bw Pentobarbital-Na (Narcoren®). Under deep anaesthesia, the animal was then exsanguinated by transection the jugular vein and finally terminated by intracardiac injection with approximately 10 mL of the veterinary drug "T 61®". Following exsanguination, the following edible organs and tissues were dissected: muscle (round and loin), liver (without gall bladder) and kidneys. Omental fat and perirenal fat could not be found. The goat was relatively young and fatless.

Preparation of Organs and Tissues

The organs or tissue samples were transferred into tared plastic vessels. After determination and recording of the individual weights, muscle, liver and kidney samples were passed several times through a mincing machine in half-frozen state. Aliquots of the individual organ and tissue samples were combusted and the radioactivity measured by LSC. All samples were stored at ≤ -18 °C until the start of metabolite analysis.

For metabolism investigations, pooled samples of milk (collected from 32 h until 101 h) and muscle (loin and round muscle) were prepared. Liver, kidney and faeces (0 - 24 h) were homogenised and aliquots were stored frozen until start of extraction. The radioactivity and TRR-values of the samples were calculated from the in-life data

C. Analytical Procedures

Sample Extraction and Analysis of Extracts

Aliquots from liver, kidney and faeces were conventionally extracted three times, aliquots from milk and muscle were extracted two times, with a mixture of acetonitrile/ water (8/2; v/v) using a Polytron homogeniser. The combined extracts of liver, kidney and faeces, were partitioned against n-heptane, the combined extracts of milk and muscle were purified using a C18 cartridge. The purified extracts were concentrated by rotary evaporation and subjected to HPLC analysis based on reversed phase chromatography with an acidic water/acetonitrile/THF gradient.

Solids of liver from the conventional extraction were exhaustively extracted twice with acetonitrile/water (1/1; v/v) using microwave assistance. The metabolites in the combined exhaustive extracts were further characterised using TLC analysis.

Aliquots of the conventional liver and kidney extracts were incubated for 20 hours at 37 °C with a defined amount of ß-glucuronidase/arylsulfatase. After incubation, the enzymatic suspensions were purified and analysed by HPLC.

Determination of the Radioactivity in the Cream Fraction of Milk

To evaluate the radioactivity in the cream fraction of milk, an aliquot of the milk sample was partitioned against n-heptane.

Radioactivity measurement

The radioactivity measurement in liquid samples was carried out by liquid scintillation counting (LSC). The solid samples were either dissolved in BIOLUTE S or combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

Metabolite analysis

Parent compound and metabolites were quantified in the extracts by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. The peaks in the individual HPLC profiles were numbered increasingly in the order of elution in the HPLC-profiling methods. Corresponding metabolites were named with the same peak-ID.

The assignment of parent compound and metabolites was achieved by comparison of HPLC metabolite profiles of the analysed samples among each other and compared to the goat metabolism study with the pyrazole label. Furthermore, metabolites were isolated from urine by HPLC. They were identified in the isolated fractions by spectroscopic methods. Other metabolites were identified by chromatographic comparison of the metabolic profile or by co-chromatography with radiolabelled test and reference compounds in selected samples. The conventional extracts of liver and kidney were enzymatically digested. The glucuronic acid conjugates were thereby digested and converted into their corresponding aglycons.

Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

II. Results and Discussion

A. Recovery and Elimination of Radioactivity

The overall recovery in the lactating goat after administration of a mean daily dose of 1.0 mg [phenyl-

UL-^{14}C]BCS-CN88460 per kg body weight (according to 20.57 mg a.s./kg feed/day) on five consecutive days accounted for approximately 51% of the total dose . The remaining amount of radioactivity was expected to still be present in the non-edible part of the animal body and especially in the gastrointestinal tract.

Table 7.2.3-13: Recovery of radioactivity in dissected organs and tissues, milk, and excreta of lactating goats following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Biological matrix	Percent of total dose administered
Liver	0.19
Kidney	0.01
Total body muscle	0.06
Total of organs/tissues	0.27
Milk, 0 – 101 h	0.06
Urine, 0 – 102 h (plus funnel rinsing)	9.81
Faeces, 0 – 102 h	40.78
Total excreted	50.59
Total Recovery	50.91

An amount of approximately 0.06% of the total dose was secreted with the milk, only. At sacrifice, radioactive residues in the organs and tissues dissected from the body were calculated to be 0.27% of the total dose.

Up to the time of sacrifice, 9.81% of the total dose was excreted with the urine and 40.78% with faeces (see table above). The daily renal excretion of the radioactivity started shortly after the first dosing before the daily renal excretion rate reached a more or less constant level with round about 1.2% to 3.6%. The daily faecal excretion of the radioactivity started after the first dosing. After the second dosing, the faecal excretion rate exhibited a more or less constant gradient and the faecal excretion reached its maximum with 17.5% after the fourth dosing. The cumulative renal and faecal excretion was characterised by a linear increase from day 3 until sacrifice.

Table 7.2.3-14: Distribution of residues in liver, kidney, muscle and milk of lactating goats following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Organ/Tissue	Collection Time	Fresh weight (g)	TRR (mg/kg)	Transfer factor [TF]***	Percent of total dose administered
Liver	6 h after last admin.	1,321.66	0.348	0.017	0.19
Kidney	6 h after last admin.	155.38	0.183	0.009	0.01
Round muscle (sample)	6 h after last admin.	1,922.53	0.011	-----	-----
Loin muscle (sample)		140.80	0.010	-----	-----
Total body muscle**		13,650.00	0.011	0.001	0.06
Total of organs/tissues					0.27
Milk, total	day 1 to 5	11,321.80	0.011	0.001	0.06
Milk, plateau-level	day 3-4	5,873.21	0.012	0.001	0.03
Feeding level		20.57	mg a.s./kg dry feed/day		

* Percentage values and fresh weights were calculated from the body weight at sacrifice, assuming 30% of the body weight for total body muscle.

** weighted mean TRR-values from the two types of muscle

*** The transfer factor was calculated by dividing the TRR-value of the respective sample by the feeding level (milligrams of a.s. per kilograms dry feed for each day).

B. Levels and Time Course of Total Radioactive Residues in Milk

The radioactivity levels measured in milk samples and the calculated amounts are shown in the table below. The TRR-values in milk samples ranged from 0.008 mg/kg after the first administration to 0.016 mg/kg after the fourth administration. The time course of TRR-values of the evening and morning milk indicated a diurnal pattern for the testing period. The radioactive residues increased significantly during the eight-hour period after the first three administrations.

A residue plateau-level of 0.012 mg/kg was reached at about day 3-4 after the first administration. This value was calculated from the evening sample of day 3, both samples of day 4 and the morning sample of day 5.

Table 7.2.3-15: Time course of total radioactivity in the milk of lactating goats following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Time after the first admin. (h)	Admin. no.	Cumulative secretion [% of total dose admin.]	Secretion per day [% of total dose admin.]	TRR (mg/kg)
0	1	-----	-----	-----

96	5	-----	-----	-----
101		0.0550	0.005	0.015

C. Total Radioactive Residues in the Dissected Organs and Tissues

The highest TRR-value was determined in liver (0.348 mg/kg; 0.19% of total administered dose) indicating the significance of this organ for metabolism. The TRR-value for kidney accounted for 0.183 mg/kg (0.01% of total administered dose) and demonstrated that test compound related radioactivity partly was eliminated from the animal via urinary excretion. The lowest TRR-value was determined in muscle (0.011 mg/kg; 0.06% of total administered dose assuming a value of 30% of the body weight for this tissue).

D. Extraction Efficiency of Residues

The majority of the residues in the milk as well as organs and tissues were efficiently extracted (88.3% to 100.0%) using acetonitrile/water mixtures. In case of liver, the solids after conventional extraction were exhaustively extracted using acetonitrile/water mixtures with microwave treatment. Up to 8.2% of the TRR (0.029 mg/kg) remained in the post extraction solids (PES). After clean-up and concentration procedure the main portion of the extracted radioactivity was quantitatively analysed by HPLC.

A summary of the extraction efficiency is shown in the table below.

Table 7.2.3-16: Extraction efficiency of milk, muscle, liver and kidney samples of lactating goats following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

Sample	Milk (32 – 101 h)		Muscle		Liver		Kidney

E. Quantification, Identification and Characterisation of Residues

Quantification of Parent Compound and Metabolites

Parent compound and metabolites were quantified in the conventional extracts of milk, edible organs, tissues and faeces as well as in urine (0 - 24 h) by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Metabolites in the exhaustive extract of liver as well as co-eluting metabolites in an fraction of kidney were quantified by TLC.

Metabolites in the extracts as well as in the sample of urine (0 - 24 h) were assigned to each other by comparison of the metabolite profiles and their retention times. Corresponding metabolites were named with the same peak ID. Detailed information can be found in the report.

Isolation and Identification of Parent Compound and Metabolites

The assignment of parent compound and metabolites was achieved by comparison of HPLC metabolite profiles of the analysed samples among each other and by comparison of the metabolite profiles of the current study with the profiles of the goat metabolism study of the pyrazole label.

Metabolites were isolated from urine (24 - 48 h) by HPLC. They were identified in the isolated fractions by spectroscopic methods. In addition parent compound and metabolites were identified in urine (0 - 24 h), in the conventional extracts of milk and muscle as well as in isolated fractions from milk, muscle, liver and kidney by HPLC co-chromatography with radiolabelled reference compounds taken from the hen metabolism study with the pyrazole label or from the goat metabolism study with the pyrazole label. Conjugates were subjected to enzymatic cleavage with an aqueous solution of ß-glucuronidase/sulfatase before HPLC-analysis.

F. Distribution of Parent Compound and Metabolites in Milk, Organs and Tissues

The identification rates amounted to 50.4% of the TRR for milk, 64.0% for muscle, 47.2% for liver, and 42.4% for kidney.

Parent compound was detected in milk, muscle, liver and kidney and amounted to 0.004 mg/kg (33.9% of the TRR) for milk, 0.002 mg/kg (21.5% of the TRR) for muscle, 0.018 mg/kg (5.3% of the TRR) for liver and 0.003 mg/kg (1.6% of the TRR) for kidney.

Metabolites in milk

Besides parent compound as the main residue in milk, BCS-CN88460-desmethyl-propanol (**M06**) was the major metabolite (6.7% (0.001 mg/kg) of the TRR). Metabolites BCS-CN88460-2-propanol (**M02**) and BCS-CN88460-propanol-GlucA (isomer 1 and 2) were minor metabolites (all ≤5.0% (0.001 mg/kg) of the TRR).

Metabolites in muscle

Besides parent compound as the main residue in muscle, BCS-CN88460-2-propanol (**M02**) was the major metabolite accounting for 14.2% (0.002 mg/kg) of the TRR. Other prominent metabolites were BCS-CN88460-propanol-GlucA (isomer 2) (6.5% (0.001 mg/kg) of the TRR), BCS-CN88460-carboxylic acid (**M12**) (9.0% (0.001 mg/kg) of the TRR) and BCS-CN88460-propanol (**M01**) (9.0% (0.001 mg/kg) of the TRR). BCS-CN88460-desmethyl-propanol (**M06**) was present in minor amounts (3.7% (<0.001 mg/kg) of the TRR).

Metabolites in liver

BCS-CN88460-2-propanol-GlucA (**M20**) was the main residue in liver and accounted for 0.045 mg/kg (13.0% of the TRR). Other prominent metabolites BCS-CN88460-propanol-GlucA (**M19**) (isomer 1 and 2) accounting for 0.031 mg/kg (8.8% of the TRR) and 0.021 mg/kg (5.9% of the TRR), respectively. The six metabolites BCS-CN88460-lactic acid (**M10**), BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-desmethyl-propanol, BCS-CN88460-carboxylic acid (**M12**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-2-propanol (**M02**) were minor metabolites, amounting between 0.002 mg/kg (0.5% of the TRR) and 0.017 mg/kg (4.9% of the TRR).

Metabolites in kidney

Prominent metabolites in kidney were BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol-GlucA (**M19**) (isomer 2). They accounted for 0.012 mg/kg (6.8% of the TRR) and 0.016 mg/kg (8.6% of the TRR), respectively. Two further abundant metabolites in kidney were identified as BCS-CN88460-2-propanol-GlucA (**M20**) (4.0% (0.007 mg/kg) of the TRR) and BCS-CN88460-propenol-GlucA (**M25**) (6.2% (0.011 mg/kg) of the TRR). The five minor metabolites BCS-CN88460-lactic acid (**M10**), BCS-CN88460-propanol-GlucA (**M19**) (isomer 1), BCS-CN88460-desmethyl-carboxylic acid (**M11**), BCS-CN88460-propanol (**M01**) and BCS-CN88460-2-propanol (**M02**) were detected (≤0.008 mg/kg or ≤4.2% of the TRR).

More metabolites in the matrices may be present as indicated by broad non-resolved zones in the chromatograms. All unknown metabolites in the extracts were characterised by their extraction and chromatographic behaviour and amounted to each ≤38.6% of the TRR but to very low mg/kg amounts (0.005 mg/kg).

The distribution of the parent compound and metabolites in milk, organs and tissues is summarised in the table below.

Table 7.2.3-17: Radioactive residues of parent compound and metabolites in milk and edible organs of lactating goats following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

aqueous phase (skimmed milk)	50.3	0.007
Total:	100.0	0.013

Conjugates in the liver and kidney like BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propanol-GlucA (**M19**) (both isomers 1 and 2) could be enzymatically cleaved to their aglycons. The cleavage of some unknown conjugates in non-resolved zones resulted in higher amounts of the aglycons. None of the unknown compounds after cleavage of the liver and kidney extract accounted for more than 9.9% (0.035 mg/kg) of the TRR (mean of all five replicates) or 6.9% (0.013 mg/kg) of the TRR, respectively. The following main aglycons could be clearly identified after enzymatic cleavage: BCS-CN88460-2-propanol (**M02**) and BCS-CN88460-propanol (**M01**).

Table 7.2.3-19: Radioactive residues of parent compound and metabolites in liver samples of first and second conventional extraction and after enzymatic cleavage for 20 h

* BCS-CN88460-2-propanol-GlucA (**M20**) and BCS-CN88460-propenol-GlucA (**M25**) were only detected in kidney in a ratio of 6/4.

Distribution of Metabolites in Urine and Faeces

The metabolic profile of urine (0 - 24 h) and faeces (0 - 24 h) were similar to the profiles of edible materials, especially liver and kidney, except that parent compound was not present in the sample of urine. In faeces, parent compound was the main residue (8.0% of the first dose). All identified metabolites in urine and faeces accounted for ≤1.2% of the first dose.

The distribution of the parent compound and metabolites in urine and faeces is summarised in the table below.

Table 7.2.3-21: Radioactive residues of parent compound and metabolites in non-edible samples of lactating goat following oral administration of 5 daily doses of [phenyl-UL-^{14}C]BCS-CN88460 at a dose rate of 1.0 mg/kg

G. Storage Stability of Residues

During the study, all samples and extracts were stored in a freezer at ≤ -18 °C or for a short time in a refrigerator. All samples of milk, and edible organs and tissues were extracted within four months after sample collection. The first metabolite profile was recorded not later than four days after the start of the extraction and sample preparation.

The storage stability was exemplarily demonstrated for all other matrices. A second conventional extraction of liver was performed approximately 11 months after sampling. The extract was used for enzymatic cleavage experiments.

III. Conclusion

The metabolic behaviour of [phenyl-UL-^{14}C]BCS-CN88460 in the lactating goat can be characterised by the following observations:

The TRR-values and the transfer factors in milk, organs and tissues were very low compared to the dose level of 20.57 mg a.s./kg feed/day and a dosing period of five days. The highest TRR-value was detected for liver and was caused by the short time period of 6 hours between last dosing and sacrifice. It indicates the significance of this organ for metabolism. The significantly lower TRR-value for kidney shows that no residues were retained in this tissue and reflects the low amount of radioactivity, which was excreted by the urine. The TRR-values in the respective evening and morning milk samples showed a diurnal pattern as they declined slightly prior to the delivery of the next dose for most days. A continuous increase was observed before a residue plateau-level was reached at day three after the

first administration.

The elimination of radioactivity was mainly faecal and only 9.8% were eliminated via urine. This excretion behaviour was similar to the findings in the ADME studies with rats.

The radioactive residues were efficiently extracted from milk as well as from edible organs and tissues; extraction rates ranged from 88.3% to 100.0%.

The identification rates of parent compound and metabolites in milk, edible organs and tissues ranged between 42.4% and 64.0% of the TRR.

Parent compound was a major compound in milk and muscle, a prominent compound in liver and a minor compound in kidney. Overall up to ten metabolites were identified.

BCS-CN88460-2-propanol (**M02**) was detected as a major metabolite in muscle, BCS-CN88460-desmethyl-propanol (**M06**) as a major metabolite in milk (32 – 101 h), BCS-CN88460-2-propanol-GlucA (**M20**) as a major metabolite in liver and BCS-CN88460-propanol-GlucA (isomer 2, **M19** – isomer 2) as a major metabolite in kidney. Further abundant metabolites were BCS-CN88460-propanol-GlucA (isomer 1, **M19** – isomer 1) in liver and kidney, BCS-CN88460-propanol-GlucA (isomer 2, **M19** – isomer 2) in muscle, liver and kidney, BCS-CN88460-carboxylic acid (**M12**) in muscle, liver and kidney and BCS-CN88460-propanol (**M01**) in muscle and liver. BCS-CN88460-lactic acid (**M10**) and BCS-CN88460-desmethyl-carboxylic acid (**M11**) were minor metabolites in liver and kidney. BCS-CN88460-propenol-GlucA (**M25**) was only detected as a minor metabolite in kidney and in urine.

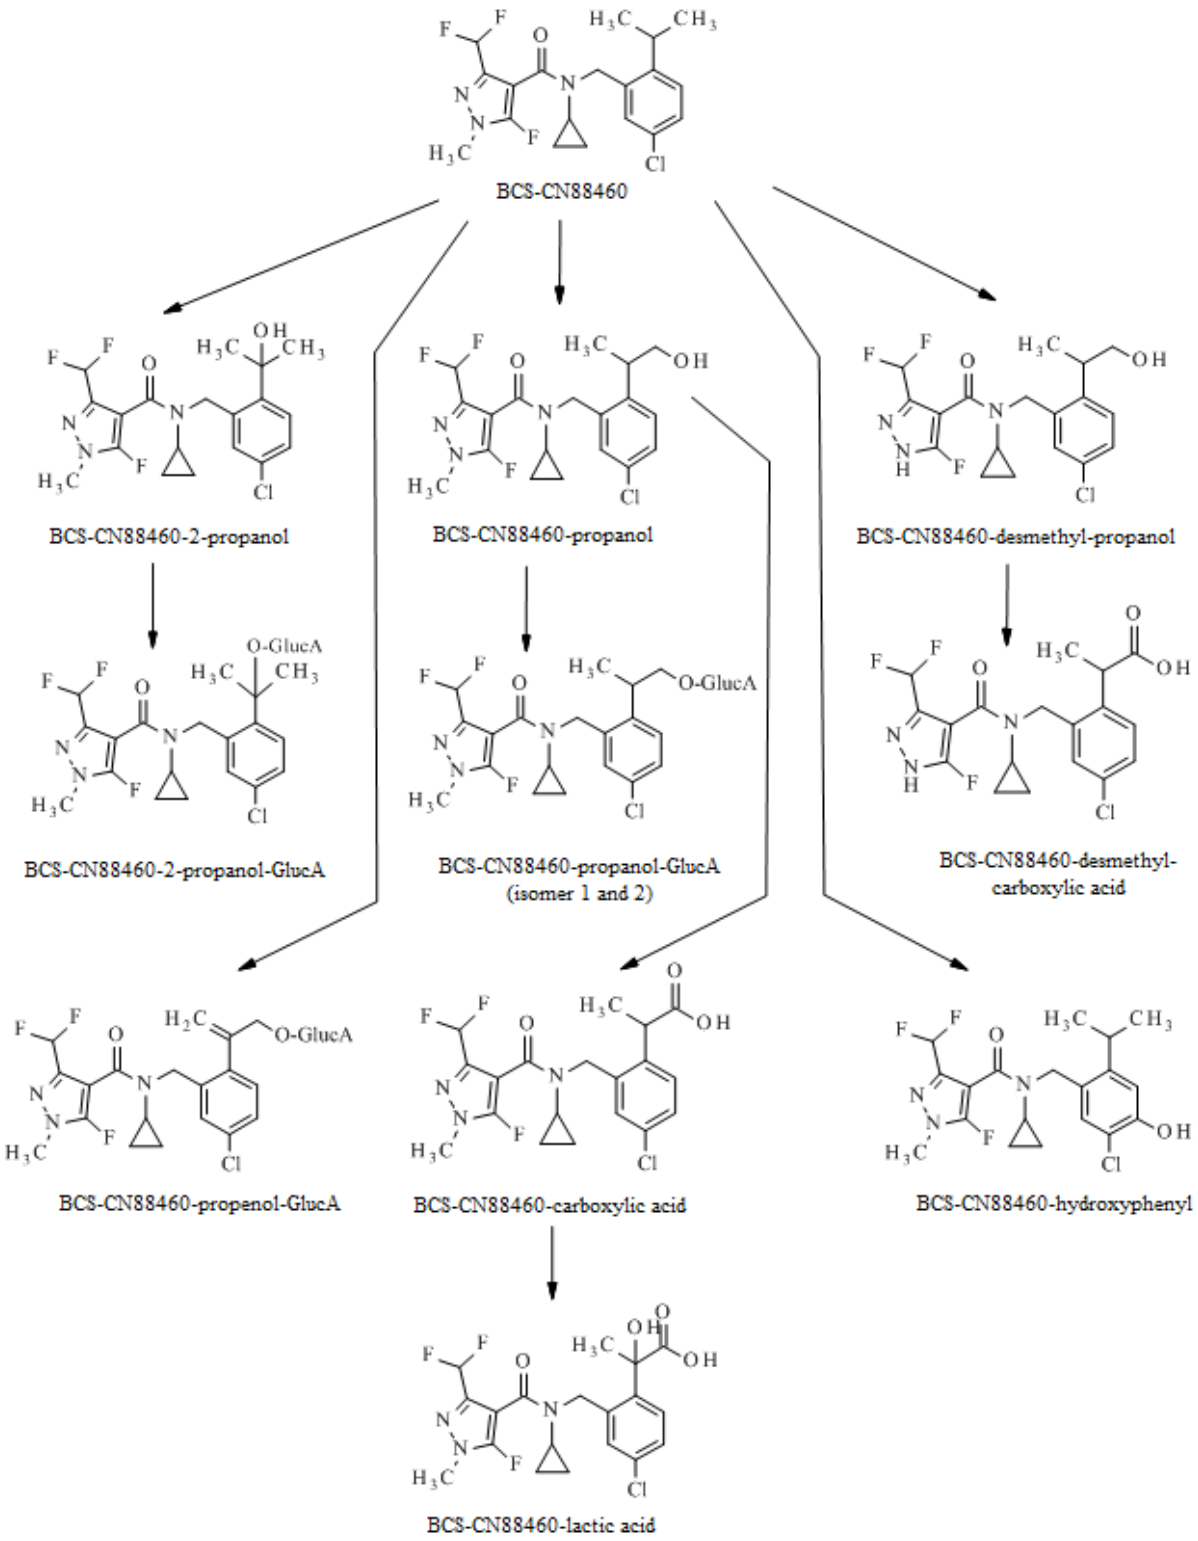
The metabolic profile of urine and faeces were similar to the profiles of edible materials, especially liver and kidney.

The principal metabolic reactions of [phenyl-UL-^{14}C]BCS-CN88460 in the lactating goat are listed below:

- hydroxylation in position 1 and position 2 of the propyl group in the phenyl ring;
- conjugation with glucuronic acid;
- oxidation of the 1-propanol group was leading to a carboxylic acid group or with a hydroxyl group in position 2 to lactic acid;
- demethylation of the pyrazole moiety;
- hydroxylation in position 4 of the phenyl moiety;
- dehydration after hydroxylation in position 1 and 2 of the propyl group followed by conjugation with glucuronic acid.

Based on these results, the metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in the lactating goat is considered as sufficiently understood and a metabolic pathway is proposed.

Figure 7.2.3-2: Proposed metabolic pathway of [phenyl-UL-^{14}C]BCS-CN88460 in the lactating goat



B.7.2.4. **Pigs**

As the metabolic pathways in ruminants and hens were similar to the metabolic pathway in rats, no metabolism study in pigs is required.

B.7.2.5. **Fish**

As outlined in the EU-Directive 91/414/EEC, the EU Aquatic Guidance Document, as well as in EPA and PMRA guidelines, a log P_{ow} >3 should be used as a general trigger for a fish bioconcentration study. The nature of the residue in fish was investigated using [pyrazole-4-^{14}C]BCS-CN88460 and is summarised here in more detail (Appendix VI of the study report).

Table 7.2.5-1: Overview of available fish bioconcentration and metabolism studies

Fish	Exposure	Concentration	Reference
Bluegill sunfish	continuous exposure for 42 days of pyrazole-labelled **isoflucypram**	5 µg/l	M-610008-01-1

Report:	KCA 6.2.5/01; [redacted] 2017
Title:	[pyrazole-4-^{14}C]BCS-CN88460 - Aqueous exposure bioconcentration fish test and biotransformation in fish (Lepomis macrochirus)
Report No.:	EBLNN359
Document No.:	M-610008-01-1
Guidelines:	OECD Test Guideline 305; Regulation (EC) 1107/2009; EU Directive 91/414/EEC; US EPA OCSPP 850.1730.
Guideline deviation:	According to the guideline and the study protocol, the measurement of the total organic carbon (TOC) will be performed 48 and 24 hours prior to test initiation. However, due to scheduling issues the TOC content was measured 72 hours and 24 hours prior to test initiation. This deviation has no negative impact on the outcome of the study, since there results of both measurements were reasonable (< 2 mg/L)
GLP/GEP:	Yes

Summary

The metabolism of **isoflucypram** in bluegill sunfish was investigated as part of the fish bioconcentration study. The test compound was radiolabelled in the pyrazole-4 moiety.

The analysis of stock solutions of the test compound from all aquariums showed that [pyrazole-4-^{14}C]BCS-CN88460 was stable in the stock solutions during the exposure phase.

Water samples were collected during the exposure period of 28 days for aquarium C and 14 days for aquarium D. All water samples taken after day 28 were not further analysed due to low radioactivity. The radioactive residue was extracted from water samples by solid phase extraction (SPE) with RP18. The residues were eluted with acetonitrile and methanol/tetrahydrofuran, concentrated and analysed by HPLC with radio detection. The radioactive concentrations in the water ranged from 3.9 to 6.4 µg/L. Parent compound was the main compound in the water samples and amounted to ≥ 98.2% in aquarium C and ≥ 90.9% in aquarium D. The following minor metabolites were detected in the water samples: conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-desmethyl-GlucA (**M35**) (isomer 1), BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). Each of these metabolites accounted to ≤ 0.1 µg/L.

Total Radioactive Residues in Edible and Viscera Fish Parts

Edible parts and viscera of fish sampled on Day 7 and 14 from aquarium D (metabolism test with 5 µg/L) were conventionally extracted with acetonitrile/water mixtures. The TRRs were moderate for edible fish parts and amounted to 0.565 mg/kg for day 7 and 0.567 mg/kg for day 14. In viscera fish parts the TRR was 3.955 mg/kg on Day 7 and 3.365 mg/kg on Day 14. The extraction rates amounted

between 92.8 and 98.7%. The post extraction solids (PES) amounted to 5.8% (0.033 mg/kg) of TRR for edibles on Day 7, 7.2% (0.041 mg/kg) of TRR for edibles on Day 14, 1.3% (0.053 mg/kg) of TRR for viscera on Day 7 and 1.7% (0.058 mg/kg) of TRR for viscera on Day 14.

Metabolism

Parent compound and metabolites were analysed and quantified in the concentrated extracts by HPLC with radio detection. They were assigned to each other in the profiles based on the metabolite pattern and their retention times. Parent compound and metabolites were identified in isolated fractions by HPLC- and TLC-co-chromatography with radiolabelled reference compounds, which were identified by structure elucidation in the ADME studies with rats.

Parent compound was a prominent compound in edible parts of fish and amounted to 16.7% (0.095 mg/kg) of TRR for day 7 and 19.2% (0.109 mg/kg) of TRR for day 14. In viscera parts of fish parent compound was detected with 5.1% (0.201 mg/kg) of TRR for day 7 and 9.7% (0.326 mg/kg) of TRR for day 14.

The main metabolite in edible fish parts was BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**) and amounted to approximately 31% of the TRR for day 7 and 14. At day 14 the conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid was detected with 15.1% (0.086 mg/kg) of TRR and BCS-CN88460-propanol (**M01**) with 10.0% (0.057 mg/kg) of the TRR. The conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid could be cleaved to its aglycon with hydrochloric acid at elevated temperatures. Further metabolites in edible fish parts were BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-desmethyl (**M13**), BCS-CN88460-desmethyl-propanol (**M06**) and conjugates like BCS-CN88460-desmethyl-propanol-GlucA (**M31**) (isomer 1, **M31**), BCS-CN88460-propanol-GlucA (**M19**) (isomer 1 and 2, **M19**) and BCS-CN88460-desmethyl-GlucA (**M35**) (isomer 1, **M35**). They amounted to ≤ 5.0% (0.028 mg/kg) of TRR.

Beside parent compound the major part of radioactivity in viscera of fish was represented by the two metabolites BCS-CN88460-propanol-GlucA (**M19**) (isomer 1 and 2, **M19**) and amounted to in sum approximately 40% of the TRR. Other metabolites in viscera fish tissues were BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-desmethyl-propanol-GlucA (**M31**) (isomer 1, **M31**), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-propanol (**M01**), BCS-CN88460-desmethyl-GlucA (isomer 1, **M35**) and BCS-CN88460-desmethyl (**M13**). These metabolites amounted to ≤ 6.6% (0.262 mg/kg) of TRR.

Unknown metabolites in all fish tissues were characterised by their extraction and chromatographic behaviour and amounted to ≤ 3.4% (0.019 mg/kg) of TRR for edible fish parts and ≤ 5.4% (0.213 mg/kg) of TRR for viscera fish parts. Details of the distribution of parent compound and metabolites in fish tissues are presented below:

Figure 7.2.5-1: Radioactive residues of parent compound and metabolites in edible and viscera tissues of fish after 14 days exposure of [pyrazole-4-^{14}C]BCS-CN88460 to bluegill sunfish

Compound/fraction	**Edible parts of fish**				**Viscera of fish**

* Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

** The aglycon BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) could be clearly identified after acidic cleavage of the conjugate.

The principal metabolic reactions of [pyrazole-4-^{14}C]BCS-CN88460 in fish are listed below:

- demethylation of the pyrazole moiety was leading to desmethyl compounds;
- hydroxylation in position 1 of the propyl group was leading to propanol compounds;
- conjugation with glucuronic acid after hydroxylation in position 1 of the propyl group or via nitrogen was leading to several glucuronic acid-conjugates;
- cleavage of the phenyl moiety was leading to the cyclopropyl-pyrazole-carboxamide compound;
- cleavage of the phenyl moiety in combination with cleavage of the cyclopropyl ring and further followed by oxidation was leading to a N-methyl-pyrazole-carboxylic acid compound;
- conjugation of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) was also observed.

On the basis of the results of this study it was concluded that [pyrazole-4-^{14}C]BCS-CN88460 was stable in water and intensely metabolised in fish and a pathway of [pyrazole-4-^{14}C]BCS-CN88460 in fish is proposed.

I. Materials and Methods

A. Materials

1. Test Material

Chemical structure	 * denotes the ^{14}C-label position
Radiolabelled test material	[Pyrazole-4-^{14}C]BCS-CN88460
Specific radioactivity	4.22 MBq/mg
Radiochemical purity	>99% (HPLC)
Chemical purity	>99% (HPLC)
Non-labelled test material	BCS-CN88460 (**isoflucypram)**
Chemical purity	94.2%

B. Study Design

Preparation of the Test Compound for Administration

For the experiments, the radiolabelled test compound was diluted with appropriate amounts of non-radiolabelled test compound, yielding 2 L of stock solution for each of aquarium B and C and 1.4 L of stock solution for aquarium D. The stock solution for each individual aquarium was prepared by using dimethylformamide (DMF) as solvent.

The purity of the test compound in the stock solutions was checked before application by HPLC. In addition, an aliquot of stock solutions B and C were taken on Day 28 after application and an aliquot of stock solution D on Day 14 after application. After a storage period of the aliquots for approximately 2 months at approximately - 18 °C, the stability of the test compound was checked by HPLC. In all cases the purity of the test compound was ≥ 99.29%.

Water samples

Water samples were taken from day 0, 1, 28 and 29 for aquarium C, and from day 7 and 14 for aquarium D.

Fish samples

For analysis of parent compound and metabolites from aquarium D (nominal test concentration of 5.0 µg [pyrazole-4-^{14}C]BCS-CN88460 / L water) a number of 15 fishes were sampled after an exposure period of 7 and 14 days, respectively. Fishes were dissected into edible tissues (fillet, body muscle, skin and skeleton) and viscera / non-edible parts (viscera = head, fins and internal organs). The coarse pieces of the edibles or viscera of each day were combined and homogenised with a high speed blender. From these samples, a sub-sample was taken for extraction and analysis of parent compound and metabolites.

C. Analytical Procedures

Sample Extraction and Preparation for Chromatographic Analysis

Preparation of water samples

Each individual water sample (1000 mL) was applied to a pre-conditioned RP18 solid phase extraction (SPE) cartridge (to concentrate the radioactive compounds from the water sample). The aqueous flow through was collected and the retained radioactivity on the RP18 phase was eluted with approximately 500 mL acetonitrile followed by approximately 250 mL methanol/tetrahydrofuran (1/1; v/v). The acetonitrile eluates were concentrated to an aqueous remainder using a rotary evaporator (bath temperature approximately 35 °C). Each remainder was diluted with acetonitrile/water (1/1; v/v)

yielding the final extracts. The final extracts and the other eluates were stored in a freezer (≤ 18 °C).

The radioactivity in the flow through fraction, eluates, concentrates and distillates was determined by LSC. The total radioactive residue (TRR) of each water sample was determined by summing up the radioactivity measured in the flow through fraction and the eluates based on the volume of the sample and the specific radioactivity of the test compound.

Extraction and Preparation of Fish Samples

Samples of the edible parts of fish and viscera were extracted successively three times with acetonitrile/water (8/2; v/v) using a high speed homogeniser. Solids and extracts were separated by centrifugation. Extracts were combined and concentrated to an aqueous remainder using a rotary evaporator (bath temperature approximately 35 °C). The remainder was diluted with acetonitrile/water (1/1; v/v) yielding the final extract. Radioactivity in the extracts was determined by LSC after volume measurement. Radioactive residues in the remaining solids were determined by combustion of aliquots followed by LSC.

The TRR (Total Radioactive Residue) in fish samples was calculated by summing up the radioactivity measured in the extracts and PES (post extraction solids) based on the used sample amount and the specific radioactivity of the test compound.

Radioactivity measurement

The radioactivity measurement in liquid samples was carried out by liquid scintillation counting (LSC). The solid samples combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

Metabolite analysis

Parent compound and metabolites were quantified in the extracts by HPLC based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

They were assigned to each other in the profiles based on the metabolite pattern and their retention times. Parent compound and metabolites were identified in isolated fractions by HPLC- and TLC co-chromatography with radiolabelled reference compounds taken from ADME studies with rats.

II. Results and Discussion

Water Samples

The radioactive concentrations in the water samples collected during the exposure period of 28 days for aquarium C and 14 days for aquarium D ranged from 3.9 to 6.4µg/L. All samples taken after day 28 were not further analysed due to low radioactivity.

Parent compound was the main component in the water samples and amounted to ≥ 98.2% in water samples of aquarium C and ≥ 90.9% in water samples of aquarium D. The following minor metabolites were detected in the water samples: conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-desmethyl-GlucA (**M35**) (isomer 1), BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-desmethyl-propanol (**M06**) and BCS-CN88460-propanol (**M01**). Each of these metabolites accounted to ≤0.1 µg/L.

Distribution of Radioactivity in Fish Samples

Edible parts and viscera of fish sampled on Day 7 and 14 from aquarium D (metabolism test with 5 µg/L) were conventionally extracted with acetonitrile/water mixtures. The TRRs were moderate for edible fish parts and amounted to 0.565 mg/kg for day 7 and 0.567 mg/kg for day 14. In viscera fish parts the TRR was 3.955 mg/kg on Day 7 and 3.365 mg/kg on Day 14.

The extraction rates amounted between 92.8 and 98.7%. The post extraction solids (PES) amounted to 5.8% (0.033 mg/kg) of TRR for edibles on Day 7, 7.2% (0.041 mg/kg) of TRR for edibles on Day 14, 1.3% (0.053 mg/kg) of TRR for viscera on Day 7 and 1.7% (0.058 mg/kg) of TRR for viscera on Day 14.

Distribution of Parent compound and Metabolites in Fish Samples

Parent compound was a prominent compound in edible parts of fish and amounted to 16.7%

(0.095 mg/kg) of TRR for day 7 and 19.2% (0.109 mg/kg) of TRR for day 14. In viscera parts of fish parent compound was detected with 5.1% (0.201 mg/kg) of TRR for day 7 and 9.7% (0.326 mg/kg) of TRR for day 14.

Isoflucypram was intensely metabolised in the fish. The main metabolite in edible fish parts was BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**) and amounted to approximately 31% of the TRR for day 7 and 14. At day 14 the conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) was detected with 15.1% (0.086 mg/kg) of TRR and BCS-CN88460-propanol (**M01**) with 10.0% (0.057 mg/kg) of the TRR. The conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) could be cleaved to its aglycon with hydrochloric acid at elevated temperatures. Further metabolites in edible fish parts were BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-desmethyl (**M13**), BCS-CN88460-desmethyl-propanol (**M06**) and conjugates like BCS-CN88460-desmethyl-propanol-GlucA (**M31**) (isomer 1), BCS-CN88460-propanol-GlucA (**M19**) (isomer 1 and 2) and BCS-CN88460-desmethyl-GlucA (**M35**) (isomer 1). They amounted to ≤ 5.0% (0.028 mg/kg) of TRR.

Besides parent compound, the major part of radioactivity in viscera of fish was represented by the two metabolites BCS-CN88460-propanol-GlucA (**M19**) (isomer 1 and 2) and amounted to in sum approximately 40% of the TRR. Other metabolites in viscera fish tissues were BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**), BCS-CN88460-desmethyl-propanol-GlucA (**M31**) (isomer 1), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-propanol (**M01**), BCS-CN88460-desmethyl-GlucA (**M35**) (isomer 1) and BCS-CN88460-desmethyl (**M13**). These metabolites amounted to ≤ 6.6% (0.262 mg/kg) of TRR.

Unknown metabolites in all fish tissues were characterised by their extraction and chromatographic behaviour and amounted to ≤ 3.4% (0.019 mg/kg) of TRR for edible fish parts and ≤ 5.4% (0.213 mg/kg) of TRR for viscera fish parts.

** The aglycon BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) could be clearly identified after acidic cleavage of the conjugate.

III. Conclusion

The metabolism of **isoflucypram** in bluegill sunfish was investigated as part of the fish bioconcentration study. The test compound was radiolabelled in the pyrazole-4 moiety. **Isoflucypram** was stable in the fish water during the testing period.

After exposure of the fishes for 7 days and for 14 days with [pyrazole-4-^{14}C]BCS-CN88460 at a concentration of 5.0 µg/L, the total radioactive residues (TRRs) in the edible parts (0.565 mg/kg for day 7 and 0.567 mg/kg for day 14) were moderate. In viscera parts the TRRs amounted to 3.955 mg/kg for day 7 and 3.365 mg/kg for day 14.

Residues from edible and viscera fish parts could be sufficiently extracted with conventional methods. **isoflucypram** was intensely metabolised in the fish.

Parent compound was detected in edible and viscera fish parts. Besides parent compound as a major compound in edibles, the metabolite BCS-CN88460-cyclopropyl-pyrazole-carboxamide (**M58**) was found with higher amounts. Metabolites BCS-CN88460-propanol-GlucA (**M19**, isomer 1 and 2) were found as main compound (in sum approximately 41% of TRR) in viscera fish parts.

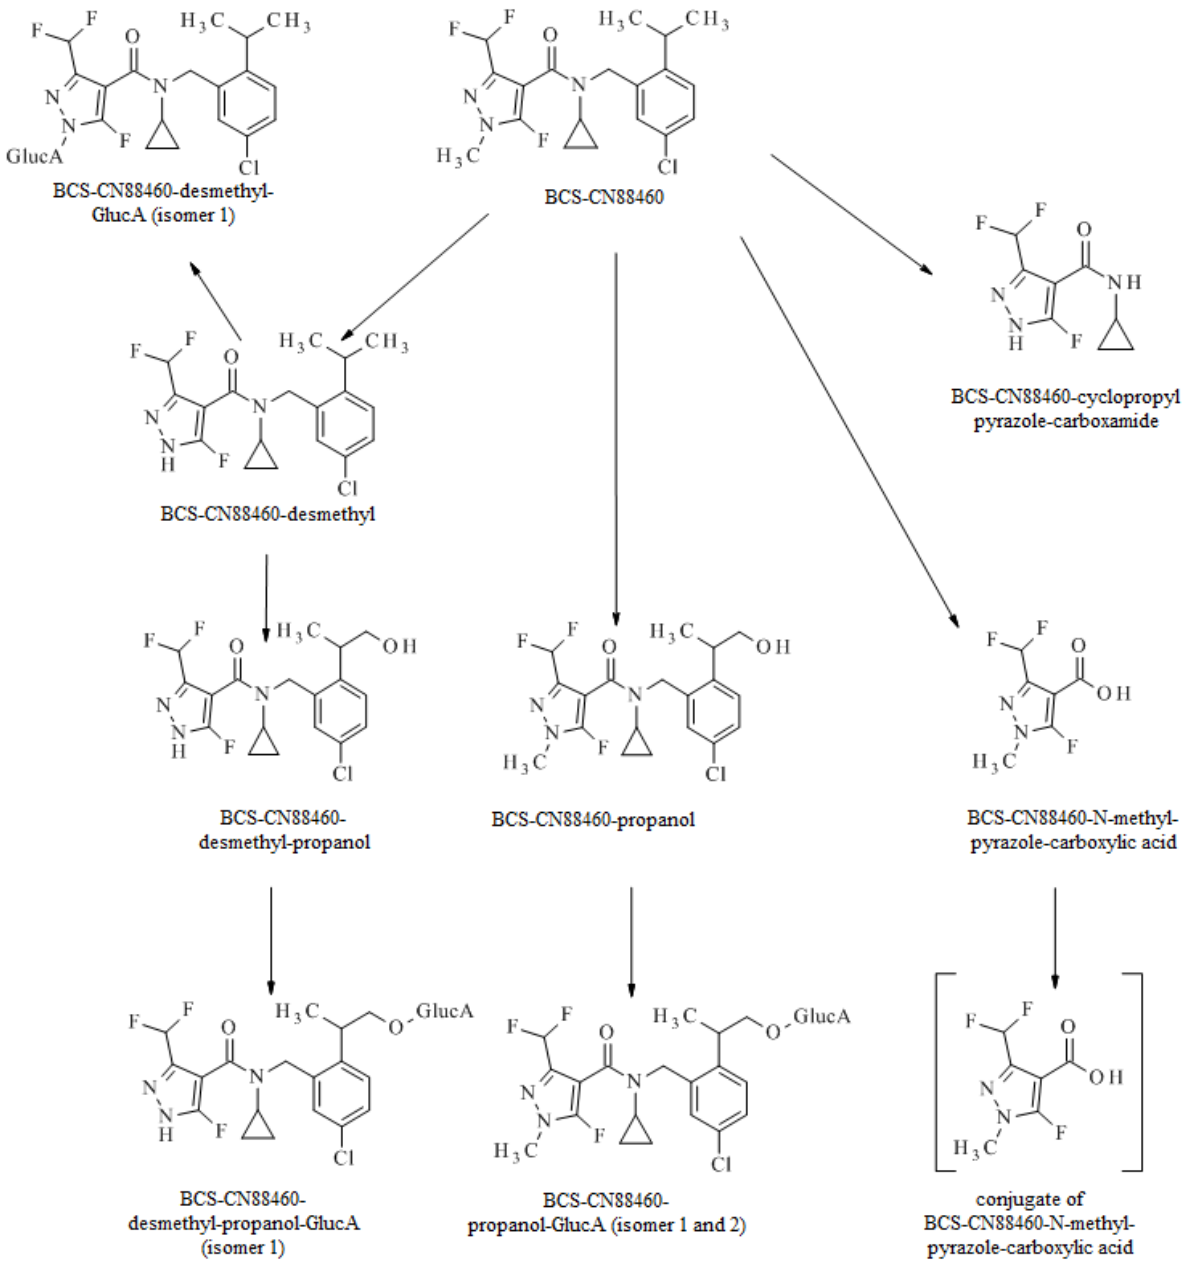
Further metabolites in the fish parts were BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), conjugate of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**), BCS-CN88460-desmethyl-propanol-GlucA (**M31**, isomer 1), BCS-CN88460-desmethyl-propanol (**M06**), BCS-CN88460-propanol (**M01**), BCS-CN88460-desmethyl-GlucA (**M35**, isomer 1) and BCS-CN88460-desmethyl (**M13**).

The principal metabolic reactions of [pyrazole-4-^{14}C]BCS-CN88460 in fish are the demethylation of the pyrazole moiety, the hydroxylation in position 1 of the propyl group, conjugation with glucuronic acid after hydroxylation or via nitrogen, cleavage of the phenyl moiety and cleavage of the phenyl moiety in combination with cleavage of the cyclopropyl ring followed by oxidation. Conjugation of BCS-CN88460-N-methyl-pyrazole-carboxylic acid (**M50**) was also observed.

Based on the results, it is concluded that the metabolic behaviour, as well the pathway of [pyrazole-4-^{14}C]BCS-CN88460 in fish are sufficiently understood. The following pathway of

isoflucypram in bluegill sunfish is proposed:

Figure 7.2.5-2: Proposed metabolic pathway of isoflucypram in bluegill sunfish



B.7.3. MAGNITUDE OF RESIDUE TRIALS IN PLANTS

The proposed representative uses of **isoflucypram** (BCS-CN88460) in the EU are on cereals (barley, oat, wheat, durum wheat, rye, spelt and triticale) according to the GAPs summarised in the Table below:

Table 7.2.5-1: Proposed representative GAPs for spray applications of formulations containing isoflucypram on cereals in the EU

Crop	F/G	No. of appls.	Growth stage at application (BBCH Code)	Application rate (g a.s./ha)	Water (L/ha)	PHI
Barley, oat*	F NEU SEU	1	30-61	75	100-400	Not Applicable; timing defined by Growth Stage
Wheat, Durum wheat, rye, spelt and triticale *	F NEU SEU	1	30-69	75	100-400	Not Applicable; timing defined by Growth Stage

* Agricultural use based on EC formulations (BCS-CN88460 EC050 and Prothioconazole & BCS-CN88460 EC 150)

B.7.3.1. **Barley**

13 independent GAP compliant GLP trials were conducted on barley in the NEU and 12 were conducted in the SEU in 2015/16. In these trials, barley was treated with one application of 62.5-75 g **isoflucypram**/ha formulated as an EC at the latest intended growth stage of BBCH 61. Three different formulations were tested. The available trials are summarised in the Table below:

Table 7.3.1-1: Overview of EU residue trials conducted on barley

Crop	Region	No. of independent trials*			Report No. (Formulation)	Document number	Reference

Materials and Methods

13 independent field trials, each applying **isoflucypram** formulated into one of 3 different ECs, were conducted on barley (both spring and winter varieties) in the NEU in either 2015 or 2016.

4 trials (NL, DE, FR(N), UK; **2015**) were conducted on winter and spring barley (Schulte, G.; 2017) using one spray application of 1.5 L/ha **BCS-CN88460 EC 050** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 61. In one of the trials (15-2110-02), application was slightly earlier at BBCH 59; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 200-400 L water/ha prior to spraying.

4 trials (NL, DE, FR(N), UK; **2015**) were conducted on winter and spring barley (Glaubitz, J.; 2017) using one spray application of 1.5 L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 61. In one of the trials (15-2113-02), application was slightly earlier at BBCH 59; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 200-400 L/ha prior to spraying.

Trials 15-2113-02, 15-2113-03 and 15-2113-04 were located side by side with trials 15-2110-02, 15-2110-03 and 15-2110-04, respectively. Thus, for the studies 15-2110 and 15-2113, only 5 trials are considered as independent trials.

4 trials (UK, FR(N), HU, CZ; **2015**) were carried out on winter and spring barley (Noss, G.; 2017) using one spray application of 1.25 L/ha **Prothioconazole & Tebuconazole & BCS-CN88460 EC 250** (equivalent to 62.5 g **isoflucypram**/ha) at BBCH 61. The formulation was diluted with 200-300 L water/ha prior to spraying.

4 trials (UK, DE, FR(N), NL; **2016**) were carried out on winter and spring barley (Kaussmann, M.; 2017) by spraying 1.5L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g **isoflucypram**/ha) at BBCH 61. The formulation was diluted with 200-400 L water/ha prior to spraying.

In all these trials, samples of green material (whole plants without roots) were taken immediately after application and at several further intervals up to 28 days (one of the samplings was at BBCH 75 which is relevant for hay). Samples of grain and straw were collected at commercial harvest (BBCH 89).

Each field sample was stored at ≤-18 °C within 24 hours of sampling and remained at this temperature, including during transportation to the analytical laboratory (apart from two instances in 15-2118-04 where the temperature reached -13 °C and -7 °C for no more than 24 h), until sample preparation. The frozen field samples were shredded and homogenised with dry ice in a cutter. Representative parts of the shredded samples were stored at ≤18 °C until analysis.

The samples were analysed for **isoflucypram** using method 01475 (Uceda, L.; 2016; validated in accordance with SANCO 3029/99 rev.4 to an LOQ of 0.01 mg/kg). Additional recoveries were conducted for barley (grain, straw and green material) in study 15-2066. The samples of grain and straw were analysed according to the method procedure for dry matrices (includes a soaking step with water before extraction) and the green material samples were prepared according to the procedure for high-water commodities (no soaking step before extraction).

Findings

Acceptable procedural recoveries were obtained from green material, grain and straw samples spiked at 0.01 - 4 mg/kg, which covers the LOQ and residue levels found in treated samples; see Table below.

Table 7.3.1-2: Procedural recovery data for isoflucypram in barley

		2	0.1	111;107	107	111	109
	Straw	1	0.01	93	-	-	-
		1	0.1	101	-	-	-
		1	2.0	85	-	-	-
16-2051	Green material	4	0.01	94; 86; 79; 85	79	94	86
		2	0.1	93; 95	93	95	94
		1	1.0	94	-	-	-
		1	4.0	95	-	-	-
	Grain	3	0.01	83; 90; 94	83	94	89
		2	0.1	94; 101	94	101	98
	Straw	1	0.01	96	-	-	-
		1	0.1	97	-	-	-
		1	1.0	84	-	-	-

Appropriate representative chromatograms were provided and no residues above the LOQ were found in any control samples.

Residues of **isoflucypram** were observed to dissipate rapidly in green material, from 0.87-2.4 mg/kg on Day +0 to 0.051-0.56 mg/kg on Day 27/29.

At harvest, residues in grain ranged from <0.01 mg/kg to 0.041 mg/kg and residues in straw ranged from 0.049 to 1.2 mg/kg.

The detailed results are summarised in Table 7.3.1-3 and are not corrected for procedural recoveries. The residue results in grain and straw relevant to the critical GAP have been underlined. Where similar trials were conducted in side-by-side plots, to ensure a worst case assessment, the highest residue across the two trials has been selected (it is noted that the only difference in the side-by-side trials was the absence or presence of a second active ingredient in the EC formulation used; the formulation type and all the application parameters were identical. Consequently, it could also be valid to consider the trials as duplicates and therefore use a mean residue value).

Samples were stored for a maximum of 390 days prior to analysis. In most cases, the time between the start of sample preparation and analysis did not exceed 24 hours. If not the case, the maximum storage period of extracts (30 hours for green material and 55 hours for straw) was covered by stability experiments conducted in the course of residue study 15-2066 (Schulte, G.; 2017); See Table 7.1.2-3.

Table 7.3.1-3: Residue trials on barley in NEU

When trials were conducted in parallel plots, the highest residue level from the 2 plots is selected (underlined).

Materials and Methods

12 independent field trials, each applying **isoflucypram** formulated into one of 3 different ECs, were conducted on barley (both spring and winter varieties) in the SEU in either 2015 or 2016.

4 trials (PT, ES, FR(S); **2015**) were conducted on barley (Schulte, G.; 2017) using one spray application of 1.5 L/ha **BCS-CN88460 EC 050** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 61. In one of the trials (15-2066-03), application was slightly earlier at BBCH 53; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 300 L water/ha prior to spraying.

4 trials (PT, ES, FR(S); **2015**) were carried out on barley (Glaubitz, J.; 2017) using one spray application of 1.5 L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 61. In one of the trials (15-2114-03), application was slightly earlier at BBCH 53; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 300 L water/ha prior to spraying.

Trials 15-2066-01, 15-2066-02, 15-2066-03 and 15-2066-04 were located side by side with trials 15-2114-01, 15-2114-02, 15-2114-03 and 15-2114-04, respectively. Thus, for the studies 15-2066 and 15-2114, only 4 trials are considered as independent trials.

It is noted that in trials 15-2066-02 and 15-2114-02 rain fell within 6 hours of application. Day +0 sampling was collected before rainfall in trial 15-2066-02 and after rainfall in trial 15-2114-02. Whilst an impact on residue levels cannot be excluded, rainfall reflects what can happen in practice and so these trials are considered acceptable.

4 trials (FR(S), IT, ES, PT; **2015**) were carried out on barley (Noss, G.; 2017) using one spray application of 1.25 L/ha **Prothioconazole & Tebuconazole & BCS-CN88460 EC 250** (equivalent to 62.5 g **isoflucypram**/ha) at BBCH 61. The formulation was diluted with 300-400 L water/ha prior to spraying.

4 trials (PT, FR(S), ES; **2016**) were carried out on barley (Kaussmann, M.; 2017) using one spray application of 1.5 L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g/ha **isoflucypram**) at nominally BBCH 61. The formulation was diluted with 300 L water/ha prior to spraying.

In all these trials, samples of green material (whole plants without roots) were taken immediately after application and at several further intervals up to 27/28 days (one of the samplings was at BBCH 75 which is relevant for hay). Samples of grain and straw were collected at commercial harvest (BBCH 89). There was a very minor deviation in the weight of grain sampled in trial 16-2052-03 (0.96 kg cf. 1 kg in study plan) which is not considered to have impacted the results.

Each field sample was stored at ≤-18 °C within 24 hours of sampling and remained at this temperature, including during transportation to the analytical laboratory, until sample preparation. The frozen field samples were shredded and homogenised with dry ice in a cutter. Representative parts of the shredded samples were stored at ≤18 °C until analysis. During storage of samples in trials 15-2117-03, 15-2117-04, and 16-2052-01, the temperature rose above -18 °C, reaching a maximum of -9 °C for a short time. These deviations are not expected to have had a negative impact on the studies.

The samples were analysed for **isoflucypram** using method 01475 (Uceda, L.; 2016; validated in accordance with SANCO 3029/99 rev.4 to an LOQ of 0.01 mg/kg). Additional recoveries were conducted for barley (grain, straw and green material) in study 15-2066. The samples of grain and straw were analysed according to the method procedure for dry matrices (includes a soaking step with water before extraction) and the green material samples were prepared according to the procedure for high-water commodities (no soaking step before extraction).

Findings

Acceptable procedural recoveries were obtained from green material, grain and straw samples spiked at 0.01 - 5 mg/kg, which covers the LOQ and residue levels found in treated samples; see Table below.

Table 7.3.1-4: Concurrent recovery data for isoflucypram in barley

Appropriate representative chromatograms were provided and no residues above the LOQ were found in any control samples.

Residues of **isoflucypram** were observed to dissipate rapidly in green material, from 0.87-3.1 mg/kg on Day +0 to 0.048 - 1.4 mg/kg on Day 27/28.

At harvest, residues in grain ranged from <0.01 mg/kg to 0.037 mg/kg and residues in straw ranged from 0.021 to 3.1 mg/kg.

The detailed results are summarised in Table 7.3.1-5 and are not corrected for procedural recoveries. The residue results in grain and straw relevant to the critical GAP have been underlined. Where similar trials were conducted in side-by-side plots, to ensure a worst case assessment, the highest residue across the two trials has been selected (it is noted that the only difference in the side-by-side trials was the absence or presence of a second active ingredient in the EC formulation used; the formulation type and all the application parameters were identical. Consequently, it could also be valid to consider the trials as duplicates and therefore use a mean residue value).

Samples were stored for a maximum of 390 days prior to analysis. In most cases, the time between the start of sample preparation and analysis did not exceed 24 hours. If not the case, the maximum storage period of extracts (80 hours for green material and 76 hours for straw) was covered by stability experiments conducted in the course of residue study 15-2066 (Schulte, G.; 2017). See Table 7.1.2-3.

Table 7.3.1-5: Residue trials on barley in SEU

When trials were conducted in parallel plots, the highest residue level from the 2 plots was selected (underlined).

References:
GLP: Yes
Crop/crop group: Barley
Indoor/Outdoor: SEU outdoor
Formulation: EC 050; EC 150 or EC 250
Content of active substance (g/L): 50 for all 3 formulations
Sample storage conditions: Frozen (-18 °C)
Analytical method: 01475 (Validation Data in 01475 and study 15-2066)
Limit of Quantification (mg/kg): 0.01
Residues calculated as: **Isoflucypram** (BCS-CN88460)

Summary

A summary of all the relevant residue results for barley are presented in the table below:

Table 7.3.1-6: Summary of isoflucypram residue data for barley

Crop	NEU/ SEU	Trial results relevant to the critical representative GAP (mg/kg)	STMR (mg/kg)	HR (mg/kg)	Rounded MRL; OECD (mg/kg)
Barley Grain	NEU	10 × <0.01; 0.013; 0.020; 0.041	<0.01	0.041	0.05
	SEU	9 × <0.01; 0.022; 0.027; 0.037	<0.01	0.037	0.05
	NEU + SEU	19 x <0.01; 0.013; 0.020; 0.022; 0.027; 0.037; 0.041	**<0.01**	0.041	**0.05**
Barley Straw	NEU	0.049; 0.11; 0.13; 0.16; 0.20; 0.24; 0.32; 0.40; 0.44; 0.51; 0.94; 0.96; 1.2	0.32	1.2	N/A
	SEU	0.021; 0.13; 0.16; 0.18; 0.24; 0.29; 0.29; 0.31; 0.85; 0.96; 1.0; 3.1	0.29	3.1	N/A
	NEU + SEU	0.021; 0.049; 0.11; 2 x 0.13;2 x 0.16; 0.18; 0.20; 2 x 0.24; 2 x 0.29; 0.31; 0.32; 0.40; 0.44; 0.51; 0.85; 0.94; 2 x 0.96; 1.0; 1.2; 3.1	**0.29**	**3.1**	N/A

Table 7.3.1-7: Mann-Whitney U-test comparison of barley straw NEU and SEU data

Mean	0.44	0.63		
STMR	0.32	0.29		
	Number of values:		13	12
	Sum Rank:		167	158
	U_1 and U_2 values:		80.0	76.0
	Critical value:		41	(α= 0.05)
	n_a = 12		n_b = 13	
	Result:	**Populations similar**		

The results of the statistical Mann-Whitney U-test, $\alpha = 0.05$ (and the Kruskal-Wallis H-Test) indicate that the NEU straw residue data are not significantly different from the SEU straw residue data, hence the NEU and SEU data sets have been combined in the Table above.

B.7.3.2. **Oat**

The representative use on oats is supported by the residue trials conducted on barley, as allowed for in the EU Guidance document SANCO 7525/VI/95 rev. 10.3 (13 June 2017). See Table 7.3.1-6.

B.7.3.3. **Wheat**

12 independent GAP compliant GLP trials were conducted on wheat in the NEU and 13 were conducted in the SEU in 2015/16. In these trials, wheat was treated with one application of 62.5-75 g **isoflucypram**/ha formulated as an EC at the latest intended growth stage of BBCH 69. Three different formulations were tested. The available trials are summarised in the Table below:

Table 7.3.3-1: Overview of residue trials conducted on wheat

Crop	Region	No. of independent trials*			Report No. (Formulation)	Document number	Reference
		Veget. period		Total			
		2015	2016				
Wheat	NEU	8	4	12	15-2111 (EC 050) 15-2115 (EC 150) 15-2120 (EC 250) 16-2053 (EC 150)	M-586570-02-1 M-578221-03-1 M-584680-03-1 M-593778-02-1	KCA 6.3.2/01 KCA 6.3.2/02 KCA 6.3.2/03 KCA 6.3.2/04

Guideline deviations:	None
GLP/GEP:	Yes

Materials and Methods

12 independent field trials, each applying **isoflucypram** formulated into one of 3 different ECs, were conducted on wheat (both spring and winter varieties) in the NEU in either 2015 or 2016.

4 trials (FR(N), UK, NL, DE; **2015**) were conducted on spring and winter wheat (Schulte, G.; 2017) using one spray application of 1.5L/ha **BCS-CN88460 EC 050 (**equivalent to 75 g **isoflucypram**/ha) at BBCH 69. The formulation was diluted with 200-400 L water/ha prior to spraying.

4 trials (FR(N), UK, NL, DE; **2015**) were conducted on spring and winter wheat (Glaubitz, J.; 2017) using one spray application of **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g **isoflucypram**/ha) at BBCH 69. The formulation was diluted with 200-400 L water/ha prior to spraying.

Trials 15-2111-01, 15-2111-02, 15-2111-03 and 15-2111-04 were located side by side with trials 15-2115-01, 15-2115-02, 15-2115-03 and 15-2115-04. Thus, for the studies 15-2111 and 15-2115, only 4 trials are considered as independent trials.

4 trials (UK, HU, FR (N), PL; **2015**) were conducted on spring and winter wheat (Noss, G.; 2017) using one spray application of 1.25 L/ha **Prothioconazole & Tebuconazole & BCS-CN88460 EC 250** (equivalent to 62.5 g **isoflucypram**/ha). The formulation was diluted with 200-300 L water/ha prior to spraying.

4 trials (FR(N), BE, NL, DE; **2016**) were carried out on winter and spring wheat (Kaussmann, M.; 2017) using 1.5L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 69. In one of the trials (16-2053-02), application was slightly earlier at BBCH 65; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 300-400 L water/ha prior to spraying.

In all these trials, samples of green material (whole plants without roots) were taken immediately after application and at several further intervals up to 28/29 days. Samples of grain and straw were collected at commercial harvest (BBCH 89).

Each field sample was stored at ≤-18 °C within 24 hours of sampling and remained at this temperature, including during transportation to the analytical laboratory, until sample preparation. The frozen field samples were shredded and homogenised with dry ice in a cutter. Representative parts of the shredded samples were stored at ≤18 °C until analysis.

The samples were analysed for **isoflucypram** using method 01475 (Uceda, L.; 2016; validated in accordance with SANCO 3029/99 rev.4 to an LOQ of 0.01 mg/kg. Additional recoveries were conducted for wheat (grain, straw and green material) in study 15-2069. The samples of grain and straw were analysed according to the method procedure for dry matrices (includes a soaking step with water before extraction) and the green material samples were prepared according to the procedure for high-water commodities (no soaking step before extraction).

Findings

Acceptable procedural recoveries were obtained from green material, grain and straw samples spiked at 0.01 - 4 mg/kg, which covers the LOQ and residue levels found in treated samples; see Table below.

Table 7.3.3-2: Concurrent recovery data for isoflucypram in wheat

Study	Portion	n	Fortification level (mg/kg)	Recovery (%)			
				Individual recoveries	Min	Max	Mean
15-2111	Green material	3	0.01	99; 117; 102	99	117	105
		2	0.10	97; 98	97	98	98

Appropriate representative chromatograms were provided and no residues above the LOQ were found in any control samples.

Residues of **isoflucypram** were observed to dissipate rapidly in green material, from 0.97 - 2.1 mg/kg

on Day +0 to 0.065 - 0.84 mg/kg on Day 28/29.

At harvest, residues in grain were all <0.01 mg/kg and residues in straw ranged from 0.054 to 3.6 mg/kg.

The detailed results are summarised Table 7.3.3-3 and are not corrected for procedural recoveries. The residue results in grain and straw relevant to the critical GAP have been underlined. Where similar trials were conducted in side-by-side plots, to ensure a worst case assessment, the highest residue across the two trials has been selected (it is noted that the only difference in the side-by-side trials was the absence or presence of a second active ingredient in the EC formulation used; the formulation type and all the application parameters were identical. Consequently, it could also be valid to consider the trials as duplicates and therefore use a mean residue value).

Samples were stored for a maximum of 381 days prior to analysis. In most cases, the time between the start of sample preparation and analysis did not exceed 24 hours. If not the case, the maximum storage period of extracts (38.5 hours for green material) was covered by stability experiments conducted in the course of residue study 15-2069 (Schulte, G.; 2017); See Table 7.1.2-3.

Table 7.3.3-3: Residue trials on wheat in NEU

When trials were conducted in parallel plots, the highest residue level from the 2 plots was selected (underlined values).

Materials and Methods

13 independent field trials, each applying **isoflucypram** formulated into one of 3 different ECs, were conducted on wheat (including durum varieties) in the SEU in either 2015 or 2016.

4 trials (FR(S), PT, ES; **2015**) were conducted on wheat and durum wheat (Schulte, G.; 2017) using one spray application of 1.5 L/ha **BCS-CN88460 EC 050** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 69. In one of the trials (15-2069-04), application was slightly earlier at BBCH 65; however, the timing to harvest is not expected to be significantly impacted. The formulation was

diluted with 300 L water/ha prior to spraying.

4 trials (FR(S), PT, ES; **2015**) were conducted on wheat (Glaubitz, J.; 2017) using one spray application of 1.5 L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g **isoflucypram**/ha) at nominally BBCH 69. In one of the trials (15-2116-04), application was slightly earlier at BBCH 65; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 300 L water/ha prior to spraying. The formulation was diluted with 300 L water/ha prior to spraying.

Trials 15-2069-01, 15-2069-02, 15-2069-03 and 15-2069-04 were located side by side with trials 15-2116-01, 15-2116-02, 15-2116-03 and 15-2116-04, respectively. Application dates, sampling dates and varieties differ slightly between 15-2069-04 and 15-2116-04 due to 15-2116-04 having to be restarted. Nevertheless, all other application parameters were identical and both trials were located very close to each other geographically and so the soil, weather and cultivation practices were also the same. Therefore, to ensure a worst case assessment, these trials have not been treated as independent trials. Thus, for the studies 15-2069 and 15-2116, only 4 trials are considered as independent trials.

4 trials (FR(S), ES, PT, IT; **2015**) were carried out on wheat and durum wheat (Noss, G.; 2017) using one spray application of 1.25 L/ha **Prothioconazole & Tebuconazole & BCS-CN88460 EC 250** (equivalent to 62.5 g/ha **isoflucypram**) at BBCH 69. In one of the trials (15-2119-01) the application was slightly (5.9%) overdosed, but still conducted within the ±25% acceptable tolerance. The formulation was diluted with 300 L water/ha prior to spraying.

5 trials (FR(S), IT, ES, HE; **2016**) were carried out on wheat (Kaussmann, M.; 2017) using one spray application of 1.5 L/ha **Prothioconazole & BCS-CN88460 EC 150** (equivalent to 75 g/ha **isoflucypram**) at nominally BBCH 69. In two of the trials (16-2054-03 and 16-2054-05), application was slightly earlier at BBCH 65; however, the timing to harvest is not expected to be significantly impacted. The formulation was diluted with 300-400 L water/ha prior to spraying.

In all these trials, samples of green material (whole plants without roots) were taken immediately after application and at several further intervals up to 27/29 days. Samples of grain and straw were collected at commercial harvest (BBCH 89) except in two trials (side-by-side plots from 15-2069-03 and 15-2116-03) where samples of grain and straw were not collected since plots had been harvested in error prior to sample collection.

Each field sample was stored at ≤-18 °C within 24 hours of sampling and remained at this temperature, including during transportation to the analytical laboratory, until sample preparation. The frozen field samples were shredded and homogenised with dry ice in a cutter. Representative parts of the shredded samples were stored at ≤18 °C until analysis. During storage/transport of samples in trials 15-2119-02, 15-2119-03 and 16-2054-01, the temperature rose above -18 °C for a short time. These deviations are not expected to have had a negative impact on the studies.

The samples were analysed for **isoflucypram** using method 01475 (Uceda, L.; 2016; validated in accordance with SANCO 3029/99 rev.4 to an LOQ of 0.01 mg/kg). Additional recoveries were conducted for wheat (grain, straw and green material) in study 15-2069. The samples of grain and straw were analysed according to the method procedure for dry matrices (includes a soaking step with water before extraction) and the green material samples were prepared according to the procedure for high-water commodities (no soaking step before extraction).

Findings

Acceptable procedural recoveries were obtained from green material, grain and straw samples spiked at 0.01 - 8 mg/kg, which covers the LOQ and residue levels found in treated samples; see Table below.

Table 7.3.3-4: Procedural recovery data for isoflucypram in wheat

Study	Portion analysed	n	Fortification level (mg/kg)	Recovery (%)

Appropriate representative chromatograms were provided and no residues above the LOQ were found in any control samples.

Residues of **isoflucypram** were observed to dissipate rapidly in green material, from 0.76-2.5 mg/kg on Day +0 to 0.14-1.5 mg/kg on Day 27-29.

At harvest, residues in grain were <0.01 mg/kg apart from in one trial where a residue of 0.042 mg/kg was identified. Residues in straw ranged from 0.22 to 2.4 mg/kg.

The detailed results are summarised in Table 7.3.3-5 and are not corrected for procedural recoveries. The residue results in grain and straw relevant to the critical GAP have been underlined. Where similar trials were conducted in side-by-side plots, to ensure a worst case assessment, the highest residue across the two trials has been selected (it is noted that the only difference in the side-by-side trials was the absence or presence of a second active ingredient in the EC formulation used; the formulation type and all the application parameters were identical. Consequently, it could also be valid to consider the trials as duplicates and therefore use a mean residue value).

Samples were stored for a maximum of 398 days prior to analysis. In most cases, the time between the start of sample preparation and analysis did not exceed 24 hours. If not the case, the maximum storage period of extracts (30.5 hours for grain, 39 hours for green material and 76 hours for straw) was covered by stability experiments conducted during validation of the method 01475 (Uceda, L.; 2016), or by additional experiments conducted in the course of the residue study 15-2069 (Schulte, G.; 2017). See Table 7.1.2-3.

Table 7.3.3-5: Residue trials on wheat in SEU

When trials were conducted in parallel plots, the highest residue level from the 2 plots was selected (underlined values).

Summary

A summary of all the relevant residue results for wheat are presented in the table below:

Table 7.3.3-6: Summary of isoflucypram residue data for wheat

Crop	NEU /SEU	Trial results relevant to the critical representative GAP (mg/kg)	STMR (mg/kg)	HR (mg/kg)	Rounded MRL; OECD (mg/kg)
Wheat Grain	NEU	12 × <0.01	<0.01	<0.01	0.05
	SEU	11 × <0.01; 0.042	<0.01	0.042	0.05
	NEU + SEU	23 x <0.01; 0.042	**<0.01**	0.042	**0.05**
Wheat Straw	NEU	0.054; 0.071; 0.12; 0.19; 0.38; 0.40; 0.82; 0.94; 1.5; 1.7; 3.3; 3.6	0.61	3.6	N/A
	SEU	0.22; 0.33; 0.41; 0.87; 1.3; 1.4; 1.6; 1.8; 1.9; 1.9; 2.3; 2.4	1.5	2.4	N/A
	NEU + SEU	0.054; 0.071; 0.12; 0.19; 0.22; 0.33; 0.38; 0.40; 0.41; 0.82; 0.87; 0.94; 1.3; 1.4; 1.5; 1.6; 1.7; 1.8; 1.9; 1.9; 2.3; 2.4; 3.3; 3.6	**1.12**	**3.6**	N/A

Table 7.3.3-7: Mann-Whitney U-test comparison of wheat straw NEU and SEU data

Mean	1.09	1.37		
STMR	0.61	1.50		
	Number of values:		12	12
	Sum Rank:		126	174
	U_1 and U_2 values:		96.0	48.0
	Critical value:		37	(α= 0.05)
	n_a = 12		n_b = 12	
	Result:	**Populations similar**		

The results of the statistical Mann-Whitney U-test, α = 0.05 (and the Kruskal-Wallis H-Test) indicate that the NEU straw residue data are not significantly different from the SEU straw residue data – the grain data is clearly similar without the use of a statistical test; hence the NEU and SEU data have been combined in the Table above.

B.7.4. FEEDING STUDIES

European dietary burden calculations

Isoflucypram is proposed for use on cereals, parts of which might be fed to livestock in the EU (grain, straw and processed grain commodities).

The dietary burdens for different groups of livestock have been estimated as described in the OECD Guidance Document on Residues in Livestock (ENV/JM/MONO(2013)8 dated of 04-Sep-2013) and using the Excel spread sheet 2017 available on the EU Commission website: (pesticides_mrl_guidelines_animal_model_2017.xls).

Based on the proposed plant residue definition for risk assessment (**isoflucypram** parent compound), input values were derived from the residue data as summarised under Sections B.7.3.1 and. B.7.3.3. These input data are summarised in the Table below:

Table 7.3.3-1: Input residue data for livestock dietary burden calculations

Feed commodity	Median dietary burden		Maximum dietary burden	
	Residue (mg/kg)	Comment	Residue (mg/kg)	Comment
Barley straw	0.29	STMR (NEU+SEU)	3.1	HR (NEU+SEU)
Oat straw				
Rye straw	1.12	STMR (NEU+SEU)	3.6	HR (NEU+SEU)
Triticale straw				
Wheat straw				
Barley grain	0.01	STMR (NEU+SEU)	0.01	STMR (NEU+SEU)
Oat grain				
Rye grain	0.01	STMR (NEU+SEU)	0.01	STMR (NEU+SEU)
Triticale grain				
Wheat grain				
Brewer's grain	0.007	STMR-P (0.01 x 0.67 [a])	0.007	STMR-P (0.01 x 0.67 [a])
Distiller's grain	0.033	STMR-P (0.01 x 3.3 [b])	0.033	STMR-P (0.01 x 3.3 [b])
Wheat gluten	0.011	STMR-P (0.01 x 1.1 [c])	0.011	STMR-P (0.01 x 1.1 [c])
Wheat milled by-products	0.014	STMR-P (0.01 x 1.4 [c d])	0.014	STMR-P (0.01 x 1.4 [c d])

HR: Highest Residue
STMR: Supervised Trial Median Residue
a: processing factor P derived from M-579494-01-1;
b: default processing factor P
c: processing factor P derived from M-600505-02-1;
d: highest value from wheat middlings (<0.73), bran (1.4), and shorts (0.98)

Table 7.3.3-2: Estimated dietary burden of livestock exposed to residues of isoflucypram

Animal	Dietary burden (mg/kg bw/d)		Above 0.004 mg/kg bw?	Dietary burden (mg/kg DM)		Highest contributing commodity

Livestock feeding studies were conducted on dairy cow and poultry hens. Multi-region livestock diet

calculations were conducted in order to conduct the studies in a manner appropriate to the entire scope of isoflucypram use, allowing data to be generated in a fashion such that, for animal welfare considerations, a low number of animals will be used, while yielding valid data to evaluate expected residue levels in all key animal tissues and products.

The test substance used in the feeding studies should be representative of the residue in the feedstuffs. In the case of the new fungicide **isoflucypram**, by far the major part of the residue in plants is formed by parent compound **isoflucypram**.

Based on the results of the metabolism studies several compounds were measured in the feeding studies:

- In milk, eggs and all tissues free residues of **isoflucypram** parent compound and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) were individually determined;

- Additionally, the sum of BCS-DC20298 (**M02**) and its conjugate **M20**, and the sum of BCS-CY24813 (**M01**) and its conjugate **M19** were determined in cow liver and kidney;

- Moreover, the sum of BCS-DC22055 (**M06**) and its conjugate **M37** was determined in hen liver.

B.7.4.1. **Poultry**

Report:	KCA 6.4.1/01; [redacted] 2017
Title:	BCS-CN88460: Feeding study with laying hens
Report No.:	M-605909-01-1
Document No.:	M-605909-01-1
Guidelines:	OECD Test Guideline 505; EU Directive EC 91/414, Appendix G, 7031/VI/95 rev. 4; OCSPP 860.1480.
Guideline deviations:	None
GLP/GEP:	Yes

I. Materials and Methods

Test system, dosing

After an acclimatisation phase of about 3 weeks, forty-two laying hens (*Gallus gallus domesticus*) were dosed orally, via gelatin capsules, for 28 consecutive days with BCS-CN88460 (**isoflucypram**) at dose rates of 0 mg/kg bw/day (control; 2 subgroups, 6 hens), 0.03 mg/kg bw/day (1X EU dose group; 3 subgroups, 9 hens), 0.12 mg/kg bw/day (4X EU dose group; 3 subgroups, 9 hens) and 0.48 mg/kg bw/day (16X EU dose group; 3 subgroups, 9 hens). An additional group 16XE (3 subgroups, 9 hens) was dosed at the rate of 0.48 mg/kg bw/day for 28 consecutive days simultaneously with the animals from dose group 16X. Thereafter, dosing was stopped and the animals were kept alive for further 4, 7 or 14 days in order to investigate the depuration of residues of **isoflucypram** in eggs and tissues after the end of dosing.

The exact amounts of test item to be administered daily to each hen were calculated weekly based on the body weight determined on the Thursday preceding the week of dosing (starting on Monday). Based on this procedure 5 batches of capsules were prepared for each animal (one batch per calendar week). C.E.R. groupe prepared a dosing solution for each dose level by dissolving the test item in methanol. Depending on the animal weight and dose group, a suitable volume of about 50 µL of the corresponding test item solution was pipetted into gelatine capsules filled with cellulose powder to absorb the solvent and prevent soaking of the capsule itself. The capsule was then left open for minimum 30 min to allow the solvent to evaporate and after that it was closed. The capsules and the dosing solutions were stored in a fridge at +2 °C to +8 °C at the animal unit of the in-life test site until use. The **isoflucypram** content of the dosing solutions and capsules was verified by the residue analytical team at BAG-CS-HS-RA directly after preparation and at appropriate intervals during and at

the end of their storage at C.E.R.. The analyses were conducted using method 01511 (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1).

The hens were fed with non-supplemented commercial laying hen meal (Avi Pondeuse Farine, 88+/-1% dry matter). The feed was screened for residues of **isoflucypram** with an LOQ of 0.01 mg/kg according to method 01475 (Uceda, L.; 2016; M-558986-01-1). The amount of feed consumed was monitored daily. The hens were allowed *ad libitum* access to tap water. The dose rates employed in the study are summarised in the Table below:

Table 7.4.1-1: Summary of isoflucypram dose administration

Dose groups	Sub-groups	Number of hens	Dose levels	
			(mg/kg bw/day)	(mg/kg DM feed)*
control	A1, A2	6	0	0
1X dose	B1, B2, B3	9	0.03	0.530
4X dose	C1, C2, C3	9	0.12	2.119
16X dose	D1, D2, D3	9	0.48	8.698
16XE dose	E1, E2, E3	9	0.48	8.140

DM: Dry Matter

*: Actual dose based on average feed consumption data collected from the study

The hens were dosed daily during 28 consecutive days via capsules given orally in the mornings just prior to the feeding period. The control animal received a placebo (empty capsule) concurrently with the treated animals.

Sampling

For the purpose of this study, a “Study Day” period was defined from morning inspection, feeding and watering to sampling of eggs on the following morning. The changeover to the following study day took place after sampling of eggs.

Eggs were collected thrice before the first dosing, at least every third day during the first three weeks of dosage and twice during the last week of dosage. Egg samples for the depuration dose group E were collected once before the dosing phase and then at least twice again starting on the last week of the dosing phase again until the final slaughtering.

The eggs were collected in the evening and the following morning, if available. The eggs were shipped on the same day to the sample preparation and logistic lab (PVTL) at Bayer AG - Crop Science Division, 40789 Monheim. Upon arrival at PVTL, all eggs of each sub-group were mixed (without shell), chopped with dry-ice and stored at ≤ -18 °C until analysis.

The eggs samples collected on the overall study day 30 of dosing from the 0X (sub-group A2) and from the 16X group animals were separated into yolk and egg white.

On the day after the final dosing (less than 6 hours after the final dose), the hens were weighed, anaesthetized with an electric shock followed by immediate exsanguination by decapitation.

Liver (entire organ), muscle (approximately equal sized pieces of leg and breast, trimmed of adherent connective tissue and fat) and fat with adhering skin (overlaying skin with subcutaneous fat and abdominal fat) were taken for analysis. The tissue samples (refrigerated with dry ice) were shipped to PVTL within 24 h of sampling. Upon arrival at PVTL the tissue samples were chopped together with dry ice by means of a meat chopper and stored at ≤ -18 °C until analysis.

Twelve hens (3 from the control group and 9 from the 16XE group) entered into a 14-day depuration phase, following the administration of the final dose. Egg and tissue samples were collected on study days 35, 38, and 45 for analysis.

Analysis

Tissues and eggs samples were analysed for free residues of **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) by high performance liquid chromatography-electrospray ionization / tandem mass spectrometry (HPLC-MS/MS) using isotopically labelled internal standards. The analyses were conducted according to the method 01511 (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1.

In addition the sum of BCS-DC22055 (**M06**) and its conjugate **M37** was determined in liver, after a hydrolysis step, according to the method 01511 (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1).

The method 01511 was validated prior to sample analysis in a separate study (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1).

Concurrent recoveries were performed during sample analysis to demonstrate acceptable method performance. The Limit of Quantitation (LOQ) for **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) was 0.01 mg/kg per analyte expressed as **isoflucypram** in all the matrices. The LOQ for the sum of BCS-DC22055 (**M06**) and its conjugate **M37** in liver was 0.01 mg/kg expressed as **isoflucypram**.

II. Findings

Dose verification and storage stability

The dosing solutions for the preparation of the capsules of the different batches were analysed for **isoflucypram** in order to determine the content and homogeneity as well as the storage stability of **isoflucypram** for the duration of use in the in-life phase of the study. The dose preparation was accurate and the capsules were shown to be stable over the course of the study.

Analysis of feedstuff

No residues of **isoflucypram** were found above the LOQ (0.01 mg/kg) in the feedstuff. Concurrent recoveries were in the acceptable range of 70-110% with a Relative Standard Deviation (RSD) <20% (see Table 7.4.1-2).

In-life observations

Feed consumption, body weights, and egg production were not adversely affected by treatment with **isoflucypram**. The appearance and the behaviour of all birds were observed once daily throughout the study. Nothing special was observed. Hens were healthy during the whole study.

Analysis of eggs and tissues

The mean values of the concurrent recovery rates per compound, sample material, and spiking level were in the range of 70-110%, with relative standard deviations <20%. In few cases the recovery means were slightly above 110%, or the RSD was slightly above 20%. Nevertheless, the obtained results were considered acceptable since they meet the criteria laid down in the OECD Guidance document on pesticide residue analytical methods ENV/JM/MONO(2007)17. Details of recovery data are shown in Table 7.4.1-2 to Table 7.4.1-8.

The control samples of eggs and tissues were analysed concurrently with the treated samples. The residues of **isoflucypram** and its metabolites were below the respective LOQ of 0.01 mg/kg in all the control samples.

In the eggs samples, no free residues of **isoflucypram**, BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) were found above the LOQ of 0.01 mg/kg at any dose. Quantifiable residues above the LOQ (0.01 mg/kg) were only found for BCS-CY24813 (**M01**)

of the highest dose group 16X and 16XE. The highest residue level of BCS-CY24813 (**M01**) in eggs was 0.020 mg/kg. The plateau concentration in eggs was reached after approximately 9-11 days.

The eggs samples collected on the overall study day 30 of dosing from the 16X group animals were separated by centrifugation into egg white and yolk. Both, the yolk and the egg white samples did not contain any residues of **isoflucypram** or its metabolites above the LOQ (0.01 mg/kg).

The residues found in the egg samples are summarised in Table 7.4.1-9 and the results for egg white and yolk in Table 7.4.1-10. For the calculation of the mean residues, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.01 mg/kg as being equal to 0.01 mg/kg. This approach differs from what is reported in the study.

In the fat with adhering skin and muscle samples at all doses, free residues of **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) were found below the LOQ of 0.01 mg/kg.

In the liver samples at all doses, free residues of **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY24813 (**M01**) and BCS-DC22055 (**M06**) were found below the LOQ of 0.01 mg/kg.

Free residues of BCS-CY26497 (**M12**) and BCS-CX99799 (**M11**) reached levels of up to 0.040 mg/kg and 0.11 mg/kg, respectively, in the samples from the 16X group. Residues for the sum of BCS-DC22055 (**M06**) and its conjugate **M37** reached levels of up to 0.079 mg/kg in the samples of the16X group.

Overall residues of **isoflucypram** were not quantifiable in eggs and tissues. The free residues of BCS-CY26497 (**M12**), BCS-CY24813 (**M01**) and BCS-CX99799 (**M11**) as well as free and conjugated BCS-DC22055 (**M06**) quantified in eggs and liver were found to increase linearly with the dose level of **isoflucypram.**

After a depuration phase of 4, 7 and 14 days, all measured residues of **isoflucypram** and its metabolites had declined to below the LOQ of 0.01 mg/kg in eggs and tissues.

Detailed results on the residue levels found in tissues are summarised in Table 7.4.1-11. For the calculation of the mean residues, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.01 mg/kg as being equal to 0.01 mg/kg. This approach differs from what is reported in the study.

All the analyses were conducted within less than 30 days after sample collection and the samples that were not analysed within 24 h of sampling were stored deep frozen until analyses.

III. Conclusions

A feeding study was conducted with **isoflucypram** on poultry in order to elucidate the levels of relevant residues in poultry tissues and in eggs.

Isoflucypram was administered orally (via capsule) to laying hens for 28 consecutive days at average dose rates of 0.03 mg/kg bw/d (1X EU dose), 0.12 mg/kg bw/d (4X) and 0.48 mg/kg bw/d (16X). Feed consumption, body weights, and egg production were not adversely affected by compound administration.

Prior to sacrifice, residues in eggs were measured at various intervals. After the final dose, the animals were sacrificed and the key edible tissues were analysed for the free residues of **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) in all matrices. In addition, the sum of BCS-DC22055 (**M06**) and its conjugate **M37** was determined in liver.

Overall, free residues of **isoflucypram** parent, BCS-DC20298 (**M02**) and BCS-DC22055 (**M06**) were below the LOQ in eggs and tissues for all doses. Residues of BCS-CY26497 (**M12**), BCS-CY24813

(**M01**) and BCS-CX99799 (**M11**) as well as the sum of BCS-DC22055 (**M06**) and its conjugate **M37**, increase linearly with the dose level of **isoflucypram**. In the eggs, residues above the LOQ of 0.01 mg/kg were only found for BCS-CY24813 (**M01**) in the samples from the highest dose group of 16X (maximum 0.02 mg/kg). The plateau concentration in eggs was reached after approximately 9-11 days.

After a depuration phase of 4, 7 and 14 days, all measured residues of **isoflucypram** and its metabolites had declined to below the LOQ of 0.01 mg/kg in eggs and tissues.

The residue data provided in this study are suitable for regulatory purposes.

* overall study day

** Mean of the 3 sub-groups calculated based on the unrounded residue results. For the calculation of the mean residues, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.01 mg/kg as being equal to 0.01 mg/kg. This approach differs from what is reported in the study.

*** Mean value of 2 sub-groups

**** Value from one sub-group since only one sub-group 16XE remained alive on overall study day 45

n.a. not applicable

All metabolite residues expressed in parent compound equivalents

LOQ = 0.01 mg/kg for each compound

** All metabolite residues expressed in parent compound equivalents. Mean values are calculated based on the unrounded residue values and, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.01 mg/kg as being equal to 0.01 mg/kg. This approach differs from what is reported in the study.
LOQ = 0.01 mg/kg

B.7.4.2. **Ruminants**

Report:	KCA 6.4.2/01; [redacted] 2017
Title:	Amendment no. 1: BCS-CN88460: Feeding study with dairy cows
Report No.:	17-8001
Document No.:	M-604191-02-1
Guidelines:	OECD Test Guideline 505; OCSPP 860.1480.
Guideline deviations:	None
GLP/GEP:	Yes

I. Materials and Methods

Test system, dosing

After an acclimatisation phase of about 3 weeks, eighteen healthy dairy cows (Holstein Frisian black) were dosed orally, via gelatine capsules, for 28 consecutive days with **isoflucypram** at dose rates of. 0 mg/kg bw/day (control, 3 cows), 0.05 mg/kg bw/day (1X dose group, 3 cows), 0.15 mg/kg bw/day (3X dose group, 3 cows), 0.5 mg/kg bw/day (10 X dose group , 3 cows) and 1.5 mg/kg bw/day (30X dose group, 3 cows). An additional group 30XE (3 cows) was dosed at the rate of 1.5 mg/kg bw/day for 28 consecutive days simultaneously with the animals from dose group 30X. Thereafter, dosing was stopped and the animals were kept alive for further 4, 7 or 14 days in order to investigate the depuration of residues of **isoflucypram** in milk and tissues after the end of dosing.

The exact amounts of test item to be administered daily to each cow were calculated based on the body weights measured at the beginning of the second week of the acclimatisation period. Capsules were prepared at the test facility in Monheim. The test item was weighed into capsules, which were then closed and placed in another slightly larger capsule adapted to the size of the bolus applicator. The prepared capsules were filled in bottles and handed over to Dr. Stephan Groeger (PI of in-life phase) At the in-life test site the capsules were stored at ambient temperature in the dark. A representative number of capsules were analysed using method 01511 (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1) after preparation to verify the amount of technical **isoflucypram**. Further capsules were analysed 41 days after the final administration to determine the stability of the test item during the in-life phase.

The cows were fed with a combination of cob mix and feed concentrate for dairy cattle, which were supplemented with minerals (Cobs mixture, prepared by AGRO-COBS, batch 10350000301216 (Prepared by AGROBS GmbH, Angerbreite 27, 82541 Münsing-Degerndorf, Germany). The feed was screened for residues of **isoflucypram** with an LOQ of 0.01 mg/kg (expressed as **isoflucypram**) according to method 01475 (Uceda, L.; 2016; M-558986-01-1). The amount of feed consumed was monitored daily. The cows were allowed ad libitum access to tap water. The dose rates employed in the study are summarised in the Table below.

Table 7.4.2-1: Summary of actual isoflucypram dose administration.

Dose groups	**Number of cows**	**Dose levels**	
		per animal	**in feed**
		(mg/kg bw/day)	**(mg/kg DM) ***
Control (0X)	3	0	0
1X dose	3	0.05	1.61
3X dose	3	0.15	4.18
10X dose	3	0.5	15.54
30X dose	3	1.5	48.13
30XE dose	3	1.5	47.13

DM: dry matter

*: Actual dose based on average feed consumption data collected from the study

The cows were dosed daily during 28 consecutive days via capsules using a pill gun every evening after feeding and milking. The control animal received a placebo (an empty capsule) concurrently with the treated animals.

Sampling

Milk samples of the animals of the groups 0X, 1X, 3X, 10X, 30X and 30XE were taken twice before the 1st application, at least every third day during the first three weeks of dosage and twice during the last week of dosage.

The analytical samples per day consisted of about 1 L of the evening milk and 1 L of the morning milk. The analytical milk sample is then a mixture of both the evening and the morning milk sample, respecting the proportion of the produced milk quantity from the evening and morning. An aliquot was subjected to the residue analysis while the remainder was chopped with dry-ice and stored at ≤ - 18 °C.

The milk samples collected on the overall study day 31 of dosing from the 0X (animal H940) and from the 30X group animals were separated by centrifugation into whey (whey) and cream.

The diagnostic slaughtering of the animals took place on the day after the final application less than 24 hours after the final dose. The animals were terminated by stunning via a captive bolt gun followed immediately by exsanguination through severing the blood vessels of the neck. After termination, the animals were eviscerated and tissue samples were taken.

Kidneys, samples of liver (without gall bladder), perirenal fat, mesenteric fat, subcutaneous fat and muscle samples (right flank, right hind leg and right loin) were collected at necropsy. Tissue samples were cut in cubes of approximately 5 cm edge length. The liver was cut in cubes and a representative sample of approximately 500 g was taken thereafter. Kidneys were processed in the same way. Different muscle samples were pooled. Fat tissue samples were kept separately. All tissue samples were immediately weighed packed into plastic bags and transported to the analytical laboratory. Upon arrival at the laboratory facility the tissue samples, were chopped with dry ice. All samples were deep-frozen within 24h after sampling and stored at ≤ - 18 °C until analysis. One portion of the fat samples was sent deep-frozen to SGS Germany GmbH, Laboratory Services Hamburg, Weidenbaumsweg 137, D-21035 Hamburg to determine the actual fat content.

The three dairy cows of the 30XE group were kept alive for 4 - 14 days after the last dosing in order to investigate the depuration of residues in milk and tissues. During the depuration phase milk was collected periodically. At sacrifice samples of liver, muscle, kidney and fat (perirenal, subcutaneous and mesenteric) were taken for analysis.

Analysis

Tissues and milk samples were analysed for free residues of **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) by high performance liquid chromatography-electrospray ionization / tandem mass spectrometry (HPLC-MS/MS) using isotopically labelled internal standards. The analyses were conducted according to the method 01511 (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1).

In addition the sum of BCS-DC20298 (**M02**) and its conjugate **M20** and the sum of BCS-CY24813 (**M01**) and its conjugate **M19** were determined in liver and kidney, after a hydrolysis step, according to the method 01511 (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1).

The method 01511 was validated prior to sample analysis in a separate study (Glaubitz, J.; Kuppels, U.; Eickstaedt, D.; 2017; M-599206-01-1). Concurrent recoveries were performed during sample analysis to demonstrate acceptable method performance. The Limit of Quantitation (LOQ) for **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) was 0.01 mg/kg per analyte expressed as **isoflucypram** in all tissues and 0.005 mg/kg in milk, cream and whey. The LOQ for the sum of BCS-DC20298 (**M02**) and its conjugate **M20** in liver and kidney was 0.01 mg/kg expressed as **isoflucypram**. The LOQ for the sum of BCS-CY24813 (**M01**) and its conjugate **M19** in liver and kidney was 0.01 mg/kg expressed as **isoflucypram**.

II. Findings

Dose verification and storage stability

Upon analysis by LC-MS/MS immediately after preparation the actual concentration of **isoflucypram** in the capsules ranged between 88% and 100% of the nominal content (average of 3 capsules per dose group), demonstrating an accurate preparation.

The stability of **isoflucypram** in the capsules during storage for the time of the in-life phase was investigated by analysing capsules stored at the in-life test site under the same conditions as the capsules administered to the cows. This analysis was performed 41 days after the preparation of the capsules (4 days after the final administration). The analysed set comprised 5 capsules of the 1X group and 5 capsules of the 30X group. The actual concentration of **isoflucypram** was 104% and 100% of the nominal content in the capsules of the 1X and 30X group, respectively. Therefore, the capsules were shown to be stable over the course of the study.

Analysis of feedstuff

No residues of **isoflucypram** above the LOQ (0.01 mg/kg) were found in the feedstuff. Concurrent recoveries were in the acceptable range of 70-110% with Relative Standard Deviations RSDs <20% (see Table 7.4.2-2).

In-life observations

In general the feed consumption was higher during the dosing period compared to the predosing period. It is very unlikely that **isoflucypram** did increase feed intake. It is more likely that cows were still adapting to the feeding and husbandry system when dosing started. The data given indicate that the mean calculated energy demand was not fully met by the feed consumed. But since cows were not ketotic (no findings in repeated physical examinations), milk yields were stable, and cows did not lose body weight in the course of the study it is concluded that energy supply was met adequately.

Analysis of milk, milk products and tissues

The mean values of the concurrent recovery rates per compound, sample material, and spiking level were in the range of 70-110%, with relative standard deviations <20%. In few cases the recovery means were slightly above 110%, or the RSD was slightly above 20%. Nevertheless, the obtained results were considered acceptable according to the criteria laid down in the OECD Guidance document on pesticide residue analytical methods ENV/JM/MONO(2007)17. Details of recovery data are shown in Table 7.4.2-2 to Table 7.4.2-8.

The control samples of milk and tissues were analysed concurrently with the treated samples. The residues of **isoflucypram** and its metabolites were below the respective LOQ of 0.005 mg/kg and 0.01 mg/kg of the control milk and tissue samples.

In the milk samples, quantifiable residues above the LOQ (0.005 mg/kg) were only found for **isoflucypram** in the highest tested dose group (30X and 30XE). The highest residue level of **isoflucypram** in milk was 0.013 mg/kg. The plateau concentration in milk was reached after approximately 9 days. No residues of metabolites above the LOQ of 0.005 mg/kg were found in any dose groups.

The milk samples collected on the overall study day 30 of dosing from the 30X group animals were separated by centrifugation into skim milk (whey) and cream. The cream samples were found to contain up to 0.15 mg/kg of **isoflucypram**, 0.009 mg/kg of BCS-DC20298 (**M02**) and 0.005 mg/kg of BCS-CY24813 (**M01**) while the residues of BCS-CY26497 (**M12**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) were less than the LOQ of 0.005 mg/kg. The skim milk (whey) samples showed no residues of **isoflucypram** or its metabolites above the LOQ of 0.005 mg/kg.

The residues found in the milk samples are summarised in Table 7.4.2-10 and the results for skim milk and cream in Table 7.4.2-11. For the calculation of the mean residues, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.005 mg/kg

as being equal to 0.005 mg/kg. This approach differs from what is reported in the study.

In muscle, no residues of **isoflucypram** and its metabolites were found above the LOQ of 0.01 mg/kg at any dose.

Free residues of BCS-DC20298 (**M02**), BCS-CY24813 (**M01**) and BCS-DC22055 (**M06**) at or above the LOQ of 0.01 mg/kg were not found in any of the tissue samples of any dose group.

The residues of **isoflucypram** were found to be < 0.01 mg/kg in the tissue samples of the 0X-, and 1X-groups. Residues of **isoflucypram** above the LOQ were found in perirenal fat up to 0.087 mg/kg in the samples of the 3X, 10X, 30X and 30XE-group (H953; 5 days of depuration).

Residues of **isoflucypram** in kidney were only found in the 30X-group up to 0.011 mg/kg. Residues of **isoflucypram** in liver were only found in the 10X, 30X-group up to 0.02 mg/kg.

Residues of BCS-CY26497 (**M12**) were found to be < 0.01 mg/kg in the tissue samples of the 0X, 1X and 3X groups. Residues of BCS-CY26497 (**M12**) were found in liver up to 0.037 mg/kg only in the 30X group. Residues of BCS-CY26497 (**M12**) in kidney were found up to 0.074 mg/kg in the 10X and 30X group.

Residues of BCS-CX99799 (**M11**) were found to be < 0.01 mg/kg in the tissue samples of the 0X, 1X, 3X and 10X groups. Residues of BCS-CX99799 (**M11**) were found in liver up to 0.014 mg/kg only in the 30X-group.

Residues of BCS-CX99799 (**M11**) in kidney were found up to 0.023 mg/kg in the 30X-group.

The residues for the sum of BCS-DC20298 (**M02**) and **M20** were found to be < 0.01 mg/kg in kidney at any dose and <0.01 mg/kg in liver of the 0X, 1X and 3X groups. The sum of BCS-DC20298 (**M02**) and **M20** were found up to 0.091 mg/kg in liver in the 10X and 30X-groups.

The residues for the sum of BCS-CY24813 (**M01**) and its conjugate **M19** were found to be < 0.01 mg/kg in kidney of the 0X, 1X, 3X and 10X groups and < 0.01 mg/kg in liver of the 0X and 1X groups. Free and conjugated residues of BCS-CY24813 (**M01**) were found up to 0.15 mg/kg in liver in the 3X, 10X and 30X-groups and up to 0.016 mg/kg in kidney of the 30X-group.

Overall, residues of **isoflucypram** above the LOQ were found only in milk, fat, kidney and liver. Residues of BCS-CY26497 (**M12**) and BCS-CX99799 (**M11**) were found only in kidney and liver and free and conjugated residues of BCS-DC20298 (**M02**) and BCS-CY24813 (**M01**) were found in liver and kidney. The free residues of **isoflucypram**, BCS-CY26497 (**M12**) and BCS-CX99799 (**M11**) as well as free and conjugated residues of BCS-DC20298 (**M02**) and BCS-CY24813 (**M01**) in fat, liver and kidney were found to increase linearly with the dose level of **isoflucypram**.

After a depuration phase of 4 days, the measured residues of **isoflucypram** had declined to below the LOQ of 0.005 mg/kg in milk and 0.01 mg/kg in tissues except for **isoflucypram** in fat (0.014 mg/kg).

After a depuration phase of 7 and 14 days, all measured residues were found to be below their respective LOQ in all samples.

Detailed results on the residue levels found in tissues are summarised in Table 7.4.2-12. For the calculation of the mean residues, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.01 mg/kg as being equal to 0.01 mg/kg. This approach differs from what is reported in the study.

All the analyses were conducted within less than 30 days of sampling and the samples that were not analysed within 24 h of sampling were stored deep frozen until analyses.

III. Conclusions

A feeding study was conducted with **isoflucypram** on cows in order to elucidate the levels of relevant residues in cow tissues and in milk.

isoflucypram was administered orally (via capsule) to cows for 28 consecutive days at average dose rates of **isoflucypram** at 0.05 mg/kg bw/day test item for the dose group 1X, 0.15 mg/kg bw/day for the dose group 3X, 0.5 mg/kg bw/day for the dose group 10X and 1.5 mg/kg bw/day for the dose groups 30X and 30XE. Feed consumption, body weights, and milk production were not adversely affected by compound administration.

Prior to sacrifice, residues in milk were measured at various intervals. After the final dose, the animals were sacrificed and the key edible tissues were analysed for the free residues of **isoflucypram** and its metabolites BCS-DC20298 (**M02**), BCS-CY26497 (**M12**), BCS-CY24813 (**M01**), BCS-DC22055 (**M06**) and BCS-CX99799 (**M11**) in all matrices. In addition the sum of BCS-DC20298 (**M02**) and its conjugate **M20** and the sum of BCS-CY24813 (**M01**) and its conjugate **M19** were determined in liver and kidney.

Overall, residues of **isoflucypram** above the LOQ were found only in milk, fat, kidney and liver. Residues of BCS-CY26497 (**M12**) and BCS-CX99799 (**M11**) were found only in kidney and liver and free and conjugated residues of BCS-DC20298 (**M02**) and BCS-CY24813 (**M01**) were found in liver and kidney. The free residues of **isoflucypram**, BCS-CY26497 (**M12**) and BCS-CX99799 (**M11**) as well as free and conjugated residues of BCS-DC20298 (**M02**) and BCS-CY24813 (**M01**) in fat, liver and kidney were found to increase linearly with the dose level of **isoflucypram**.

Residues of **isoflucypram** were found in milk samples only in the 30X and 30XE groups up to 0.013 mg/kg, in cream samples up to 0.15 mg/kg in the 30X-group. The plateau concentration in milk was reached after approximately 9 days.

After a depuration phase of 4 days, the measured residues of **isoflucypram** had declined to below the LOQ of 0.005 mg/kg in milk and 0.01 mg/kg in tissues except for **isoflucypram** in fat (0.014 mg/kg).

After a depuration phase of 7 and 14 days, all measured residues were found to be below their respective LOQ in all samples.

The residue data provided in this study are suitable for regulatory purposes.

Table 7.4.2-2: Concurrent recovery data for isoflucypram in feedstuff and cattle matrices

Crop / Sample material	FL (mg/kg)	Single values (%)	Mean value (%)	RSD (%)	LOQ (mg/kg)

FL = Fortification level, RSD = Relative standard deviation, LOQ = Practical limit of quantification
Fortified with BCS-DC20298 (**M02**), determined as BCS-DC20298 (**M02**) and calculated as **isoflucypram**

These recoveries were performed during the conduct of the study 17-8001.

* These recoveries are considered acceptable, because they were not identified as outliers by a Grubbs outlier test with a level of significance of 95%.

** This average recovery is considered acceptable, because it is only slightly exceeding the range and because it is considered acceptable according to OECD guideline ENV/JM/MONO(2007)17

*** This average recovery is considered acceptable, because there were found no residues of BCS-DC20298 in this sample material.

**** This RSD is considered acceptable, because it is only slightly exceeding the range of 20% and because this value is considered acceptable according to OECD guideline ENV/JM/MONO(2007)17 at this fortification level.

cattle / liver	0.01	89; 96; 99; 104	97	6.5	0.01
	0.25	104; 104; 106; 112	107	3.6	
		Overall recovery (n = 8)	**102**	**6.9**	

FL = Fortification level, RSD = Relative standard deviation, LOQ = Practical limit of quantification
Fortified with BCS-CX99799 (**M11**), determined as BCS-CX99799 (**M11**) and calculated as **isoflucypram**
These recoveries were performed during the conduct of the study 17-8001
* These average recoveries are considered acceptable, because there were found no residues of BCS-CX99799 (**M11**) in the sample material cream
** These recoveries are considered acceptable, because they were not identified as outliers by a Grubbs outlier test with a level of significance of 95%.

Table 7.4.2-8: Concurrent recovery data for free and conjugated BCS-DC20298 (M02)

Sample material	FL (mg/kg)	Single values (%)	Mean value (%)	RSD (%)	LOQ (mg/kg)
cattle / kidney	0.01	85; 105; 111; 117	105	13.3	0.01
	0.25	106; 111; 105; 106	107	2.5	
		Overall recovery (n = 8)	**106**	**8.9**	
cattle / liver	0.01	114; 81; 74; 111	95	21.5*	0.01
	0.20	98; 105; 104; 102	102	3.0	
		Overall recovery (n = 8)	**99**	**14.3**	

FL = Fortification level, RSD = Relative standard deviation, LOQ = Practical limit of quantification
Fortified with BCS-DC20298 (**M02**), determined as free and conjugated BCS-DC20298 (**M02**) and calculated as **isoflucypram**
These recoveries were performed during the conduct of the study 17-8001

* This RSD value is considered acceptable, because it is only slightly exceeding the range and because it is considered acceptable according to OECD guideline ENV/JM/MONO(2007)17.

Table 7.4.2-9: Concurrent recovery data for free and conjugated BCS-CY24813 (M01)

Sample material	FL (mg/kg)	Single values (%)	Mean value (%)	RSD (%)	LOQ (mg/kg)
cattle / kidney	0.01	96; 106; 83; 94	95	10.0	0.01
	0.25	98; 112; 90; 103	101	9.1	
		Overall recovery (n = 8)	**98**	**9.4**	
cattle / liver	0.01	94; 95; 96; 110	99	7.6	0.01
	0.25	96; 98; 109; 110	103	7.0	
		Overall recovery (n = 8)	**101**	**7.2**	

FL = Fortification level, RSD = Relative standard deviation, LOQ = Practical limit of quantification
Fortified with BCS-CY24813 (**M01**), determined as free and conjugated BCS-CY24813 (**M01**) and calculated as **isoflucypram**
These recoveries were performed during the conduct of the study 17-8001.

[a] – mean value of three animals calculated based on unrounded residue results. For the calculation of the mean residues, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.005 mg/kg as being equal to 0.005 mg/kg. This approach differs from what is reported in the study.

* overall study day

*** mean value of 2 individual residue results (animal H954 & H955)

**** Since only one cattle of dose group 30XE remained alive on overall study day 45 (H955), no mean values were calculated.

n.a. not applicable

All metabolite residues expressed in parent compound equivalents

LOQ = 0.005 mg/kg

** All metabolite residues expressed in parent compound equivalents. Mean values are calculated based on the unrounded residue values and, in case one or two individual values are >LOQ and the others < LOQ, it was deemed appropriate to consider residues <0.01 mg/kg as being equal to 0.01 mg/kg. This approach differs from what is reported in the study.
LOQ = 0.01 mg/kg

B.7.4.3. **Pigs**

The maximum dietary burden for pigs remains <0.004 mg/kg bw/day. Besides, the metabolic pathways do not differ significantly in the rat as compared to ruminants. Therefore, a feeding study in pigs is not required.

B.7.4.4. **Fish**

No residue study in fish was conducted. Currently, no test method or Guidance document is available for conducting such study. In these cases, waiving of this particular data requirement is considered acceptable according to the "Guidance document for applicants on preparing dossiers for the approval of a chemical new active substance and the renewal of approval of the chemical active substance according to Regulation (EU) No. 283/2013 and Regulation (EU) No. 284/2013" (SANCO/10181/2013-rev.2 of 2-May-2013).

B.7.5. EFFECTS OF PROCESSING

B.7.5.1. Nature of the residue

Report:	KCA 6.5.1/01; Heinemann, D.; Doebbe, A.; 2017
Title:	Nature of the residues of [pyrazole-4-14C]BCS-CN88460 and [phenyl-UL-14C]BCS-CN88460 in processed commodities - High temperature hydrolysis
Report No.:	EnSa-16-0135
Document No.:	M-594825-01-1
Guidelines:	OECD Test Guideline 507; Commission Regulation (EU) No 283/2013 of 1 March 2013;
Guideline deviations:	None
GLP/GEP:	Yes

Executive Summary

The hydrolytic degradation behaviour of [pyrazole-4-^{14}C]BCS-CN88460 and [phenyl-UL-^{14}C]BCS-CN88460 under conditions representative for food processing operations was investigated. The following conditions were tested:

Pasteurisation:	90 °C at pH 4 for 20 min
Baking, brewing, boiling:	100 °C at pH 5 for 60 min
Sterilisation:	120 °C at pH 6 for 20 min

BCS-CN88460 (**isoflucypram**) was predominantly stable under all tested conditions. The identification rates were very high and in the range of 98.0% to 99.1%. Degradation products detected under the tested conditions representatively for food processing were very minor (≤ 0.5% and ≤ 0.005 mg/L) and were not further investigated.

All material balances were in the range of 104.2 to 110.5% demonstrating that no volatile degradation products were formed.

I. Materials and Methods

A. Materials

Table 7.5.1-1: List of test materials

Chemical structure		Radiolabel position	[pyrazole-4-^{14}C]	[phenyl-UL-^{14}C]
Radiochemical purity	99% (HPLC), >99% (TLC)	>98% (HPLC), >98% (TLC)
Chemical purity (%)	> 99% (HPLC)	> 99% (HPLC)
Specific activity	3.90 MBq/mg 234,000,000 dpm/mg	4.13 MBq/mg 247,800,000 dpm/mg

B. Study Design

Preparation of radiolabelled Stock and Test Solutions:

The [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C] labelled test compound was each dissolved in acetonitrile. An aliquot of each solution was filled up to 10 mL with acetonitrile. An aliquot of the diluted solution (4 mL) was again further diluted with 6 mL acetonitrile yielding the respective stock solutions.

The targeted application rate in this study was approximately 1 mg test compound/L buffer solution. Therefore, both pyrazole- and phenyl-labelled test compounds were prepared as stock solution dissolved in acetonitrile and aliquots thereof containing the respective amount of test compound for the target concentration were added to buffer solution to create final test solutions with acetonitrile content < 1%.

After preparation of each final test solution, aliquots were taken for LS and HPLC analyses and the remaining aliquot (7 mL) of the test solution in the test vial was exposed to the respective processing condition.

Experimental conditions:

Based on different processing operations, tests for each test compound were carried out with sterilised, citrate buffered drinking water at three different pH levels and three different temperatures: pH 4 / 90 °C, pH 5 / 100 °C and pH 6 / 120 °C. The treatment duration was 20 min, 60 min and 20 min for the three scenarios, respectively. The tests at 90 °C and 100 °C were carried out using a Reacti Therm heating/stirring module. The tests at 120 °C were performed in an autoclave. The intended test periods listed in the table above do not include the time until reaching the test temperature or the ambient temperature after test termination. The temperature was recorded in a separate vial filled with 7 mL buffer.

The vials of the test solutions were closed with a septum and crimp top and placed in a dry block heater or an autoclave. The vials were weighed before and after hydrolysis to correct for possible losses by evaporation of water.

Sampling:

After termination of the test, the test samples were cooled to room temperature as rapidly as possible and the pH values of the samples were measured at room temperature. The samples were transferred to a measuring cylinder and the test vials were washed with a defined amount of acetonitrile to release any possible remaining radioactivity in the test vial. The wash solution was then added to the samples and the solution was sonicated.

C. Analytical Procedures

The radioactivity content of each vessel was determined by LSC (three aliquots of each test solution before and after the test). For HPLC profiling of the test solutions at test termination, a further aliquot of each test solution was mixed with a defined amount of emulgator to facilitate HPLC sample preparation and minimization of surface adhesion. The mixtures were sonicated and concentrated using a rotary evaporator. Defined amount of water was added and the mixture was sonicated for homogenisation. The volume was determined, aliquots were again taken for the determination of the radioactivity content by LS measurement to check for possible losses during HPLC sample preparation and aliquots were taken for HPLC profiling of the test solution at test time after hydrolysis. Recoveries for HPLC sample preparations determined for all test solutions ranged from 99.0% to 103.2% confirming that no radioactivity was lost during HPLC sample preparation.

Aliquots of all samples were analysed and quantified by HPLC with radio detection by reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

Parent compound was identified in both pyrazole- and phenyl-labelled test solution pH 5 after processing by LC-MS and LC-MS/MS analysis and by HPLC co-chromatography with the non-radiolabelled reference compound. Furthermore, the assignment and identification of parent compound was achieved by comparison of HPLC metabolite profiles of the sample extracts of the current study with each other.

II. Results and Discussion

Material Balance

For each test, the concentration of the test compound was calculated from the radioactivity concentrations determined in the test solutions before and after incubation and a material balance was established for all tests. The amount of acetonitrile in the test solutions accounted for 0.7% for the tests with the pyrazole-label and 0.9% for the tests with the phenyl-label.

Based on the results of the LSC measurements of the test solutions after hydrolysis, the concentration of the test compound applied was ≥ 0.970 mg/L for both the tests with the pyrazole-labelled test compound and for the phenyl-labelled test compound. All material balances were in the range of 104.2% to 110.5% demonstrating that no radioactivity dissipated from the test systems. Detailed results for measured radioactivity balances are provided below:

Table 7.5.1-2: Material Balance of Radioactivity in all Samples

Test item	Processing medium	Measurement pre-processing	Measurement post-processing	Recovery (%)
		mg/L		
[pyrazole-4-^{14}C] BCS-CN88460	pH 4	0.894	0.970	108.6
	pH 5	0.933	0.972	104.2
	pH 6	0.922	0.981	106.4
[phenyl-UL-^{14}C] BCS-CN88460	pH 4	0.930	1.027	110.5
	pH 5	0.928	0.987	106.3
	pH 6	0.928	0.972	104.8

The concentration in the test solutions at test termination were calculated using the following formula:

$$\text{Concentration after hydrolysis [mg/L]} = \frac{\text{Total dpm}_{\text{sample after hydrolysis}}}{\text{SA} * \text{Total Volume}_{\text{sample before hydrolysis}}} * 1000$$

Aliquots of all test solutions were analysed by HPLC before and after hydrolysis. HPLC profiling of the test solutions of both labels showed that **isoflucypram** was stable under the tested conditions representative of food processing.

For all tests, almost complete recovery of the parent compound was observed (≥ 98.0%). Degradation products detected under the tested conditions were very minor (≤0.5% and ≤0.005 mg/L) and hence were not further investigated (see Tables below).

Identification rates of parent compound were very high and in the range of 98.0% to 99.1% of the radioactivity in the test solutions.

Table 7.5.1-3: Radioactive residues of isoflucypram and hydrolysis products in the [pyrazole-4-^{14}C]BCS-CN88460 test solution under different processing conditions

III. Conclusions

Isoflucypram was predominantly stable under all tested conditions. The identification rates were very high. Degradation products detected under the tested conditions very minor (≤ 0.5% and ≤ 0.005 mg/L) and were not further investigated.

All material balances were in the range of 104.2 to 110.5% demonstrating that no volatile degradation products were formed.

B.7.5.2. Distribution of the residue in peel and pulp

The distribution of residues of **isoflucypram** between peel and pulp is not relevant for the proposed representative uses.

B.7.5.3. Magnitude of residues in processed commodities

According to the data requirements of the EU Regulation (EC) No 1107/2009, studies investigating the magnitude of residues in processed commodities of cereals are not required because:

- The residues in cereal grains are < 0.1 mg/kg (maximum 0.042 mg/kg for wheat grain)
- The contribution of cereal grain to the theoretical maximum daily intake (TMDI) is ≤ 10% of the ADI (actually maximum of 0.7% for wheat grain using the proposed MRL of 0.05 mg/kg) and the estimated daily intake is ≤ 10% of the ARfD (actually maximum of 0.06% for wheat grain using the proposed MRL of 0.05 mg/kg) for any EU consumer group diet.

Nevertheless representative processing studies on barley and wheat were conducted with field samples collected from supervised residue trials conducted in Europe or Northern America and are summarised below.

Barley

Report:	KCA 6.5.3/01; Freitag, T.; Hoffmeister, R.; 2017
Title:	Determination of the residues of BCS-CN88460 in/on barley and the processed fractions (malt sprouts; brewer's malt; brewer's grain; hops draff; brewer's yeast; beer; pearl barley rub off and pearl barley) after spray application of BCS-CN88460 EC 050 in the field in the Netherlands and Spain
Report No.:	15-3407
Document No.:	M-579494-01-1
Guidelines:	OECD Test Guideline 509; OECD Test Guideline 508; Commission Regulation (EU) No 283/2013 of 1 March 2013; OECD ENV/JM/MONO(2008)23; US EPA OCSPP 860.1500; US EPA OCSPP 860.1520.
Guideline deviations:	None
GLP/GEP:	Yes

I. Materials and Methods

The study included two supervised residue trials with barley, conducted in the field in southern Europe (Spain) and northern Europe (the Netherlands) in the 2015 season in order to determine the magnitude of the residues of **isoflucypram** in/on barley grain and their processed fractions for the processing of beer (malt sprouts, brewer's malt, brewer's grain, hops draff, brewer's yeast and beer) and pearl barley (pearl barley rub off and pearl barley).

Field part

In the field trials **BCS-CN88460 EC 050** was sprayed once at a nominal growth stage of BBCH 61 and at a nominal rate of 7.5L /ha, corresponding to 375 g a.s./ha. The water rate was of 300-400 L/ha, reflecting local practice in the trial regions. The application was performed with an exaggerated dose rate (5X) to attempt to generate a commodity with quantifiable residues. All treatments were made at the scheduled rates. In the trial 15-3407-02, the application was done at growth stage BBCH 53 instead of BBCH 61. Nevertheless this deviation was considered acceptable since the timing between application and harvest is not expected to be significantly impacted.

Barley grain samples were sampled at BBCH 89, 61 and 58 days after the last treatment (DALT) in trials 15-3407-01 and 15-3407-02, respectively.

Barley grain samples for the processing of grain into beer consisted of at least 25 kg and samples intended for the processing of barley grain into pearl barley consisted of at least 5 kg sample material. The specimens for processing were sent after sampling to the processing test site at BioChem agrar GmbH (Kupferstraße 6, 04827 Gerichshain, Germany) under ambient conditions.

Furthermore, barley grain samples of at least 1 kg were taken (sampling called “barley grain”) to determine the residues at harvest. They were stored deep-frozen within 24 hours after sampling, until dispatch to the Laboratory for Sampling, Preparation Technique and Sample Logistics (PVTL), Bayer AG - Crop Science Division, formerly Bayer CropScience AG, in 40789 Monheim am Rhein, Germany.

Finally, barley grain samples were taken in the field (samplings called “grain, stored” and also referenced as Raw Agricultural Commodity (RAC)) at the same time as the samples for processing, stored and shipped under the same conditions (ambient temperature) as the samples for processing and deep frozen at ≤ 18 °C at the very time when the processing started.

Processing procedures

The cleaning of barley grain samples took place at the processing test site at BioChem agrar GmbH, Labor fuer biologische und chemische Analytik, Kupferstraße 6, 04827 Gerichshain, Germany. The malting process for the production of beer was performed under the responsibility of BioChem agrar GmbH at Versuchs- und Lehranstalt fuer Brauerei in Berlin (VLB) e.V., Seestrasse 13, 13353 Berlin, Germany and the subsequent brewing process was conducted by Fermtec GmbH, Köpenicker Str. 325, 12555 Berlin, Germany. The processing to pearl barley took place at Technische Universität Berlin, Seestrasse 13, 13353 Berlin, Germany under the responsibility of BioChem agrar GmbH.

The processing simulates industrial practice at a laboratory scale. The processing of spring barley grain into the processed fractions (malt sprouts; brewer's malt; brewer's grain; hops draff; brewer's yeast; beer; pearl barley rub off and pearl barley) was performed simulating the common industrial processes.

Cleaning:

All field specimens for processing were cleaned which allows the separation of soil particles and other contaminations from the grain in a steady air flow.

Before processing, the corresponding fresh grain samples were deep-frozen, identified as **grain, stored (RAC)** samples and stored deep frozen at <-18ºC until analysis.

Malting (for the production of beer):

Sieving

Before malting was started, the cleaned grain samples were sieved (sieve mesh 2.5 mm). Field samples for processing into beer were then shipped by car at ambient temperature to Versuchs- und Lehranstalt fuer Brauerei e.v. (VLB, Berlin, Germany).

Steeping

The steeping process was conducted as a combined wet and dry steeping. Sieved barley grain was transferred in a special steeping vessel. During steeping water is supplied to the interior of the kernel. As a result the enzymes become active and germination begins. Water uptake depends on the steeping time, steeping temperature, kernel size, barley variety and harvest year.

Germination

The processes during germination can be divided into growth processes, enzyme formation and metabolic changes. Towards the end of steeping the rootlets break through the base of the corn and become visible. Activation of enzymes and formation of new enzymes are essential processes during germination (starch degrading enzymes, cytolytic enzymes, protein degrading enzymes and phosphoric acid splitting enzymes). For proper performance of germination it is necessary to control the duration of germination, the mean temperature of wet air and the relative humidity of the air around the kernels. During the intensive respiration the steeped good was turned over continuously.

Kiln-drying

After germination, the life processes are terminated by kilning. During kilning the water content of green malt is lowered down to < 10%, germination and modification are stopped; colour and flavour compounds are formed. The malt becomes stable and storable. Kiln-drying was conducted in a dry chamber. After kiln-drying the germs (= malt sprouts) were removed mechanically by a trimmer. **Brewer's malt** and **malt sprouts** were sampled immediately after end of malting and were transported to BioChem agrar GmbH. Until brewing the malt was stored at room temperature at BioChem agrar GmbH.

Brewing (processing of malt to beer):

The brewer's malt specimens for brewing processing were shipped by car at ambient temperature to the processing location at fermtec GmbH (Berlin, Germany).

Mashing

Mashing is the homogeneous mixing of ground malt and water according to a definite temperature time regime (mash program). The main purpose of mashing (the dissolution and enzymatic conversion of ingredients) is to form as much extract and as good an extract as possible. Before mashing, the brewer's malt was dry milled in a special malt mill. The crushed malt was mixed with brew water. To produce "Pilsener beer", mashing was conducted in a heatable tun where the mash was heated up to 76 °C.

Lautering: Wort extraction and separation

After mashing, the wort was separated from the insoluble malt components (brewer's grain). The extract remaining in the brewer's grain was extracted by washing with hot water (first filter runnings). The wort separation was done using a refining vat. After separation, the **brewer's grain** was sampled and immediately deep-frozen.

Wort boiling and conditioning

After addition of hop pellets, the separated wort was boiled (about 90 min at normal pressure). This process deactivates the malt enzymes, sterilises the wort, extracts and isomerises the essential components of the hops, precipitates high molecular proteins (called "Bruch") and expels unwanted aromatic substances.

After boiling, the flocs (hops draff) were separated in a whirlpool causing the sludge to deposit on the bottom in the shape of a cone. For cooling and ventilating the wort, an intra-plant circulation was used. By adding oxygen (intra-plant circulation) the conditions for the start of the fermentation were prepared. **Hops draff** was sampled and immediately deep frozen.

Fermentation and maturation

The pure culture yeast ferments sugar of the wort to alcohol and CO_2, but in the course of the yeast metabolism also unwanted by-products are formed (diacetyl, higher alcohols and others). In the pilot plant the classical primary fermentation (low fermentation) was carried out in bottom fermentation containers. The fermentation temperature was 9 °C. Fermentation heat was dissipated by means of room ventilation.

The duration of main fermentation depends on temperature, on starting extract concentration of the finished wort, on the ratio of non-fermentable sugars to the extract, on the final attenuation and on the yeast cell number. As soon as the extract content of the fermented young beer was 2% higher than the final attenuation, the storing time began. Before maturation the young beer was cooled down.

During the main fermentation the yeast deposits on the tank bottom and was sampled as **brewer's yeast** and immediately deep-frozen.

At the beginning of maturation the young beer was stored at room temperature (warm maturation to break down the diacetyl) in casks. Then the young beer was stored under pressure (approximately 0.7 – 2.1 bar) at 2 °C (cold maturation) for approximately 4 weeks.

In this time the remaining extract was fermented. Unwanted flavour and odorous substances were decomposed or expelled. Sludge particles and yeast settled at the bottom.

The rack beer was filtered using a special filter combination. During filtration all organisms harming the beer (bacteria and yeast) were removed and sludge particles were separated.

The final product **beer** was sampled and immediately deep-frozen.

The processed products (brewer's grain, hops draff, brewer´s yeast and beer) were kept in frozen stage (at or below -18 °C within 24 h after end of sampling) and shipped under deep-frozen conditions from fermtec GmbH to BioChem agrar GmbH and stored deep-frozen at <-18 °C until analysis.

Pearl barley production:

The processing part for the preparation of pearl barley was conducted at TU Berlin; Seestrasse 13, D-13353 Berlin. The specimens of cleaned barley grain, for processing into pearl barley, were shipped by car at ambient temperature from BioChem agrar GmbH to the processing location TU Berlin.

Conditioning

Before beginning of pearl barley production, an optimal moisture content of barley grain of approximately 14% was achieved. In order to obtain acceptable milling results a moisture content of up to 16% was possible. Therefore the grain was not dried or damped because the optimal moisture content was already achieved.

Hulling

The corresponding samples were hulled using a vertical hulling machine. Each sample was hulled until the stipulated abrasion for pearl barley (30 - 35%) was reached. The degree of abrasion (pearling dust/bran and flour) was determined by the proportion of pearl barley with respect to the total portion of cleaned grain used for hulling process. **Pearl barley** and **pearl barley rub off** were sampled.

The processed products (pearl barley, pearl barley rub off) were shipped at ambient temperature to BioChem agrar GmbH and stored deep frozen at <-18 °C until analysis.

The processes are illustrated in Figure 7.5.3-1 to Figure 7.5.3-3.

During processing of barley grain, laboratory samples of the various processing fractions taken at specific processing steps were immediately deep frozen and stored deep frozen at the processing test site until dispatch to PVTL. Upon reception at PVTL, samples of grain and processed commodities were stored in a freezer at -18 °C or below until preparation of the examination samples. For the preparation of examination samples, the samples of grain and processed commodities were shredded and homogenised with dry ice in a cutter and stored at -18 °C or below until analysis.

Residue analysis

The samples were analysed for the parent compound using analytical method 01475 (Uceda, L.; 2016; M-558986-01-1) which was validated prior to the residue analysis of the samples. Additional validation recoveries were conducted for barley (grain) and barley (beer and brewer's yeast) in the studies 15-2066 and 15-3407, respectively. The samples of barley (grain), barley (brewer's grain), barley (brewer's malt), barley (brewer's yeast), barley (grain stored), barley (hops draff), barley (malt sprouts), barley (pearl) and barley (pearl rub off) were analysed according to the procedure described in the method for dry matrices (with a soaking step with water before extraction) and the barley (beer) samples were prepared according to the procedure for higher-water containing commodities (no soaking step before extraction). The LOQ was 0.01 mg/kg for **isoflucypram** in all sample materials.

Figure 7.5.3-1: Industrial processing of grain to malt

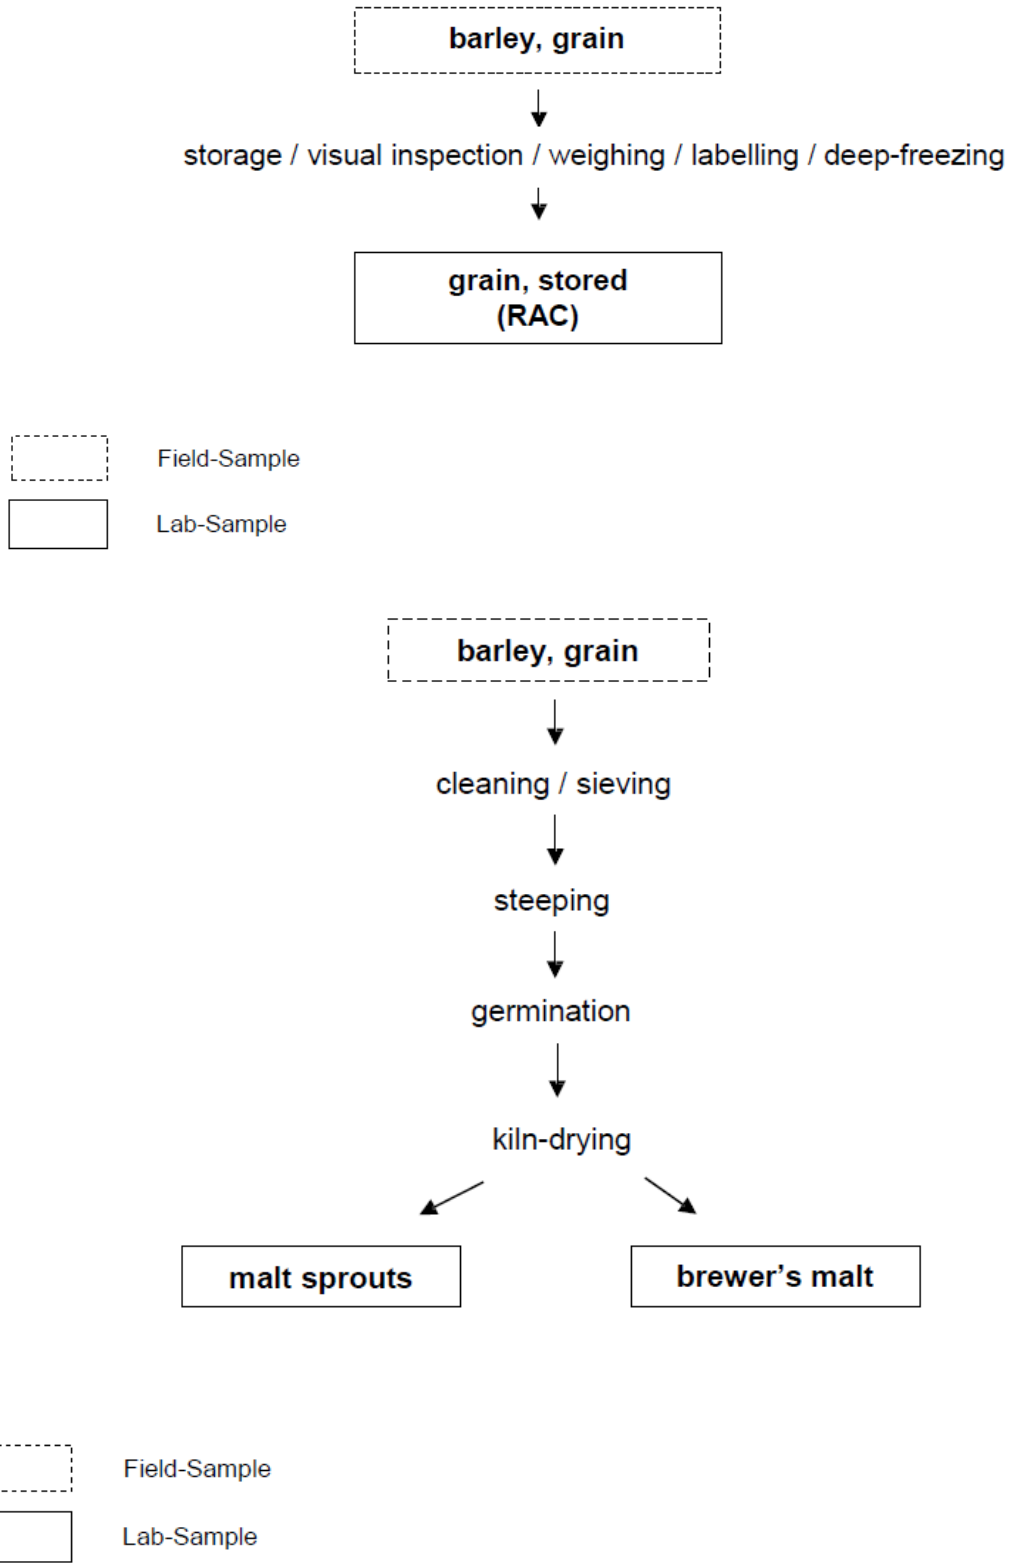

Figure 7.5.3-2: Industrial processing of malt to beer

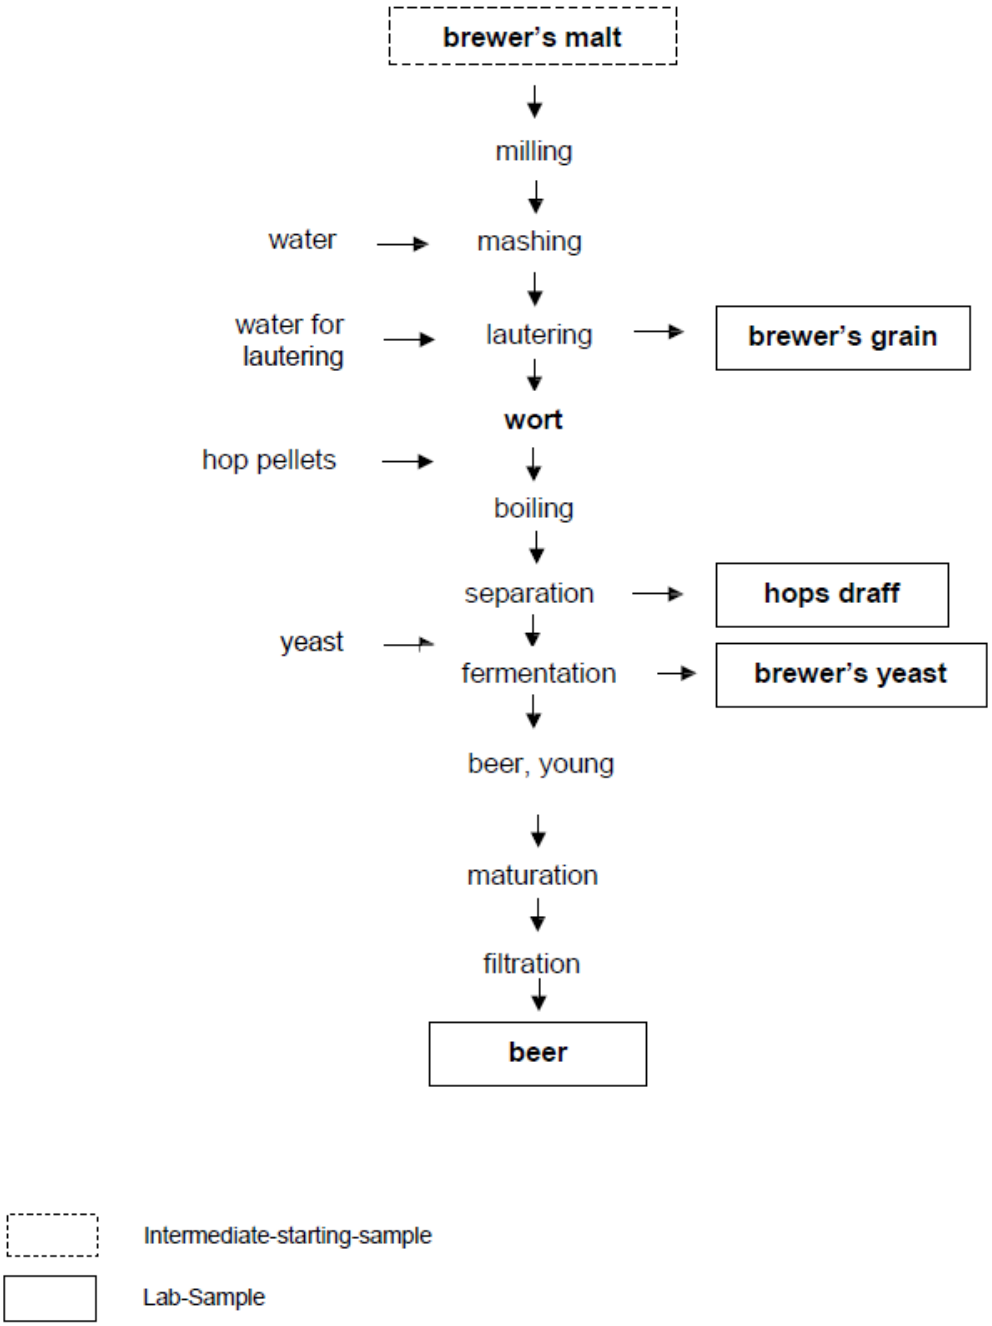

Figure 7.5.3-3: Industrial processing of spring barley to pearl barley

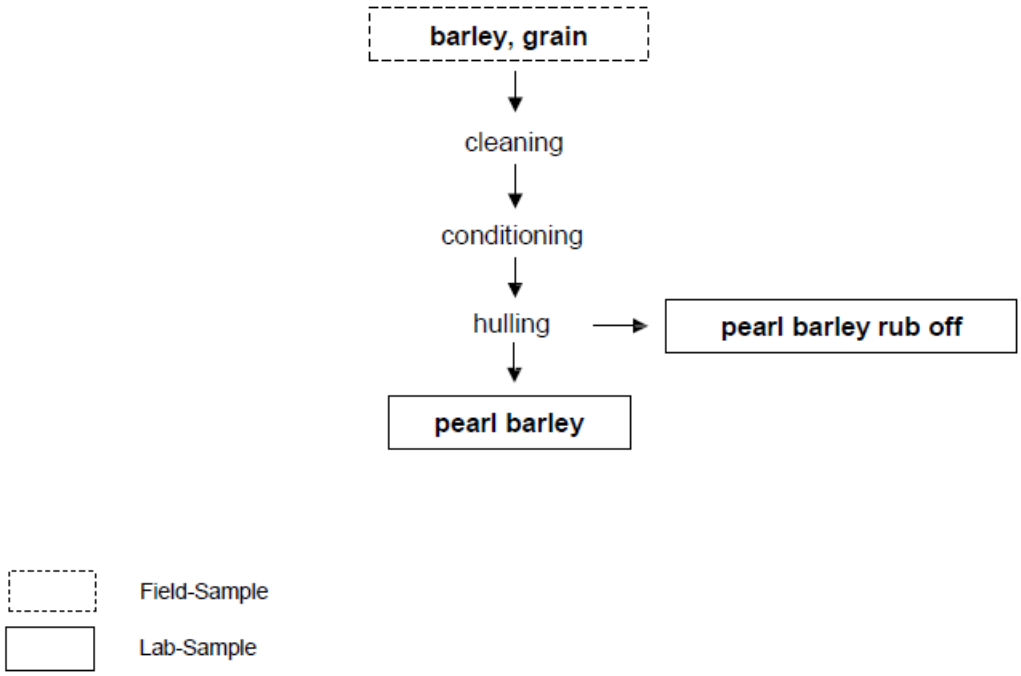

II. Findings

In order to check the performance of the method, recovery determinations were included in each set of analyses (at least one recovery for ten study samples). All the recovery determinations were performed concurrently to the analyses of control and treated samples from the study.

The sample materials barley brewer's grain, brewer's malt, grain stored, malt sprouts, barley pearl and barley pearl rub off are considered equivalents to barley grain sample and the sample material barley hops draff is considered equivalent to sample barley brewer's yeast.

Details on concurrent recovery data are shown in Table 7.5.3-1. The average recoveries were within the acceptable range of 70 – 110%. The RSD values were below 20%.

The levels of residues of **isoflucypram** in the treated samples are summarised in Table 7.5.3-2. No residues above the LOQ were found in the control samples. The results were not corrected for concurrent recoveries.

Residues of **isoflucypram** in barley grain at harvest were found at 0.012 mg/kg in the first trial (the Netherlands) but < 0.01 mg/kg in the second trial (Spain).

The mean residues levels in the stored, barley grain (RAC for the calculation of the processing factors) were 0.015 mg/kg and < 0.01 mg/kg in the first trial (the Netherlands) and second trial (Spain), respectively.

The levels of residue of **isoflucypram** were < 0.01 mg/kg in all processed fractions except pearl barley rub off (0.032 mg/kg in the Dutch trial and 0.017 mg/kg in the Spanish trial).

The processing factors were calculated based on the residue levels in the treated processed fractions and the mean residue level of the rounded individual residues of the two RAC specimens for the corresponding processing procedure ("grain stored").When residues in the RAC and in the processed fractions were both <0.01 mg/kg a processing factor could not be calculated. The proposed processing factors are summarised below in Table 7.5.3-3.

The analyses were done after a maximum frozen storage period of 396 days (grain) and 397 days (processed commodities). The time between the beginning of the sample preparation and the sample analysis did not exceed 24 hours.

III. Conclusions

Two residue trials were conducted in northern and southern Europe in 2015. Barley was treated at a growth stage of BBCH 61 (53 in one trial) with an exaggerated dose rate (5X; 375 g a.s./ha) to attempt to generate a commodity with quantifiable residues. All applications were at the required rates.

Barley grain was processed in order to obtain beer and pearl barley. The samples (RAC and processed fractions) were analysed for the residues of **isoflucypram** parent compound.

The study was conducted according to GLP.

The results of the study clearly indicate that residues of **isoflucypram** are diluted by the brewing processing.

When barley grain are processed into pearl barley, residues of **isoflucypram** remain to a large extent in pearl barley rub-off and can be removed from barley grain by hulling, resulting in lower residues in the end product, pearl barley.

Table 7.5.3-1: Concurrent recovery data for isoflucypram in barley and barley matrices

Study	Portion analysed	n	Fortification level (mg/kg)	Recovery (%)				
				Individual recoveries	Min	Max	Mean	RSD

(a): Processing factors (PF) = residues in processed commodities / residues (mean) in the RAC collected at the processing lab ("grain stored")

n.c .: No processing factor can be calculated (residues <LOQ in RAC and in processed commodity)

< value: in case the mean residue level in the RAC is ≥ LOQ but residues in the processed commodity are < LOQ, the processing factor is calculated as to be below the worst case value calculated with the LOQ of the processed commodity

> value: in case the mean residue level in the RAC is < LOQ but residues in the processed commodity are ≥ LOQ, the processing factor is calculated as to be above the value calculated with the LOQ of the RAC

Wheat

Report:	KCA 6.5.3/02; Harbin, A. M.; 2017
Title:	BCS-CN88460: Magnitude of residues in/on wheat processed fractions following treatment with BCS-CN88460 EC50
Report No.:	RALNN137
Document No.:	M-600505-02-1
Guidelines:	OECD Test Guideline 509; PMRA DACO 7.4.1; PMRA DACO 7.4.5.
Guideline deviations:	None
GLP/GEP:	Yes

I. Materials and Methods

The study included two supervised residue trials with wheat, conducted in the field in Canada in the 2015 season in order to measure the potential concentration of BCS-CN88460 (**isoflucypram**) residues in the wheat processed products of grain, aspirated grain, middlings, germ, flour, shorts, bran, wheat white bread, whole meal flour, whole meal, bread, gluten, starch, fresh pasta, cooked pasta, cooking water, dry pasta, dried and cooked pasta.

Field part

In these two trials (C1101-15PA and C1102-15PA) one untreated control plot (UTC) was used for the generation of the control samples (untreated samples).

The study design included two treated plots for each trial. The application rate in the TRTD1 plot was made at 3X the maximum seasonal label use rate. The application rate in the TRTD2 plot was made at 5X the maximum seasonal label use rate. Only the treated wheat from the TRTD2 plot was harvested, the TRTD1 plot was not used, and no further data were reported from this plot.

In each field trial, the treated plot TRTD2 was sprayed once at BBCH 69 (end of flowering) with **BCS-CN88460 EC50** at an application rate of 375 g a.s./ha using a spray volume of 120-122 L/ha. The applications were made using ground-based equipment with no adjuvant. The application was performed with an exaggerated dose rate (5X) to attempt to generate a commodity with quantifiable residues.

A single composite sample of wheat grain was harvested from the TRTD2 treated plots at commercial maturity (pre-harvest intervals (PHIs) were 69 and 67 days for C1101-15PA and C1102-15PA respectively). A single composite sample of wheat grain was harvested from the control plot on the same day the sample was harvested from the treated plot.

One control and one treated bulk wheat grain sample weighing at least 300 kg were harvested at maturity following commercial agronomic practices (threshed using a plot combine). The bulk wheat grain samples were placed into labelled (study number and sample number) containers and placed in cool (ambient) storage until shipment, via ambient transport, to the processing facility. Upon receipt at the processing facility, the samples were transferred to frozen storage, and remained frozen until processing (maximum bulk sample ambient temperature interval was 33 days).

Triplicate samples of wheat grain, weighing a minimum of 1 kg, were collected from the UTC and TRTD2 plots at the same time the bulk wheat grain samples were harvested (samples called “grain collected at the field site”). These samples were frozen within four hours after collection, and shipped frozen, via ACDS freezer truck, directly to the laboratory. Upon arrival at Bayer CropScience RTP, all samples, were immediately transferred to frozen storage (average temperature -21 °C).

Processing procedures

Processing took place at the processing site at GLP Technologies, 22723 State Highway 6 South Navasota, TX 77868 USA.

Samples were handled and processed in a manner that minimizes the possibility of contamination. Trials were processed independently. Control samples were processed prior to treated samples.

After removing bulk wheat grain samples for aspirated grain fraction generation and processing from freezer storage, representative unprocessed wheat (RAC) samples were collected in triplicate and placed into frozen storage (samples called "grain" or "grain collected at the processing site" in Table 7.5.3-5).

Commercially representative aspirated grain and processed food/feed fractions were produced as follows.

Generation of Aspirated Grain Fraction (AGF)

Moisture content of the samples was determined with an electronic moisture analyser. If the moisture content was greater than 13.0%, a sample was dried at 110-135°F (43.3 – 57.2 ºC) in a Steelman Industries oven until the moisture content was 10.0-13.0%. Samples from trial C1102-15PA required drying.

To generate aspirated grain fractions, each sample was placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the sample was moved in the system, aspiration was used to remove light impurities (grain dust). Each sample was moved for 120 minutes. Light impurities were classified using the following sieves: 2360 µm (8 mesh); 2000 µm (10 mesh); 1180 µm (16 mesh); 850 µm (20 mesh); and 425 µm (40 mesh). After classification of each sample, the material through the 2360 µm sieve was recombined according to Study Director's instructions to produce one **aspirated grain fraction (AGF)**. A representative sample was removed and the ash content was determined.

Wheat Milling

Cleaning

Following AGF generation, samples were cleaned by aspiration and screening. Light impurities were removed using a Kice aspirator. After aspiration, samples were screened in an Enhanced 2 screen cleaner to separate large and small foreign particles (screenings) from the cleaned grain.

Germ Production

Cleaned wheat was moisture adjusted (tempered) to 16% by adding reverse osmosis (R/O) water to the wheat and mixing. After tempering for 1-1.5 hours, the wheat was passed through the Glen Mills disc mill. Ground material was sifted with a Sweco Dynascreen equipped with a 8-, 14-, and 30-mesh sieve. Material on top of the 30 mesh sieve was aspirated to remove bran from the germ fraction. Germ (with endosperm) was passed through the reduction side of the Chopin CD-1 mill. Germ and reduced endosperm were separated using the Great Western sifter equipped with the following screens: 18, 20, 24, and 28 mesh. Germ material was aspirated again to remove additional bran and milled/sieved to remove additional endosperm. A 0.5-1.0% recovery of germ was expected. **Germ** fractions were collected and placed into frozen storage.

Flour Production

Cleaned wheat was moisture conditioned (tempered) depending on the physical property of the wheat. The physical property of the grain kernel varies depending on whether the grain has a floury or vitreous kernel. In a floury kernel, a cross-section of the grain reveals a grainy soft white structure. The cross-section of a vitreous grain is hard and amber coloured. There are grains with an intermediate structure (a floury and vitreous part). All samples were determined to be of intermediate structure and were moisture adjusted and tempered accordingly:

- floury grain wheat: 16.5% moisture adjustment with a 24 hour +/-30 minute resting period before milling

- vitreous grain wheat: 17.5% moisture adjustment with a 48 hour +/-30 minute resting period before milling

- intermediate structure: 17.5% moisture adjustment with a 24~hour +/- 30 minute resting period before milling

Tempered wheat was fed through the spout on the break side of a Chopin mill. Breaking of the wheat was accomplished by three break rolls. After passing through the break rolls, the material was fed onto the break sifter screen. The screen consists of two sizes. The screens are numbers 120 (140 µm) and 25 (800 µm). Material exiting the break rolls passed over the 120 first. Material passing through the 120 screen is "Break Flour." Material not passing through was conveyed over the 25 screen. Material passing through the 25 screen is middlings. Material not passing through was conveyed to the end of the sifter. Material exiting the end is Bran (Coarse). After breaking, it is necessary to determine if more than one reduction will be required. If the "Middling" fraction is 48% or less of the starting weight, then one reduction is required. If more than 48% is obtained, two reductions are required. Samples from both trials required one reduction. Requested **middling** fractions were collected and placed into frozen storage.

Remaining middlings were poured into the feed hopper of the reduction system. Reduction is achieved through two reduction rolls. After passing through the reduction rolls, the material was fed onto a number 100 (160 µm) reduction sifter screen. Material passing through the screen is reduction flour. Material not passing through and conveyed to the end of the sifter is shorts. Representative amounts of break and reduction flours were mixed to produce standard mill run (**white flour**). Requested flour fractions were collected and placed into frozen storage.

Remaining standard mill run flour was used in the production of white bread. Remaining break and reduction flour was used in the production of starch, gluten, and pasta.

Bran exiting the break sieve is placed in the reduction side of the mill, but is not reduced with the rollers. The coarse bran is conveyed by beater bars over a number 140 screen (128 µm). Material passing through the screen is "Shorts" and is added to "Shorts" from the reduction mill. Material passing over the screen and exiting the end is "Bran". Requested **bran** and **shorts** fractions were collected and placed into frozen storage.

Processing into White Bread

Standard mill run flour, sugar, dry milk, salt, margarine, water and dry yeast were placed in a Sunbeam bread machine. The machine was set for type bread (Basic), 2 lb (0.91 kg), loaf size and medium colour. The machine automatically mixed the ingredients, let the dough rise and baked the bread. After cooling, requested **white bread** fractions were collected and placed into frozen storage.

Processing into Whole Meal Flour and Whole Meal Bread

Cleaned wheat was ground in an Alpine pin mill. Ground material was whole meal flour. Requested "**Whole Meal Flour**" fractions were collected and placed into frozen storage. Remaining whole meal flour was used to produce "Whole Meal Bread".

Whole meal flour, brown sugar, salt, margarine, water and dry yeast were placed in a Sunbeam bread machine. The machine was set for type 3 bread (Whole Wheat), 2 lb (0.91 kg) loaf size and medium colour. The machine automatically mixed the ingredients, let the dough rise and baked the bread. After cooling **whole meal bread** fractions were collected and placed into frozen storage.

Wheat Gluten and Starch Production

For vital wheat gluten and starch, break flour was mixed with water at a rate of 0.4-0.8 pounds (0.18 – 0.6 kg) of water to one pound of flour (0.45 kg). The dough was allowed to rest for two hours. After resting, the dough was kneaded as water washed away the starch, leaving the gluten. Product was water washed until water ran clear, indicating all starch was removed leaving gluten. Starch was

separated from the water using centrifugation and dried in a dehydrator or Steelman Industries oven at 130-160°F (54.4 – 71.1ºC) until the moisture content was less than 15%. Gluten was dried with a Blaw-Knox steam heated drum dryer. Temperature is not monitored during drying. After drying, requested **starch** and **gluten** fractions were collected and placed into frozen storage.

Pasta (Noodle) Production

Equal parts of break and reduction flours were mixed with R/O water and salt to form a dough. This dough was kneaded and allowed to rest for 20-40 minutes. Dough was fed into a Lello pasta machine to produce a fresh Asian noodle. A portion of the **fresh noodles** were collected and placed into frozen storage. Requested fresh cooked noodles were produced by placing fresh noodles into boiling water (10:1 ratio water to noodles) for 1-4 minutes. **Cooked noodles** were cooled, collected and placed into frozen storage. Requested **cooking water** fractions were also collected and placed into frozen storage.

A portion of the fresh noodles were dried for eight hours at 75-95°F (23.9 – 35.0 ºC). Requested **dried noodle** fractions were collected and placed into frozen storage. Remaining dried noodles were placed into boiling water (10:1 ratio) for 1-4 minutes. After cooling, requested **dried cooked noodles** were collected and placed into frozen storage.

The processes are illustrated in Figure 7.5.3-4.

Wheat aspirated grain fractions, and the wheat processed commodities were stored deep-frozen ≤ 12 °C) until shipment to Bayer CropScience, RTP, NC. Upon arrival at Bayer CropScience RTP, all samples, were immediately transferred to frozen storage (average temperature -21 °C). The wheat grain RAC, bran, pasta (fresh, dry, cooked, and dried and cooked) white bread, and whole meal bread were homogenised with dry ice using a Robot Coupe (Model RSI2Y1 or RSI30B); wheat flour, whole meal flour, germ, middlings, shorts, gluten, starch, aspirated grain fractions, and cooking water were considered homogenous. All samples were returned to frozen storage immediately following homogenisation, and the samples remained frozen at all times except during subsampling for analysis.

Residue analysis

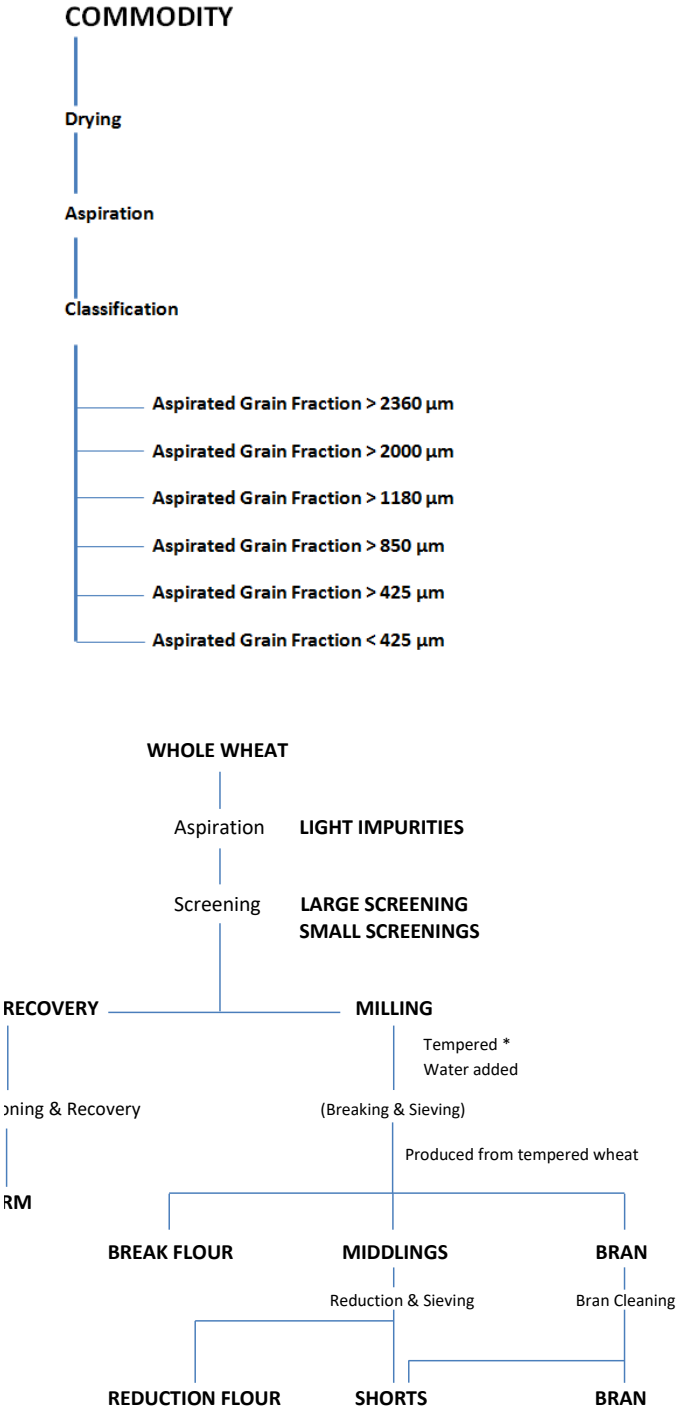
The samples were analysed for the parent compound using analytical method LN-002-P16-01 (Miller, A.; 2017; M-606616-01-1). The LOQ was 0.01 mg/kg for parent for all sample materials.

Isoflucypram residue was extracted from wheat grain, aspirated grain fractions, and all commodity samples except cooking water by blending an aliquot of the homogenised sample in acetonitrile/water (4:1, v/v). The extract was amended with an isotopic internal standard (IS) mixture, and an aliquot was further diluted and analysed by high performance liquid chromatography/triple stage mass spectrometry (LC/MS/MS).

Isoflucypram residue was extracted from cooking water samples by diluting an aliquot with acetonitrile/water (4:1, v/v) and shaking. The extract was amended with an isotopic internal standard (IS) mixture, and an aliquot was further diluted and analysed as noted above.

Method performance was evaluated during method validation and by use of concurrent recovery samples in the report RALNN137 (Harbin, A. M.; 2017; M-600505-02-1) by fortifying wheat grain and the wheat processed commodities at 0.01 mg/kg and at 0.10 mg/kg. The method was validated in wheat aspirated grain fractions at 0.01 mg/kg and at 2.50 mg/kg.

Figure 7.5.3-4: Industrial processing of wheat



Reduction and Break Flours were combined to produce White Flour. White Bread was prepared from white flour.

* Additional wheat tempered with water was milled. From this batch break flour and middlings were produced. All middlings were reduced to produce reduction flour. The additional break and reduction flours were used in the production of starch, gluten and pasta (fresh, fresh cooked, dried, and dried cooked).

Cleaned wheat was ground into Whole Meal Flour. Whole Meal Bread was prepared from whole meal flour.

Break flour was used to produce Gluten. Starch was dried and collected during gluten production.

Break and reduction flour were used to produce Fresh Noodles; Cooked pasta (Noodles) were prepared from fresh noodles. Fresh Noodles were dried to produce Dried Noodles. Dried noodles were used to prepare Dried Cooked Noodles.

II. Findings

The method for determining **isoflucypram** residue was validated in/on wheat grain, wheat grain fractions, and wheat processed commodities by measuring the recovery of **isoflucypram** from control matrices fortified at their LOQs of 0.010 mg/kg. Additional recoveries at 0.100 mg/kg were measured for all commodities except aspirated grain fractions. The high method validation for **aspirated grain fractions** was conducted at 2.5 mg/kg. These recoveries levels validated the method for the highest residues observed in individual matrices. Concurrent recoveries of all analytes were measured with each set of samples to verify method performance.

Details on concurrent recovery data are shown in Table 7.5.3-4. The average recoveries were within the acceptable range of 70 – 110%. The RSD values were below 20%. The method was considered valid for the analysis of **isoflucypram** residue in all wheat matrices.

No residues above the LOQ were found in the control samples. The levels of residues of **isoflucypram** in the treated samples are summarised in Table 7.5.3-5. Only residue values above the LOQ are reported. Any residue value that was below the LOQ is reported as less than the LOQ. The reported residue values were not corrected for residues in controls or for concurrent recoveries.

Analysis of the triplicate wheat grain subsamples collected at the field site on the day the bulk samples were harvested confirmed that no significant degradation of **isoflucypram** residue occurred during ambient storage and shipment of the bulk samples. Indeed, the mean residues levels of **isoflucypram** in wheat grain (collected at the field site) were found at 0.0160 mg/kg in the first trial (C1101-15PA) but < 0.010 mg/kg in the second trial (C1102-15PA). The mean residues levels of **isoflucypram** in wheat grain (collected at the processing site) were found at 0.0137 mg/kg in the first trial (C1101-15PA) but < 0.010 mg/kg in the second trial (C1102-15PA).

In trial C1101-15-PA, where residues in the RAC were above the LOQ, residues of **isoflucypram** in **white flour**, **middlings**, **white bread**, **whole meal bread**, **starch** and **pasta** (fresh, fresh and cooked, dry, dry and cooked) and **cooking water** were below the LOQ. Residues of **isoflucypram** were at 2.35, 0.0189, 0.0181, 0.0134, 0.0107 and 0.0151 mg/kg in **aspirated grain fraction**, **bran**, **germ**, s**horts**, **whole meal flour** and **gluten**, respectively.

In trial C1102-15-PA, where residues in the RAC were below the LOQ, residues of **isoflucypram** were below the LOQ in all processed commodities except **aspirated grain fraction** (0.919 mg/kg).

The proposed processing factors calculated for each commodity for each of the two independent field trials are summarised below in Table 7.5.3-6. They slightly differ from the table on page 18 of the report. In Table 7.5.3-6, the processing factors were defined as the residue in the processed commodity divided by the residue in the RAC collected at the processing laboratory. When residues in the RAC and in the processed fractions were both <0.01 mg/kg a processing factor could not be calculated.

The analyses were done after a maximum frozen storage period of 402 days (grain) and 119 days (processed commodities). All sample extracts were analysed within five days of extraction. Acceptable recoveries measured concurrently with each set of samples ensured the integrity of the sample extracts during the period of time between extraction and analysis.

III. Conclusions

Two residue trials were conducted in Canada. Wheat was treated once at a growth stage of BBCH 69 with an exaggerated dose rate (5X; 375-382 g a.s./ha) to attempt to generate a commodity with quantifiable residues.

Wheat grain was processed in order to obtain aspirated grain fraction, middlings, germ, white flour, shorts, bran, white bread, whole meal flour, whole meal bread, gluten, starch, fresh pasta, cooked fresh pasta, cooking water, dried pasta, dried and cooked pasta.

The samples (RAC and processed fractions) were analysed for the residues of **isoflucypram** parent compound.

The study was conducted according to GLP.

The results of the study indicate that residues of **isoflucypram** are concentrated in the **aspirated grain fraction**, and in a lesser extent in **bran** and **germ**. Similar residue levels as in wheat grain are observed in **shorts**, **whole meal flour** and **gluten**, whereas a dilution of residues is observed in **middlings, starch**, **white flour** and the subsequent production of **pasta** (fresh, dried, fresh and cooked, and dried and cooked), as well as in **bread** (prepared from white and whole meal flours).

(a): Processing factors (PF) slightly differ from the table on page 18 of the report.
PF = residues in processed commodities / residues (mean) in the RAC collected at the processing lab

n.c .: No processing factor can be calculated (residues <LOQ in RAC and in processed commodity)

< value: in case the mean residue level in the RAC is ≥ LOQ but residues in the processed commodity are < LOQ, the processing factor is calculated as to be below the worst case value calculated with the LOQ of the processed commodity

> value: in case the mean residue level in the RAC is < LOQ but residues in the processed commodity are ≥ LOQ, the processing factor is calculated as to be above the value calculated with the LOQ of the RAC

B.7.6. RESIDUES IN SUCCEEDING OR ROTATIONAL CROPS

The nature and level of residues in succeeding crops (confined rotational crops, field rotational crops) is influenced by the amount of active ingredient applied to the soil, by the degradation behaviour in soil, and by the uptake of parent compound and soil metabolites by the roots. Additionally, parent compound and soil metabolites can be metabolized by the plants.

Based on the Fate and Behaviour assessment, the following applies to isoflucypram:

Worst case field dissipation DT90 values: isoflucypram= 3090 days, M12 = 2370 days

For isoflucypram, the maximum PEC soil accumulation value is 0.0616 mg/kg, with a plateau concentration of 0.0416 mg/kg reached after 21 years.

For the M12 metabolite, the max PEC soil accumulation is: 0.0069 mg/kg, with a plateau of 0.00486 mg/kg reached after 20 years.

For isoflucypram, the maximum PEC soil value of 0.0616 mg/kg is equivalent to an application rate of:

10000 m^2 (1 ha) at a 0.05 m depth of soil = 500 m^3 soil; asuming a soil density of 1500 kg/m^3 (1.5 g/cm^3), this is 750,000 kg soil. Hence, a concentration of 0.0616 mg/kg is equivalent to 0.0616 x 750,000 = 46200 mg/ha, or 46.2 g/ha.

The aerobic degradation of **isoflucypram** in soil was investigated in laboratory studies using two different radiolabel positions - either [pyrazole-^{14}C] or [phenyl-^{14}C] radiolabelled active substance (see Hellpointner, E.; Junge, T.; 2014; M-486690-01-1, Gabbert, D.; McConnell, L. L.; Arthur, E. L.; 2017; M-588260-01-1 and Heinemann, O.; Kasel, D.; 2017; M-599926-01-1). From these studies, it can be concluded that **isoflucypram** was slowly but steadily degraded in soil under aerobic conditions to the final degradation product CO_2. In parallel to mineralisation, bound residues (NER) were formed. Three metabolites were identified in the soil extracts along with the parent compound and $^{14}CO_2$. The only major metabolite was BCS-CN88460-carboxylic acid (**M12**), which is degradable under aerobic conditions.

In the metabolic pathway of **isoflucypram** in soil the following processes are involved:

- oxidation of **isoflucypram** to result in BCS-CN88460-carboxylic acid (**M12**);
- hydroxylation of BCS-CN88460-carboxylic acid (**M12**) to result in BCS-CN88460-lactic acid (**M10**);
- demethylation of BCS-CN88460-carboxylic acid (**M12**) to result in BCS-CN88460-desmethyl-carboxylic acid (**M11**);
- mineralisation (carbon dioxide formation);
- formation of non-extractable residues (NER).

Since the exposure of following crops to **isoflucypram** soil residues cannot be excluded, the metabolism of **isoflucypram** was investigated in representative rotational crops (wheat, Swiss chard and turnips) following soil application at a nominal rate of 200 g a.s./ha of either [pyrazole-4-^{14}C] or [phenyl-UL-^{14}C] radiolabelled active substance.

The TRRs in the confined rotational crop commodities were generally low accounting for less than 0.08 mg/kg except in wheat hay and wheat straw where the values accounted for 0.114-0.220 mg/kg and 0.131-0.340 mg/kg, respectively. Parent compound was only detected in wheat forage, wheat hay, Swiss chard and turnip leaves with amounts of equal or less than 17.0% (0.004 mg/kg) of the TRR. None of the identified metabolites accounted for more than 0.022 mg/kg and none of the unknown compounds accounted for more than 0.021 mg/kg.

B.7.6.1. **Metabolism in rotational crops**

Summary of metabolism in rotational crop

The metabolism of the fungicide **isoflucypram** was investigated in two different metabolism studies in rotational crops following application with **isoflucypram** either labelled in the pyrazole or in the phenyl moiety.

Table 7.6.1-1: Overview of available metabolism studies in confined rotational crops

Rotated crops	Application	Target application rate	Reference
turnips, Swiss chard and wheat, plant back interval 30, 140 and 287 days	pyrazole-labelled **isoflucypram**	201.9 g a.s./ha	M-595694-02-1
turnips, Swiss chard and wheat, plant back interval 30, 140 and 287 days	phenyl-labelled **isoflucypram**	197.7 g a.s./ha	M-595695-01-1

In the two confined rotational crop studies applied with an application rate of 198 - 202 g/ha of pyrazole and phenyl labelled **isoflucypram**, the residues of **isoflucypram** in rotational crops planted at all intervals were less than 0.08 mg/kg except in wheat hay and wheat straw of the pyrazole labelled confined rotational crop study where the content of **isoflucypram** was 0.114-0.220 mg/kg and 0.131-0.340 mg/kg, respectively. The TRRs in the different raw agricultural commodities (RACs) were generally low, increased slightly from the 1st to the 2nd rotation and stayed stable or declined to lower values in the 3rd rotation. The TRRs in the RACs of the phenyl labelled study were lower as the TRRs found in the study with the pyrazole label.

In the confined rotational crop study with **isoflucypram** labelled in the pyrazole moiety, unchanged parent compound was only detected in wheat forage, Swiss chard and turnip leaves with amounts of equal or less than 7.0% (0.003 mg/kg) of the TRR. Up to thirteen pyrazole derivative metabolites were identified. As the TRR values of the confined study was generally low, none of the identified metabolites accounted for more than 0.022 mg/kg and none of the unknown compounds accounted for more than 0.021 mg/kg.

The main metabolic reactions were the cleavage of the parent compound to BCS-CN88460-N-methyl-cyclopropyl-pyrazole-carboxamide (**M49**) (named as BCS-CR60082) and following conjugation of BCS-CR60082 (**M49**) with alanine (with or without defluorination) or the hydroxylation and defluorination of BCS-CR60082 (**M49**) followed by conjugation with cysteine or glutathione. Other metabolic reactions were demethylation, hydroxylation, deamination or defluorination of BCS-CR60082 (**M49**), followed by conjugation with glucose, lactic acid, acetic acid, cysteine or glutathione. The glutathione group was afterwards degraded to mercapto alcohol with an additional conjugation with malonic acid.

In the confined rotational crop study with **isoflucypram** labelled in the phenyl moiety, unchanged parent compound was only detected in wheat forage, wheat hay and Swiss chard with amounts of equal or less than 17.0% (0.004 mg/kg) of the TRR. Due to very low TRR values in the confined study, no further metabolites were identified in the conventional extracts as none of the unknown compounds was larger than 0.009 mg/kg. Acidic hydrolysis of selected extracts exhibited that the major part of residues were parent compound and conjugates of BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**). No label specific metabolites were detected in the CRC study with the phenyl label.

Report:	KCA 6.6.1/01; Lamshoeft, M.; 2017
Title:	Amendment no. 1: Metabolism of [pyrazole-4-14C]BCS-CN88460 in confined rotational crops
Report No.:	EnSa-16-945
Document No.:	M-595694-02-1
Guidelines:	OECD Test Guideline 502; Commission Regulation (EU) No 283/2013 of 1 March 2013; OPPTS 860.1850.
Guideline deviations:	None
GLP/GEP:	Yes

Executive Summary

The metabolism of the fungicide **isoflucypram** (BCS-CN88460) was investigated in confined rotational crops after one spray application onto bare soil. The test compound was ^{14}C-radiolabelled in the pyrazole moiety. The soil was treated with 201.9 g a.s./ha according to the envisaged use pattern.

Root crops are represented by turnips, leafy crops by Swiss chard and cereals by wheat. They were sown 30 days (1st rotation), 140 days (2nd rotation) and 287 days (3rd rotation) after soil treatment.

A sample of immature Swiss chard was harvested at BBCH stage 45. Wheat forage was sampled at BBCH stage 29 and wheat hay at BBCH stage 75 to 83. At maturity turnip leaves, turnip roots, Swiss chard, wheat straw and wheat grain were harvested.

The TRRs in the different RACs were generally low, increased slightly from the 1st to the 2nd rotation and stayed stable in the 3rd rotation as shown in the following table:

Table 7.6.1-2: TRR values in confined rotational crops after spray application onto bare soil with [pyrazole-4-^{14}C]BCS-CN88460

Matrix	1st rotation	2nd rotation	3rd rotation
wheat forage	0.041	0.078	0.072
wheat hay	0.114	0.220	0.187
wheat straw	0.131	0.247	0.340
wheat grain	0.004*	0.011	0.016
Swiss chard (immature)	0.031	0.062	0.056
Swiss chard (at maturity)	0.026	0.062	0.052
turnip roots	0.006*	0.006*	0.006*
turnip leaves	0.018	0.031	0.026

* TRR values were determined by LSC measurement following combustion. Samples were not extracted due to their amount being <0.01 mg/kg.

The majority of radioactive residues of all RACs was conventionally extracted with a mixture of acetonitrile/water (8/2; v/v). The residues in the conventional extracts amounted from 52.9% to 97.2% of the TRR. Solids after extraction of wheat hay (1st, 2nd and 3rd rotation), straw (1st, 2nd and 3rd rotation) and grain (2nd and 3rd rotation) were exhaustively extracted using microwave assistance with a mixture of acetonitrile/water/formic acid (50/50/1, v/v/v). Solids after microwave extraction, apart from the solids of wheat grain, were subsequently extracted with a mixture of dioxane/5M HCl using microwave assistance. Exhaustive extracted residues were not further characterised due to high matrix load or low TRR values (≤ 0.023 mg/kg).

All RACs were sufficiently extracted. The total radioactivity in the post extraction solids (PES) amounted to ≤ 9.0% except for wheat grain. In wheat grain, PES amounted for up to 19.6%. As this accounted for only 0.002 mg/kg of the TRR, solids were not further extracted.

Parent compound and metabolites in the conventional extracts were quantified by HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

The identification rates ranged from 21.2% to 76.6% of the TRR in wheat, from 43.9% to 81.1% of the TRR in Swiss chard and from 55.4% to 92.3% of the TRR in turnips.

BCS-CR60082 (**M49**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Ala (**M66**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 2, **M62**-i2), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys (**M52**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH (**M54**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 2, **M69**-i2), BCS-CN88460-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala (**M67**) and BCS-CN88460-desfluoro-N-methyl-cylclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA (**M57**) were identified as major compounds.

Parent compound and metabolites BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 1, **M62**-i1), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 1, **M69**-i1), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc (**M56**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-desamino-Cys (**M55**) and BCS-CN88460-cyclopropyl-pyrazole-carboxamide-acetic acid (**M68**) were quantified in low amounts only (TRR <10%) in the conventional extracts of the RACs.

All other metabolites were detected in low amounts and were characterised by their extraction and chromatographic behaviour.

On the basis of the nature and amount of metabolites found in the extracts of the crops of all rotations the metabolic pathway of [pyrazole-4-^{14}C]BCS-CN88460 in confined rotational crops was proposed.

The following metabolic reactions were observed:

- cleavage of molecule leading to BCS-CN88460-N-methyl-cyclopropyl-pyrazole-carboxamide (**M49**) (BCS-CR60082)
- conjugation of BCS-CR60082 (**M49**) with alanine, lactic acid or acetic acid with or without defluorination of the pyrazole ring
- demethylation of BCS-CR60082 (**M49**) followed by conjugation with glucose
- hydroxylation, deamination and defluorination of BCS-CR60082 (**M49**) followed by conjugation with cysteine or glutathione
- defluorination of BCS-CR60082 (**M49**) followed by conjugation with glucose and glutathione and degradation of the glutathione group to mercapto alcohol, additional conjugation with malonic acid

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure		* denotes the position of the ^{14}C-label
Radiolabel position	[pyrazole-4-^{14}C]
Specific radioactivity	4.22 MBq/mg (113.92 µCi/mg)
Radiochemical purity	> 98% (determined by HPLC) > 99% (determined by TLC)
Chemical purity	> 98% (determined by HPLC, UV at 210 nm)

Formulation of the Test Compound

356 mg of the EC 200 blank formulation was added to 22 mg of the radiolabelled test compound. After homogenisation a water/acetonitrile mixture (50/50; *v/v*) was added to receive the ready-to-use application suspension (total volume: 100 mL). The radioactivity in the final application suspension was determined by LSC and amounted to 0.945 MBq/mL. The formulated test compound was used as test item.

2. Soil: "Monheim 4", pH ($CaCl_2$) = 6.7, 15% clay, 20% silt and 65% sand 1.3% organic carbon, cation exchange capacity (CEC) of 7.5 meq/100 g

3. Plants:

rotational crop	**variety**	**representative for crop group**
Spring wheat	Thasos	cereals
Swiss chard	Lucullus	leafy crops
Turnips	Rondo	root crops

B. Study Design

Experimental conditions:

The application conditions simulated the maximum annual rate of 200 g a.s./ha, according to the envisaged use pattern.

The bare soil was treated on 2014-03-25. An approximately 10% higher field rate (approximately 220 g a.s./ha) was used to compensate losses during the application. The application was performed with 100 mL of the application suspension (according to 94.45 MBq) using a computer controlled track sprayer fitted with a flat fan nozzle. The homogeneity of the spray application was checked by determination of the radioactivity on eight filter papers (1.5 cm diameter), which were randomly placed on the soil before application. The spray application was homogeneous. After application the stock container of the application apparatus was rinsed twice with acetonitrile/water (50/50; *v/v*). The rinsing solution was measured for radioactivity by LSC. By subtraction of all these losses from the radioactivity of the application suspension, the actual amount applied to the soil was calculated. As a result, 201.9 g a.s./ha (85.19 MBq/m^2) was applied.

The stability of the test compound in the application suspension was checked before and after the application by HPLC. No degradation was observed. The purity of the test compound was analysed

after the application by HPLC analysis and amounted to >99%.

For ageing, the soil remained undisturbed for 30 days. The soil was watered in order to maintain adequate moisture content. Before each sowing of the crops the upper soil layer was intensively mixed (approximately 10 cm depth) and soil cores (10 to 15 cm depth) were taken. Additional soil cores were sampled at the end of the 3rd rotation (harvest of wheat, 15-30 cm depth). The radioactivity in the air-dried soil cores was determined by combustion of aliquots followed by LSC.

Sampling:

Wheat

Definition of BBCH-codes for cereals:
BBCH 29 - end of tillering; maximum no. of tillers detectable
BBCH 75 - medium milk: grain content milky, grains reached final size
BBCH 83 - early dough
BBCH 89 - fully ripe: grain hard, difficult to divide with thumbnail

Wheat forage

Forage was taken at approximately BBCH 29 (62, 175 and 335 days after application). One of five rows wheat plants was cut from the roots, which remained in the soil. The forage was cut in small pieces and homogenised with liquid nitrogen using a Polytron (Kinematica). An aliquot of the homogenised sample was used for extraction. Residual sample material was stored at approximately -18 °C.

Wheat hay

Hay was taken at BBCH 75 - 83 (101, 233 and 387 days after application). One of five rows wheat plants was cut from the roots, which remained in the soil. The hay sample was dried for four days. The dried hay sample was cut in small pieces and homogenised with liquid nitrogen using a Polytron (Kinematica). An aliquot of the homogenised sample was used for extraction. Residual sample material was stored at approximately - 18 °C.

Wheat straw and grain

Straw and grain were harvested together at BBCH 89 to 92 (139, 286 and 427 days after application). The wheat plants were cut shortly above soil surface. The roots remained in the soil. The seeds were collected manually yielding the grain sample. The remaining ears and chaff were combined with the straw.

Grain and straw samples were homogenised as described for forage. The homogenised samples were stored in aliquots at approximately - 18 °C. One aliquot of each sample was used for extraction.

Swiss chard

Definition of BBCH-codes for leaf vegetables (not forming heads):

BBCH 45: 50% of the leaf mass typical for the variety reached

BBCH 49: typical leaf mass reached

Swiss chard was harvested as an immature RAC (BBCH 45; 56, 177 and 330 days after application) and at maturity (BBCH 49; 62, 189 and 342 days after application). The samples were cut from the roots, which remained in the soil. The samples were homogenised as described for forage. The homogenised samples were stored in aliquots at approximately - 18 °C. One aliquot of each sample was used for extraction.

Turnip leaves and roots

Definition of BBCH-codes for root and stem vegetables:
BBCH 49 - expansion complete; typical form and size of roots reached

Turnip leaves and roots were harvested together at maturity (BBCH 49; 79, 212 and 356 after application). The turnips were pulled out of the soil and the leaves were separated from roots. The roots were cut into slices and the leaves into small pieces. Both were homogenised as described for forage and stored in aliquots at approximately - 18 °C. One aliquot of each sample was used for extraction.

C. Analytical Procedures

Conventional Extraction and Sample Preparation of all RACs

Aliquots of the homogenised samples were extracted 2 to 5 times with acetonitrile/water (8/2, v/v). The extraction steps were conducted using a Polytron homogeniser. The residues were -dried and weighed yielding the solids. The TRR of each RAC was calculated from the specific radioactivity of the test compound, the amount of the sample used for extraction and the sum of radioactivity, measured in the extracts and the remaining solids. The purified (solid phase extraction (SPE)) and concentrated combined extracts were subjected to HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Recoveries of the concentration processes amounted from 90.9% to 111.2%.

Exhaustive Extraction of Solids

Depending on the amount of residues in the solids of the conventional extraction, an exhaustive extraction was performed once with acetonitrile/water/formic acid (50/50/1; *v/v/v*) using microwave assistance. All samples were purified using SPE cartridges. In case of wheat straw of the 1st rotation this was followed by a concentration process. Recoveries of the purification process amounted from 92.5% to 140.6%. Recovery of the concentration process amounted for 92.7%.

The remaining solids of wheat hay and straw were again subjected to an exhaustive extraction procedure using dioxane/5 M hydrochloric acid and microwave assistance. Recovery rates amounted for 97.2% to 103.6%.

Quantification:

Parent compound and metabolites were quantified in the conventional extracts by HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Corresponding metabolites were named with the same report name and peak ID. They were assigned to each other by comparison of the metabolite profiles and retention times based on the HPLC profiling method.

Identification and characterisation:

Parent compound was identified by comparison of HPLC profiles with each other.

Metabolites BCS-CN88460-N-methyl-cyclopropyl-pyrazole-carboxamide (**M49**) (BCS-CR60082), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys (**M52**) and BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH (**M54**) were isolated in HPLC peak fractions from purified and concentrated extract of Swiss chard of the 1st rotation.

Metabolites BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Ala (**M66**) and BCS-CN88460-cyclopropyl-pyrazole-carboxamide-lactic-acid (**M69**, isomer 2) were isolated in HPLC peak fractions from purified and concentrated extract from wheat hay of the 1st rotation.

Metabolites BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**, isomer 1 and isomer 2), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc (**M56**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA (**M57**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-desamino-Cys (**M55**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (**M69**, isomer 1), BCS-CN88460-

desfluoro-cyclopropyl-pyrazole-carboxamide-Ala (**M67**) and BCS-CN88460-cyclopropyl-pyrazole-carboxamide-acetic acid (**M68**) were isolated in peak fractions from purified wheat hay of the 2nd and 3rd rotation.

All isolated compounds were identified by spectroscopic methods.

To support metabolite identification HPLC co-chromatography of extracts with isolated radiolabelled metabolites was performed.

All other peaks or regions additionally detected in the respective HPLC chromatograms were assigned as "unknown" and numbered accordingly. They were characterised by their extraction and chromatographic behaviour.

Storage stability:

All samples were stored at temperatures ≤ -18 °C before extraction and analysis. All RACs of the 1st rotation were extracted within maximal 12 days, of the 2nd rotation within 9 days and of the 3rd rotation not later than 41 days. Within maximal one month after extraction, the earliest metabolite profiles (used for quantitation of metabolites) were obtained by HPLC-analysis analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

Therefore, it was concluded that the results of this study were not negatively influenced by storage effects.

II. Results and Discussion

The TRR of each raw agricultural commodity (RAC) was calculated from the specific radioactivity of the test compound, the amount of the sample used for extraction and the sum of radioactivity, measured in the conventional extracts and the remaining solids.

The TRRs in all raw agricultural commodities (RACs) reached from low to very low values. The TRR values in the 1st rotation ranged from 0.004 mg/kg (wheat grain) to 0.131 mg/kg (wheat straw). In the 2nd rotation, the TRRs increased slightly to values between 0.006 mg/kg (turnip roots) and 0.247 mg/kg (wheat straw) and stayed constant for the 3rd rotation with values between 0.006 mg/kg (turnip roots) and 0.340 mg/kg (wheat straw).

RACs with an amount of > 0.01 mg/kg were conventionally extracted with a mixture of acetonitrile/water (8/2, *v/v*). The conventional extraction rates amounted from 52.9% to 97.2% of the TRR. Solids after conventional extraction of wheat straw (1st, 2nd and 3rd rotation), hay (1st, 2nd and 3rd rotation) and grain (2nd and 3rd rotation) were further extracted with either acetonitrile/water/acetic acid (1/1/1; *v/v/v*) or with acetonitrile/water/formic acid (50/50/1; *v/v/v*) using microwave assistance. Apart from the solids of wheat grain, solids after microwave extraction were subsequently extracted with a mixture of dioxane/5 M HCl (49/1; *v/v*).All RACs were sufficiently extracted with extraction rates above 90%, except for wheat grain (80.4 and 85.2%). Significant losses of radioactivity during the concentration process of the extracts or radioactivity in the distillates were not observed.

All RACs were sufficiently extracted. The post extraction solids (PES) in the RACs ranged from 2.8% (= 0.001 mg/kg) of the TRR for Swiss chard (immature, 1st rotation) to 9.0% (= 0.007 mg/kg) of the TRR for wheat forage (2nd rotation). PES in wheat grain amounted for up to 19.6%. As this accounted for only 0.002 mg/kg TRR, solids were not further extracted.

Parent compound and metabolites were quantified in the conventional extracts by HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. They were assigned in all extracts by comparison of the metabolite profiles and retention times based on the profiling method. Corresponding metabolites were named with the same report name and peak ID.

<u>Spring Wheat</u>

The identification rates ranged from 44.9% to 60.6% in the 1st rotation, from 44.0% to 76.6% in the 2nd rotation and from 45.1% to 47.7% in the 3rd rotation. Identification rates in grain were 21.2% in the 2nd rotation and metabolites were only characterised in the 3rd rotation due to very low TRR values.

Parent compound was a minor compound in wheat, only identified in forage of the 1st and 2nd rotation with up to 7.0% (0.003 mg/kg) of the TRR. BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Ala (**M66**) was a major metabolite with up to 25.6% (0.020 mg/kg) of the TRR in forage (all rotations) and hay (1st and 2nd rotation) but a minor metabolite in straw (all rotations), hay (3rd rotation) and grain (2nd rotation). BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (**M69**) (isomer 2) was identified as a major compound with up to 11.9% (0.016 mg/kg) of the TRR in straw (1st rotation) and forage (2nd rotation). It was a minor compound in forage (1st and 3rd rotation), hay (all rotations) and straw (2nd and 3rd rotation). BCS-CN88460-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala was identified as a major compound in wheat grain (2nd rotation) with up to 13.4% (0.002 mg/kg) of the TRR. It was a minor compound in forage (1st rotation), hay (2nd and 3rd rotation) and straw (3rd rotation).

Minor metabolites (<10% of the TRR) ranging from 1.1% of the TRR (0.002 mg/kg) to 9.3% of the TRR or 0.026 mg/kg were BCS-CR60082 (**M49**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**) (isomer 1), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**) (isomer 2), BCS-CN88460-desfluoro-N-methyl cyclopropyl-pyrazole-carboxamide-OH-Cys, BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH (**M54**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc (**M56**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (**M69**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-desamino-Cys (**M55**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA (**M57**) and BCS-CN88460-cyclopropyl-pyrazole-carboxamide-acetic acid (**M68**). The respective metabolites were not detected in every part and/or rotation of wheat (see tables below).

All other metabolites were detected in low amounts and were characterised by their extraction and chromatographic behaviour.

Swiss chard

The identification rates ranged from 73.0% to 81.1% in the 1st rotation, from 44.7% to 56.4% in the 2nd rotation and from 43.9% to 51.3% of the TRR in the 3rd rotation.

Parent compound was only a minor compound in Swiss chard accounting for 6.0% of the TRR (0.002 mg/kg) and not identified in Swiss chard (at maturity) in the 2nd rotation. The main metabolite BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys accounted for up to 34.2% of the TRR or 0.016 mg/kg in all three rotations. BCS-CR60082 (**M49**) was identified as a major compound in immature and mature Swiss chard in the 1st rotation with up to 19.4% (0.005 mg/kg) of the TRR and as a minor compound in the other rotations. BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**) (isomer 1) was identified as a major compound in Swiss chard (at maturity, 2nd rotation) with 12.2% (0.008 mg/kg) of the TRR and a minor metabolite in immature (2nd and 3rd rotation) and Swiss chard (at maturity, 3rd rotation). BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH (**M54**) was identified as major compound in immature and mature Swiss chard of the 1st rotation with up to 22.9% (0.006 mg/kg) of the TRR and as a minor compound in the 2nd and 3rd rotation.

Minor metabolites (<10% of the TRR) ranging from 0.5% of the TRR (<0.001 mg/kg) to 7.3% of the TRR (0.004 mg/kg) were BCS-CN88460-cyclopropyl-carboxamide-Ala, BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**) (isomer 2), BCS-CN88460-cyclopropyl-carboxamide-OH-lactic acid (isomer 1), BCS-CN88460-cyclopropyl-carboxamide-OH-lactic acid (isomer 2), BCS-CN88460-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala and BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxyamide-desamino-Cys.

All other metabolites were detected in low amounts and were characterised by their extraction and

chromatographic behaviour.

Turnips leaves

The identification rates accounted for 92.3% in the 1st rotation, for 73.3% in the 2nd rotation and for 55.4% of the TRR in the 3rd rotation.

Parent compound was only detected as a minor compound in turnip leaves of the 1st rotation. The main metabolite BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH accounted for up to 25.7% of the TRR or 0.006 mg/kg in all three rotations. BCS-CR60082 was a major compound in the 1st and 2nd rotation with up to 18.4% of the TRR or 0.004 mg/kg and a minor compound in the 3rd rotation. BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**) (isomer 2) was a major compound in the 1st rotation with 13.0% (0.002 mg/kg) of the TRR and a minor compound in the 2nd and 3rd rotation. BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA (**M57**) was a major compound in the 1st rotation with 12.3% (0.002 mg/kg) of the TRR and a minor compound in the 2nd and 3rd rotation.

Minor metabolites (<10% of the TRR) ranging from 1.8% of the TRR (<0.001 mg/kg) to 8.1% of the TRR (0.002 mg/kg) were BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Ala (**M66**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (**M62**) (isomer 1), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys, BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc (**M56**), BCS-CN88460-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala (**M67**), and BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-desamino-Cys (**M55**).

All other metabolites were detected in low amounts and were characterised by their extraction and chromatographic behaviour.

The distribution of the radioactive residues as well as the identified and characterised compounds in confined rotational crops after spray application onto bare soil is shown in the tables below.

Table 7.6.1-3: Distribution of radioactivity in confined rotational crops (1st rotation) after spray application onto bare soil with [pyrazole-4-^{14}C]BCS-CN88460

Fraction	wheat forage		wheat hay		wheat straw		wheat grain	
	TRR = 0.041 mg/kg		TRR = 0.114 mg/kg		TRR = 0.131 mg/kg		TRR = 0.004* mg/kg

III. Conclusions

The metabolism of the fungicide **isoflucypram** (BCS-CN88460) was investigated in confined rotational crops after one spray application onto bare soil. The application rate amounted to 201.9 g a.s./ha and the test compound was ^{14}C-radiolabelled in the pyrazole moiety.

The TRRs in the raw agricultural commodities (RACs) were low and ranged from 0.004 mg/kg for wheat grain (1st rotations) to 0.340 mg/kg for wheat straw (3rd rotation). The TRR values increased slightly from the 1st to the 2nd rotation and stayed stable in the 3rd rotation. TRR values in turnip roots

were constantly low at 0.006 mg/kg throughout the three rotations.

Radioactive residues were first extracted with conventional methods. In case of wheat hay, straw and grain, solids had to be further extracted.

BCS-CN88460-N-methyl-cyclopropyl-pyrazole-carboxamide (**M49**) (BCS-CR60082) (**M49**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Ala (**M66**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 2, **M62**-i2), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys (**M52**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH (**M54**), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 2, **M69**-i2), BCS-CN88460-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala (**M67**) and BCS-CN88460-desfluoro-N-methyl-cylclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA (**M57**) were identified as major compounds.

Parent compound and metabolites BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 1, **M62**-i1), BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 1, **M69**-i1), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc (**M56**), BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-desamino-Cys (**M55**) and BCS-CN88460-cyclopropyl-pyrazole-carboxamide-acetic acid (**M68**) were quantified in low amounts only (TRR <10%) in the conventional extracts of the RACs. All other metabolites were detected in low amounts and were characterised by their extraction and chromatographic behaviour.

The following metabolic reactions were observed:

- cleavage of the parent compound leading to BCS-CN88460-N-methyl-cyclopropyl-pyrazole-carboxamide (**M49**) (BCS-CR60082)
- conjugation of BCS-CR60082 (**M49**) with alanine, lactic acid or acetic acid with or without defluorination of the pyrazole ring
- demethylation of BCS-CR60082 (**M49**) followed by conjugation with glucose
- hydroxylation, deamination and defluorination of BCS-CR60082 (**M49**) followed by conjugation with cysteine or glutathione
- defluorination of BCS-CR60082 (**M49**) followed by conjugation with glucose and glutathione and degradation of the glutathione group to mercapto alcohol, additional conjugation with malonic acid

Based on these results, the metabolism of [pyrazole-4-^{14}C]BCS-CN88460 in confined rotational crops is adequately understood and the following metabolic pathway is proposed.

Figure 7.6.1-1: Proposed metabolic pathway of [pyrazole-4-^{14}C]BCS-CN88460 in confined rotational crops

Executive Summary

The metabolism of the fungicide **isoflucypram** (BCS-CN88460) was investigated in confined rotational crops after one spray application onto bare soil. The test compound was ^{14}C-radiolabelled in the phenyl moiety. The soil was treated with 197.7 g a.s./ha according to the envisaged use pattern.

Root crops are represented by turnips, leafy crops by Swiss chard and cereals by wheat. They were sown 30 days (1st rotation), 140 days (2nd rotation) and 287 days (3rd rotation) after soil treatment.

A sample of immature Swiss chard was harvested at BBCH stage 45. Wheat forage was sampled at BBCH stage 29 and wheat hay at BBCH stage 75 to 83. At maturity turnip leaves, turnip roots, Swiss chard, wheat straw and wheat grain were harvested.

The TRRs in the different RACs ranged from low to very low. The TRR values increased slightly from the 1st rotation to the 2nd rotation and declined to lower values in the 3rd rotation, as shown in the following table:

Table 7.6.1-15: TRR values in confined rotational crops after spray application onto bare soil with [phenyl-UL-^{14}C]BCS-CN88460

Matrix	1st rotation	2nd rotation	3rd rotation
wheat forage	0.023	0.018	0.015
wheat hay	0.039	0.062	0.036
wheat straw	0.051	0.070	0.055
wheat grain	0.001*	0.004*	0.003*
Swiss chard (intermediate)	0.029	0.016	0.020
Swiss chard (at maturity)	0.020	0.016	0.025
turnip roots	0.003*	0.003*	0.003*
turnip leaves	0.004*	0.006*	0.006*

* TRR values were determined by LSC measurement following combustion. Samples were not extracted due to their amount being <0.01 mg/kg.

The TRRs in the raw agricultural commodities (RACs) of the current study were lower as the TRRs found in the study with the pyrazole label. The majority of the radioactive residues of all RACs was conventionally extracted with a mixture of acetonitrile/water (8/2; v/v). The residues in the conventional extracts amounted from 78.4% to 97.7% of the TRR. Solids after extraction of wheat hay and wheat straw (1st, 2nd and 3rd rotation) were exhaustively extracted with a mixture of acetonitrile/water/formic acid (50/50/1; v/v/v) using microwave assistance.

Exhaustive extracted residues were not further characterised due to low TRR values (≤ 0.006 mg/kg).

All RACs were sufficiently extracted. The total radioactivity in the post extraction solids (PES) amounted to ≤ 9.6% of the TRR except for wheat straw (1st rotation, 11.5% of the TRR and 0.006 mg/kg) and hay (3rd rotation, 11.7% of the TRR and 0.004 mg/kg).

Isoflucypram was the only major compound identified in the conventional extracts with up to 17% (0.004 mg/kg) of the TRR. All other metabolites were detected in low amounts and were characterised

by their extraction and chromatographic behaviour.

Further characterisation of residues by acidic hydrolysis of crude extracts of Swiss chard (immature and mature, 1st rotation) and wheat straw (1st rotation) indicated presence of conjugates of BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**) besides parent compound in these selected extracts.

Based on these results, the metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in confined rotational crops is adequately understood. Parent compound was the only residue component identified.

I. Materials and Methods

A. Materials

1. Test Material:

Chemical structure		* denotes the position of the ^{14}C-label
Radiolabel position	[phenyl-UL-^{14}C]
Specific radioactivity	4.13 MBq/mg (111.6 µCi/mg)
Radiochemical purity	> 98% (determined by HPLC) 99% (determined by TLC)
Chemical purity	> 98% (determined by HPLC, UV at 210 nm)

356 mg of the EC 200 blank formulation was added to 22 mg of the radiolabelled test compound. After homogenisation a water/acetonitrile mixture (50/50; *v/v*) was added to receive the ready-to-use application suspension (total volume: 100 mL). The radioactivity in the final application suspension was determined by LSC and amounted to 0.907 MBq/mL. The formulated test compound was used as test item.

2. Soil: "Monheim 4", pH ($CaCl_2$) = 6.7, 15% clay, 20% silt and 65% sand 1.3% organic carbon, cation exchange capacity (CEC) of 7.5 meq/100 g

3. Plants:

rotational crop	variety	representative for crop group
Spring wheat	Thasos	cereals
Swiss chard	Lucullus	leafy crops
Turnips	Rondo	root crops

B. Study Design

Experimental conditions:

The application conditions simulated the maximum annual rate of 200 g a.s./ha, according to the envisaged use pattern.

The bare soil was treated on 2014-03-25. An approximately 10% higher field rate (approximately 220 g a.s./ha) was used to compensate losses during the application. The application was performed with

100 mL of the application suspension (according to 90.74 MBq) using a computer controlled track sprayer fitted with a flat fan nozzle. The homogeneity of the spray application was checked by determination of the radioactivity on ten filter papers (1.5 cm diameter), which were randomly placed on the soil before application. The spray application was homogeneous. After application the stock container of the application apparatus was rinsed twice with acetonitrile/water (50/50; *v/v*). The rinsing solution was measured for radioactivity by LSC. By subtraction of all these losses from the radioactivity of the application suspension, the actual amount applied to the soil was calculated. As a result, 197.7 g a.s./ha (81.63 MBq/m^2) was applied.

The stability of the test compound in the application suspension was checked before and after the application by HPLC. No degradation was observed. The purity of the test compound was analysed after the application by HPLC analysis and amounted to 100%.

For ageing, the soil remained undisturbed for 30 days. The soil was watered in order to maintain adequate moisture content. Before each sowing of the crops the upper soil layer was intensively mixed (approximately 10 cm depth) and soil cores (10 to 15 cm depth) were taken. Additional soil cores were sampled at the end of the 3rd rotation (harvest of wheat, 15-30 cm depth). The radioactivity in the air-dried soil cores was determined by combustion of aliquots followed by LSC.

Sampling:

Wheat

Definition of BBCH-codes for cereals:

BBCH 29 - end of tillering; maximum no. of tillers detectable
BBCH 75 - medium milk: grain content milky, grains reached final size
BBCH 83 - early dough
BBCH 89 - fully ripe: grain hard, difficult to divide with thumbnail

Wheat forage

Forage was taken at approximately BBCH 29 (62, 175 and 335 days after application). One of five rows wheat plants was cut from the roots, which remained in the soil. The forage was cut in small pieces and homogenised with liquid nitrogen using a Polytron (Kinematica). An aliquot of the homogenised sample was used for extraction. Residual sample material was stored at approximately -18 °C.

Wheat hay

Hay was taken at BBCH 75 - 83 (101, 233 and 387 days after application).One of five rows wheat plants was cut from the roots, which remained in the soil. The hay sample was dried for four days. The dried hay sample was cut in small pieces and homogenised with liquid nitrogen using a Polytron (Kinematica). An aliquot of the homogenised sample was used for extraction. Residual sample material was stored at approximately - 18 °C.

Wheat straw and grain

Straw and grain were harvested together at BBCH 89 (139, 286 and 427 days after application). The wheat plants were cut shortly above soil surface. The roots remained in the soil. The seeds were collected manually yielding the grain sample. The remaining ears and chaff were combined with the straw.

Grain and straw samples were homogenised as described for forage. The homogenised samples were stored in aliquots at approximately - 18 °C. One aliquot of each sample was used for extraction.

Swiss chard

Definition of BBCH-codes for leaf vegetables (not forming heads):

BBCH 45 - 50% of the leaf mass typical for the variety reached

BBCH 49 - typical leaf mass reached

Swiss chard was harvested as an immature RAC (BBCH 45; 56, 177 and 330 days after application) and at maturity (BBCH 49; 62, 189 and 342 days after application). The samples were cut from the roots, which remained in the soil. The samples were homogenised as described for forage. The homogenised samples were stored in aliquots at approximately - 18 °C. One aliquot of each sample was used for extraction.

Turnip leaves and roots

Definition of BBCH-codes for root and stem vegetables:

BBCH 49 - expansion complete; typical form and size of roots reached

Turnip leaves and roots were harvested together at maturity (BBCH 49; 79, 212 and 356 after application). The turnips were pulled out of the soil and the leaves were separated from roots. The roots were cut into slices and the leaves into small pieces. Both were homogenised as described for forage and stored in aliquots at approximately - 18 °C. One aliquot of each sample was used for extraction.

C. Analytical Procedures

Conventional Extraction and Sample Preparation of all RACs

Aliquots of the homogenised samples were extracted 2 to 4 times with acetonitrile/water (8/2, v/v). The extraction steps were conducted using a Polytron homogeniser. The residues were -dried and weighed yielding the solids. The TRR of each RAC was calculated from the specific radioactivity of the test compound, the amount of the sample used for extraction and the sum of radioactivity, measured in the extracts and the remaining solids. The purified (solid phase extraction (SPE)) and concentrated combined extracts were subjected to HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. Recoveries of the concentration processes amounted from 90.3% to 111.6%.

Exhaustive Extraction of Solids

Depending on the amount of residues in the solids of the conventional extraction, an exhaustive extraction was performed once with acetonitrile/water/formic acid (50/50/1; *v/v/v*) using microwave assistance. All samples were purified using SPE cartridges. Recoveries of the purification process amounted from 88.0% to 129.7%.

Hydrolysis of Extracts

For isolation of parent compound and degradation products, extracts of wheat straw and Swiss chard (immature and at maturity) of the 1st rotation were hydrolysed for 1 h in 1M HCl at 100 °C.

Quantification:

Parent compound and metabolites were quantified in the conventional extracts by HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

Identification and characterisation:

Corresponding metabolites were named with the same report name and peak ID. They were assigned to each other by comparison of the metabolite profiles and retention times based on the HPLC profiling method.

Parent compound was identified by comparison of HPLC profiles with each other.

Acidic hydrolysis of crude extracts of the 1st rotation from Swiss chard (immature and at maturity) and wheat straw, revealed the presence of three major aglyca. Parent compound and the two metabolites BCS-CN88460-carboxylic-acid and BCS-CN88460-propanol (**M01**) were isolated in HPLC fractions from purified and concentrated hydrolysed extract from Swiss chard (at maturity, 1st rotation).

All isolated compounds were identified by spectroscopic methods.

To support metabolite identification, comparison of HPLC-profiles of isolated compounds with HPLC profiles of hydrolysed extracts of the 1st rotation from Swiss chard (immature and at maturity) and wheat straw was performed.

In addition, the presence of BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**) in the hydrolysed extracts was confirmed by comparing these HPLC profiles with profiles from laying hen metabolism studies.

The obtained aglyca after hydrolysis, which were isolated and identified from the crude extracts after hydrolysis, were not assigned to any peaks in the native extracts. All other peaks or regions additionally detected in the respective HPLC chromatograms were assigned as "unknown" and numbered accordingly. They were characterised by their extraction and chromatographic behaviour.

Storage stability:

All samples were stored at temperatures ≤ -18 °C before extraction and analysis. All RACs were extracted within maximal 8 days. Within maximal 41 days after extraction, the earliest metabolite profiles (used for quantitation of metabolites) were obtained by HPLC-analysis analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient.

Therefore, it was concluded that the results of this study were not negatively influenced by storage effects.

II. Results and Discussion

The TRR of each raw agricultural commodity (RAC) was calculated from the specific radioactivity of the test compound, the amount of the sample used for extraction and the sum of radioactivity, measured in the conventional extracts and the remaining solids.

The TRRs in all RACs reached from low to very low values. The TRR values in the 1st rotation ranged from 0.001 mg/kg (wheat grain) to 0.051 mg/kg (wheat straw). In the 2nd rotation, the TRR values slightly increased in wheat hay, straw, grain, turnip roots and turnip leaves and ranged from 0.004 mg/kg (wheat grain) to 0.070 mg/kg (wheat straw) whereas the TRR values in wheat forage and Swiss chard (immature and at maturity) slightly decreased to 0.016 mg/kg (Swiss chard, immature and at maturity) and 0.018 mg/kg (wheat forage). In the 3rd rotation, the TRR values for Swiss chard (immature and at maturity) increased slightly to 0.020 mg/kg and 0.025 mg/kg, respectively. The TRR values in the other RACs decreased and ranged from 0.003 mg/kg (wheat grain) to 0.055 mg/kg (wheat straw).

RACs with an amount of >0.01 mg/kg were conventionally extracted with a mixture of acetonitrile/water (8/2, v/v). The conventional extraction rates amounted from 77.2% to 97.7% of the TRR.

Due to low extraction rates in wheat straw and hay, the solids remaining after conventional extraction were further extracted by microwave assistance with acetonitrile/water/formic acid (50/50/1; v/v/v).

After the exhaustive extraction all RACs were sufficiently extracted with total extraction rates between 87.3% (wheat straw, 1st rotation) and 97.7% (Swiss chard immature and at maturity, 1st rotation). Significant losses of radioactivity during the concentration process of the extracts of radioactivity in the distillates were not observed. The post extraction solids (PES) in the RACs ranged from 2.3% (<0.001 mg/kg) of the TRR for Swiss chard (at maturity, 1st rotation) to 11.7%

(0.004 mg/kg) in wheat hay (3rd rotation). Solids were not further extracted.

Parent compound and metabolites were quantified in the conventional extracts by HPLC analysis based on reversed phase chromatography using an acidic water/acetonitrile/THF gradient. They were assigned in all extracts by comparison of the metabolite profiles and retention times based on the profiling method. Corresponding metabolites were named with the same report name and peak ID.

The identification rates in the three rotations were low. A total of 1.1% to 17.0% of the TRR was identified in RACs of the 1st rotation, up to 12.2% of the TRR in RACs of the 2nd rotation and up to 5.2% of the TRR in RACs of the 3rd rotation. The low identification rates are due to the generally low amounts of residues in the according RACs.

Parent **isoflucypram** was the only compound identified. In wheat forage it accounted for 17.0% (0.004 mg/kg) of the TRR, 12.2% (0.002 mg/kg) of the TRR and 5.2% (0.001 mg/kg) of the TRR in the 1st, 2nd and 3rd rotation, respectively. In wheat hay of the 1st rotation and Swiss chard (immature and at maturity) of the 1st rotation it accounted for up to 6.1% (0.001 mg/kg) of the TRR. In total 16 metabolites were observed with maximum amounts ≥ 10% of the TRR in different crops and rotations. Since the TRR was in the range of 0.002 to 0.007 mg/kg for all compounds, no identification was possible and they were only characterised by their characteristic behaviour via HPLC.

Further characterization by acidic hydrolysis indicated, that the majority of these metabolites are conjugates of aglycons and parent compound representing up to 74.7% of TRR. Two aglyca (BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol) and parent compound were isolated from hydrolysed extracts and identified by LC-MS and LC-MS/MS.

The distribution of the radioactive residues as well as the identified and characterised compounds in confined rotational crops after spray application onto bare soil is shown in the tables below.

III. Conclusions

The metabolism of the fungicide **isoflucypram** (BCS-CN88460) was investigated in confined rotational crops after one spray application onto bare soil. The application rate amounted to 197.7 g a.s./ha and the test compound was ^{14}C-radiolabelled in the phenyl moiety.

The TRRs in the raw agricultural commodities (RACs) ranged from very low to low with values between 0.001 mg/kg in wheat grain (1st rotation) to 0.070 mg/kg in wheat straw (2nd rotation).

Radioactive residues were extracted with conventional methods. In case of wheat hay and straw, solids had to be further extracted.

isoflucypram was the only compound identified in the conventional extracts, amounting for up to 17.0% (0.004 mg/kg) of the TRR.

Further characterisation of residues by acidic hydrolysis of crude extracts of Swiss chard (immature and mature, 1st rotation) and wheat straw (1st rotation) indicated presence of conjugates of BCS-CN88460-carboxylic acid (**M12**) and BCS-CN88460-propanol (**M01**) besides parent compound in these selected extracts.

Based on these results, the metabolism of [phenyl-UL-^{14}C]BCS-CN88460 in confined rotational crops is adequately understood. Parent compound was the only residue component identified.

B.7.6.2. **Magnitude of residues in rotational crops**

Report:	KCA 6.6.2/01; Freitag, T.; Effertz, C.; 2017
Title:	Determination of the residues of BCS-CN88460 in/on soil and the field rotational crops barley, carrot, turnip and lettuce after spray application of BCS-CN88460 EC 050 to bare soil in Germany, the Netherlands, southern France and Italy
Report No.:	15-2502
Document No.:	M-605725-02-1
Guidelines:	OECD Test Guideline 509; OECD Test Guideline 504; Commission Regulation (EU) No 283/2013 of 1 March 2013; US EPA OCSPP Guideline No. 860.1900; US EPA OCSPP Guideline No. 860.1500.
Guideline deviations:	Yes, see report
GLP/GEP:	Yes

I. Materials and Methods

The purpose of the study 15-2502 was to determine the magnitude of the relevant residues of **isoflucypram** in/on barley, lettuce and carrot or turnip grown as rotational crops after one spray application to bare soil with **BCS-CN88460 EC 050** an emulsifiable concentrate (EC) formulation containing 50 g/L **isoflucypram**, followed by plant-back intervals of 21 to 34 days (1st rotation), 100 to 201 days (2nd rotation) and 299 to 370 days (3rd rotation).

The study included four supervised residue trials conducted in northern Europe (Germany and the Netherlands) and southern Europe (France and Italy) during the 2015 and 2016 growing seasons.

One spray application of **BCS-CN88460 EC 050** was made to bare soil at an application rate of 3.6 L/ha (equivalent to 0.18 kg/ha active substance) with a water rate of 300 to 400 L/ha. The application procedure was followed by incorporation of the test item into the soil via ploughing to a depth of ≤ 8 cm. All treatments were made at the scheduled rates.

At various intervals, crops were planted onto the test area in order to simulate a crop failure ("rotation 1", plant-back interval [PBI] 21-34 days), a second use of the plot in the same year ("rotation 2", PBI 100-201 days), or use of the same plot in the succeeding year ("rotation 3", PBI 299-370 days). In each rotation, 3 different crops representing different botanical groups were planted: a root crop (carrots or turnips), a leafy crop (lettuce), or a small grain cereal (barley).

Samples of representative soil commodities were taken on the day after sowing/planting the crop for each individual rotation from each of the subplots. Moreover, samples of the rotational crops were taken at their respective harvest times, as well as at one earlier interval (immature RACs for lettuce and root crops, or green material (whole plant without roots) for barley).

Each field sample was placed in double labelled bags and stored deep-frozen within 24 hours after sampling and until dispatch to the Laboratory for Sampling, Preparation Technique and Sample Logistics (PVTL), Bayer AG – Crop Science Division, BAG-CS-HSRA in D-40789 Monheim am Rhein. All field samples were shipped deep-frozen under monitored conditions during shipment and arrived at PVTL in good condition. The field samples were stored in a freezer at -18 °C or below until

preparation of the examination samples.

For the preparation of the soil examination samples, the deep-frozen field samples were grounded with dry-ice and homogenised in a Stephan mill. Representative parts of the homogenised samples were transferred into polystyrene boxes and stored at -18 °C or below until analysis. For the preparation of examination samples, the deep-frozen field samples were shredded and homogenised with dry ice in a cutter. Representative parts of the shredded samples were transferred into polystyrene boxes and stored at -18 °C or below until analysis.

Residues of **isoflucypram** and its metabolite BCS-CN88460-carboxylic acid (**M12**) were determined in soil using method 01432 (Koch, V.; 2014; M-499794-01-1). The LOQs for each analyte were 0.001 mg/kg, the metabolite being not expressed in parent equivalents.

The samples of the rotational crops were analysed for the parent compound and its metabolite BCS-CR60082 (**M49**) using method 01475 (Uceda, L.; 2016; M-558986-01-1) which was validated prior to the residue analysis of the samples. Additional validation recoveries were conducted for all sample materials in the study 15-2502. Samples of barley (grain, straw and green material) were analysed according to the procedure described in the method for dry matrices (soaking step before extraction) and the samples of carrot (root and leaf), turnip (root and leaf) and lettuce (head) were prepared according to the procedure for higher-water containing commodities (no soaking step before extraction). The LOQs for each analyte were 0.01 mg/kg (all in parent equivalents).

II. Findings

Concurrent recoveries for **isoflucypram** and its metabolite BCS-CN88460-carboxylic acid (**M12**) were obtained from samples of soil. The recovery samples were spiked at levels of 0.001 mg/kg and up to 0.01 mg/kg. Details of concurrent recovery data are shown in Table 7.6.2-1 for **isoflucypram** and in Table 7.6.2-2 for BCS-CN88460-carboxylic acid (**M12**). The average recoveries were within the acceptable range of 70 – 110%. The RSD values were below 20%.

Besides, concurrent recoveries for **isoflucypram** and its metabolite BCS-CR60082 (**M49**) were obtained from samples of carrots, turnips, lettuce, and barley. The recovery samples were spiked at levels of 0.01 mg/kg and up to 0.10 mg/kg. Details of concurrent recovery data are shown in Table 7.6.2-3 for **isoflucypram** and in Table 7.6.2-4 for BCS-CR60082 (**M49**). The average recoveries were within the acceptable range of 70 – 110%. The RSD values were below 20% for each compound and all sample materials.

No residues above the LOQs were found in the control samples. The detailed results obtained for soil samples are summarised below in Table 7.6.2-5 and the results obtained for rotational crop samples are summarised in Table 7.6.2-6 to Table 7.6.2-8. The results were not corrected for concurrent recoveries.

The residues of **isoflucypram** and BCS-CR60082 (**M49**) in the treated rotational crops were always found < LOQ with one exception.

In the trial 15-2501-01 (Germany), residues of **isoflucypram** reached levels of 0.057 to 0.075 mg/kg only in carrot leaves (2nd rotation, plot T-2A). These results – confirmed with re-analyses- were illogical because no residues were found in carrot roots from the same plot and no residues were found in the 1st rotation for carrot.

It appears that five days before the first harvest of carrot leafs in plot T-2A, the adjoining plot dedicated to barley (T-1C) was sprayed with **BCS-CN88460 EC 050**. There was no buffer zone between the two plots, the carrot plot was not protected during the spray of the plot T-1C, and there was a very light wind in the direction of the carrot plot. This explanation supports the fact that the residue levels of **isoflucypram** found in carrot leaves in the plot T-2A are the result of a spray drift. These residue levels should not be considered because they are not attributable to residues arising from soil treatment.

Based on all the other results, it is concluded, that after an application of **BCS-CN88460 EC 050** on bare soil at a rate of 180 g a.s./ha, the residues of **isoflucypram** and BCS-CR60082 (**M49**) are expected to be <0.01 mg/kg in barley, lettuce and carrot or turnip grown as rotational crops.

The analyses of soil were done after a maximum frozen storage period of 320 days and the analyses of plant commodities after a maximum frozen storage period of 341 days. For crop commodities, the time between the beginning of the sample preparation and the sample analysis did not exceed 24 hours. For soil, all final extracts were analysed within 8 days. This storage period of soil extracts is covered by storage stability experiments conducted in the method 01432 (Koch, V.; 2014; M-499794-01-1).

III. Conclusions

In order to support the use of **isoflucypram** in the EU for non-perennial crops, four multi-plant-back multi-crop rotational crop trials were conducted in Europe (2 each in the northern and southern residue regions) in 2015-2016. **isoflucypram** was applied once as an EC 050 formulation to bare soil at an application rate of 3.6 L/ha (corresponding to 180 g active substance/ha). Crops representing 3 different botanical groups (roots, leafy vegetables, small grain cereals) were planted on the plots at 3 intervals thereafter. All applications were at the required rates, and all trials were conducted according to GLP.

The residues of **isoflucypram** and BCS-CR60082 (**M49**) in the rotational crops were always found < LOQ with one exception.

In the trial 15-2501-01 (Germany), residues of **isoflucypram** reached levels of 0.057 to 0.075 mg/kg only in carrot leaves (2nd rotation, plot T-2A). These results – confirmed with re-analyses- were illogical because no residues were found in carrot roots from the same plot and no residues were found in the 1st rotation for carrot.

It appears that five days before the first harvest of carrot leafs in plot T-2A, the adjoining plot dedicated to barley (T-1C) was sprayed with **BCS-CN88460 EC 050**. There was no buffer zone between the two plots, the carrot plot was not protected during the spray of the plot T-1C, and there was a very light wind in the direction of the carrot plot. This explanation supports the fact that the residue levels of **isoflucypram** found in carrot leaves in the plot T-2A are the result of a spray drift. These residue levels should not be considered because they are not attributable to residues arising from soil treatment.

Based on all the other results, it is concluded, that after an application of **BCS-CN88460 EC 050** on bare soil at a rate of 180 g a.s./ha, the residues of **isoflucypram** and BCS-CR60082 (**M49**) are expected to be <0.01 mg/kg in barley, lettuce and carrot or turnip grown as rotational crops.

The dose rate of 180 g active substance/ha tested in this study adequately covers the plateau concentration of **isoflucypram** in soil overtime. Indeed, the maximum seasonal rate for **isoflucypram** is 75 g a.s./ha. The accumulation factor for **isoflucypram** parent compound in soil was calculated to be 1.5 for parent (please refer to Reinken, G.; Kallweit, W.; 2017; M-608723-01-1) Considering a crop interception of 80% applicable for cereals growth stages ranging from BBCH 30 to BBCH 69, the plateau in soil corresponds to 22.5 g a.s./ha (75 g a.s./ha x 1.5 x 0.2).

When this plateau is added to a last application rate of 75 g a.s./ha the appropriate dose to be investigated is 97.5 g a.s./ha (plateau of 22.5 g a.s./ha + seasonal rate of 75 g a.s./ha), below what was actually tested in the study 15-2502.

It is also highlighted that, for the 2nd and 3rd rotations, it would be relevant to apply the crop interception of 80% to the last seasonal rate as well since for normal rotations the treated crops are harvested and not re-incorporated into the soil. Proceeding so, the appropriate dose rate to be investigated for the 2nd and 3rd rotations is 37.5 g a.s./ha (plateau of 22.5 g a.s./ha+ 75 x 0.2), a dose rate far below the one tested in the study 15-2502.

The plateau in soil for the metabolite **M12** (BCS-CN88460-carboxylic acid) does not need to be considered since its DT_{50} value is < 150 days (worst case laboratory DT_{50} of 112 days).

It is concluded that plant-back restrictions and MRL proposals above 0.01 mg/kg based on rotational crops are not necessary.

PBI = plant-back interval DALT: days after the last treatment

a Mean of three replicates: (0.077; 0.077 and 0.070 mg/kg)

b Mean of three replicates: (<0.01; <0.01 and <0.01 mg/kg)

c Mean of three replicates: (0.057; 0.054 and 0.060 mg/kg)

d Mean of three replicates: (<0.01; <0.01 and <0.01 mg/kg)

* Plant back interval is slightly longer as requested in the study protocol. However, the timing for replanting of rotational crops as given in the OECD guideline on residues in rotational crops (limited field studies) 504 suggests 270 to 365 days for crops rotated the following year. Thus, the actual plant back interval is considered to be in an acceptable range.

* Plant back interval is slightly longer as requested in the study protocol. However the timing for replanting of rotational crops as given in the OECD guideline on residues in rotational crops (limited field studies) 504 suggests 270 to 365 days for crops rotated the following year. Thus, the actual plant back interval is considered to be in an acceptable range.

B.7.7. OTHER STUDIES

B.7.7.1. Effect on the residue level in pollen and bee products

No residue study in pollen and bee products was conducted. Currently, no test method or Guidance document is available for conducting residue studies in pollen or bee products. In these cases, waiving of this particular data requirement is considered acceptable according to the "Guidance document for applicants on preparing dossiers for the approval of a chemical new active substance and the renewal of approval of the chemical active substance according to Regulation (EU) No 283/2013 and Regulation (EU) No 284/2013" (SANCO/10181/2013-rev.2 of 2-May-2013).

Moreover, the current draft guidelines relating to determining the magnitude of pesticide residues in bee products and setting specific Maximum Residue Levels in honey (SANCO 11956/2016 rev.6 dated of 20 November 2017) indicates that cereals have no melliferous capacities. Therefore, residues in honey are not expected following application of **isoflucypram** on cereals.

APPENDIX

Substances and metabolites referred to in this document:

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
a.s.	 $C_{19}H_{21}ClF_3N_3O$ [399] Molecular weight: 399.84 g/mol	**isoflucypram** BCS-CN88460 CAS: 1255734-28-1 ISY LYA**M82**3-1-2 smiles code: C1(C(F)F)C(C(=O)N(CC3=C(C(C)C)C=CC(Cl)=C3)C2CC2)=C(F)N(C)N=1	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide CA name: 1H-pyrazole-4-carboxamide, N-[[5-chloro-2-(1-methyl-ethyl)phenyl]methyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-	animal: rat (faeces, liver, kidney); hen (eggs, muscle leg, fat); goat (milk, muscle, fat, liver, kidney, faeces) sunfish (edible parts, viscera) plant: soybean (forage, hay, straw, seed); wheat (hay, straw, grain); CRC (wheat forage, Swiss chard, turnip leaves); oilseed rape (intermediate harvest, mature plants, seeds), tomatoes; potatoes (tubers, leaves) soil: aerobic & anaerobic, field dissipation, photolysis water: hydrolysis, photolysis, water-sediment
M01	 $C_{19}H_{21}ClF_3N_3O_2$ [415]	**BCS-CN88460-propanol** BCS-CY24813 (**M01**)	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	animal: rat (faeces); hen (eggs, muscle, fat, liver, excreta); goat (muscle, fat, liver, kidney, faeces, urine); sunfish (edible parts, viscera) plant: wheat hay, straw) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M02	 $C_{19}H_{21}ClF_3N_3O_2$ [415]	**BCS-CN88460-2-propanol** BCS-DC20298 (**M02**)	N-[5-chloro-2-(2-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	animal: rat (faeces); goat (milk, muscle, fat, liver, kidney, faeces, urine) plant: - soil: - water: -
M03	 $C_{19}H_{21}ClF_3N_3O_3$ [431]	**BCS-CN88460-1,2-propandiol**	N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoro-methyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	animal: hen (excreta) plant: - soil: - water: -
M04	 $C_{19}H_{21}ClF_3N_3O_2$ [415]	**BCS-CN88460-hydroxyphenyl**	N-(5-chloro-4-hydroxy-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	animal: goat (urine) plant: - soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M06	 $C_{18}H_{19}ClF_3N_3O_2$ [401]	**BCS-CN88460-desmethyl-propanol** BCS-DC22055 (**M06**)	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	animal: rat (faeces, bile); hen (eggs, muscle, fat, liver, excreta); goat (milk, muscle, liver, kidney, faeces, urine); sunfish (edible parts, viscera) plant: wheat (straw) soil: - water: -
M07	 $C_{18}H_{19}ClF_3N_3O_3$ [417]	**BCS-CN88460-desmethyl-1,2-propandiol**	N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	animal: hen (eggs, muscle, fat, liver, excreta) plant: - soil: - water: -
M10	 $C_{19}H_{19}ClF_3N_3O_4$ [445]	**BCS-CN88460-lactic acid** ROI 3	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}-2-hydroxypropanoic acid	animal: rat (faeces, plasma, liver, kidney, bile); goat (liver, kidney, faeces, urine) plant: - soil: met., aerobic water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M11	 $C_{18}H_{17}ClF_3N_3O_3$ [415]	**BCS-CN88460-desmethyl-carboxylic acid** BCS-CX99799 ROI 5	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propanoic acid	animal: rat (urine, faeces, plasma, liver, kidney, bile); hen (muscle, fat, liver, excreta); goat (liver, kidney, faeces, urine) plant: - soil: met., aerobic water: -
M12	 $C_{19}H_{19}ClF_3N_3O_3$ [429]	**BCS-CN88460-carboxylic acid** BCS-CY26497 MXM 7275-1-5 ROI 1 smiles code: C1(CN(C(=O)C3C(C(F)F)=NN(C)C=3F)C2CC2)=C(C(C)C(=O)O)C=CC(Cl)=C1	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}-propanoic acid	animal: rat (urine, faeces, plasma, liver, kidney, bile); hen (eggs, muscle, fat, liver, excreta); goat (muscle, fat, liver, kidney, faeces, urine) plant: - soil: met., aerobic water: met., aerobic
M13		**BCS-CN88460-desmethyl**	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	animal: rat (faeces, plasma, liver, kidney); sunfish (edible parts, viscera) plant: - soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
	$C_{18}H_{19}ClF_3N_3O$ [385]			
M18	 $C_{25}H_{31}ClF_3N_3O_7$ [577]	**BCS-CN88460-propanol-Glyc**	N-{5-chloro-2-[1-(hexopyranosyloxy)propan-2-yl]benzyl}-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	animal: - plant: wheat (hay, straw) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M19	 $C_{25}H_{29}ClF_3N_3O_8$ [591]	**BCS-CN88460-propanol-GlucA** (isomer 1 and 2)	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)methyl]phenyl}propyl glucopyranosiduronic acid	animal: rat (faeces, bile); goat (milk, muscle, liver, kidney, faeces, urine); sunfish (edible parts, viscera) plant: - soil: - water: -
M20	 $C_{25}H_{29}ClF_3N_3O_8$ [591]	**BCS-CN88460-2-propanol-GlucA**	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propan-2-yl beta-D-glucopyranosiduronic acid	animal: goat (liver, kidney, faeces, urine) plant: - soil: - water: -
M21	 $C_{28}H_{33}ClF_3N_3O_{10}$ [663]	**BCS-CN88460-propanol-Glyc-MA**	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)methyl]phenyl}propyl 6-O-(carboxyacetyl)hexopyranoside	animal: - plant: wheat (hay, straw); oilseed rape (intermediate harvest, mature plants) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M22	 $C_{28}H_{33}ClF_3N_3O_{10}$ [663]	**BCS-CN88460-2-propanol-Glyc-MA**	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}propan-2-yl 6-O-(carboxy-acetyl)hexopyranoside	animal: - plant: oilseed rape (intermediate harvest, mature plants); potato (leaves) soil: - water: -
M23	 $C_{28}H_{33}ClF_3N_3O_{10}$ [663]	**BCS-CN88460-hydroxyphenyl-Gluc-MA**	2-chloro-4-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]-5-isopropyl-phenyl 6-O-(carboxyacetyl)-beta-D-glucopyranoside	animal: - plant: oilseed rape (intermediate harvest, mature plants) soil: - water: -
M23a	 	**BCS-CN88460-OH-phenyl-Glyc-MA**		plant: potato (leaves)
M24	 	**BCS-CN88460-hydroxyphenyl-Glyc-MA**	2-chloro-4-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]-5-isopropyl-phenyl 6-O-(carboxyacetyl)-hexopyranoside	animal: - plant: oilseed rape (intermediate harvest, mature plants) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
	$C_{28}H_{33}ClF_3N_3O_{10}$ [663]			
M25	 $C_{25}H_{27}ClF_3N_3O_8$ [589]	**BCS-CN88460-propenol-GlucA**	2-{4-chloro-2-[(cycloprop yl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}prop-2-en-1-yl beta-D-glucopyranosiduronic acid	animal: goat (kidney, urine) plant: - soil: - water: -
M26	 $C_{19}H_{21}ClF_3N_3O_5S$ [495]	**BCS-CN88460-propanol-SA**	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propyl hydrogen sulfate	animal: hen (liver, excreta) plant: - soil: - water: -
M27	 $C_{19}H_{21}ClF_3N_3O_6S$ [511]	**BCS-CN88460-1,2-propandiol-SA**		animal: hen (excreta) plant: - soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M31	 $C_{24}H_{27}ClF_3N_3O_8$ [577]	**BCS-CN88460-desmethyl-propanol-GlucA** (isomer 1 and 2)	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propyl glucopyranosiduronic acid	animal: rat (faeces, bile); sunfish (edible parts, viscera) plant: - soil: - water: -
M35	 $C_{24}H_{27}ClF_3N_3O_7$ [561]	**BCS-CN88460-desmethyl-GlucA** (isomer 1 and 2)	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-(beta-D-glucopyranuronosyl)-1H-pyrazole-4-carboxamide	animal: rat (bile); sunfish (edible parts, viscera) plant: - soil: - water: -
M36	 $C_{24}H_{27}ClF_3N_3O_9$ [593]	**BCS-CN88460-desmethyl-1,2-propandiol-N-GlucA**	N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-(gluco-pyranuronosyl)-1H-pyrazole-4-carboxamide	animal: hen (muscle leg, liver, excreta) plant: soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M37	 $C_{24}H_{27}ClF_3N_3O_8$ [577]	**BCS-CN88460-desmethyl-propanol-N-GlucA**	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-(gluco-pyranuronosyl)-1H-pyrazole-4-carboxamide	animal: hen (eggs, muscle leg, liver, excreta) plant: - soil: - water: -
M38	 $C_{24}H_{27}ClF_3N_3O_8$ [577]	**BCS-CN88460-desmethyl-2-propanol-N-GlucA**	N-[5-chloro-2-(2-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoro-methyl)-5-fluoro-1-(gluco-pyranuronosyl)-1H-pyrazole-4-carboxamide	animal: hen (liver, excreta) plant: - soil: - water: -
M41	 $C_{27}H_{31}ClF_3N_3O_{10}$ [649]	**BCS-CN88460-desmethyl-propanol-Glyc-MA**	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propyl 6-O-(carboxyacetyl)hexopyranoside	animal: - plant: wheat (hay, straw) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M42	 $C_{18}H_{19}ClF_3N_3O_6S$ [497]	**BCS-CN88460-desmethyl-1,2-propandiol-SA**		animal: hen (excreta) plant: - soil: - water: -
M44	 $C_{30}H_{39}ClF_2N_6O_7S$ [700]	**BCS-CN88460-desfluoro-homoGSH**	gamma-glutamyl-S-{4-[(5-chloro-2-isopropylbenzyl)(cyclopropyl)carbamoyl]-3-(difluoromethyl)-1-methyl-1H-pyrazol-5-yl}cysteinyl-beta-alanine	animal: - plant: soybean (forage, hay, straw) soil: - water: -
M45	 $C_{25}H_{29}ClF_2N_4O_6S$ [586]	**BCS-CN88460-desfluoro-Cys-MA**	N-(carboxyacetyl)-S-{4-[(5-chloro-2-isopropylbenzyl)(cyclopropyl)carbamoyl]-3-(difluoromethyl)-1-methyl-1H-pyrazol-5-yl}cysteine	animal: - plant: soybean (forage, hay, straw) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M46	 $C_{22}H_{26}ClF_2N_3O_5S$ [517]	**BCS-CN88460-desfluoro-mercapto-lactic acid-OH**		animal: - plant: soybean (forage, hay, straw) soil: - water: -
M47	 $C_{28}H_{36}ClF_2N_3O_9S$ [663]	**BCS-CN88460-desfluoro-mercapto-lactic acid-Glyc**	3-({4-[(5-chloro-2-isopropylbenzyl)(cyclopropyl)carbamoyl]-3-(difluoromethyl)-1-methyl-1H-pyrazol-5-yl}sulfanyl)-2-(hexo-pyranosyloxy)propanoic acid	animal: - plant: soybean (forage, hay, straw) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M48	 $C_{28}H_{36}ClF_2N_3O_{10}S$ [679]	**BCS-CN88460-desfluoro-mercapto-lactic acid-propyl-OH-Glyc**		animal: - plant: soybean (forage, hay, straw) soil: - water: -
M49	 $C_9H_{10}F_3N_3O$ [233]	**BCS-CN88460-N-methyl-cyclopropyl-pyrazole-carboxamide** BCS-CR60082	N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	animal: - plant: CRC (wheat forage, wheat hay, wheat straw, Swiss chard immature, Swiss chard at maturity, turnip leaves) soil: - water: -
M50	 $C_6H_5F_3N_2O_2$ [194]	**BCS-CN88460-N-methyl-pyrazole-carboxylic acid** BCS-AB72918 BCS-CR73065 CAS: 1255735-09-1	3-(difluoromethyl)-5-fluoro-1-methyl-pyrazole-4-carboxylic acid CA name: 1H-Pyrazole-4-carboxylic acid, 3-(difluoromethyl)-5-fluoro-1-methyl-	animal: rat (urine), goat (urine, kidney); sunfish (edible parts, viscera) plant: - soil: - water:

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M52	 $C_{12}H_{16}F_2N_4O_3S$ [334]	**BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys**		animal: rat (bile) plant: CRC (wheat forage, wheat hay, wheat straw, Swiss chard immature, Swiss chard at maturity, turnip leaves) soil: - water: -
M54	 $C_{19}H_{26}F_2N_6O_7S$ [520]	**BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH**		animal: rat (bile) plant: CRC (wheat forage, wheat hay, wheat straw, Swiss chard immature, Swiss chard at maturity, turnip leaves) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M55	 $C_{12}H_{15}F_2N_3O_4S$ [335]	**BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-desamino-Cys**		animal: - plant: CRC(wheat forage, wheat hay, wheat straw, Swiss chard immature, turnip leaves) soil: - water: -
M56	 $C_{15}H_{21}F_2N_3O_6S$ [409]	**BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc**		animal: - plant: CRC (wheat forage, wheat hay, wheat straw, turnip leaves) soil: - water: -
M57		**BCS-CN88460-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA**		animal: - plant: CRC (wheat forage, wheat hay, wheat straw, turnip leaves) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
	$C_{18}H_{23}F_2N_3O_9S$ [495]			
M58	 $C_8H_8F_3N_3O$ [219]	**BCS-CN88460-cyclopropyl-pyrazole-carboxamide** BCS-CX99798	N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	animal: rat (urine, plasma, liver, kidney); sunfish (edible parts, viscera) plant: potato (leaves, tubers) soil: - water: -
M62	 $C_{14}H_{18}F_3N_3O_6$ [381]	**BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Glyc** (isomer 1 and 2)		animal: - plant: CRC (wheat forage, wheat hay, wheat straw, Swiss chard immature, Swiss chard at maturity, turnip leaves) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M66	 $C_{11}H_{13}F_3N_4O_3$ [306]	**BCS-CN88460-cyclopropyl-pyrazole-carboxamide-Ala**	3-[4-(cyclopropylcarbamoyl)-3-(difluoromethyl)-5-fluoro-1H-pyrazol-1-yl]alanine	animal: - plant: CRC(wheat forage, wheat hay, wheat straw, wheat grain, Swiss chard immature, Swiss chard at maturity, turnip leaves) soil: - water: -
M67	 $C_{11}H_{12}F_2N_4O_3$ [286]	**BCS-CN88460-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala**	3-[4-(cyclopropylcarbamoyl)-3-(difluoromethyl)-1H-pyrazol-1-yl]alanine	animal: - plant: CRC (wheat forage, wheat hay, wheat straw, wheat grain, Swiss chard immature, Swiss chard at maturity, turnip leaves) soil: - water: -

No.	Structure Empirical formula [Nominal mass]	Name Code no. Synonyms	IUPAC name	Found in:
M68	 $C_{10}H_{10}F_3N_3O_3$ [277]	**BCS-CN88460-cyclopropyl-pyrazole-carboxamide-acetic acid**		animal: - plant: CRC (wheat hay, wheat straw) soil: - water: -
M69	 $C_{11}H_{12}F_3N_3O_4$ [307]	**BCS-CN88460-cyclopropyl-pyrazole-carboxamide-OH-lactic acid** (isomer 1 and 2)		animal: - plant: CRC (wheat forage, wheat hay, wheat straw, Swiss chard immature, Swiss chard at maturity) soil: - water: -
